The opinions expressed in this publication are those of the authors alone. Under no circumstances should they be taken as an authoritative statement of the views of the Commission of the European Communities.

Panorama is commissioned by the Unit "Competitiveness and general questions of industrial and technological policy" of the Directorate-General Industry of the Commission of the European Communities (DG III), with the cooperation of the trade and professional associations of the European Community.

All professional associations/organisations known to the Commission which represent industry at the European level were asked to contribute material on their sector. At the end of each monograph, addresses and telephone and fax numbers of the respective professional association concerned are indicated.

The many consultants and associations that contributed to this edition of Panorama are listed in the introduction section of the publication.

Questions about the content of the Panorama of EU Industry should be directed to the association concerned or to the Commission service responsible for this publication:

Message from Mr Jacques Delors

President of the European Commission

In adopting the White Paper on "Growth, competitiveness, employment", the European Council took a decision of a more complex nature than the many others taken along the road of European construction since its revitalization with the 1992 project. Earlier decisions had been aimed at overhauling the way in which the Community works, but the White Paper is both a plan of action and an invitation to thought and debate on the challenges facing us in the coming decade.

An invitation to thought in that it evokes a new economic model, one that is respectful both of human diversity and natural resources. This is going to involve major changes. An attitude of considerable openness and innovation will be needed to keep abreast of these changes.

A plan of action in that it proposes measures aimed at furthering competitive growth in Europe, while steering this in the direction of a new form of economics, perhaps even of society.

As responsible individuals, we have an immense obligation, while remaining faithful to the ideals which make up Europe's personality and are its hall-mark, to work out a new synthesis between the aspirations of our society - employment as a means of social integration, equality of opportunities - and economic imperatives - competitiveness and job creation.

It is in this context that the Union must face up to international competitiveness, while providing each individual with a place from which to contribute to the improvement, inter alia, of the position of industry within markets as a whole.

The White Paper maps out the territory for the 21st Century, one full of challenges which we will have to meet. The consolidation of industrial potential is one, the creation of large trans-European networks is another, the enhancement of research and the putting in place of an information society - all must serve this objective.

This 5th edition of the "Panorama of EU Industry" fits into this context by virtue of its thoroughness and the exhaustiveness of the information which it provides. It represents an extremely useful tool for a better understanding of the needs of industry in the face of future changes.

Jacques Delors

Preface by Martin Bangemann

Member of the European Commission

With the entry into force of the Maastricht Treaty the European Community was transformed from a purely economic community into a European Union the citizens of which now expect, more than ever before, practical answers to today's major economic and political problems.

In this connection, the European Commission plays an important role since, as the "voice of reason", it must point the way towards more growth, greater competitiveness and more jobs. There can be no doubt that the economic and social policy pursued so far needs to be radically redirected since drastic cost-cutting and modernization measures no longer suffice on their own to bring about a considerable improvement in European industry's international competitiveness. We really must concern ourselves more with the markets of the future. I am referring in particular to the modern information and telecommunications technologies which in future will form the principal basis for innovation and greater productivity, especially as our new competitors on the world markets use the most modern technologies from the outset. The decisive factor in international competition is the productive application of knowledge, i.e. we must be quicker than the others to turn our knowledge into successful innovations, an objective which can only be achieved if we focus on the technologies of the future, e.g. the development and extension of European telecommunications networks. Otherwise European industry runs the risk of losing the international race towards the "information society".

An essential task of European industrial policy is to continue to provide an optimum environment for European industry. For example, the cost of using new telecommunications services is the biggest obstacle to the creation of new jobs in the information and telecommunications sector. This obstacle can only be removed if the national monopolies are completely dismantled. The rapid development of mobile communications is an impressive example of the commercial potential that can be released if the Member States allow more competition in the telecommunications sector. However, the intention is not that European industrial policy should pick the winners, since the responsibility for commercial success must continue to lie with enterprises themselves.

In close consultation with European industry, the European Commission will take all necessary measures to maintain the international competitiveness of European enterprises. That is why in the fourth research framework programme we are focusing on "generic technologies" which can be widely applied in various areas rather than the prestigious megaprojects of the past which have failed to produce significant results. However, we must also take the pains to ensure that European research findings are circulated more quickly and in a more targeted fashion, so that the knowledge acquired through research can be exploited to the full in order to promote innovation and improve productivity.

Last but not least, we must step up industrial cooperation with our European partners. The Central and Eastern European countries are counting on us to provide them with all possible assistance with the economic and political reform process in their countries. It would be quite wrong to regard such assistance as a threat to our own industry. Instead we should see it as a contribution towards strengthening Europe's position as an industrial region, since the only way that Europe can have a decisive influence on world competition is to achieve a judicious mix of lower wage costs and advanced technologies.

Martin Bangemann

Preface by Henning Christophersen

Vice-President of the European Commission

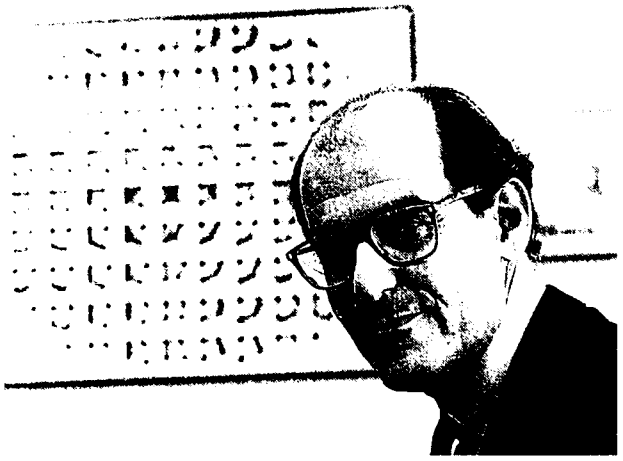
The December 1993 White Paper on Growth, Competitiveness and Employment emphasizes at one and the same time the need for a macro-economic policy and a structural policy approach to promote growth, competitiveness and employment in the Union. Particularly the objective of facilitating structural adjustment presents a demanding task to policy makers in finding innovative and effective policy instruments. Successful structural policy in turn requires access to much information which has not traditionally been readily available.

One of the strong points of the Panorama of EU Industry is exactly the wealth of statistics that it presents. These are vital for effective analysis. The publication gives up-to-date statistics on employment, output, trade and other key variables for nearly 200 manufacturing and service industries, making it an invaluable source for analysts and policy makers.

The collection of such detailed statistics involves a long-term commitment from all the participants in the process. The enterprises wich supply the information devote time and resources to complete questionnaires. The statistical agencies which collect and process the data have to plan the operation meticulously in order to minimize the cost of collection. Furthermore, efforts are needed to harmonize methods of collection of information and its presentation. This is part of the ongoing work of Eurostat, the National Statistical Institutes in the Member States, and with the European trade associations.

This publication is a result of collaborative effort by a large number of people, and a considerable effort has gone into assembling timely and relevant statistics and analyses. I hope that this new edition of Panorama of EU Industry will help towards meeting the information needs of all those concerned with European industry.

Henning Christophersen



Introduction by Riccardo Perissich

Director-General for Industry of the European Commission

"The wealth of nations is increasingly based on the creation and exploitation of knowledge. Optimum advantage must be taken of this new form of progress available to Union firms since it is an area in which the Union enjoys a substantial head start."

This sentence from the section on competitiveness in the Commission's White Paper on "Growth, competitiveness, employment" is especially relevant to this new edition of the "Panorama of EU Industry".

With the accelerating globalization of the world's economies and markets and the intensification of competition world-wide for a growing array of goods, services and factors, the performance of businesses is going to depend increasingly on specific competitive advantages rather than on traditional comparative advantages.

And whereas the latter depend directly on socio-economic-cultural circumstances in the different regions and are thus largely preordained, the latter are the product of the savoir-faire, imagination and dynamism of individuals.

Many in positions of authority still tend to explain the success or failure of businesses, and by extension of the economies of the countries in which they are located, in terms of variations in the cost of traditional factors (exchange rates, cost of manpower/energy/capital, taxation, legislation). I hold with those who see this interpretation as no longer adequate to the realities of today's economic structures, because it conceives of world trade as based essentially on the exchange of goods. The role of services and of immaterial factors is expanding rapidly in our increasingly technology-based society, in which geographical markets are becoming an increasingly vague concept.

Without wishing to under-estimate the impact that major variations between the levels of such factors can have on the profitability of businesses, I am convinced that narrowing these differences significantly is not in itself any guarantee of success in the long term. Success must also, indeed above all, depend on the individual strategies of businesses to optimize the most qualitative elements available to them so that differences vis-à-vis competitors can be fully exploited.

It is up to public authorities to create an environment propitious to the development of such strategies. Amassing and disseminating information which otherwise would be unobtainable is one element of the approach which the Commission intends to follow.

The "Panorama of EU Industry" is an example of the tools which the Commission is making available to business circles to help them direct their own strategies. The ambition of this publication - which will act both as reference work and working tool for numerous people involved in political, economic and academic life - is to help expand our knowledge of the different industrial sectors in the Union.

Its originality resides in its methodology, which is based on close cooperation between the specialized departments of the Commission and trade associations representing industry.

Many associations have continued to update and expand their previous year's contribution. Many others have provided statistics or partial reports. All the associations whose names feature at the end of the sectoral studies were consulted on the contents of the texts now being published and were thus able to make comments and observations.

This also explains why the opinions expressed in a number of analyses do not necessarily coincide with the views held at the Commission and therefore commit only the authors, whose names are given at the end of the monographs.

Forecasts were difficult to make for many sectors, but they will help clarify future prospects and facilitate business decisions. They were produced thanks to the joint efforts of the authors of the monographs, trade associations and Eurostat (the Statistical Office of the European Communities), whose help and statistical knowledge greatly helped the authors in their work.

Overall responsibility for this edition lay with the Unit for competitiveness and general questions of industrial and technological policy of the Directorate-General for Industry, which contracted the technical coordination and editing to an outside consultancy.

As in earlier editions, the opening section contains analyses covering questions of topical interest (this time: the investment strategies of European companies outside the Union, the restructuring of industries in Eastern European countries, the sectoral characteristics of strategic alliances, the economic aspects of quality policies, trends in the services sectors and in the area of the internationalization of SMEs). The results of these analyses provide significant indicators on how the relevant public and private entities might adjust their operations.

I remain convinced that the information contained herein will continue to guide the activities of all those for whom a better knowledge of industry in the Union is a vital asset.

Riccardo Perissich

Time frames and statistics

Panorama 1994 provides a comprehensive picture of industry and services within the European Community. It is intended for all those requiring an update on the present situation and probable future developments in manufacturing and service industries in the EC.

Panorama opens with a "special features" section, which takes a global approach to a number of horizontal subjects of topical interest. The main part of the book - the industry reviews - provides a macroeconomic survey of EC industry and services, tracing the major developments in production, employment, trade and structural change and includes, in most cases, detailed statistical data and forecasts.

Time frame

The industry reviews and forecasts were written during the third and fourth quarters of 1993 (explaining why texts, tables and graphics refer to EC and not EU). Time series run from 1983 to 1992. Gaps in the data were filled by estimates wherever information was available, and these estimates are footnoted in the tables.

For the main indicators table, 1993 estimates have also been added. Forecasts, if available, were provided by the professional trade associations or consultants involved in the compilation of individual reports.

Industry classification system

The selection and ordering of industries and services included in Panorama is based on the NACE coding system. This system classifies economic activity in terms of the nature of goods and services produced or by the nature of the production process employed. It is arranged on the decimal system and is subdivided into divisions (1-digit codes), classes (2-digit codes), groups (3-digit codes), sub-groups (4-digit codes) and items (5-digit codes). Panorama is primarily focused on the 3-digit level.

More detailed information on the NACE codes is contained in the General Industrial Classification of Economic Activities within the European Community published by Eurostat (1985 reprint of the 1970 edition). This publication is available from the usual outlets for Community publications.

Although most chapters are headed by the appropriate NACE code, some do not have a NACE code indicated as the sector represents too small a fraction of the total NACE group. This is particularly common in the service sectors.

Revisions to the NACE classification have been incorporated in a Council Regulation (OJ L293, 24th October 1990) and will start being used for data collection over the next few years. One of the objectives of this revision is a further breakdown of some service and industrial categories.

Even when a NACE code appears beneath the sector title this should be viewed with caution. In some cases the NACE classification does not exactly coincide with the industrial sector under discussion. Each chapter includes a preliminary section explaining the sectoral coverage of the chapter in question, and indicating the extent to which this deviated from the NACE classification. There are cases where an overlap occurs between sectors and therefore data cannot be cumulated.

Statistical data

The three main sources of data are Eurostat, DEBA (Data for European Business Analysis, which contributed estimates for recent years) and the professional trade associations. Data sources are indicated for each statistical table.

For manufacturing industries most chapters include a summary table containing the main indicators for the industry. These cover apparent consumption (defined as production + extra-EC imports - extra-EC exports), production, extra-EC exports, net exports (the trade balance of the Community with the rest of the world) and employment.

Data in the tables are current ECU unless otherwise stated. Indices (reference year: 1985=100) have been calculated for production and trade data providing easier reference for trend changes. The productivity measure used in certain monographs is based on deflated value added at factor cost per person employed, and expressed in 1992 prices using the most appropriate producer price index as deflator.

Every effort has been made to include data for all 12 Member States. All figures are on a pre-unification basis, and exclude East Germany unless otherwise stated. However, where data are not available for the EC-12, country coverage is clearly indicated in the footnotes appearing below each table. The statistical data in Panorama should be regarded with some caution, particularly for the more recent years where data have often been estimated. Production figures for the USA derived from the census of manufactures have also been included, as have Japanese data from Nikkei. To compare the Panorama of EC Industry with the US Industrial Outlook, Eurostat can provide you with a table correlating NACE to the US SIC.

Production and employment

Data for production and employment come from annual enquiries conducted by Member States relating to **all enterprises with 20 or more employees**. The exceptions to this are Spain and Portugal where the coverage is for firms of all sizes. Figures are generally available at the NACE 3-digit level. The production data exclude VAT, and the employment data relate to persons employed excluding home workers. The definitions are standardised, and so the figures are comparable across industries and countries.

Estimates are not supplied to Eurostat by Member States for the firms not covered by the enquiries, and the figures under-report actual employment and production. Where this is significant, either industry association sources are used or note is made in the commentary. Derived statistics which are calculated from both production and trade statistics will also be affected. Apparent consumption will be understated, and import penetration ratios and export rates will be overstated.

Gaps in Eurostat's data for production and employment sent by the Member States have where possible been filled using estimation techniques by DEBA. Denmark and Greece provided final data up to 1991, Germany, Spain, France, the Netherlands, and the United Kingdom up to 1990; and the remaining countries provided data up to 1989 (except Luxembourg, up to 1988). EC totals contain estimates for missing countries. Estimates are derived from short-term indicators such as indices of production, producer prices and employment. Data for 1992 are based on monthly indicators for the

majority of the year, but also take into account independent sectoral forecasts. DEBA's estimates are only made for the NACE 2-digit and 3-digit level. Gaps in industry association figures at the 4 or 5-digit level have normally not been filled due to the scarcity of statistics at this level.

Exchange rate conversion and deflators

All data are reported in ECU, and national currencies have been converted at the average exchange rate prevailing for the year in question. The exchange rates used for the conversions are stated in the 'Annex' section at the end of the 'Highlights' chapter. With the large fluctuations seen in currency markets at the end of 1992 and the beginning of 1993, the reader should consider such effects on ECU values (especially at an individual country level).

Producer price indices have been used to deflate production and value added data. It should be noted that the constant price value added data found in National Accounts publications is often calculated by deflating output and costs separately, and so may differ from the industry series given. In the cases where the corresponding NACE 3-digit index has not been available, the NACE 2-digit index has been used. For Portugal, where such indicators are not yet available, the corresponding retail price indices have been taken.

Trade data

The trade data are reported in terms of Community trade flows with the rest of the world. In most cases, these data are based on Eurostat figures. Exports valuations are generally fob (free on board, i.e. excluding freight and insurance costs) whereas import data are c.i.f. (i.e. inclusive of carriage, insurance and freight). Import statistics may generally be regarded as slightly more accurate than export statistics due to greater ease of data collection in the former case.

All trade figures are in current ECU. For comparative purposes, the ratio of exports to imports (X/M) has been calculated for each set of trade data.

Trade figures for Spain and Portugal for 1983 have been estimated from non-Eurostat sources.

Q U E S T I O N N A I R E

FOR THE ATTENTION OF READERS OF PANORAMA OF EU INDUSTRY

This is the fifth edition of "Panorama of EU Industry" published by the Office for Official Publications of the European Communities. We would be grateful if you could complete this short questionnaire which will enable us to adapt future editions of Panorama to your needs.

Please mark the appropriate response(s)

1) How do you know about Panorama?

Advertisements	( )
Recommendations (specify)	( )
Through work	( )
Don't know	( )
Other (specify)	

2) Where did you obtain your copy of Panorama 1994?

Office for Official Publications of the European Communities	( )
Bookshop	( )
Local agents	( )
Library	( )
Other (specify)	

3) Do you read Panorama every year or is this the first time?

Every year	( )
1st time	( )
2nd time	( )
3rd time	( )

4) What do you think of Panorama 1994?

Presentation	--	-	0	+	++
Content of industrial reviews	--	-	0	+	++
Quality of information	--	-	0	+	++
How comprehensive the information is	--	-	0	+	++
Choice of subjects for the "special features"	--	-	0	+	++
Quality of the "special features"	--	-	0	+	++

5) If you have read Panorama before, how does this new edition compare with previous ones?

Presentation	--	-	0	+	++
Content of industrial reviews	--	-	0	+	++
Quality of information	--	-	0	+	++
Comprehensiveness of the information	--	-	0	+	++
Choice of subjects for the "special features"	--	-	0	+	++
Quality of the "special features"	--	-	0	+	++

6) For what reasons do you read Panorama ? (several answers possible)

Occasional reference tool	( )
For information about specific sectors	( )
Statistics	( )
Overview of Community industry	( )
Others (specify)	

7) Would you be interested in the following proposals:

Did you know that Panorama is now also available in CD-Rom	Yes	No
Ordering a selection of certain chapters	Yes	No
An update of statistics every six months	Yes	No

Other suggestions:

.....

Special Features

Highlights

INTRODUCTION

This edition of the Panorama of EU Industry has been prepared during the second half of 1993, in the midst of the most severe recession that hit European economies since the oil crisis of the 1970s. Output suffered its biggest decline for nearly 20 years, and profits fell almost everywhere in Europe, while unemployment continued to increase, reaching 10.6% of the labour force in the EU-12, compared to 8.8% in 1991. Ireland and Spain presently report the worst employment situations, with their 1993 unemployment rates at 18.4% and 21.2% respectively. In 1994 it is expected that a timid recovery will eventually take place. However, the effects of the currency turmoil of 1993 combined with competitiveness problems and political uncertainty in some Member States still cast a shadow over the future of the EU economy.

Some important pending issues have been resolved during 1993:

- At political level, the ratification of the Maastricht Treaty by all Member States has been successfully completed, albeit not always without difficulty. The creation of the European Union establishes the political framework for Europe.
- At trade level, the last minute positive conclusion of the GATT Uruguay Round has set the basis for an increase in global economic welfare. The ratification of the NAFTA Treaty between the USA, Canada and Mexico is to be seen in the same context.
- At the exchange rate level, the widening of the ERM bands has temporarily given relief to European central banks and governments in their fight with speculators. The creation of the European Monetary Institute is to be interpreted as a signal of the political will to continue on the road to European Monetary Union.

The positive conclusion of the Uruguay Round has been achieved thanks to a last minute decision to leave out some sensitive areas upon which no agreement could be found, namely audio-visual services, sea transport, financial services and aerospace. These issues will inevitably be the subject of the next round of negotiations. The last bargaining marathon has also spurred a debate on the necessity to reform the GATT to make it more effective.

On the monetary front, the troubles on currency markets have been smoothed down, but not solved, by the widening of the ERM bands. As this book went to press the pound sterling and the Italian lira had not yet re-entered the system, such that the road to EMU still looks very long and full of obstacles. The role which can be played by the European Monetary Institute is, at present, somewhat limited.

It is in this highly uncertain environment that the fifth edition of the Panorama of EU industry tries to give its readers an overall picture of the present situation of European industry. The publication provides an overview of the main factors affecting the activity of about 200 manufacturing and service sectors. Several "horizontal" issues (i.e. which are relevant for a number of different sectors) are discussed in the first part of the book: these cover a wide spectrum of subjects and range from an analysis of recent patterns in strategic alliances and of the investment strategies of EU firms in non-European countries, to a discussion of the economic importance of total quality management and a review of the eco-industries in the EU.

THE ECONOMY IN 1994 AND BEYOND

1994 will be a year of transition, as the European economies gradually move from recession to recovery. In addition to economic uncertainty, this year will also see elections in Germany and Italy, both driving forces of the European Union. To complete the global picture, recession is also looming in Japan, while the USA are entering their third consecutive year of (slow) growth. In 1994, the Commission services expect GDP growth of 1.3% in the European Union, followed by 2.1% in 1995.

Table 1: EC macroeconomic trends

(% annual change)	1986-90 (1)	1991	1992	1993 (2)	1994 (3)	1995 (3)
GDP at constant market prices	4.1	1.4	1.1	-0.4	1.3	2.1
Employment	1.7	0.2	-1.2	-1.8	-0.5	0.2
Inflation (4)	4.1	5.4	4.6	3.8	3.5	3.2

In **Germany**, the end of the tunnel does not look near yet, despite some encouraging signs that the worst might have been over in the last months of 1993. In 1993 the country suffered from the worst recession since the oil crisis in the 1970s: consumer demand was squeezed by rising taxes (to finance the rebuilding the eastern part of the country), combined with falling employment and lower wage increases. This in turn caused serious overcapacity problems for most industries in the manufacturing sector, which were forced to implement further restructuring. No relief could be provided by export markets, once the pride of German industry, because the high cost of labour combined with unfavourable exchange rate developments gave way to foreign competition. On the brighter side, inflation sensibly decreased because of reduced domestic demand. This allowed the Bundesbank to ease its tight monetary policy and reduce interest rates. Another timidly positive note comes from the eastern German economy, which showed the first signs of sustained growth in the past two years. Although vast problems remain (high unemployment, low productivity), there is hope that the situation is finally on its way to improvement. In 1993, German GDP fell by 2.0%, and DRI estimates that it will stagnate in 1994 (0.1%).

In **France**, the elections of March 1993 saw the collapse of the Socialist party and the return to power of a centre-right coalition guided by Mr Balladur. The new government's most immediate concern has been and continues to be the rising unemployment, which reached 12% of the active population at the end of 1993. The main reason behind the decline in employment lies in the decreasing demand, a phenomenon which has been accelerated by recession. In August 1993, the government launched a five-year unemployment plan which aims at reducing labour costs and introducing more flexibility into the labour market. Apart from the fight against unemployment, the government has launched a far-reaching privatisation programme which should help to alleviate the budget deficit. The first privatisations have been quite successful (Banque Nationale de Paris, Rhône-Poulenc). The privatisation of Elf Aquitaine started in early 1994, and more such moves expected to take place, particularly in the financial services sector. In 1994, the French economy is expected to grow by a sluggish 0.7%, just offsetting the 1993 fall, while inflation should decrease further mainly because of reduced demand.

In **Italy**, 1993 has been a revolutionary year indeed: the mounting corruption scandals have wiped out the old political class which ruled the country since the end of World War II, and have thrown Italy into a chaotic political environment. A general election is now to be held in March (the first one with a past-the-post system). On the economic level, the country has taken good advantage of the devaluation of the Lira after it left the ERM in September 1992: thanks to a low inflation rate generated by reduced domestic demand, Italian manufacturers have been able to reap the full benefits of the improved competitiveness of their products abroad (particularly outside the EU). Getting the inflation under control has allowed the Central Bank to reduce its interest rate from 15% to about 8%, with beneficial effects on the public debt. The government has also embarked on a long awaited privatisation programme which aims to reduce the heavy presence of the state in the Italian industry: the privatisation plan is well underway and has already put onto the market several firms (particularly in the credit and food and drink sectors) which encountered the favour of domestic and foreign investors. DRI expects real GDP in Italy to grow by 1.0% in 1994, following a 0.4% contraction in 1993.

The **United Kingdom** is the only large European country to have shown positive growth during 1993 (1.9%). The main reason behind this good performance is that the UK went down into recession before the rest of Europe, and therefore it could recover first. The recession which affected most European markets reduced the gains of the expected export-led recovery following the devaluation of the pound sterling, but sustained domestic demand compensated for this drawback. At the top of government's agenda is the problem of reducing the public deficit, which has reached disturbing levels: the way which seems to be preferred to tackle the problem is a mix of tax increases (particularly VAT) and spending cuts (mainly in defence and social benefits). Additionally, the drive towards privatisation / deregulation will continue, and will include the railways and the health care system. In 1994, we expect the recovery to consolidate, with GDP growing by 2.5%.

Contrary to Europe, the recovery in the **USA** looks quite stable since 1992. At the beginning of 1994 employment was still growing, inflation was at its lowest point since 20 years and interest rates low enough to stimulate investment and

Table 3: Fast growth/low export intensity sectors, 1992

(%)	Production growth (1986-92)	Export intensity	Import penetration

spending. The present situation is a direct consequence of the general business restructuring process which took place starting from the beginning of the 1990s, which greatly enhanced the competitiveness of US firms in both the domestic and foreign market. The ratification of the NAFTA Treaty is expected to have only a marginal impact on the short term future of the US economy. The major concern for the country in 1994 is thus the effectiveness of the reform of the health care system. In 1994, real GDP in the USA is expected to grow by 3.0%.

On the other hand, **Japan** is going through a painful recession. The strong yen hampered the once flourishing export sector, so that any buoyancy in the economy could only come from domestic demand. However, beside the relatively small size of the domestic market, the unprecedented threat of increasing unemployment has kept consumer spending down. Additionally, low productivity in some markets closed to foreign and even domestic competition (in particular in the food and drink segment) is taking its toll. As a result, Japanese firms, which traditionally operate at comparatively low profit margins, have seen profits coming down even further and have started a general re-thinking of their strategies. Life-long employment is being questioned, as well as market penetration based on volumes only. Moreover, as the drive towards relocation of production facilities in neighbouring countries is well underway, this further reduces potential employment growth within Japan. In response, the Japanese government released an emergency package in April 1993 which was aimed at stimulating the recovery. After falling by 0.6% in 1993, Japanese GDP is forecast to stage a mild recovery in 1994, growing by 1.2%.

In 1993, and surely in the next future as well, it is **East Asia**, and in particular China, which attracted most of the attention from investors. The introduction of market economy measures (in China) and good government management of the economy (in South Korea, Malaysia) have paved the way for buoyant growth in the area: some estimates indicate a steady 6.5% annual growth rate of GDP for the developing countries of the region. At present, however, as reported in another chapter in the first part of this Panorama, EU companies are far behind the Japanese companies in terms of foreign direct investment in East Asia. They are thus failing to take full advantage of the possibility to build a strategic competitive position in this increasingly important region of the world.

The situation in **Eastern Europe** is characterised by political and economic mess in Russia and by the difficulties experienced by the ancient Soviet Union's satellites of transforming into a market economy. The EU has concluded association agreements with Poland, the Czech and Slovak Republics, Hungary, Romania and Bulgaria, as a preliminary step towards

full membership. The agreements arranged a timetable to shelve trade barriers for manufactured products to ease these countries' transition to market economies. At the meeting in Copenhagen in June 1993, the Council adopted a number of additional measures aimed at speeding up the trade liberalisation process in order to further assist the economic restructuring of these countries.

The fact that Western Europe is in the midst of recession is, however, not contributing favourably to the process, as Western demand for those products that are exported from the East is low. Furthermore, the fact that there are serious problems of overcapacity in the same sectors in western Europe (steel, basic chemicals, ...) makes acceptance within the EU of the need to open markets difficult.

PERFORMANCE OF EU INDUSTRY

Figure 1 ranks 76 industrial sectors of the European industry on the basis of the average annual growth of production over the 1986-92 period. A quick look at the data presented by the chart reveals that the large majority of investment goods sectors (with the notable exception of medical and surgical equipment, telecommunications equipment and computer and office equipment) enjoyed slow growth over the period considered. On the other hand, most of the intermediate goods producing sectors rank amongst the medium to strong growth sectors from 1986 to 1992, the best ranked sectors being rubber and plastics processing and the secondary transformation of metals. Consumer goods sectors are more evenly distributed in the chart, and take the first place with the fast growing segment of pharmaceuticals.

The weakness of the EU investment goods producing sectors is thus continuing, and is a main concern for public authorities which are aware of the need to maintain a strong capital goods sector to stay competitive in the world market.

In Figure 1, most of the sectors enjoying strong growth are high technology sectors which have been characterised by increasing demand at world level within the last few years.

At the other end of the spectrum, many of the sectors which recorded the slowest and sometimes negative growth during the 1986-92 period are consumer goods producing sectors. The stalemate in production reflects either changes in consumer tastes (e.g. furs and furs' goods, all sorts of alcoholic drinks, tobacco products) or the take-over of large market shares by foreign competitors (e.g. musical instruments, clocks and watches, toys and sports goods) to the detriment of EU producers.

Among the eight sectors which experienced fastest growth (i.e. above 5%) during the 1986-92 period, two, pharmaceuticals and medical and surgical equipment, are strictly linked to the rapid rise in demand for health services. Another two, telecommunications equipment and computer and office equipment, have profited from buoyant demand for industrial services and the drive towards "electronification". Another three, rubber, plastics and secondary transformation of metals, owe their growth to the rapid expansion of the transport equipment sector during the period considered. Finally, growth in the soft drinks and mineral waters sector has to be interpreted in the light of the above-mentioned changes in consumer preferences.

Figure 4 ranks 65 industrial sectors in the EU by the number of employees. According to the figures presented in the chart, electrical and electronic engineering, food, drink and tobacco, mechanical engineering and metal products are the largest employers, followed by the motor vehicles industry. The chart also shows for each sector the variation in employment for the period 1987-92. Although productivity growth has not been homogeneous throughout industry, most of the sectors in which the largest cuts in employment have taken place over the period are the same which experienced low or negative growth during the past five years.

Tables 2 to 7 classify the sectors under consideration into six categories, on the basis of their average real annual growth of production and their export intensity.

Table 2 lists those sectors which recorded strong output growth (in excess of 5% per year) during the 1986-92 period and which export a relevant share of their production (in excess of 15%). These sectors are therefore heavily dependant on world market conditions, particularly demand and changes in international competitive and regulatory environment. The four sectors listed in Table 2 are high-tech sectors, and three out of four are investment goods sectors. For two sectors, i.e. medical and surgical equipment and computer and office equipment, the import penetration rate is also high, indicating a strong presence of foreign producers in the EU market. On the employment side, the strong demand for these sector's products on both domestic and foreign markets has translated into new jobs in the pharmaceuticals (1.7%) and medical equipment (1.9%) sectors. The maintenance of the EC's market position in the two other sectors, telecommunications equipment and computers and EDP, which are exposed to fierce competition at world level has, however, required some rationalisation moves and increased focus on product efficiency and productivity. This has caused employment in the telecommunications equipment (-0.5%) and computer (0.0%) sectors to stagnate over the 1987-92 period.

In Table 3 are those sectors which posted a strong increase in production over the 1986-92 period, but whose export intensity is low (less than 15%). The main engine of growth for these sectors is thus domestic demand, as opposed to exports. Three out of four sectors are intermediate goods sectors (linked particularly to the transport equipment sector): all four sectors are also characterised by low import penetration rates, a situation which reinforces the mainly domestic nature of

these industries. Employment in these industries has enjoyed healthy growth over the 1987-92 period, particularly in the secondary transformation of metals (2.3%) and rubber and plastics (1.8%) sectors.

The sectors listed in Table 4 are characterised by medium growth rates of production (between 3% and 5%) over the 1986-92 period and high export intensity. The presence of the electrical engineering industry and some of its subsectors (electric lighting and domestic electrical appliances) is relevant. Additionally, we find the chemical industry which owes its good position mainly to the positive development of downstream branches such as pharmaceuticals, soaps and detergents, paints and varnishes, and man-made fibres. Import penetration rates in this group are not particularly high, except for the consumer electronics sector. Employment in this group of sectors generally stagnated or decreased slightly during the 1987-92 period, with the exception of the electric lighting segment (0.4%). This group of sectors thus achieved important gains in labour productivity over the period, which contributed to their remaining competitive on world markets.

Table 5 lists the sectors characterised by medium growth and low export intensity. Among these are food products, along with the food, drink and tobacco industry as a whole. This group of sectors also includes most of the wood processing activities, as well as constructional steelworks and other sectors whose development is strictly linked to the activity in the construction sector. Import penetration in this category is generally low, apart from some segments of the wood and food industries which import some of their raw materials from abroad. As for employment, no general trend can be detected in this large group, which includes many different industry sectors. More specifically, it is interesting to note the positive growth in employment in several food segments (e.g. bread and flour with 2.0%, meat with 1.5%, etc.), while total employment in the food, drink and tobacco industry stagnated over the 1987-92 period.

In Table 6 are those sectors whose growth has been slow (less than 3%) over the 1986-92 period, and which are highly export oriented. These sectors suffered from sluggish demand both at domestic and at world level (e.g. basic industrial chemicals, shipbuilding, railway rolling stock, agricultural machinery) and/or saw important losses in market shares by EU producers both at domestic and at world level (e.g. footwear, toys and sports goods, leather and leather goods, machine tools). This group is also characterised by high import penetration rates (e.g. clocks and watches, toys and sports goods, musical instruments, optical and photographic equipment), which underlines the lack of competitiveness of EU producers vis-à-vis their international counterparts. Unsurprisingly, the employment trends in all sectors considered in this group have been negative during the 1987-92 period with the exception of a marginal increase of 0.1% in the optical instruments segment.

Finally, Table 7 ranks those sectors which suffered from slow growth over the 1986-92 period and which are characterised by a low export intensity. For most of these sectors, the main cause of their decline is to be found in the slow domestic demand growth, since their import penetration rate is generally also quite low. The exception is provided by the sectors of clothing and cycles and motorcycles, where EU producers have list significant market shares to foreign competitors. The rest of the category is mainly formed by sectors which are ancillary to the construction sector and which have thus hardly felt the effects of the crisis, and by some food products which witness a shift in consumer taste. Once again, as in the case of the sectors listed in Table 6, slow growth has negatively affected employment in all of the sectors during the period under consideration.

In order to complete the analysis of the performance of the EU industry over the 1986-92 period, we have calculated a "vulnerability index" which measures the relative change of the EU's net trade position with the rest of the world. The index is calculated as the change in the rate of export intensity

during the 1986-92 period minus the change in the rate of import penetration over the same period.

A high negative value of this index points to a deterioration of the net trade position of the EU vis-à-vis the rest of the world, hence a loss of competitiveness. Vice versa, a positive value of the index means an improvement of the competitive position of EU producers on world markets. Taking into account only the sectors which have a high degree of export intensity, we found that over the 1986-92 period the two sectors which had their competitive position most negatively affected were cycles and motorcycles and motor vehicles parts and components. On the other hand, the sectors which marginally improved their relative trade position over the same period were shipbuilding, textile machinery and the food, drink, tobacco industry.

Figure 2 indicates the reasons behind the change in the net trade position of several manufacturing sectors: change in export intensity, change in import penetration or a combination of both factors.

Figure 6 visualises the performance of various industrial sectors according to the combination of two factors, i.e. change in the cover ratio (exports/imports) and in export intensity, in order to define both the intensity of trade and the competitive position of the sectors considered.

One of the most notable consequences of the need to further enhance competitiveness in order to maintain and hopefully increase market share in an increasingly competitive world environment has been the recent upward trend in alliance formation. As explained in the horizontal chapter on strategic alliances, this surge in alliances can be explained by three main factors: first, companies are no longer able to lead in all areas of their activities; secondly, there is less capital available for acquisitions; and thirdly, already high concentration makes acquisitions very expensive.

Trade creation

The upper right quadrant of Figure 2 contains the majority of sectors under consideration. These sectors experienced a growth in both their export intensity and in the rate of import penetration during the 1986-92 period, indicating the increasing degree of openness of trade. Among the sectors which enjoyed the strongest trade creation effect over the 1986-92 period, we find several transport equipment industries: aerospace equipment, railway rolling stock and shipbuilding. To a large extent, the trade creation in these sectors reflects the increased specialisation of production across producers located in different regions of the world, combined with the Single Market incentived transformation of national champions into truly European producers. Another homogeneous grouping is formed by the electrical and electronic engineering, and the subsectors of computer and office equipment and domestic electrical appliances, again sectors where technology is key to competitiveness and where massive R&D costs can only be covered through specialisation on a limited number of standardised items, each of which can then be sold on a large end-market.

The difficulties experienced by the EC producers in these technology intensive market segments are illustrated by the fact that for most of the sectors in this quadrant, the rise in export intensity has been offset or exceeded by the increase in import penetration (with the notable exception of the European shipbuilding industry, which has completed its restructuring and is now specialising in a limited number of market segments in which its technological leadership is well recognised). The location of the sectors in this quadrant thus reflects a growing specialisation of the EC industry in some sections of the market, together with decreasing market share in other segments.

Increased competitiveness

The lower right hand quadrant of Figure 2 comprises those sectors which enjoyed rising export intensity along with declining import penetration. The only industry included in this quadrant is the food, drink and tobacco sector, which has been concentrating its activity on the European market, and slightly turned away from extra-EC imports in favour of increasing intra-EC trade.

Trade destruction

In the lower left quadrant of Figure 2 are those sectors which saw both export intensity and import penetration decrease during the 1986-92 period. The only sector included in this category is sawing and first processing of wood. The main reason behind this situation, given the simultaneous healthy growth rate of output, is an increase in intra-EC trade.

Loss of competitiveness

The second largest group in Figure 2 is represented by sectors which suffered from increasing competition abroad and at home, with decreasing export intensity and growing import penetration: some large sectors such as chemicals, mechanical engineering and rubber and plastics are included in this group. The reasons behind this negative result can be very different: unfavourable cost structure vis-à-vis foreign competitors (e.g. footwear and clothing, motor vehicles), or unfavourable exchange rate developments and problems of overcapacity (e.g. chemicals). It is interesting to note that two transport equipment sectors (motor vehicles and parts, cycles and motorcycles) are contained in this quadrant. However, whereas the cycles and motorcycles industry is clearly facing a loss of competitiveness both at home and abroad, the automotive industry's problem chiefly reflect a loss in market share of EU producers on foreign markets, as the rise in import penetration within the EU has been somewhat contained through trade agreements and inward investment of foreign producers within the domestic market.

THE EU AND INDUSTRY RESPONSE

At the end of 1993, the EU response to the challenges ahead became apparent, with two documents being issued which outline the future direction that economic policy should take in the EU: the Commission's White Paper on Growth, Competitiveness and Employment, and the broad guidelines which were adopted by the Council on December 22, 1993. The White Paper, which was prepared by the European Commission at the invitation of the European Council in Copenhagen in June 1993, presents an analysis of the economic situation in the Community and outlines a medium-term strategy for growth, competitiveness and employment. The broad guidelines effectively translate some of the actions suggested in the White Paper into operational policy recommendations.

Starting from the observation that the EU's competitive position with respect to Japan or the US has deteriorated on many fronts, the White Paper sets forth a series of structural recommendations which can be grouped under four major themes:

- Macroeconomic policies;
- Competition/industrial/enterprise policy;
- Employment/labour market policies;
- TransEuropean networks.

Some of the policy recommendations that are made can be followed up directly by the Commission, but most are under the direct responsibility of the Member States.

On the macroeconomic policy front, the White Paper sets a macroeconomic reference framework to be implemented in two stages - the first stage would aim at pulling the EU out of recession, while the second aims at achieving greater stability as well as long term macroeconomic and monetary con-

vergence. The medium-term economic policy objective is to foster investment-led growth through measures permitting increases in investment profitability and contributing to improving business confidence. A careful balancing of competition policy in order to encourage co-operation between firms, while ensuring that a healthy competitive climate is maintained, will also have a positive effect on investment, in particular in R&D. The White Paper underlines the importance of SMEs, and outlines a set of measures that would strengthen SMEs and facilitate the start-up of new businesses. On the employment/labour market policy front, the White Paper endorses many of the conclusions of the study on Employment and Structural Change in EC Industry and Services which is summarised elsewhere in this Panorama, by stressing the importance of on-going education and training, of enhancing both the internal and external flexibility of the workforce and of adapting national social legislation in order to contribute to a greater mobility of labour.

One of the recommendations of the White Paper which received much attention when the report was published was the development of pan-European information networks. The development of such networks is expected to enhance the competitiveness of European businesses, by reducing transaction and transport costs and facilitating the exchange of information at all levels.

Last but not least, it is important to note that the measures proposed by the European Commission will be effective only if the European industry acts simultaneously on its own. The recent industrial philosophy of the European Commission is based on the assumption that the EU's role is to provide a stable operating framework for the industry, within which companies have to do their best to remain competitive. Other initiatives by firms to complete the EU's action include developing medium and long-term strategies for markets outside the EC; and improving productivity of both capital and labour, respectively by introducing modern management and training practices, which are already widely used in the USA or Japan.

Sectoral patterns in strategic alliances

INTRODUCTION

During the latter half of the 1980s, the business and financial news media were hardly without stories of mergers and acquisitions between companies of all sizes and disciplines. The size of some of those buyouts still sit in the record books as the largest deals ever, with the effects still visible in the balance sheets and cash flow statements of the acquiring company. Lately, however, another form of business "combination" has taken a front seat to predatory acquisitions and highly leveraged equity buyouts: the strategic alliance. Business literature abounds with theories on alliances, methods for managing them and techniques for rescuing them from a premature death. What has been less discussed, however, is how partnerships between businesses differ from industry to industry, how they are typically structured and how they behave.

The following article attempts to analyse the strategic alliance from a sectoral perspective, by addressing the question of whether different industrial sectors exhibit distinctive alliances patterns and how these patterns may have evolved over time. The following ten sectors were examined:

- aerospace;
- computers;
- electronics;
- telecommunications equipment;
- pharmaceuticals;
- automotive equipment;
- basic chemicals;
- biotechnology;
- food & drink;
- airlines.

In addition, we examine possible geographical differences in the formation of strategic partnerships. This is done through an analysis of the frequencies of alliance formations within each sector and of the motivations underlying these alliances, using data on alliances between European and US and European and Japanese firms, and data on alliances between European firms respectively.

BACKGROUND

Due to the internationalisation of markets, rising competition and the increasing complexity and speed of change of technology, the number of strategic alliances has significantly risen since the early 1970's. Companies have turned to alliances to help share the cost and spread the risk of commercialising new products on a global scale.

During the first half of the 1980's, the number of international co-operative agreements signed each year by companies in the USA, Japan and EC increased by more than five times. Europe was the leader in terms of number of agreements, followed by the USA and Japan in third position during the 1978-1989 period. Of course, in interpreting this information one should take account of the fact that Europe is the most fragmented market and thus offers greater numbers of opportunities for alliances.

THEORETICAL FRAMEWORK

What is an alliance?

Alliances are any form of company cooperation, involving equity investment or not, regardless of the duration and objectives of the partnership. Mergers and acquisitions fall out of the alliance definition because they no longer suppose the cooperation of two distinct companies but aim at forming one aggregate company with total control of the acquired business. Strategic alliances may concern any aspect of company activity from R&D to distribution channels of final product, but rarely involve the entire core business of either participant. Alliances are normally designed to improve or defend the competitive advantage of the participating firms by exploiting new global product and marketing strategies, obtaining or maintaining cost leadership, obtaining access to new technologies or new markets, quickly constructing a presence in a new market, developing a specialisation or re-establishing a minimal operations size as well as to share R&D cost and other risks and to build scale economies. Alliances can also serve the purpose of a growth tool, as they can eventually have an impact on the entire fate of the company.

Tactical alliances should be distinguished from strategic alliances as they typically address a punctual or specific area of the company activity. Strategic alliances are more specifically aimed at defending or improving the participating firms' competitive situation and market positioning.

Strategic alliances can take many forms, but are often classified under three broad categories: the informal cooperation that

may or may not involve a contractual agreement; the equity alliance that involves common ownership of the alliance, often referred to as a joint venture (JV); and, the strategic network that may be composed of both of the above types and involve many partners with varying degrees of commitment.

In this article, we mainly focus on joint ventures which are a more elaborate type of commitment between two firms.

There are six interesting questions about alliances that deserve additional discussion:

- what is their average duration?
- what is their rate of success?
- what is the critical recipe for a successful marriage of two or more companies who may actually be competitors in at least one market?
- to what extent do firms in Europe choose alliances over acquisitions, and what are the optimising conditions of adopting one versus the other?
- are there distinct sectoral patterns in the formation of alliances?
- how do alliances influence competition?

Generally speaking, it appears that the average age of alliances is around seven years. There are, of course, important differences around this average as some alliances, such as the one linking Ford and Mazda, existed for more than 13 years whereas others have ended within a few months. Alliances involving Japanese companies exhibit an average life span approximately double that in the rest of the world: 15 to 20 years. This may be a result of the fact that business ventures

in Japan nearly always entail a longer time frame for reaching the required return on investments.

The relatively short life span of alliances involving European firms is, in fact, not necessarily a sign of failure. Alliances are indeed usually intermediate term strategies meant to end once they have successfully reached their objective. Alliances evolve over time and, since they are usually a temporary step in a long-term business strategy, parent companies generally make provisions in their LT plans as to how and when the alliance should be laid to rest. In a majority of cases, the alliance ends with one of the partners acquiring the JV company. In some cases, the trade-off between the advantages one company tries to capture and what it gives in exchange can become unbalanced, placing one partner in a better position to purchase the JV company - an outcome that may not have been planned for at the start.

While the literature reports that although approximately two thirds of alliances run into serious managerial or financial trouble within the first two years, half are eventually successful. This finding stresses the need to build the alliance around the theoretical requirements for a prosperous partnership. These are that partners carry equal financial and managerial strength into the relationship. Equality implies even commitment to, and reliance on, the project, balanced decision making and equal sharing of risk and reward. The strength of the parent companies going into the JV should also be equal, as a partner that is technologically, managerially or financially weak has the potential to drag down the alliance, or to be dragged along by the stronger partner. Another important condition is that the JV must have the ability to adjust and evolve as the business environment changes around it.

A last requirement is that the JV has independence from the parent companies, that it has the potential to adapt to the evolution of the business climate and that it is able to direct and manage change in the relationship between the parent companies (to take credence of the fact that alliances must evolve over time).

The monitoring of alliances also represents a difficult challenge for competition policy makers. Competition varies according to sectors but it certainly constitutes a major issue that the European Commission is focusing on by monitoring co-operative relationships and acquisitions on a case by case basis. The major issue lies in an arbitrage between the viability of an industry and the eventual decrease in competition.

Alliances versus M&A: under which conditions?

Both alliances and M&A provide a vehicle for growth or are parts of defensive strategies. Table 1 for instance presents the theoretical strategy to be followed by firms in Europe depending on their present market position and the nature of the business, as reported by Roger Abravanel and David Ernst of McKinsey & Co. Alliances and M&As, however, have different and sometimes mutually exclusive goals that entail different conditions for success. These differences lie in the scope of activities and geographical requirements.

Mergers and acquisitions typically involve the transfer of a high degree of technologies and skills, either to or from a target. The challenge is when these business competencies have to be transferred across-borders while the companies are still trying to reap synergies from consolidation. The successful M&As are generally between companies with both overlapping activities or product lines and with overlapping

Table 4: Airline sector

geographical coverage, and which involve the core business activities. Killing one's acquired competitor can also be the objective of an acquisition, but it is never that of an alliance.

In contrast, alliances meet shorter and more specific requirements and appear far more successful than M&As if the goal is to enter new geographical areas, new business activities or both. In the book "Collaborating to Compete" (Bleeke and Ernst, eds. John Wiley and Sons, Inc. 1993), it is reported that 60% of alliances involving partners in non-overlapping geographic markets succeed, while only 8% of acquisitions succeed. Alliances require complementary activities and well matched functional strengths. The lowest rate of success was with alliances between firms bringing competing products to the same shared distribution channel (this situation in fact leads to acquisition success).

The main conclusion is that to expand core business, alliances and acquisitions are both efficient, but to expand abroad or to edge out into new businesses, alliances work better. Both strategies, given their own requirements, have about the same 50% success rate.

Depending on the competitive situation of the various sectors in Europe and the typical growth strategy of firms in the sector at the present time, it will thus make more sense for companies in certain industries to choose an alliances over an M&A, or vice versa. This will be discussed in more detail in the next section.

SECTORAL ANALYSIS

The sectoral analysis below will address the question of whether sectors show distinct patterns of alliances, depending on the objectives pursued by firms in these sectors.

Because broad theoretical conditions establish a connection between market structure and alliance goals (Table 1), factors such as the degree of concentration in industry, market maturity, internationalisation, capital intensity (for R&D purposes, among others), risk, and market life cycle are to be considered for each sector. There is, in fact, a relation between the optimal (theoretical) form of partnership between firms in one sector and the market life cycle. Indeed, given that each phase of the market life cycle corresponds to a different form of competitive advantage, the life cycle concept is likely

to influence the type of alliance that firms in this market will seek to form.

The analysis below will seek to understand whether past trends in alliances involving EC firms have indeed shown distinct sectoral patterns, given past and present market conditions. From this, we will then be able to comment upon the likely future pattern of alliances/JV/M&As by sector in the 1990s, given present and expected future market conditions.

Airlines

The European airline industry is in a maturing stage of development. The top EC companies are British Airways (BA), Air France and Lufthansa. Together, these accounted for nearly 60% of both the total number of passenger-kilometres and revenue of the EC carriers in 1991.

Nearly 90% of EC passenger transport by air is international. More generally, world traffic demand is dominated by six specific traffic flows. These are, in decreasing order of importance, the USA domestic market, the intra-European market, the transatlantic market, the Asian market, the Pacific market and Asia-Europe. Given the above, global operation is perceived by the major international airlines as not only a condition for profitability but also a condition for survival. As a result, the differentiation of services between these companies is mainly done in marketing terms.

Nevertheless, whereas US companies have a relatively homogeneous set of characteristics, as they are all in private ownership and have to conform to the same labour regulations, European companies have very different working practices, ownership structures and cost basis.

Given the effects of globalisation and deregulation in the industry, past trends in alliances can be classified along two dimensions: geographic scope and financial structure. Most early alliances were domestic in scope and represented the initial consolidation of deregulated national markets in the 1970s and 1980s for the USA, and in the late 1980s and early 1990s in Europe and Asia. The next set of partnerships to emerge were in the form of regional alliances in Europe and Asia, as airlines attempted to consolidate their position across a broader market base in anticipation of further deregulation. Most of the recent alliances have occurred in the intercontinental arena to capture the maximum amount of traffic flow expansion, representing the beginning of globalisation during the 1990's.

Given the present market condition, although the corporate strategies of firms in this sector still slightly differ by country, the following appear as core strategies: (i) having a lean and efficient cost base; (ii) having an efficient means of distribution via membership to one of the main computer reservation systems; (iii) achieving domination of a hub where there is a large local population (thus providing a natural source of traffic); and, (iv) being profitable enough to attract capital for fleet renewal.

Alliance objectives can then be grouped into four main categories:

- the most common is traffic feed, both to increase load factors and to improve yield or passenger mix;
- the second is to achieve scale economies through the sharing or pooling of resources across operational areas and costs centres (such as sales/marketing, flight equipment, station or ground facilities, maintenance and purchasing);
- the third is to access new markets by tapping a partner's unused route rights or unused slots; and, finally,
- airlines form alliances to defend current markets by assuming the role of gate-keeper through managing seat capacity of shared operations.

Within Europe, large companies have thus far fully or partially acquired some small and medium sized companies, but co-operation between large companies is still rare. This will change, however, as competition between carriers forces the airlines with relatively high cost structures and smaller domestic markets to co-operate. One example is the now defunct "Alcazar" project of a merger between SAS, KLM, Austrian Airlines and Swissair. Another example is the Air France purchase of an equity stake in SABENA, where the two companies have a similar corporate philosophy, language compatibility and complementary route structures.

Most domestic alliances began simply as co-operative agreements. Mergers and acquisitions then progressively became more numerous and national markets tended to consolidate under the control of dominant flag carriers. Alliances took many forms ranging from the interlining of passengers to equity stakes across national markets as foreign ownership regulations for airlines changed.

In intercontinental cooperation, joint-ventures and non-controlling equity investment are still the norm as merger and acquisition activity is largely restricted by regulatory barriers. Agreements are numerous, however, particularly marketing ones such as code sharing and block spacing. Many alliances have occurred with large US and some East Asian companies to extend market access to a global scale.

The overall importance of equity investments has increased from 40% of all alliances to approximately 55% over recent years. This reflects two major trends: further USA domestic and regional market consolidations, and privatisation activity in Asia, Latin America and Europe. Current EC ownership rules require that the majority ownership and control of an EC airline is by Member States and/or EC nationals. As regulatory frameworks regarding foreign ownership of airlines change, one would expect to see many of the co-operative and minority equity agreements that exist in the regional and international arenas to become increasingly majority control positions or outright acquisitions.

Considering that intercontinental cooperation is now the most frequent, joint agreements are the most numerous alliance process. Common agreements are code sharing and block spacing, methods aimed at giving market access with a minimum investment and relatively little commitment.

Code sharing enables two airlines to offer connecting flights which appear to the public to be all on one carrier as both flights are prefixed by the same code. This is commonly used by long-haul airlines to increase their domestic feed and by niche carriers wanting to tap into new markets without shouldering the expense of launching additional services. Block-spacing, which is a parallel concept where airlines add their code to another carrier's flight and buy seats on its service, is a proven method of gaining valuable access to a market. In June 1993, Swissair bought seats on partner Delta Air Lines' new Cincinnati-Zurich services and Delta took space on Swissair's flights from Zurich and Geneva to New-York. BA and USAir had been code sharing since June 1993 on eight routes and plan to do it on thirty more within twelve months. British Midland-United Airlines and SAS-Austrian Air Lines agreements provide other examples.

Aerospace

The aerospace industry is engaged in the production of aircraft, spacecraft, engines and equipment. Aircraft production represents the main activity of the sector. These products have both civil and military applications, however, civil activities have grown rapidly in importance as military demand was declining.

As far as the fragmentation is concerned, the sector is organised in a pyramid format: a few assembly manufacturers coordinate the work of thousands of sub-contracting companies across

different countries. Concentration is variable according the field and stage of production: Boeing, Airbus and McDonnell Douglas share the large commercial aircraft market. More manufacturers compete in the regional transport aircraft market: ATR (F), British Aerospace, Fokker (NL), CASA (E) and DASA (D) in the EC, de Havilland in Canada, Embraer in Brazil and Saab in Sweden. The engines market is dominated by four manufacturers: General Electric (USA), Pratt & Whitney (USA), Rolls-Royce (UK) and SNECMA (F).

Following a period of sustained expansion, the aerospace industry is currently facing structural adjustment problems. The European aerospace industry continues to suffer from the consequences of having maintained a fragmented industry structure, despite efforts both on national and European levels. R&D expenses are extremely high (approximately 30% of turnover) driving up break-even points on investments: aircraft motors need 2 000 sales and ten years to reach their break-even point, whereas large commercial jets require ten to fourteen years with a minimum output 400 to 500 aircraft. Indeed, the costs are often far greater than the firm's own equity capital.

R&D expenses and risk explain the frequencies and the importance of alliances in this sector. The huge financial involvement of the state in the USA, Europe and Japan should, however, not be underestimated, even if the state intervention does not happen during the same stages of business cycle in the various regions. One characteristic of alliances in the aerospace industry lies precisely in the risk-sharing with companies in other countries through partner ownership structure or in relation to public funding provided.

In addition to the costs reasons for alliances, market reasons should be added given that the government sector is also the largest purchaser of aerospace production.

For 31 of the 46 major worldwide aerospace companies in 1991, there were 35 alliances called "programmes" (cross participation among companies excluded), which aimed at developing and producing a specified set of products from the entire range of the aerospace industry. This makes the rate of alliances quite high relative to fragmentation. As far as the geographical split is concerned, the companies involved in these alliances included seven American companies, three Japanese and about 30 European firms.

All of the seven alliances involving American companies are international and most of them are with European companies. European firms are participating in almost every alliance and, given the preceding results, often tend to ally among themselves; names such as Euromissile or Eurocopter clearly announce the European character of the product. The most famous European alliance, Airbus, embodies the cooperation between British Aerospace (UK), Deutsche Aerospace (D), Aérospatiale (F) and CASA (E). Aérospatiale and several other industrial European companies not listed above cooperate on Arianespace.

The Japanese companies Kawasaki, Mitsubishi and Ihi Ishikawajima Heavy Industries are co-operating on engine projects with European and American companies: two of them in programs to develop the hypersonic aeroplane engine and one on the GE90 engine. Although the Japanese contribution is currently fairly small, the Japanese firms carry the potential to be both future competitors, given their government's focus on the aerospace industry, and attractive to become alliance partners due to their financial strength and government support. In addition, alliances with Japanese firms are the perfect opportunity to penetrate the Japanese market even further while it is expanding.

So far, European firms have usually solved the problem of critical size by co-operating mostly within Europe. Intra-EC cooperation was an alternative to industrial integration which has only occurred within national borders and mostly as a result of M&A that formed companies such as DASA, Aérospatiale, British Aerospace and CASA. These consolidated companies are now forming cross-border alliances, however, no multinational aerospace company yet exists.

Consolidation of the European industry through alliances is expected to grow since the risks are not expected to decrease, especially since the growth in the commercial segment of the space market will not make up for the falloff in government programs. In addition, co-operative initiatives are expected with the Russian aerospace industry given their enormous potential. The collapse in some military markets such as missiles will also accelerate the restructuring of the industry, much of it taking the form of alliances / exchanges of business lines as companies focus on critical size and complementary product lines. Rationalisation through integration or the complete disappearance of some firms is also expected in some sub-sectors until they reach their critical size, such as in the regional aircraft industry where it appears that only about a half dozen companies will be able to succeed in the market.

Computers

The entire industry is undergoing a downturn. Europe's large, indigenous IT suppliers, Siemens Nixdorf (D), Groupe Bull (F) and Olivetti (I), are loosing money and are implementing strenuous restructuring measures. After some improvements in their competitive position (market share) in the second part of the 1980s, they have suffered more than their American competitors from the market slowdown in the early 1990s. The key weakness in Europe seems to lie in its inability to integrate research, development and innovation in an overall strategy which both exploits and orients them.

There are, however, a number of factors which may contribute to a better future for Europe than it has experienced over the recent past:

- Downsizing, moving from mainframe based operations to smaller machine data processing may prove easier in Europe where there are around a fifth as many very large machine sites as in the US (hence there will be proportionally less damage for the European large systems players than for the US players). European computing services capable of advising companies on a downsizing procedure are equal to the world's best and have the advantage of local knowledge.
- Desk top, servers and the integrating architecture will define tomorrow's data processing business; Europe has strength in the second and third of these.
- European computer companies are as advanced as any in software development.

So far, nearly 6 000 enterprises operate in the computer and office equipment sector in Europe but only 3.6% of them account for 92.8% of the industry's 1992 turnover.

Alliances in the computer industry are among the most famous: Olivetti's alliance strategy beginning in 1985 enabled this typewriter company to become of the major computer companies in Europe. IBM has set up 35 alliances, excluding IBM's partnership policy with third party software players.

Given the shake-out the sector is undergoing, alliances are numerous and diversified. It seems that most of them aim first at gaining market access through a marketing JV or marketing agreement. Later they concentrate on core activities and ally with companies capable of providing other elements in vertical alliances. Parallel alliances in the computer industry usually involve the transfer of technology. In addition, many computer companies are forming alliances in more profitable related sectors such as management facilities or customised software applications, to diversify away from the declining main-frame industry or the less profitable, commodity-like PC market. The above is a classic text book example of a

situation in which using alliances to enter product markets that are new to the firm has been more successful than using acquisition strategies to enter new markets. Such an alliance (ESI) was formed in the beginning of 1993 by a group of European companies including Sema Group (UK), Bull (F), Cap Gemini Sogeti (F) and Siemens-Nixdorf Informationssysteme (D), who established a software research group in Spain to seek better ways of writing software.

As IT and electronics are becoming critical components of products in industries ranging from the medical engineering to the automotive industry, alliances across sectors are becoming more common to share rising R&D costs and risk, and to shorten the time needed to bring a product from the drawing board to the market. Vertical alliances between computer companies and semi-conductor producers have also been set up and mainly involve Japanese computers manufacturers.

In the past, the industrial strategies of European companies did not sufficiently exist on the EC level. Largely as a result of the 1992 process, European IT companies now exploit the possibilities of cooperation with other European partners through strategic product marketing alliances, as well as through help from the EC via research programmes like Esprit, Jessi and Eureka.

Food & drink

Demand for processed food products rose significantly between 1982 and 1991. Growth of average income positively influenced consumers' preferences toward high-service content, rather than fresh products. The sector is split among numerous and diversified sub-sectors and, as a whole, is fragmented (the turnover of the top ten companies accounted for 18% of the total market in 1991). Some market segments show, however, a high degree of industry concentration, such as sugar and cocoa. The confectionery and ice cream industries are also amongst the most concentrated. Many of the larger companies are multinational conglomerates that are mostly American or from non-EC countries, with the notable exception of Unilever (NL/UK).

In terms of growth strategies, which are still mainly focused on branding, there are distinct sectoral patterns in the food and in the drinks sectors respectively. The food and soft drinks subsectors have mainly grown through M&A activity, despite the existence of some alliances, whereas the decrease in demand for alcohol and spirits forced companies to invest in quality improvement and marketing differentiation. This was done not only through M&A but also through numerous licensing and product differentiation agreements. The same goes for the wine industry, with advanced co-operative strategies in different European countries. Nonetheless, the aggregate food subsector has shown a growing interest for strategic alliances since the 1980s M&A wave. It is now common to use alliance strategy to enter difficult markets such as those in developing countries. The industry's taste for alliances has steadily grown on both sides of the Atlantic; every year has seen at least one big deal. This trend owes much to the stagnation of traditional food markets in the industrialised countries. To maintain growth, companies have to develop higher-margin products that address new tastes and fashions. These pressures have intensified the search for short cuts to faster innovation, cost reduction and the ability to launch new products on several world markets at once. In addition, strategic alliances partly reflect diminishing opportunities for acquisitions, following the mergers wave that occurred during the 1980s.

Examples of alliances that followed the theoretical keys to success were:

- Nestlé (CH) allied with Baxter Healthcare (USA) in 1989 in a 50/50 JV (Clintec) in clinical nutrition (new but related product market, equal ownership and risk sharing);
- Nestlé and General Mills (USA) formed Cereal Partners Worldwide in 1989, a 50/50 JV to make and sell ready-to-eat breakfast cereals outside US and Canada (same product line for partners with entrance into new geographic markets, equal ownership); the main aim behind this alliance was to challenge the market leader Kellogg's;
- Unilever (UK-NL) set up a JV with BSN (F) in 1993 to produce and market products worldwide combining ice cream and yoghurt (new geographic market, new product).

The goals are diverse but all belong to the willingness and the need to realise rapid innovation, to take a global market approach and to achieve economies of scale.

Branding is seeing a revival in the alcohol and spirits markets. After having experienced a sharp decrease of demand due to changes in consumer tastes and preferences, this subsector has seen a redefinition of consumption with a drift in demand from quantity to quality. This has forced firms to invest in both quality production and building brand image. This has been done through both M&As and JVs, and has led to increased control over distribution and the development of worldwide market networks.

Similarly to the food sector, the drink sector is not a capital intensive sector (in the general sense of the term) and essentially relies on distribution for success. Improvements in the distribution system have initially mainly been done through JV with domestic companies as well as acquisitions, but as premium spirits brands have become more expensive to acquire, the alcoholic drinks groups have turned increasingly towards partnerships. The market is now highly concentrated and controlled by a few large multinationals, but there are still many small firms focused on local production of a specific product. This leaves some room for further alliances and further market concentration.

Chemicals

The EC is the world leader in chemical sales (pharmaceuticals included), ahead of the USA and Japan. The EC accounts for seven of the world's top ten companies. After several years of solid growth (1960s and 1970s), the first half of the 1980s saw some stagnant production and overcapacity that led to drastic restructuring. The industry then posted strong growth in the mid to late 1980s, until prospects changed in 1990 with the economic slowdown. Since then, margins have been continuously squeezed due to falling demand and increased competitive pressures, along with poor performance on foreign markets. Weak demand and over capacity are expected to continue in the short and medium term.

The sector is somewhat concentrated, with the top ten leading companies representing 48.6% of the total turnover in 1990, the top five accounting for 32.6% of it. There are important differences by market segment, however. The speciality chemicals sector is mostly a niches market. In the basic chemicals sector, European and North American markets are highly concentrated, mature markets. Growth in both demand and activity should rise with the industrial growth in the Far East, a region that should account for 34% of the demand by the end of the decade.

As far as the trend in alliances is concerned, during the 1980s many companies moved into speciality chemicals to improve profitability. M&As had been intense, linked to positioning for the Single Market and mostly concentrated on downstream chemicals (plastic container and film, speciality chemicals, pharmaceuticals, cosmetics, etc.) to diversify into supposedly more profitable downstream activities. EC companies also undertook major investments in the USA, encouraged by the dollar fall. In the 1990s, the fall of margins and high interest rates made funding more expensive and in 1991, restructuring and cost reductions made M&A activity even more quiet. Many unprofitable businesses units bought during the M&A

fever of the 1980s were trimmed and went for sale with a new focus on core activities. In 1992 and 1993, the restructuring continued, but this has mainly been an internal restructuring. Extra funds for M&A are indeed still low and there are less and less profitable businesses to buy. Firms concentrate on reorganising the market through portfolio realignment and a focus on core competence and competitive advantage, through moves which often involve a kind of redistribution, or swap of activities between companies. This mostly happens through JVs that are in fact mergers between similar business units from different companies. These intra-sectoral mergers are quite original compared to other sectors. An example of this is the June 1993 alliance between Neste and Statoil who have agreed to merge their petrochemical and polyolefin activities in a 50:50 JV company that will be the largest polyolefins producer in Europe and will rank fifth in the world.

In addition, 1992 and 1993 saw a large number of less strategic alliances mostly through joint ventures aimed at sharing costs and risks of production. The most frequent type of alliance appears to be the JV (production and business) and the reasons are clearly cost oriented.

In 1992, there were around 80 JVs and minority participations (these figures represent only alliances involving a European company). Of these 80 agreements, the majority (32) involved only European countries (EEA), 17 included both American and European firms and 10 involved West European and East European firms. Deals involving Japanese companies involved only 3 alliances. The remainder (18) were set up between European firms and companies from Asian and South American countries.

Pharmaceuticals

The pharmaceutical industry is amongst the fastest growing sectors, has rapidly increasing R&D costs, one of the highest R&D/turnover ratios of EC industries and EC leadership in production and exports (its production was about one third higher than that of the US industry in 1991 and more than double that of Japanese production). Within Europe, the leading companies are from the United Kingdom (Glaxo and Wellcome), Germany (Hoechst and Bayer) and France (Rhône-Poulenc). Glaxo, Hoechst and Bayer are among the world's top ten companies, the remaining seven companies are two Swiss and four are USA-based firms.

The production is quite diversified and, from a global standpoint, the market remains fragmented and not highly concentrated. No company has a dominant position: the ten largest companies account for only 25 % of the world market. A lot of small and middle-sized companies survive in niche or specialised markets. The companies already enjoy a relatively high degree of internationalisation, but this internationalisation needs to shift towards globalisation to recover R&D costs.

Despite its relative good health, the industry has to address new and different challenges such as: a decrease in growth rates, increasing R&D costs, worldwide government pressure to curtail health care costs and the necessity to enlarge and review product portfolios. During the last ten years, drug companies have grown primarily through price increases. As this is no longer possible, they will now have to fill their pipeline with new and highly differentiated therapeutics or diversify into related businesses such as was done by Merck (USA) who acquired the US pharmaceutical distribution firm MedCo, a strategy that matched the textbook recommendation of acquisition strategy for entering related fields in overlapping geographical markets. Branching out into related businesses may be a necessity as some firms may have trouble keeping their new drug pipelines flowing with money makers: twenty-five major pharmaceutical products go off patent by 1995 and as of yet, there are not as many "blockbuster" replacements.

In order to cope with the contradictory requirements of surging R&D to feed the new drug pipeline and lower prices to meet government mandates, the industry that was once considered stable with the same 20 or 30 market leaders for the past 25 years experienced a shake up after 1988, as new groups of companies emerged through M&A. The trend was initiated by the merger of SmithKline Beckman (USA) and Beecham (UK) to form SmithKline-Beecham, Bristol Myers (USA) and Squibb (USA) giving Bristol Myers-Squibb and the acquisition of Rorer (USA) by Rhone Poulenc (F).

As far as alliances are concerned, they can be split into two sets: one aimed at optimising "traditional" pharmaceuticals and the one aimed at giving access to biotechnology. Although biotechnology currently represents only around 5% of the pharmaceutical companies' activity, its importance is growing and attracts a high number of R&D agreements. On the traditional pharmaceuticals side, most alliances are marketing oriented given that global expansion becomes increasingly critical to recover R&D costs. This, however, does not prevent R&D alliances to happen in R&D strategic fields, or fields that a company has decided to specialise in to extend its competitive advantage.

Two of the biggest 1990 deals were JVs: Elf Sanofi with Sterling and DuPont with Merck. The former was supposed to bring geographic market access, R&D synergies and production cost sharing, whereas the latter was partly a product swap. Welcome set up a marketing agreement with Hoechst in Germany, Sigma Tau in Italy and Sumimoto in Japan for an anti-viral medicine. More recently, Merieux (F), a subsidiary of Rhone Poulenc, and Merck (USA) allied in 1993. Merieux wanted to strengthen its leadership in vaccines; and given the trend towards multi-purpose vaccines and the rather low profitability in certain world regions, it needed Merck financial and R&D support; in return, Merck gains access to leading vaccine technology.

It seems that these cooperation processes involve major companies, with smaller ones choosing to invest in niche activities. It does not seem that one type of alliance predominates. As far as a geographical split is concerned, there is a definite trend amongst European companies to cooperate most intensively among themselves. International alliances are more common with American companies.

Thus far, the Japanese pharmaceutical industry has not been a leader due to a number of factors among which the weak government incentive to create other high value differentiated products. Government incentive has changed since 1992 and should generate more Japanese interest in technology transfer through alliances.

Biotechnology

Biotechnology is a diversified sector that is related to pharmacy (38% in 1992), diagnostics (28%), agriculture, food, energy and environmental protection. The development of this high tech-sector is in full progress. In addition, one has to distinguish between classical biotechnology (fermentation and preservation processes mainly used in food) and the modern science, characterised by the use of genetic engineering. The food sector was the first which saw the arrival of biotechnological innovations in the mid-1970s. From its birth, the biotechnology industry's progress has been governed by a unique confluence of factors: massive breakthroughs in science and technology, enormous capital needs and a long horizon to payback, financial markets turning alternatively hot and cold, heavy regulation, uncertainty about intellectual property rights and the cost crisis in its primary market (health care). Despite this whole set of hurdles to surmount, this industry produces high value added products and earns commensurate profits.

The industry is going through an accelerated commercialisation phase, characterised by licensing, acquisitions, partnership, strategic alliances and "swaps". This set of strategies is aimed at embarking companies on courses that will advance

them as commercial entities long before their flagship products are through the development process.

According to report by the Senior Advising Group on Biotechnology (SAGB, March 93), alliances in the biotechnology field are more frequent than acquisitions, at least between Europe and the USA. Most of them are set up between small, technically skilled companies with limited access to capital and large pharmaceutical and chemical groups looking for infusions of new products to branch out into from their mature markets. For both of them, commercialisation is becoming increasingly critical because of the R&D cost factor.

The majority of 1991 alliances involved marketing and distribution. Next in numbers were R&D alliances, and then license agreements. This process should continue into the near future because the market is expected to remain fragmented, as most technologies are still in a development stage.

In the future, there is a predominant attraction for the USA, Japan and Asia, whereas Europe will be worse off than the current situation since Europe is perceived as an environment providing low government encouragement, low public acceptance, high interest group opposition, high trade barriers, still high regulatory bureaucracy and rather poor intellectual property protection relative to the USA and Japan.

From a geographic standpoint, the majority of alliances involving European firms are concluded between European and USA companies. The number of such alliances is higher than those strictly involving European firms.

The general form that inter-company cooperation takes in this sector is a follows:

- few acquisitions and mergers;
- an overwhelming majority of R&D participation agreements with USA companies and some universities, but very few JV and licensing agreements;
- of the European groups, 90 % have started R&D departments of their own in the USA; in fact, European companies have initiated more alliances with American firms than the Americans have with Europeans;
- American companies rank the building of fully integrated resources and strategic partnerships as the most preferred approach, whereas European and Japanese firms prefer to form strategic partnerships, or rely on licensing.

Telecommunications equipment

The main product categories in this sector are public switching, transmission, terminals, private switching, data communications and mobile communications. The technological advances toward full digitalisation has meant that the telecommunications industry has become a multi-product industry closely involving electronic and computers industries.

The sector has experienced high growth rates globally, with the EC being no exception. Supply is very concentrated in the Triad. Although the USA are the most established and liberal services markets, the EC shows advantages in terms of benefits gained from the convergence of the 12 Members States and the resulting strength of standardisation and liberalisation of markets. Of the world's top six firms, two were EC companies in 1991: Alcatel (F) was the leader followed by the USA's AT&T (USA) with Siemens (D) in third place. Other leading companies are Northern Telecom (USA), NEC (JPN), Ericsson (S), Matra (F) and Bosch (D). The Japanese companies are becoming more competitive and are investing heavily in R&D. In some specific sectors such as telephone handsets, the competitiveness of East Asian Four Dragons manufacturers is rising.

During the last 15 years, the industry underwent major changes that changed its competitive and cost environment. It went from a national, mature market environment with a relatively low cost structure to a high-tech industry embracing the computer and electronic industries on an international scale.

As with many industries today, the high fixed costs of R&D are now more important than the variable manufacturing cost, and downward pressure on prices further undermine the smaller companies' ability to fund the high level of R&D required to remain competitive. Opportunities are nevertheless enormous, with the result being the formation of new partnerships that take advantage of the opportunities and adapt to the new market environment. Global coverage in terms of geographic markets became the keyword for most of the strategies in telecommunications. The market, still relatively fragmented given the capital intensity, is becoming more concentrated (from 38 companies in 1988 to 19 in 1990).

Non-EC manufacturers, especially USA and Japanese firms, have been preparing for the Single Market for some years; this has been achieved through locating production in the EC, vertical integration and take-overs (a lot of them in the United Kingdom) to build a local manufacturing base and a competitive advantage for selling to the usually state-owned operators. Against this background, two broad types of strategic partnerships are appearing: the first involves alliances between players already operating in the telecommunications market and the second involves alliances between the latter and companies in other sectors, mainly electronic and computers.

The goals of these partnerships are:

- reciprocal market access, especially when regulation hinders free competition;
- economies of scale in R&D, particularly in the case of large public switch manufacturers;
- divestiture- some forms of partnership provide a relatively painless fadeout strategy i.e. the formation of Alcatel allowed ITT to withdraw from public-switch manufacturing while maintaining a 37% stake in the new venture;
- to fill gaps in the product range (product market access);
- to gain access to new and complementary skills such as software development in the case of PABXs, manufacturing skills in the case of fibre optic cable and microwave technology in the case of cellular radio; and, lastly;
- access to new distribution channels. Firms that develop technology from outside the telecommunications sector will often have to rely on established telecommunications companies to distribute their products.

Semi-conductors

European companies remain competitive in certain segments of the semi-conductors market, with Philips, Siemens and SGS Thomson amongst the leading world producers in 1990. European companies are, however, clearly under threat from USA and Japanese companies in terms of technology and market. The market is very concentrated and most firms in this market have a high degree of downward vertical integration. The economics of the industry is dictated by three fundamental factors: short product lives, continuous innovation that lead to repeated technological discontinuities and high investment costs; this means that survivors exploit new products rapidly, building up maximum sales while margins are still high.

The speed with which a technical lead is eroded, the high R&D expenditures required for technology renewal and the huge investments needed for manufacturing give international market exploitation an urgency almost unparalleled in any other industry. This has led companies to forge extensive networks of global alliances and means that the speed with which new plants are brought on line can be the critical determinant of overall profitability; critical mass is the strategy key point, both in terms of markets and production capacity.

Japanese industry has become a leader in many sub-sectors, owing as usual to their effectiveness in new-process technology, manufacturing performance and high linkage with in-house customers. The VLSI project sponsored by the MITI was crucial in that development. The Japanese market is essentially composed of large electronic groups (NEC, Fujitsu, Toshiba) offering synergies between the semi-conductor sector and their in-house electronic and computers skills. But some new players focused on semi-conductors (NMB) are arriving and doing well using USA licences. Europe resembles Japan more than it does the USA industry structure; while some pure semi-conductor companies have developed (Inmos (UK) and SGS (I)), the major European players are divisions of large, diversified conglomerates (Siemens, Philips, Ericsson, etc.). Europe has also benefited from a long tradition of inward investment by American, and, more recently, Japanese companies both in the form of subsidiaries of companies (Motorola, TI, IBM) in the form of and JVs such as Matra-Harris and Eurotechnique, created in 1980 between National Semiconductor and Saint-Gobain of France. These alliances were typically a marriage of imported technology and European money. They have not been particularly successful, however.

Four patterns of strategic partnerships dominate: pre-competitive collaborative R&D, licensing agreements, alliances involving investment by users (vertical integration moves) and joint ventures to transfer technology.

Given the R&D requirements, there has been a growing trend towards R&D agreements. In theory, these often carry the guise of pre-competitive collaborative R&D (a term that avoids antitrust problems and helps secure government financing), led by the successful Japanese VLSI project in the late 1970's. In practice, the dividing line between these projects and near-market R&D is often obscure. In Europe, the principal example was the Mega Project completed in 1988 (Siemens and Philips), followed by the Siemens-IBM alliance and JESSI (Philips, Siemens SGS-Thomson) operating under the pan-European R&D EUREKA program. In the USA, MCC and Sematech, a consortium of more than a dozen companies are similarly organised. In addition, there are smaller and specialised collaborations as well as collaborations with universities. The patterns of collaboration in the semi-conductor industry is becoming increasingly international.

The most common form of collaboration is licensing in terms of second source agreements. The two reasons are market access and the creation of alternative suppliers to the marketplace. The objective is to encourage a number of second source agreements to impose a technical "de facto" standard without loosing the control or ownership over the technology in order to impose its standard (Intel with Fujitsu, Philips and Thomson, Matra-Harris and Siemens).

Access to secure sources of advanced semiconductor technology can give companies important competitive advantages. This has lead electronic companies to establish alliances or make strategic investments in suppliers (IBM and Intel; AT&T and Sun Microsystems; Fujitsu and Amdahl; Siemens; Apple and Motorola; and Thomson and European Silicon Structures (ES2)).

Joint ventures and licensing or venture capital investments are used to achieve a permanent transfer of technology and are initiated by the new entrants to the industry as well as by companies wishing to catch up in a particular technology. Several JVs have been organised in Europe to build an indigenous semiconductor business: Matra-Harris (F/USA); Austrian Microsystems International (A), American Microsystems (USA) and Voest Alpine (A).

Motor vehicles

This section will be split between alliances among the component manufacturers and alliances among car manufacturers.

Component manufacturers

The business climate of this sub-sector is highly tied to the motor vehicle sector performance, hence the competitive threat from Japanese companies poses the same challenge to EC component manufacturers. This market is highly fragmented and the trend is for increased competition.

The drivers for increased strategic alliances between component companies arise from the changes in relationships taking place between European suppliers and vehicle manufacturers. These changes tend to match Japanese relationships between these two categories of firms (it is generally accepted that the overall level of outside purchasing of components by car manufacturers is the highest among the Japanese car manufacturers, followed by the Europeans with American firms being the most integrated).

A large number of alliances in Europe involve Japanese companies and are established to enable Japanese firms to gain market access in Europe, whereas in exchange Japanese companies offer skills in operations optimisation along with joint development and manufacturing.

In North America, Japanese component companies set up greenfield manufacturing plants and tended to go it alone to support Japanese vehicle transplants set up there. The preference for greenfield investment is attributed to the weakness of the USA component industry and the fact that the latter tended to build components suitable for larger cars and not the smaller Japanese vehicles. In addition, many of the major American companies were owned by major USA vehicle manufacturers, which is not the case in Europe.

Indeed, Europe has a larger, independent, innovative and competitive component infrastructure. Japanese vehicle transplants established in Europe have relied on local sources for the majority of cases. Local sourcing was in fact an important issue to address if Japanese vehicle manufacturers were to meet local content requirements. Also, Japanese component companies tried to avoid exacerbating the political sensitivity through aggressive take-overs.

By the end of 1991, of the 350 components producers supplying Japanese car manufacturers, 41 of them followed the Japanese car manufacturers to Europe. Around half of the components producer's investments have been done through joint-ventures. They occasionally proceeded in steps, first setting up a co-operation or a license agreement.

The European Market is a clear and profitable target. During the past 10 years, the number of alliances has been estimated at around one hundred. Most of them are, of course, initiated by the Japanese suppliers for market access purposes, giving technological but mainly operation optimisation "lessons".

Both the EC and Japan have areas of technological capabilities in components. Neither has clear overall advantage. But the Japanese automotive component industry is more competitive in that it has created speed and productivity advantages (in product development, R&D processes, industry structure, labour productivity, higher quality, JIT, etc.). In addition, Japanese component manufacturers have close organisational and financial links with vehicle manufacturers.

This does not prevent acquisitions, however. In 1988, Calsonic created a JV with TI Group to produce equipment for Nissan. In 1989, it also bought TI Group shares and Lanelli radiators. More recently, Asahi Glass who owned 75% of the Belgian company Glaverbel in 1991 took the opportunity, through a double JV, of devoting itself exclusively to the production of a high quality automobile glass for Japanese production in Europe.

The opposite situation does exist, although the European presence in Japan through alliances and licensing to Japanese companies is weak (Bosch owns a minority stake in Nippondenso). There are at least two major reasons to the difficulties

EC component producers encounter: the first is the long-term relationship Japanese OEMs (original equipment manufacturers) nurture with specific, networked Japanese component producers; secondly, Japanese OEMs cite product development related weaknesses as obstacles to increase purchases from foreign component makers. In that respect, the European automotive industry is gradually moving towards a Japanese-like pattern (R&D, logistics), gradually changing OEMs and component supplier relationships to single or limited sourcing.

For European component suppliers, competition is undergoing a major restructuring that does not seem to entail alliances, although some occur such as the Lucas (UK) and Sagem (F) alliance for the development of petrol fuel systems and for the creation of critical mass, as well. Manufacturers are maintaining a cost pressure on the component suppliers and are lowering their manufacturing costs by increasing sub-contracting, disinvesting from their own components manufacturing to concentrate on their core activity and delegating larger activities to component suppliers. This adds up to the transfer of a rising share of the added-value generation to component manufacturers who are now expecting to bear design, delivery and assembly capabilities that are sometimes developed through vertical R&D and technology transfer alliances. The major trend embodies component suppliers delivering intermediate or fully assembled components.

Vehicle assembly

Europe remains the most competitive automobile market, although it remains relatively fragmented compared to its capital intensiveness. None of the competitors (six Europeans in addition to East Asian and American firms) have a clear market share advantage but they account for 75% of European sales. The EC industry has not yet overcome some of its competitors' advantages in terms of cost and quality; it still has to pursue cost reduction strategies, especially given the recent downturn. In the process of retaining or gaining market share, the EC auto industry must find a trade-off between maintaining marketing differentiation and concentration of the industry to respond to the competitive threat. Concentration did increase during the second half of the 1980s, which saw the nearly complete disappearance of independent luxury car manufacturers. This mainly happened through acquisitions (Fiat bought Alfa Romeo, Ford acquired Jaguar, GM owns up to 50% of Saab). Several companies have resorted to cooperation through alliances, however, especially for the production of commercial vehicles and components: Peugeot and Fiat manufacture vans together and Ford and Iveco joined forces in the United Kingdom.

The number of European alliances is expected to grow, however, because (i) the set of competitors are more or less of equal footing; (ii) acquisitions have become much more expensive; and, (iii) competition is still fierce. The number of European firms operating in this sector is thus expected to shrink some more, presumably by some stronger alliance process. In that respect, the positions of Latin manufacturers are weaker than those of the North Europeans.

The frequency of alliances is expected to be highest among the European (and EFTA) countries. The most ambitious cooperation is still the 1990 alliance between Renault and Volvo. This alliance, which almost resulted in a merger in the fall 1993, foreshadows the types of relationships European manufacturers may develop in the coming years.

Europe is now the clear target for Japanese manufacturers, who were more focused on the USA. Although they directly manufacture in Europe, alliances are also expected since Japanese firms still want to enlarge their market share.

Despite the danger of ultimate acquisition by Japanese manufacturers, European companies should also have technological and operational interests in alliances with Japanese producers. Several alliances have already been or are being established: Honda has an equity stake in Rover, Volvo and Mitsubishi have set up joint ventures in the Netherlands, the same occurred between Volkswagen and Suzuki and between Ford and Nissan in Spain.

As far as the USA is concerned, there should not be major new cooperations or acquisitions in Europe: the American manufacturers invested a lot in their recovery in the USA market and will be focusing on that for now. In addition, the US manufacturers are not doing too badly in Europe with their current investment situation.

SUMMARY PATTERNS OF ALLIANCES BY SECTOR

Table 5 summarises the above analysis. The results are given in terms of intensity rather than in numbers since consistent, comprehensive and recent data on alliances including information by sector are difficult to find. Hence, the fact that there is no sign in a given cell in Table 5 does not mean that the factor considered is irrelevant, but rather that it is not frequent compared to other types of factors driving alliances. Also, in most of the sectors analysed, the results reflect the global sector perspective, i.e. cover both the larger and the smaller companies. It has to be mentioned, however, that in most information sources (and notably in the news media), it is the larger companies which usually receive most of the attention. The results may thus be subject to a slight bias. Finally, as there have been significant changes over time in the patterns of alliances by sector, we have chosen to reflect only the more recent situation in Table 5.

Although, as reported in Table 5, the main reasons underlying alliances vary significantly by sector, market access is one of the most frequent reason throughout the sectors, followed by access to technology and process optimisation and cost sharing. Below, we summarise the results by groups of sectors.

Capital intensive sectors

As expected, the capital intensive sectors appear in the list of sectors which mainly seek alliances for cost and technology sharing. Some less intensive sectors, such as vehicle component manufacturers, also enter this category because of a threat from lower cost Japanese operations. Cost preoccupation appears as well through the market access objective: larger markets are necessary to cover the investment costs and reach critical mass.

Fast changing technology sectors

Product and technology access does not appear to be specifically correlated with the faster changing technology sectors. The speed of technological change may either be technology driven or consumer driven. In the first case, the speed of change is generally correlated to the capital intensiveness, and therefore entails technology access goals in the case of expensive research and current low speeds of technology change within a given company.

Mature sectors

Table 3 presented a somewhat theoretical framework for alliances by market type. The results of the analysis by sector in the previous section seem to be consistent with the expected relation between market maturity and goal specificity as reported in Table 3. Mature markets such as the automotive or chemical sectors seek cost reductions. The computer industry, though not being as mature as a whole, is undergoing a price war in addition to having to adjust to a declining main-frame market (where withdrawal goals are important). The main-frame manufacturers are entering the PC market and other diversified areas such as management facilities and software, where alliance goals include gaining access to technology and to new markets as well as diversification. The pharmaceuticals sector, which is also fairly mature, is now seeing biotechnology as a major field of diversification. In contrast, industry specificity remains dominant in the case of the semi-

conductor industry, a sector where critical mass is important and which has not yet reached maturity.

Market internationalisation

Although there is still room in the EC for strictly national or European-level players, the majority of sectors are undergoing a growing market internationalisation, reinforced by the concentration trend of the past years. In that respect, global market access remains a major alliance goal.

Concentration and fragmentation

Concentration has recently grown in many EC industrial sectors, and is now spreading to the more up-stream market segments. However, alliances are increasingly replacing M&A strategies, especially in mature markets where acquisitions have become too expensive or unmanageable. In heterogeneous markets (i.e. where many SMEs co-exist with a few global players), one sees increasingly alliances between niche and global players (as in biotechnology). According to R. Veugelers (K.U. Leuven, Aug. 1993) the relation between concentration and alliances appears to be of an inverted U-shape: when concentration is very high, there are other means besides alliances to monitor or control the competition. Alliances are most common in moderately-concentrated industries.

As far as the leading firms are concerned, it seems that their alliance goals are consistent with a reinforcement of competitive advantage. This mainly happens through diversification and scale.

Geographical split

The predominance of alliance activity involving European firms is obvious in several studies. This, however, partly reflects the greater fragmentation of the European markets.

Specific reasons by sector have been discussed above, but, from a general standpoint, intra-European alliances aim at strengthening or rebuilding competitive advantage (technological, products, brands, alliances, scale), or at reaching a wider market base within Europe. Alliances between European and USA or Japanese companies are more based on product and operation efficiency goals, except in the airlines sector, and on a desire to establish or re-enforce the European firm's presence in these countries' markets.

This reverses the trend of early alliances with Japanese companies, which mainly sought technology gains.

Access to the USA and mainly to the Japanese market indeed remains difficult for European companies, except in the airline, biotechnology and beverage industries. As far as access to the Japanese market is concerned, given the price and risk of go-it-alone strategies or acquisitions, it seems that the principal requirement for market entry lies in the ability to cooperate with local firms. One exception is in the case of totally new products or the building of new distribution channels (i.e. Avon). Thus, more than half of all foreign entries into Japan have been accomplished through alliances. The essential part of developing a local position is to deal with existing strong Japanese alliance networks that exist within keiretsu or industrial groupings. Japanese companies have in fact been the acquirers in approximately 70% of terminated ventures in Japan.

As far as access to US market is concerned, although it still contains the world's largest share of demand, it remains costly, diverse, competitive and complex. EC companies have thus been more successful using acquisition strategies there than relying on alliances.

Table 6 shows expected future trends in cross-border alliances involving EC firms, by sector.

CONCLUSION

Distinctive sectoral patterns of alliances, both in terms of the type of alliance and the motivations behind them have been identified, although the distinction can really be made between sets of sectors based upon market and competitive advantage similarities. The same holds for geographical differences.

Market structures converge in terms of increasing internationalisation, speed of technological change and competition. Factors explaining the recent upward trend in alliance formation include:

- companies are no longer able to lead in all areas of their activities;
- less capital is available for acquisitions;
- already high concentration makes valuable acquisitions very expensive.

Hence, despite the theoretical requirements for alliances and acquisitions, many alliances now take place where, in the past, efficiently or not, acquisitions would have happened.

An additional question arises: what about intra-European alliance efficiency in retaining or gaining competitive advantage towards USA and Japanese players? In the past, many alliances and acquisitions made by Europe's leading national companies were for defensive reasons and enjoyed formal or informal government protection. This is no longer the case, as companies have come to realise that home centred strategies and defensive M&As often failed because they do not address the fundamental gap in competitiveness which is based on skills and global scale and not on national leadership. Of course, attempted cross-borders partnerships in concentrated sectors can bring organisational problems that go beyond the expected benefits, and thus have to be evaluated in this respect. But, there are also examples of large companies which have pursued cross-border alliances despite the fact that the main synergy opportunities were in narrow geographical markets.

In the present situation, for many of the European companies in need of further restructuring to fully benefit from the Single Market, the critical question is whether an alliance will help them reinforce their market potential or whether they should either sell out, i.e. turn themselves into an acquisition target. This article shows that alliances should address the overall industry dynamics, taking into account such factors as critical size, skills needed to compete and an assessment of how the firm's competitive position will change in the face of heightened competition and more demanding customers. For viable national players, whether their business is global, Pan-European or local is critical in the process of determining the relative attractiveness of alliances and acquisitions, and in selecting the partners.

Restructuring industry in Eastern Europe

INTRODUCTION

This chapter of Panorama describes the changes in industry that have accompanied the transition to market economies in Eastern Europe. The chapter first evaluates the "contribution" of industry to the declines in gross domestic product (GDP) reported by these countries during the transition and assesses its role in the current recovery. Subsequently, it analyses the patterns of adjustment within industry with a particular focus on changes in the composition of industrial output and the role of the private sector. In the third section, the paper addresses the issues of ownership and corporate governance in state-owned industry, which has dominated industry heretofore. In this section, the paper evaluates the extent, manner, and success with which state-owned companies have been privatised and briefly assesses the role of foreign investment in industry in the process of transition. The paper concludes with an assessment of revealed comparative advantage in industry in the region, identifying sectors which produced successful exporters and sectors where imports have been more successful than domestic manufactures.

ROLE OF INDUSTRY IN THE ECONOMY

In no other sector has the transition to a market economy in Eastern and Central Europe had such an obvious impact than in industry. Except for the transportation sector and in some instances, construction, the declines in output in industry have been steeper than in any other sector of the economy in these countries (Table 1). Declines in output of some products have been horrific as the numbers of trucks, buses, railroad cars, and machine tools produced have plummeted.

Under the previous regimes, industry was the most highly favoured sector in the economy. Enterprises in industry and in machine-building, in particular, received better access to state investment grants and credits and to imports than other sectors of the economy. Relative wages were higher in industry, especially heavy industry, than in other sectors of the economy. Individuals who made a career in industry (coupled with extensive experience within the communist party apparatus) tended to be more successful politically. Even the statistical apparatus focused more of its energies and resources on reporting on industry than other sectors of the economy.

Because of this pattern of development skewed towards industry, the composition of GDP by sector of origin was more heavily weighted towards industry than in developing or developed market economies. Before the transition, the share of industry in GDP ran from a low of 29.1% of GDP in Hungary to a high of 55.1% in Romania. The latter figure is twice the percentage of industrial output's contribution to GDP in the US or British economies.

Because of the overweening contribution of industry to GDP, the declines in industrial output in recent years have pulled down GDP despite strong growth in services. Declines in industry accounted 50 to 80% of the declines in GDP in Eastern Europe (Table 1).

Industry has declined by more than the decline in GDP in all of the countries. Industrial output figures are reported in two forms: gross and net. Declines in gross industrial output have exceeded declines in net industrial output in all cases, primarily because many industrial activities that generated little, if any, value-added have been those that have declined most sharply. The smallest declines in gross industrial output have been in Hungary and Poland, where output fell 31% before beginning to recover (Table 1). The Czech Republic and Slovenia also report declines of 32-37%. The Balkan countries and Slovakia have suffered the most dramatic declines; gross industrial output has fallen by close to half in all four cases. Patterns for net industrial output are similar.

Table 1: Industry's contribution to the decline in GDP in Eastern Europe

Country	(%) Peak year for GDP	Industry's contribution to GDP	Maximum decline in GDP	Maximum decline in gross industrial output	Maximum decline in net industrial output	Percent of decline in GDP due to industry
Albania	1989	36.3	-42.0	-51.7	-54.8	47.5
Bulgaria	1988	52.4	-23.4	-55.3	-36.8	82.5

Hungarian net industrial output fell 29% from its previous peak before recovering in 1993. Poland, the Czech Republic, Bulgaria, and Slovakia all reported declines in net industrial output of 30-40%. Romania and Albania report declines of over half. Because Slovenia has only been a country since the end of 1991, the reported declines in Slovenian net industrial output only extend back to 1990; gross industrial output figures, however, are available for the period when Slovenia was part of Yugoslavia. The declines in Slovenian gross industrial output has been over 36% since 1990.

On a brighter note, the recent increases in industrial output across the region has spurred the general economic upturn because of the very large contribution of industry to GDP. Growth of 5 and 8% in 1993 in Poland and Albania, respectively, has been driven by very rapid increases in industrial output in these countries. Through the third quarter of 1993 industrial output in Poland was up over 8%. Figures for Romania and Hungary also showed sharp increases in industrial output in comparison with previous year's levels towards the end of 1993.

These increases should continue in 1994 and beyond. Increased competitiveness of the surviving firms, an upturn in domestic demand, a gradual recovery in Western Europe and rapidly rising labour productivity promise increased output. Also, a number of factories have now been closed. Declines in output from these factories accounted for some of the dismal statistics in previous years. As production cannot fall to less than zero, their problems will no longer pull the rest of the industrial output index down.

Because declines in industrial output have accounted for such a large share of the declines in East European GDP, a closer look at the composition of industry's contribution is warranted. In general, the East European statistical authorities still report GDP in prices from the 1980s. A number of industrial products, such as the East German Trabant car or Bulgarian cross-bar telephone switches, are no longer produced because they proved uncompetitive. Because these products accounted for a substantial share of reported output, their disappearance has contributed to the sharp decline in industrial output reported above. As noted by Leszek Balcerowicz, the former Finance Minister of Poland, the high relative values previously ascribed to these products and their subsequent disappearance have resulted in exaggerating reported declines in GDP. Conversely, when the East European statistical authorities eventually revalue past output in prices of the 1990s, the current reported declines in GDP will be much lower because levels of GDP in the 1980s and earlier will be revised downward using the market prices of the 1990s.

SECTORAL PATTERNS OF RESTRUCTURING

As East European industry begins to recover, the market is sorting out the winners from the losers. Table 2 shows the extent of decline by industrial branch and Table 3 shows patterns of recovery. Sometimes the winners are surprising.

In all countries, electric power generation has held up better than other branches. In most countries, output in this sector fell less than in any other despite declines in demand due to falls in output in energy-intensive branches of industry. Import-substitution has contributed to maintaining former output levels. A number of countries, most notably Bulgaria and Hungary, imported up to a quarter of consumption, primarily from Ukraine. As Ukraine raised prices and became an increasingly unreliable supplier, these countries have relied more on domestic production. Output is also up because the burgeoning private sector has increased consumption.

In Bulgaria and Slovakia, publishing activity actually increased during this period of transition, one of the only branches to report increases in output even during the depths of the recession. Publishing has also held up well in Poland, Romania, and Slovenia. The relatively strong performance of publishing possibly reflects the proliferation of new, independent newspapers or the publication of hundreds of pulp novels.

The output of the food processing industries has fallen in every country, but by less than the average declines in industry output. In Poland, the industry shows signs of recovery, running less than 10% below previous peaks. Elsewhere, food processing has yet to show signs of a turnaround (Table 3).

The output of the chemicals industry has more or less followed declines in aggregate industrial output. However, it is one of the sectors that is leading the recovery. Output of the chemical industry was up sharply in Poland and Slovenia in 1993 and up modestly in Bulgaria, Hungary and Romania.

Like chemicals, declines in the output of construction materials have mirrored aggregate declines in GDP. This sector is also pacing the upturn with sharp increases in output in Poland and Hungary in 1993, 10.4 and 18.7% respectively. The increases reflect increasing demand by the construction industry as new businesses renovate retail establishments or set up new facilities. This sector, especially cement and float glass, has been a prime target for foreign investors. Much of the cement industry in the Czech Republic, for example, has been

sold to foreign companies. Major glass companies in the Czech Republic, Hungary and Poland are now foreign-owned.

Light industry has generally done poorly in the transition. Textile output, in particular, has declined sharply. In almost all countries, output has roughly halved. The East European textile industry was focused on the domestic and Soviet markets. With trade liberalisation, better quality Western-made fabrics have been imported by domestic apparel makers. Former Soviet clients have also switched to Western suppliers or have stopped production.

Clothing has performed almost as poorly as textiles with the exception of Bulgaria where output had fallen only 12% through 1992. The clothing industry performed significantly better than textiles in Hungary and Poland as well, declines in output were roughly half of those in textiles.

Output declines in machine-building have been enormous. In Bulgaria, the Czech Republic, Hungary, and Romania, output of the engineering sector fell 60 to 70% below its previous peaks, and in Poland, it halved. In all these cases, declines in output of the engineering sector exceeded those in industry as a whole. Machine-building has been the sector hit hardest by the collapse in trade with the former Soviet Union. In the past, a number of manufacturers exported more than half their output to the former Soviet Union; today, they hardly export anything at all. Soviet enterprises either lack the funds to purchase investment goods from Eastern Europe or have turned to Western suppliers. Machinery producers have also been hurt by the economic changes in Eastern Europe itself. In the past, investment programs were financed by grants or concessionary loans from the national governments and enterprises were often forced to purchase equipment from domestic suppliers or from other manufacturers in the former Council for Mutual Economic Assistance (CMEA). Following cut-offs in government financing, trade liberalisation and greater independence for enterprise managers, demand for CMEA-produced machinery plummeted.

Despite past declines in output, machine-building is one of the most promising sectors in Eastern Europe. The major rebounds in industrial output in 1993 have been in machine building. Within machine-building, automobile producers have done very well. Output of transport equipment in Hungary, Poland and Romania in 1993 was up 42.2, 26.5, and 27.0%, respectively. Production of Skoda automobiles in the Czech Republic were up 24%. Because of Eastern Europe's low labour costs, high skill levels, and established industrial base, metal-working and machine-building appear to be areas in which these countries, especially the northern three, have a comparative advantage.

With the exception of Slovakia, ferrous metallurgy has been devastated by the transition. Output fell by two-thirds in Bulgaria, Hungary and Romania and by over 40% in Poland and Slovenia. The sector shows modest signs of recovery in Bulgaria, Hungary and Slovenia. This sector has been especially hurt by protectionism in the European Union and the United States, where steel has traditionally benefited from inordinately high barriers to trade. On the lower end of the market, Eastern Europe could have a comparative advantage in ferrous metals. Labour costs are much lower than in Western Europe and the technological lag in the production of rods and some other forms is fairly narrow in some plants. Eastern Europe has also shown itself to be competitive in forgings and castings.

Non-ferrous metals output has also been hammered during the transition, falling by three-fifths in the Czech Republic and one-third in Hungary. Only in Slovenia have declines been limited to 25%.

Mining, frequently included in industrial output statistics in Eastern Europe, continues to post sharp declines in output. In many countries this is a positive, not a negative sign. In a misguided attempt to ensure energy self-sufficiency, central planners propped up loss-making coal mines for decades. The planners' fixation on meeting production targets frequently led to the continued operation of highly uneconomic mines. The rationalisation of mining has led to sharp declines in output as well as employment, but has resulted in large savings in subsidies, increased labour productivity, and signs of less environmental degradation.

INDUSTRIAL PRODUCTIVITY AND EMPLOYMENT

The declines in output have partially masked very substantial changes in the operation of East European enterprises. Many of these enterprises have begun to operate as independent firms in a market environment rather than departments of the Ministry of Industry, waiting for orders from on high. These changes have shown up in improvements in efficiency and competitiveness. In particular, productivity is beginning to rise.

Eastern Europe's human capital stock, one of the primary determinants of a country's standard of living, is comparable with that of many West European countries. However, the gap in living standards between the two regions is very wide; West German living standards are on the order of 5 times higher than those in Eastern Europe. The first signs that Eastern

Europe is beginning to put its human capital stock to better use have shown up in productivity increases in industry. These have been very strong in 1993, running 11% in Poland and 13.8% in Hungary (Table 4). Even in countries like Romania and Slovenia, where industrial output continues to fall, productivity is up, rising 5.8 and 1.6%, respectively.

Recent reported increases in labour productivity are not just statistical flukes. Western companies have generally declared their pleasure with the quality of the East European labour forces. In factories where Western investors have installed modern equipment and use Western management techniques, productivity levels have been as high as 80% of West German levels despite substantially lower wages. However, many plants are still encumbered with poorer quality equipment and even poorer management systems. As plants continue to adapt, the scope for productivity improvements is great. These increases will generate increases in real incomes or greater industrial output.

A counterpart of the increases in labour productivity has been the continued declines in industrial employment. The recent increases in industrial output have been accompanied by few increases in the industrial labour force. The surviving companies have been able to increase output without hiring additional workers. Nonetheless, labour markets are improving in the region. Unemployment rates have stabilised or even declined, although it continues to be a serious problem in many regions. Many enterprises have completed the first and second rounds of layoffs so further declines in employment in these enterprises will be limited. Rapid employment growth in services and the private sector is absorbing the unemployed, especially new graduates.

The decline in unemployment rates is occurring as real wages are beginning to rise. Those individuals fortunate enough to hold onto their jobs are beginning to benefit from more substantial salary increases at a time of falling or stabilised inflation. Increased job security and fatter wage packets are feeding through into higher retail sales. As productivity continues to rise, this phenomenon will continue through 1994 and beyond.

MANAGEMENT OF STATE-OWNED ENTERPRISES

The changes in labour productivity cited above and the increases in East European export competitiveness assessed below can be traced in part to major changes in the behaviour of East European managers. Both anecdotal and statistical evidence shows that East European managers are adapting to a market environment. Managers in all the countries have had to lay off workers, at times more than half their work forces. Many have successfully sought new markets as shown by the increases in exports to the developed West. They have also begun to invest with an eye to rate of return rather than merely increasing output. Imports of machinery produced in the West are up substantially, by more than 50% in some countries, as managers are replacing existing machinery with more productive Western models. In short, managers have begun to adapt to the market.

The key to changes in managerial behaviour has been to liberalise prices, lower barriers to entry, and cut off subsidies; privatisation of large state-owned enterprises has been of lesser importance. Price liberalisation, the first step towards creating markets in these countries, has eliminated excess demand, forcing managers to focus on sales, rather than production, as consumers exercise their new-found freedoms to pick and choose what they wish to buy. Lower barriers to entry and to trade introduce competition as state-owned enterprises must compete against new, private firms and imports.

Successful enterprise adaptation follows a pattern. Immediately after prices are liberalised, enterprises have initially raised prices more than expected by the authorities. Real wages decline dramatically during this period as prices of goods increase more rapidly than wages. Retail sales plummet and enterprises find that inventories begin to rise. Enterprises usually curtail production as they begin to run out of room to store products. Some workers are placed on short time or leave. During this period, reported enterprise profits are often quite high as wages have yet to rise and because of increases in the value of inventories.

Subsequently, enterprises begin to feel financial pressures. This is the crucial period of the transition. Increased financing costs because of increases in nominal interest rates (part of successful stabilisation polices) and lower sales squeeze profits. Enterprises stretch out payments to suppliers and other creditors. The transition may be stymied at this point, if enterprises continue to receive supplies and finance even though they fail to pay for them. In this case, managers do not adapt. Credit creation balloons. When the central bank eventually bails out the enterprises and commercial banks, stabilisation policies fail and inflation accelerates, derailing the reform.

If, however, enterprises face a "hard" budget constraint, managers begin to adapt. They begin to market to new clients at home and abroad. These activities have led to the substantial increases in exports to western Europe from the successful reformers in Eastern Europe. In some cases, enterprises reduce prices so as to increase sales. Enterprise managers also begin to make selective investments to improve product quality, eliminate bottlenecks, or cut costs. These investments were frequently the first investments that managers had liberty to decide themselves without interference from the supervising ministry, and also the first in which rate of return was the major determinant, as opposed to increasing output. The results of these investment decisions has shown up in the surge of

imports of machinery from Western Europe. Finally, managers begin to reduce the labour force, at first through voluntary departures, but later through forced redundancies.

Changes in managers' behaviour have been reinforced by commercialisation, the process of creating limited liability companies from state-owned enterprises. These new companies are no longer run by a ministry, although ministries continue to have a powerful voice. Managers now answer to a board of directors, created when the enterprise is transformed into a state-owned joint stock company. The boards have made the managers both more accountable and more independent. Managers now produce and report financial results to the board rather than negotiating export or production targets with a ministry. This change has concentrated minds on reducing losses and turning a profit.

When successful, the result has been extensive restructuring. Subsidiaries have become independent companies, units have been bought out by their managers, and loss-making operations have been closed down. Management systems have been revised. Companies set up profit centres and change their accounting systems to provide better information as well as to better conform to Western standards. In most cases, these East European firms still do not operate like their Western counterparts, but their activities are much closer than they were four years ago when the centrally-planned systems were last in place.

Management has changed because of changes in personnel as well as changes in behaviour. The new, non-communist governments have replaced some managers. Others have quit, unable to operate in the new environment, replaced by more dynamic individuals. On the other hand, some former managers have adapted and most new managers are recruited from the ranks of employees, not from outside the company.

THE PRIVATE SECTOR

Despite the improvements in management of state-owned enterprises, a number of indicators suggest that the new private firms and the newly privatised firms operate more efficiently than their state-owned predecessors. Average wages in private firms are higher than in similar state-owned enterprises. Not surprisingly, workers have been migrating to these new employers. Private firms have also been generally profitable, whereas a very large share of state-owned enterprises made losses in 1992 throughout the region.

Despite the benefits of private ownership, industry has been a laggard in privatisation. In Poland, one of the countries most advanced in privatisation, 83.4% of employees in the trade sector and 69.7% in construction worked in the private sector in 1992; 52% of total employment was in the private sector in 1992. In industry, this percentage was only 34.4%.

This pattern is repeated throughout the region; in industry, the state-owned sector remains dominant in every country. The one partial exception is the Czech Republic, where a large share of industrial companies was included in the first voucher privatisation. However, even after voucher privatisation, the state continues to own a majority stake in many of these "privatised" companies.

The smaller share of the private sector in industrial employment than in other sectors stems from the difficulties in privatising state-owned industry. The most effective form of privatisation in all these countries has been through the entry of new private firms into particular markets. Entry is easiest in sectors with few economies of scale and which require little capital, such as retailing and construction, and most difficult in capital-intensive activities such as heavy industry.

Aside from permitting the creation of new private firms, these governments have also adopted a number of programs to privatise existing state-owned assets. All the countries have either used auctions, direct sales, or restored property to former owners to privatise smaller businesses and residential property. These programs have been largely successful. Hungary and Poland have permitted management or employees to buy out their enterprises. This program of "liquidation" of state-owned assets, has been the most successful means of privatising industrial companies in Poland. All the countries have also permitted enterprises to sell specific assets to investors. The Czech Republic, Slovakia and Romania have experimented with mass privatisation programs whereby individuals have been given vouchers with which to purchase stocks or invest in mutual funds in the case of the Czech Republic and Slovakia or have been given shares directly in mutual funds as in Romania. Poland and Hungary have each sold over twenty companies through initial public offerings.

One of the most effective solutions for privatising larger state-owned enterprises has been to sell them to foreign investors. Foreign investors purchased 85% of all privatised assets in Hungary in 1991 and 75% in 1992, far exceeding investments by domestic investors. Sales of enterprises to foreign investors precipitate changes in management and efficiency. These investments have brought in Western management and information systems as well as capital. Cost controls, marketing expertise, ties to international distribution systems as well as new technologies have resulted in substantial improvements in the efficiency and profitability of these firms. Foreign control has often been a crucial goad to improving industrial operations.

Foreign investors are playing an increasingly important role in the economies across the region. Foreign investment in some of the countries has been very large. In Hungary, foreign investment inflows have run 1.5 billion annually, equivalent

to 4.6% of GDP at market exchange rates. Inflows into the Czech Republic have also run 1.1 billion, about 4% of GDP. These inflows as a percentage of GDP are very high compared to other countries, including the rapidly developing countries in Southeast Asia. Poland has received less foreign investment (about 700 million in 1992), but inflows are increasing. Foreign investment in Romania and Bulgaria has been small, respectively 128 million and 102 million in 1992.

A very substantial share of these investments were made in manufacturing. Although in terms of numbers most joint ventures and other investments were made in the trade sector, in dollars terms, investment in manufacturing accounted for more than half of all investment in Hungary. A similar story can be told in Poland and the Czech Republic; in dollar terms, manufacturing accounts for most of the foreign investment in Eastern Europe.

The most popular industrial sectors have been automobiles, cement, float glass, food processing, and electric power generating equipment. The largest East European automobile manufacturers, FSM in Poland and Skoda in the Czech Republic, are now under foreign control. Motor vehicle components are becoming an increasingly attractive sector. Publishing has also attracted a large number of foreign investors, especially newspapers and magazines. There have also been substantial investments in the downstream sector of the petroleum industry, especially in retail networks. Industrial gases has attracted foreign investment in Poland. Telecommunications equipment manufacturers have also attracted foreign partners, primarily to increase the likelihood that the foreign partner will win some of the large East European telecommunications orders currently being issued.

Foreign investors have shied away from the steel, truck manufacturing, and chemical industries. Truck manufacturing, in particular, has failed to attract a single foreign investor. Textiles has also failed to attract much interest. However, a number of Western companies have invested in smaller producers of clothing.

In short, industries dominated by a few large multinational companies in Western Europe have attracted substantial amounts of foreign investment in Eastern Europe as well. However, industries that have suffered from overcapacity and losses in Western Europe, such as bulk chemicals and steel, have, not surprisingly, failed to attract foreign investors.

PATTERNS OF TRADE

Since the collapse of central planning, trade in Eastern Europe, especially trade in manufactures, has gone through enormous changes. After the collapse of the communist governments, the northern three (now four countries) in the region, reported large increases in exports to the developed market economies and simultaneous sharp drops in the volume of exports to the countries in the former Council for Mutual Economic Assistance (CMEA), the Soviet Bloc's answer to the European Community, following its collapse. In contrast, the Balkan economies reported declines in both types of trade. The extent of the decline in trade with the former CMEA has been breathtaking, although probably somewhat exaggerated because of valuation problems. Based on official exchange rates, in 1992 Bulgarian exports to the former CMEA were only 9% of their levels in 1989 (Table 6). Czechoslovak and Polish exports were a third and Romanian a quarter. Even using 1990 as a base, by 1992 exports had fallen 60% in Bulgaria, 55% in Romania, 43% in Poland, and 45% in Czechoslovakia. Only Hungary posted more moderate declines, in part because official exchange rates better reflected market realities in 1989.

The increases in exports to developed market economies by some countries during this period were almost as startling as the decline in exports to the former CMEA. Through 1992, Hungary reported the largest increases with exports up by over three quarters in dollar terms (Table 7). Polish exports jumped 42% in 1990, and rose another 17% in 1991, before falling slightly in 1992. Czechoslovak exports to the developed West surged 58.1% over this period. In contrast, Romanian exports plummeted, falling to less than half their level in 1992, as economic reform failed to take hold and the pressure to export imposed by Ceausescu was released following his departure.

The third major shift in Eastern European trade was precipitated by the West European recession in 1993. Every country in the region except Albania reported declines in exports for 1993. Even countries like Romania and Bulgaria where exports had already declined during the transition, suffered another knock in 1993. In fact, after Hungary, Bulgaria reported the sharpest declines in exports. The most important factor in the decline has been the West European recession. DRI/McGraw-Hill estimates that German imports of manufactures fell 15.2% in dollar terms in 1993. As Germany is the most important market for almost every East European country and as a large share of East European exports to Germany are primary or intermediate goods purchased by German manufacturers, the decline in German demand has an immediate impact on East European suppliers. Austria and Italy, two other economies that have been hit hard economically, are also major East European markets.

East European firms are not only hurt because the European recession has been most severe in their major markets. They have also been squeezed because they have traditionally been the marginal suppliers. Since the 1960s, West European firms have turned to Eastern Europe for additional inputs when markets are booming. In recession, they return to traditional suppliers or in-house sources of supply. West European labour

policies probably exacerbate this effect. Although cost pressures increase in a recession, making lower cost East European labour more attractive, the costs of laying off labour in Western Europe are quite high. Many West European firms find it financially more palatable to avoid layoffs rather than continue to use East European subcontractors, even if the East European suppliers are cheaper. The one-off costs of layoffs are so high that many firms wish to minimise these during a recession.

In contrast to the gloomy export picture, import demand has been more mixed. Imports were very strong in Poland in 1993, up an estimated 16.8% for the year in dollar terms. Foreign aid and the recovery in Albania have permitted continued strong imports in that country as well. Excluding imports from Slovakia, which declined an estimated 30%, Czech imports increased 13.9% during the first half of 1993 to 4.577 billion. Hungarian and Slovenian imports were also up

The composition of imports has shifted dramatically, reflecting the restructuring of the economies and the effects of the recoveries. Machinery imports are up sharply in the recovering economies due to increased investment demand. Imports of consumer goods, including clothing, shoes, consumer durables, and food, have also risen as demand recovers. In a number of cases, superior Western products have eliminated domestic products. For example, Japanese and Korean consumer electronics have made great inroads in domestic markets. Branded soft drinks and consumer hygiene products have also eliminated or hurt local manufacturers.

Imports of raw materials, on the other hand, have not recovered. The closure of a number of steel operations has reduced the demand for iron ore and coke. Energy imports have also been tempered due to declining industrial demand.

Restructuring has resulted in a more "developed" pattern of imports; imports of components and subassemblies has increased sharply as the new operations of Western multinationals trade components with the parent companies. Domestically-owned manufacturers are also increasing demand for imports as they improve quality and their competitiveness by substituting superior for inferior components.

Other countries have not been able to afford more imports. Bulgaria, in particular, has been hurt by financing constraints. Financing has been a problem for Slovakia as well. In Slovakia imports are estimated to have declined 22% to 5.69 billion in 1993, compared to 7.32 billion in 1992. Imports from the Czech Republic bore the brunt of the decline.

Despite the increases in exports to developed market economies through 1992, East European exports totalled only 64.1 billion and imports, 70.8 billion in 1992, roughly equivalent to the trade of Switzerland or China in that year. The comparatively low level of East European trade would be even further depressed if intra-Czechoslovak and intra-Yugoslav trade were excluded. This trade added about 10 billion to exports and imports. With a population of over 100 million, Eastern Europe has substantial trade potential. Large increases in the volume of trade conducted by this region are likely over the next 10-15 years. These increases should greatly outstrip the growth of trade within the OECD or Western Europe.

The differing rates of change in trade with the former CMEA and the developed West have resulted in a dramatic shift in the geographical composition of trade. East European trade has shifted decisively in the direction of the developed West. In 1992 the share of the OECD in total East European trade (excluding Serbia and Montenegro) increased to 57.2% of exports and 57.8% of imports. Under the previous system, the developed West accounted for only a third of East European exports; the former CMEA accounted for well over one half. The highest share of OECD trade in total trade in 1992 was registered by Poland (72.2% of exports and 72.5% of imports), followed by Hungary and Slovenia (Table 8). The lowest share was recorded by Slovakia (29.5% of exports and 25.5% of imports). Slovakia still conducts the bulk of its trade with the Czech Republic. The country with the largest concentration of its trade with European Union in 1992 was Poland (57.9% of exports and 53.1% of imports), followed by Slovenia and Hungary. Bulgaria and Slovakia, again, reported the lowest shares, 30.8% and 22.3% of exports, respectively. The share of the EU in imports was similar. The importance of the EU to Eastern Europe is due in large part to increases in trade with Germany. Germany has become by far the most important trade partner of East European countries, accounting for 23.0% of total East European exports and 19.5% of total East European imports in 1992, followed by Russia (6.5%; 10.8%), Italy and Austria. Poland with 31.3% of its exports sold to Germany and 23.9% of its imports from there is the most dependent on Germany trade, followed by Hungary, Slovenia and the Czech Republic.

Although few of the countries provide detailed information on the commodity composition of exports by region, patterns reported by Czechoslovakia, Slovakia and Hungary are illuminating. By volume, Hungarian and Czechoslovak exports of machinery to the former CMEA tumbled 78.7 and 73.3%, respectively, between 1989 and 1991. As machinery accounted for over 60% of Czechoslovak exports to the CMEA in 1989 and 52% of Hungarian exports to this region, the declines in machinery exports accounted for a very large share of the drop in overall exports to this region. Exports of industrial consumer goods followed a similar pattern, although the falls were not quite as precipitous.

The experience of Hungary and former Czechoslovakia was repeated throughout the region. It was a consequence of rectifying the distorted, former patterns of trade. Traditionally, Eastern Europe had been a net exporter to the former Soviet Union of machinery, manufactured consumer goods, and agricultural products and a net importer of energy and raw materials. After the collapse of the CMEA, Soviet demand for machinery plummeted. In fact, much of the decline in industrial output in these countries can be traced to the collapse of trade with their former partners in the CMEA. Declines in exports to the former Soviet Union accounted for the bulk in the fall of this trade.

On the other hand, East European exports of machinery and manufactured products to the West have risen, reversing a decade of decline. In a number of instances, former East European exports to the CMEA were successfully diverted to West European markets, even in the case of such goods as machinery and transport goods. Between 1989 and 1991, Eastern Europe increased its share of the OECD market for imports of manufactures by 41%, from 0.5% in the late 1980s to 0.7% in 1990-91. Hungary and Czechoslovakia reported volume increases of 20.6 and 8.9%, respectively, in machinery exports to OECD countries and increases of 44.8 and 79.4%, respectively, in exports of manufactured consumer goods. In contrast to the 1980s, when raw materials, fuels and food products generated increases in exports, in 1990-91, exports of manufactures accounted for 96% of the increase in Czechoslovak exports to OECD countries. Key exports have been chemicals, garments, paper, construction materials, especially cement and glass, iron and steel products, manufactured metal products, and automobiles.

On the import side, the opposite pattern has occurred, with most countries reporting significant increases in imports of machinery and transport equipment (SITC 7) and miscellaneous consumer manufactures (SITC 8), while imports of fuels (SITC 3) and certain raw materials and semi-manufactures have typically declined. Clearly, the shift in East European imports towards machinery and consumer goods reflects the fact that in 1992 demand for imports was for the first time overwhelmingly driven by market factors and not by government directives in most countries. This change in economic

system also accounts for a broad diversification in East European imports. With a continued fall in GDP and industrial output in all countries except Poland and large increases in relative prices for these goods with the disappearance of implicit Soviet trade subsidies, the demand for imported energy and raw materials continued to shrink. Consequently, the share of imports of machinery and nonfood industrial consumer goods in most East European countries increased sharply in 1992 while the share of fuels, raw materials, and semi-manufactures declined.

Comparative advantage and changes in the composition of trade

Although every East European country has experienced sharp declines in exports of manufactured goods to the former CMEA and most have increased exports to developed market economies, changes in export patterns and the significance of particular commodity groups varies from country to country. Below, major changes in the commodity composition of trade are analysed for each individual country so as to provide an indication of revealed comparative advantage, especially in the case of manufactured products.

Bulgaria's most important exports in 1992 were plastics and plastic articles - 11.0%, followed by tobacco and tobacco manufactures - 7.2%, iron and steel - 6.8%, mechanical machinery - 6.2%, and electrical machinery - 6.0%. Apparel and textiles were also important, the former accounting for 2.5% of total exports. As elsewhere in Eastern Europe, the share of machinery and equipment in exports has declined dramatically, from 30.6% in 1991 to about 15.6% in 1992, because of the collapse of machinery and equipment exports to the former Soviet Union. Total machinery exports fell about 48% in dollar value terms in 1992 from 1990. Industrial non-food consumer goods still accounted for 22.3% of total Bulgarian exports in 1991, but in 1992 their share declined to about 11%. The relative importance of chemicals in Bulgarian exports has clearly risen dramatically - in 1991 these accounted for 10.9% of total exports and in 1992 they accounted for approximately 22.0% of total exports, i.e. their share almost doubled.

There was a notable increase in the share of machinery and equipment in imports over the last few years - from only 15.8% in 1991 to 23.0% in 1992, with the percentage rise in these imports reaching an impressive 86%. The share of imports of industrial consumer goods which amounted to 4.4% in 1991, rose to the 7-8% range. Imports of fuels and raw materials have fallen sharply.

Croatia's most important export category in 1992 was manufactured consumer goods (19.8% of total exports), followed by machinery and transport equipment (19.0%); and basic chemicals and chemical products (15.8%). Croatian imports in 1992 were quite diversified. Basic chemicals and chemical products were the most important, accounting for 18.0% of imports, followed by machinery and transport equipment (16.7%), and intermediate manufactures (14.0%).

The largest increase in **Czech** exports in 1992 was reported for intermediate manufactured products which rose 18.4%, primarily because of a sharp rise in exports of steel and steel products to the developed West, especially Germany. Exports of miscellaneous consumer manufactures were also up, 5.7%. However, exports of machinery and transport equipment and chemicals fell 15.3% and 5.4%, respectively. This pattern of shifts in export structure was definitely a major disappointment to the Czech government officials, who had hoped that the continued shift away from manufactured products to semi-manufactures and raw materials would be arrested in 1992. In 1992, the most important export category was intermediate manufactured products (32.2% of total exports), followed by machinery and transport equipment (25.2%), and miscellaneous consumer manufactures (11.5%).

With a 25.7% increase in total Czech imports (excluding imports from the Slovak Republic) in dollar value terms in 1992, imports of most products increased proportionately. By far the most rapid growth occurred in imports of machinery and equipment and miscellaneous consumer manufactures which were up 49.5% and 47.7%, respectively. One factor affecting growth in imports of machinery and equipment was the purchase of several Boeing aircraft from the United States towards the end of 1992. Imports of crude materials were up only slightly - 1.9% - reflecting further contraction in domestic industrial output and slow substitution of cheaper imported materials for certain more expensive domestic substitutes. With the sharp rise in imports of Western machinery and equipment, the share of these products in total Czech imports in 1992 reached 38.5%, becoming the dominant import item by a wide margin. The role of machinery in trade with Germany was especially strong. Roughly half of Czech imports from Germany were machinery and transport equipment; a little less than a fifth of its exports to Germany fell into this category.

Hungarian exports of industrial consumer goods rose 23.2% in 1992, with very dramatic increases in exports of clothing, footwear, and household textiles (53.4%). Exports of machinery, transport equipment, and other capital goods increased slightly - 1.0%. Notable increases were reported in exports of telecommunications equipment and products - 23.7%. Hungary's exports in 1992 were broadly dominated by raw materials and semi-finished products (28.7% of total exports), closely followed by industrial consumer goods - 26.3% and agricultural and food products - 24.0%. The share of machinery and equipment, including spare parts, was a comparatively low 18.4%.

On the import side, total Hungarian imports declined by 2.5% in current dollar terms in 1992 and similar declines were experienced in most key commodity categories. However,

Table 7: Total East European trade with developed market economies

(million USD)	Bulgaria	Czech Republic	Czecho-slovakia	Hungary	Poland	Romania	Slovakia	Slovenia
1989	1 301	N/A	4 741	4 249	6 667	4 417	N/A	N/A

Source: PlanEcon, based on national statistical bulletins

there were large shifts in imports within major commodity categories, with some imports up sharply and others down sharply. For example, imports of raw materials declined 20.7% while imports of semi-finished products increased 5.4%; imports of new machinery and equipment declined only 1.2% (with large increases in imports of transport machinery (up 22.9%) and other capital goods (up 63.9%), and large declines in imports of tractors and agricultural machinery (down 50.2%). There was a major change in the pattern of imports of industrial consumer goods, with substantial declines in imports of appliances and accessories (down 23.6%), radios, TV sets, and domestic electrical appliances (down 20.3%), and clothing, footwear, and household textiles (down 4.5%), while imports of other goods increased sharply, including furniture (up 83.6%) and detergents and cosmetic products (up 36.7%). The most important broad import category in 1992 was still raw materials and semi-finished products (excluding spare parts), which accounted for 30.6% of total imports, followed by machinery and equipment (including spare parts) (26.6%), and industrial consumer goods (22.3%).

As noted above, Hungary registered the worst export performance in Eastern Europe in 1993 with the possible exception of Bulgaria. Exports in dollar terms declined by over one fifth in 1993, reversing a number of the gains in exports made in 1992. The largest declines in exports were in exports to the EU which fell almost 30% in dollar terms. Exports of machinery actually rose during the year, up a scant 1-2%, but exports of industrial consumer goods were down sharply, by about a third, wiping out many of the gains of 1992. Within industrial consumer goods, the sharpest declines were registered in clothing and footwear, especially clothing manufactured on consignment, packaged pharmaceuticals, and household chemicals. Exports of transport equipment, on the other hand, were up sharply due to exports of automobiles from the assembly operations of General Motors and Suzuki.

Poland's most important export category in 1992 was intermediate manufactures, accounting for 27.2% of total exports, followed by machinery and transport equipment (19.1%). Miscellaneous consumer manufactures comprised 11.7% of total exports. The changes in the structure of Polish exports in 1992 were notably different from most other East European countries, which experienced large declines in exports of machinery and equipment (in Poland the decline was more modest) and non-food industrial consumer goods (in Poland, these exports actually increased significantly.

The pattern of change in Polish commodity imports in 1992 also departed in significant ways from the patterns observed elsewhere in Eastern Europe. In most East European countries in 1992, imports of machinery and equipment and non-food industrial consumer goods imports increased. In Poland, imports of machinery and equipment declined. Polish imports of crude materials actually increased, while most East European countries experienced declines in imports of crude materials. The most important import commodity category in 1992 remained machinery and equipment (29.8% of total imports). Chemicals and intermediate manufactures were also important, accounting for 13.5% and 11.8%, respectively. Miscellaneous consumer manufactures, accounting for 10.3% of total imports, were also important.

The commodity composition of Polish trade varies sharply between the developed market economies and the former CMEA. Intermediate manufactured goods accounted for 28.7% of exports to developed market economies in 1992; steel and non-ferrous metals exports were important products within this commodity group. In contrast, intermediate manufactured products accounted for only 12.4% of exports to the former CMEA. Machinery and transport equipment accounted for roughly the same shares of exports to both geographical regions in 1992, 17.2% to the developed market economies and 21.8% to the former CMEA. Food's share in exports to the former CMEA was almost double that to developed market economies. The share of consumer goods in total exports to developed market economies, on the other hand, was 14.1%, substantially more than the 7.8% share in exports to the former CMEA.

The most important commodity groups in **Romanian** exports in 1992 were: base metals (17.1% of the total), mechanical and electrical machinery (10.8%), textiles (10.6%), transport equipment - 10.4%, and chemicals - 9.7%. There were more dramatic shifts in the commodity structure of Romanian convertiblecurrency imports. Exceptionally large increases occurred in imports of hides and skins - up 359%, animal and vegetable oils and fats - 183%, wood pulp and cellulosic materials - 147%, plastics and rubber products - 140%, textiles and textile articles - 134% (this is a real surprise since this turned Romania into a net importer of textiles to the tune of 106 million in 1992, compared to net exports of 86 million in 1991), transport equipment - 63%, and mechanical and electrical machinery - 57%. With total convertible currency imports up only 11.3% and two or three-digit growth rates for the above, the Romanians cut other imports, primarily fuels. The extreme swings in the commodity composition of imports which occurred in 1992 reflected the process of "normalisation" of the import commodity structure from the Ceausescu days, in which energy imports swallowed an overwhelming share of the total. In terms of relative importance, fuels and mineral products still dominated imports in 1992 - they had a 32.0% share in total imports (down from 48.7% in 1991), followed by mechanical and electrical machinery - 15.3% (up from 10.8% in 1991), textiles - 9.5% (up from 4.5% in 1991), and chemicals - 7.0%.

In 1992, total **Slovak** exports (excluding exports to the Czech Republic) increased by 6.9% in dollar value terms, but as in the case of the Czech Republic there were rather diverse developments in individual commodity categories. Notable increases occurred in Slovak exports of crude materials (up 31.4%) and intermediate manufactured products (up 25.8%). The rapid increase in exports of intermediate manufactured products reflected large increases in exports of steel and steel products from the Kosice Steel Works. Kosice steel exports accounted for most of the 45% increase in exports of intermediate manufactures to the developed West in 1992. The Kosice Steel Works is undoubtedly the most modern and efficient steel producer in Eastern Europe and in terms of price it may be one of the most competitive (in its range of steel products) in all of Europe. Unfortunately for the Slovaks, it is also a major threat to less efficient Western European steel makers with high labour costs. The EU, in particular, has made it a target of quantitative restrictions on imports.

The expansion of exports in the above three categories was critical to offset significant declines in export earnings in other areas, notably from exports of machinery and equipment (down 17.7%) and fuels (down 24.4%). With significant losses from declining exports of manufactured products, the developed market economies of "containment" of Slovak steel and intermediate manufactured products is causing serious injury to the Slovak economy. The rise in exports of steel and other semi-manufactures pushed the share of this category in total Slovak exports to 42.6% in 1992, decisively overshadowing exports of machinery and transport equipment with its 17.3% share. Other important export categories for Slovakia in 1992 were miscellaneous consumer manufactures (14.4%) and chemicals (11.4%).

The pattern of changes in Slovak imports, excluding imports from the Czech Republic, in 1992 was quite similar to that in the Czech Republic with one major difference - whereas total Czech imports were up 25.7% in dollar value terms, total Slovak imports declined by 4.6%. Despite the overall decline, substantial increases took place in imports of machinery and transport equipment (up 27.4%), and miscellaneous consumer manufactures (up 26.8%). As in the Czech

Table 8: Share of trade with West in total East European trade, 1992

(%)	Share of exports	Share of imports
Poland	72.2	72.5
Hungary	70.5	69.2
Slovenia	66.1	66.3
Croatia	55.9	52.9
Romania	47.9	52.8
Czech Republic	47.3	50.2
Bulgaria	42.3	46.5
Slovakia	29.5	25.5

Source: PlanEcon, based on national statistical bulletins

Republic, significant contraction occurred in imports of fuels and crude materials. The combination of a substantial increase in imports of machinery and equipment and a contraction in imports of fuels caused the former - with a 31.9% share in total 1992 imports - to overtake the latter as the most significant import category.

The unusual aspect of **Slovenian** exports is their extreme concentration in three commodity categories - SITC 6, 7, and 8 - which together accounted for 79.7% of total Slovenian exports in 1992. The largest of the three is machinery and transport equipment which accounted for 29.4%, followed by manufactured goods classified by material (27.1%), and miscellaneous manufactured consumer products (23.2%). The extremely high share of manufactured products in exports - 88.8% if chemicals are added to the above three groups - sets Slovenia apart from the rest of Eastern Europe, showing that Slovenia's economy is much more West European in its industrial and trade orientation than other economies of Eastern Europe, with considerable similarity to Austria or Switzerland.

Slovenian imports were considerably more diversified than exports. The largest import item in 1992 was machinery and transport equipment (26.4%), followed by manufactured goods classified by material (19.6%), and chemicals (12.4%).

CHANGES IN TRADE FLOWS

The East European export "push," particularly in the case of steel and steel products, cement and certain construction materials, textiles, and food has caused considerable political problems as large increases in East European exports in these commodities have generated adverse response from domestic Western producers of identical or similar products. The problem, however, has primarily been the rapid increases in exports, rather than East European dominance in any market. In almost all cases, East European manufacturers claim very small shares (less than 5%) of EU import markets. However, the increased competition has come at a difficult time as dropping demand has pressured manufacturers throughout Europe. More importantly, increased competition from Eastern Europe in selected sectors is part of the process of integrating the economies of Eastern and Western Europe together. Somehow most Western decision makers fail to understand that any fundamental economic restructuring which will take place in the East will automatically require corresponding restructuring in the West.

The association agreements that have been signed with the East European countries have reduced standard levels of protection on East European exports. The agreements have a number of bilateral safeguards embodied within them. However, at the beginning of 1994 anti-dumping/anti-subsidy measures against Eastern Europe and the former USSR accounted for only 0.34% of total trade with these countries.

The European Council which took place in Copenhagen in June 1993 adopted important decisions to improve market access of East European products. Most custom duties on industrial products will be progressively abolished within the next couple of years, while quotas and ceilings on East European imports follow the same timetable.

Contrary to the perception of East European political circles, West European protectionism has not been the major cause of the drop in exports in 1993 nor are current levels of protection likely to forestall export increases in 1994. Czechoslovak, Hungarian and Polish exports to the EU increased rapidly in 1990-1991 despite higher barriers to East European exports than are currently in place. With the passage of the GATT agreement and continued implementation of the association agreements, overall levels of protection should decline in 1994 and beyond.

Investment strategies of EC companies in non European countries

INTRODUCTION

The completion of the Single European Market and the reduction of trade barriers between the main trading regions have considerably influenced corporate investment strategies of both EC and non-EC firms within the Community territory. Such strategic movements within Europe are, however, only one element of European and non-European companies' global strategies. During the 1980s, European companies have invested heavily in non-European countries, either to strengthen their presence in other world regions, to gain access to new markets or to take advantage of lower production costs in these regions.

This article analyses the recent trends in EC foreign direct investment (FDI), and provides an overview of the geographical concentration of the EC's FDI. Particular attention is focused on outward investment towards the developing world (Asia excluding the Middle East, Latin America excluding the Caribbean, and Africa) This article also examines the main factors underlying FDI strategies in a number of industrial sectors in the EC, and discusses the extent to which these factors will impact over the short and medium term.

RECENT TRENDS IN EC FOREIGN DIRECT INVESTMENT

Global patterns of foreign direct investment

The US, Japan and the EC are responsible for the bulk of world FDI. If intra-EC investment is included, the EC is the largest single investor, with a stock of FDI valued at 538 billion ECU at the end of 1991, compared with 345 billion ECU for the US and 264 billion ECU for Japan. Excluding intra-EC investment, the EC slips back into second place behind the US, at 297 billion ECU, as shown in Figure 1.

FDI outflows from the EC grew significantly during the 1980s, from an annual flow of 14 billion ECU in 1982 to 84 billion ECU in 1989, including intra-EC flows. Between 1985 and 1989, outflows increased dramatically, but were overwhelmingly directed internally. Intra-EC FDI peaked in 1990 and has since fallen back, while EC FDI in the developing world is still on an upward trend.

Even so, in 1991, 57% of FDI flows from the Big Four EC investors (France, Germany, the Netherlands, and the United Kingdom) were directed internally, and only 10% went outside the major industrialised nations of the OECD. Just 6% went to the developing regions that are the focus of this study. This represented a flow of 3.6 billion ECU, equivalent to 0.5% of total fixed investment within the Big Four (708 billion ECU). The most dramatic recent shift in EC FDI flows is to eastern Europe rather than Asia, Latin America or Africa. In 1992, flows to eastern Europe from France, Germany and the Netherlands alone were 1.3 billion ECU.

The ownership of EC FDI is very unevenly distributed across countries. The UK is by far the most significant EC investor in the developing world, followed by Germany, the Netherlands, France and Italy. In manufacturing alone though, the UK and Germany are very similar, since Germany's FDI is more heavily tilted towards this sector.

Foreign direct investment flows to the developing world

EC FDI to less developed countries (LDCs) represents a small, albeit growing, share of total business investment in the EC. In 1991, the main four EC foreign direct investors (France, Germany, the Netherlands, and the United Kingdom) invested 5.8 billion ECU outside the OECD (10% of their total foreign direct investment outflow) and 3.6 billion ECU in Asia excluding the Middle East, Latin America excluding the Caribbean, and Africa (6% of their total outflows). These represented 0.8% and 0.5% respectively of total domestic fixed investment in these four EC nations.

Flows of FDI from the Triad (i.e. the EC, Japan and the US) to the developing world rose dramatically during the 1980s (though not more rapidly than flows of FDI within the Triad). Outflows of investment from the EC to non-OECD nations rose from 2.8 billion ECU in 1982 to 13.0 billion ECU in 1991. The 1991 figure is inflated, though, by a 4.5 billion ECU outflow from Italy which is unidentified but which looks suspiciously like a purely financial transaction. Excluding Italy, the EC FDI outflow to the developing world in 1991 was 8.6 billion ECU, very similar to the outflows in 1988-90, but still two to three times higher than in the early 1980s. This EC performance was far from unique, though. The level and the growth rate of investment by the US and Japan in non-OECD nations in the 1980s were very similar to those for the EC.

Let us now look at the more narrow group of developing nations upon which this study focuses. By 1991, the Triad had accumulated a stock of FDI in Asia excluding the Middle East, Latin America excluding the Caribbean, and Africa of a combined total of 154 billion ECU. This was distributed very evenly between the Triad members: Japan: 54 billion ECU; US: 52 billion ECU; EC: 49 billion ECU. The Japanese stock, though, is probably overstated since it is based on cumulated flows of approved FDI, so it both includes approved FDI that never took place and ignores disinvestments. It may not in reality exceed the EC stock.

Asia and Latin America have been much more important destinations for FDI than Africa. At the end of 1991, the Triad's stock of FDI in Asia excluding the Middle East had reached 79 billion ECU, ahead of Latin America excluding the Caribbean at 56 billion ECU. In comparison with these two blocks, Africa has been only a minor destination, with a stock of just 19 billion ECU (much of that in South Africa).

It is worth noting here just how important it is to treat the Caribbean region separately. The Triad's FDI stock in the Caribbean and Panama (73 billion ECU) is bigger than its stock in the rest of Latin America, and nearly as large as the stock in Asia excluding the Middle East, but it consists almost entirely of holdings in tax havens. Combining it with the rest of Latin America would give a totally misleading picture of the international location of production.

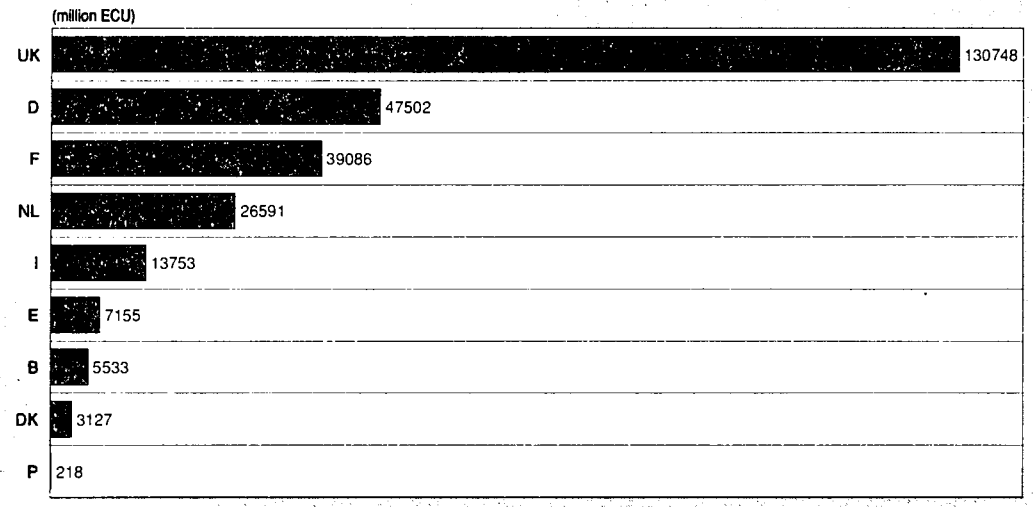
It is not surprising that geographical proximity has led Japan to be the largest investor in Asia, and the US to be the largest investor in Latin America. The EC takes third place in Asia and second place in Latin America. The EC's investment stock in both of these regions is just below 20 billion ECU. The EC leads only in Africa.

Latin America has historically been the main developing world recipient of EC FDI in manufacturing. Although Asia has been catching up, the most significant shift in EC FDI flows in recent years has been the diversion of investment flows to eastern Europe. For Germany and the Netherlands, at least, this may have come at the expense of, rather than in addition to, flows to Asia.

Asia (excluding Middle East)

Recent FDI flows to Asia have been the most substantial to any developing region and have shown the most rapid growth, with Japan the main source of the flows. EC and US FDI in developing Asia have followed a steadier but much shallower upward path. EC flows peaked in 1991, the last year for which we have complete data, at 2.0 billion ECU, just below the US level of 2.7 billion ECU. From the data available so far for 1992 it seems that EC flows to developing Asia actually fell back. Flows from France rose by 114 million ECU, but flows from Germany fell by 156 million ECU, and flows from the Netherlands fell even more steeply by around 550 million ECU. Flows from these three nations to developing Asia added up to just 546 million ECU in 1992. This can be compared with a flow of 1.3 billion ECU from the same nations to eastern Europe.

Figure 3: Cumulative FDI outflows by EC country, excluding intra-EC flows, 1982-1991



Source: OECD and National Statistical Offices

Although EC flows to the Asian region did grow in the 1980s, they should be placed in perspective. Flows grew sharply to all regions, and flows within the EC grew particularly rapidly. In 1991, Asian developing nations still accounted for less than 3% of total EC FDI. The share of EC FDI going to developing Asia actually eased back gradually over the decade of the 1980s due to the dramatic increase in intra-EC FDI.

Latin America (excluding Caribbean)

The US has been the main investor in Latin America by far. After investing only modestly there in the early part of the 1980s, (and actually disinvesting in some years) FDI outflows from the US to Latin America surged from a disinvestment of 0.9 billion ECU in 1985 to a new peak of 4.5 billion ECU in 1992. In contrast, FDI flows from the EC to Latin America have stayed roughly flat at around 1.5 billion ECU per year, while flows from Japan have fluctuated between 0.5 billion and 1 billion ECU.

An examination of flows of FDI from the EC to the two major developing regions over the last five years for which data is available (1987-1991) indicates that the total flow to Latin America and Asia was very similar, both totalling 7-8 billion ECU over the five years. The growth compared to the previous five years was much stronger for Asia. Even within the 1987-1991 period, the momentum of the flows was strongly towards Asia. The flow to Latin America was relatively static, never exceeding 1.7 billion ECU, while the flow to Asia gradually strengthened, reaching 2.0 billion ECU in 1991.

Africa

The EC is the leading investor in Africa although, even for the EC, Africa is only of minor importance as a destination for FDI relative to other developing regions. The EC and Japan continued to invest in Africa during the 1980s while the United States disinvested heavily at the end of the decade. The EC invested more in Africa during the 1980s and early 1990s than either the US or Japan, with a dramatic spike in 1989 to a level of 2.7 billion ECU.

The significance of Africa for most EC nations is very limited, though. Most of the FDI flowing from the EC to Africa in the 1980s originated in the United Kingdom.

GLOBAL STRATEGIES OF EC FIRMS IN SELECTED SECTORS

The sectoral distribution of EC FDI in the developing world is heavily concentrated in manufacturing and energy (mainly oil). Within manufacturing, chemicals is by far the most important sector, accounting for nearly half of EC FDI in the developing world. The other significant sectors are electrical engineering, food, drink and tobacco, and motor vehicles, but even combined together these sectors are less important than chemicals.

The present chapter will examine FDI strategies of EC firms in selected manufacturing sectors. It is difficult to make general statements about the EC's overall FDI activity in manufacturing by country/region and by sector because there are too many gaps in the data. Some conclusions can be derived, though, based on the data discussed in the country sections above.

If we combine the data for France, Germany, the Netherlands, and the UK (EC-4) we find a manufacturing FDI stock in Asia, Latin America, and Africa of 23 billion ECU at the end of 1991. EC manufacturing FDI in developing regions has been dominated historically by Germany and the United Kingdom. These two account for about two-thirds of this stock, in roughly equal proportions. Germany's manufacturing FDI is mainly in Latin America, the UK's mainly in Asia.

Figure 4: Sectoral breakdown of UK FDI to developing world, 1991

Table 1: The importance of FDI from the Europe-4 (1), 1991

(billion ECU)

Total FDI flows	57.1
Extra-EC flows	24.6
Flows to non-OECD nations	5.8
Flows to the developing world (2)	3.6
Total domestic fixed investment in the Europe-4	707.5

(1) France, Germany, the Netherlands, United Kingdom
(2) Asia excluding Middle East, Latin America excluding Caribbean, Africa
Source: OECD and National Statistical Offices

Manufacturing investment in developing regions is mostly concentrated in the chemicals sector. 45% of the FDI stock for the EC-4 is in chemicals. The most important regional destination for chemicals investment is Asia.

Electrical engineering (15% of the stock), transportation equipment (11%), and food, drink, and tobacco (10%) are next in importance. The investment in transportation equipment is dominated by Germany's investment in road vehicles in Latin America. Investment in the other two sectors is much more evenly spread both by source and destination.

Chemicals

The chemical industry ranks among the manufacturing sectors in Europe that perform the largest amounts of FDI in LDCs. In the group of countries for which detailed statistical information is available (the UK, Germany and France), the chemicals industry had an accumulated FDI stock of 6.6 billion ECU in LDCs at the end of 1991. This represented about 40% of manufacturing FDI by the same countries. The share of the chemicals industry in manufacturing FDI in LDCs amounted to 28% in Germany, 46% in the UK and even 54% in France. The weight of the chemical sector in European FDI in the LDCs is a result of the leading position of the European chemicals industry in world markets.

FDI in LDCs by chemical companies largely reflects a desire to diversify into new geographical markets. Especially Southeast Asia and China are chosen as new expansion areas. Their enormous growth potential, due to the combination of a huge population and an economy at the start of industrial development, is in sharp contrast with the stagnating European home market. UK firms, which already have an important presence in Asia, are still expanding production capacity to follow demand growth and are looking for new geographical markets in China where they are still only marginally involved.

LDC production mainly serves local or regional demand. This is especially the case in Southeast Asia where a rapidly growing local demand easily absorbs all production. Consequently, relocated production does not replace European production, but at most limits the growth of exports from Europe. The motivation to reduce production costs by souring cheaper labour in LDCs plays only a minor role. There is evidence though that Latin American plants, mainly in Mexico, are increasingly being used as a cheaper source of supply for the North American markets.

The business segments in which European chemicals companies concentrate their FDI are specialty chemicals (agrochemicals, fertilisers, dyestuffs, paints,...), fibres and pharmaceuticals. FDI in pharmaceuticals is extensive due to the national differentiation of markets resulting from national regulations and licensing rules. It is estimated that FDI accounts for twice the value of pharmaceuticals that enter into international trade. The output being produced or the production processes often involve proprietary technology, which the investors prefer to apply in wholly or majority-owned ventures. The fastest growing products are those being supplied to the textile and automotive industries in Southeast Asia and China: fibres, additives for textile production, plastics, dyestuffs, pigments and paints.

By contrast, European chemical companies are not interested in deploying basic petrochemical activities in the LDCs, because they have few competitive advantages to exploit in that business segment. The manufaeture of basic petrochemicals has a low value added and uses fairly unsophisticated and widely known technologies. If western companies are (or were, since this is mainly a thing of the past) involved in petrochemicals in the LDCs, it is mainly through ventures that involve no or only small capital investments: joint ventures with minority share, licensing, technical assistance, plant engineering and construction.

Mining and metals processing

The metals industry is highly dependent on downstream industries for demand. Depressed levels of investments by these industries had caused a heavy drop in demand for metals and reactions to overcapacity is causing industry concentration and capacity cuts, particularly in steel. A rapid rise in imports from Eastern Europe and the CIS, whose products are artificially cheap due to energy subsidies and cheaper labour, has hastened the decline in demand for EC metal goods; this is especially true for both steel and aluminium.

Under the current circumstances recent foreign investment activity by metal producers has been slight. Those foreign investments that exist today were generally made more than one decade ago. Reasons for the investments were more for locating production closer to the natural resource that forms the raw material for the industry. Since European iron ore quality is low and expensive to mine, EC steel makers import a high volume of ore from mines that they partially or wholly own within the LDCs, as well as within the framework of management/technology exchange contracts or directly from the world market.

Crude and semi-finished products made in the foreign country of investment were also targeted for the markets in and around that nation or for supplying the world market in general. This results in EC-based metal processing firms purchasing semi-finished materials for final products. The EC thus remains a net exporter of steel products, although in the past three years there has been a negative growth rate in extra-EC exports.

As developing countries grew both in economic and technological terms, these nations began making investments of their own within the metals industries. These entailed either the formation of new firms that directly competed with EC owned local companies, or the purchase of all or a portion of the EC subsidiary. During the recent global economic downturn, companies formed by the foreign countries have had difficult times since they have now essentially taken on the majority of the business risks formally shouldered by the EC investing company who supplied the majority of the original capital. The more recent investments made by EC companies have been more in the form of joint ventures, technology licences and management assistance, with some loans and partial investments. Majority or wholly-owned subsidiaries are not as common because of the high risk of foreign demand fluctuations, exchange risks, and, occasionally, political risks.

There is unfortunately not enough statistical data available to give a price figure for FDI flows by EC metal producers in the LDCs. However the EC metal industry does not rank among the largest direct investors in foreign countries. Furthermore, FDI does not play the prominent role in direct capital formation for this particular industry. Other forms of investment, such as technical assistance contracts, licensing or other contractual forms are more common in this sector.

Mechanical engineering

The stock of FDI by the mechanical engineering industry in the LDCs amounted to 988 million ECU at the end of 1991 in the countries for which statistical information is available (Germany, the UK and France). This represents about 6% of manufacturing FDI in LDCs by these three countries.

Foreign investments by EC mechanical engineering producers have mainly been targeted at gaining access to local markets in the LDCs and their surrounding area. This is mainly the case for heavy industrial equipment and construction related products, but has also been the case of some smaller construction equipment such as industrial hand tools. The relocation of EC capital has either been in wholly owned subsidiaries or joint ventures with new or existing foreign companies. The reasons cited were closer proximity to the foreign market, avoidance of import tariffs, high transport costs, lowering the company's vulnerability to business cycles and lower labour costs. In one case, it was cited that relocated production did replace former EC production for export. In another case, a German manufacturer stated that relocated production increased activity within the EC for the provision of support to the foreign activities.

Electrical and electronic engineering

The stock of FDI in the LDCs by the electrical engineering and electronics industries amounted to 3,415 million ECU at the end of 1991 in the countries for which statistical information is available (Germany, the Netherlands, the UK and France). This represents about 15% of manufacturing FDI in LDCs by these four countries.

The electrical and electronics engineering sector has a clear strategy toward foreign expansion through direct investment in wholly owned subsidiaries or, more commonly, joint ventures. The main goal of these investments has been to penetrate markets in the region of the host country. Sometimes a local presence was required to avoid tariff barriers. Lower labour costs are a secondary benefit in most investment decisions. LDCs are considered to offer attractive investment opportunities because of their growth prospects. EC firms are targeting Southeast Asian countries for mid-term growth and East European and former Soviet Union countries for longer term growth.

In general, production of consumer electronics takes place where the products will be marketed. However, there is an increasing tendency to relocate production to low-wage regions. For example, on the ground that European labour costs are too high, a large EC consumer electronics producer is running down mass production of laser disc players and other audio equipment in the EC and transferring most production to the Far East, which has become the major destination of FDI by EC consumer electronics manufacturers. Not only do lower labour costs weigh in the choice to process FDI, however. EC firms are also increasingly locating production facilities in countries characterised by high market growth. As a matter of fact, a large amount of FDI stocks by EC firms occurred in the past years in Asian or far east countries.

It is nevertheless interesting to note that the employment and production effects in Europe of these relocation movements by EC companies outside of the EC are partly offset by recent moves in the opposite direction by Asian companies relocating production from Asia to Europe. According to Kaisui, the labour cost for assembling a TV set in Europe represents only 10% of the total cost of the set. Production costs in Asia are therefore only marginally lower, and the gap is narrowing as wages in these countries increase.

The location and size of production in the electronics industry is generally determined by increasingly fewer large companies or groupings of companies operating globally, which either own or effectively control the location of production in the component industry. Consequently, electronics manufacturing is now for the most part a global business, i.e. globally co-ordinated production of globally standard products by multinational enterprises.

Production tends to be kept close to home where the product or process is at a technological leading edge, while they are still in development, and when volumes are low. Otherwise, manufacturing location is mainly determined by the size of regional markets, the economics of production and the availability of skills. During the boom years of the 1980s, there has been a noticeable shift in the centre of gravity of electronics production, mainly to the newly industrialised countries and the developing countries of the Far East. Indeed, these areas combined low wage costs with a well educated workforce and a rapidly growing market.

The NICs in Southeast Asia (namely South Korea, Singapore, Taiwan and Hong Kong) have become favoured sites where EC companies set up semiconductor facilities, in order to benefit from low costs and highly educated workforces. In contrast, Latin American and African countries do not represent a significant destination for investment in such production activities. The analysis of the origin of extra-EC imports gives further evidence of the preference for EC companies to locate production facilities in South East Asia. In 1990, above 13% of total extra-EC imports of electronic engineering products originated in Singapore and Taiwan.

Motor vehicles and components

The motor vehicles and components industry accounts for about 10% of FDI in LDCs by the manufacturing sectors in the countries for which statistical information is available (Germany, the UK and France). At the end of 1991 the stock of FDI in LDCs by the transport equipment industry (mostly automotive) stood at 2,420 million ECU.

FDI in LDCs by EC automotive companies mainly consists of the investments of the large German firms in Latin America, notably in Brazil, Mexico and Argentina. The predominance of Latin America as destination of the investments of German firms has historical reasons. In the 60s and 70s the Latin American subsidiaries only served the protected local market. In the 80s however they were integrated in the global production strategies of their parent companies and now they export vehicles and components to the US and Europe. One can conclude that FDI by the German automotive companies in Latin America has reached its final stage. Indeed, with the exception of Volkswagen in Mexico, the Latin American subsidiaries grow in line with the groups they are part of.

In Asia, German and European automotive manufacturers are still largely absent. While the investments of German firms in Asia are growing rapidly, they still represent only a small fraction of total group assets. Japanese car manufacturers on the other hand are very active in this region, mostly through joint ventures with limited financial stakes and the government as partner. These ventures follow the same evolution as European and American subsidiaries in Latin America: from production for the local protected market to integration into the parent strategy. Within the ASEAN countries, specialisation in production between countries is possible because many protectionist import duties depend on ASEAN content and not on local content. Only Japanese producers have an ASEAN-wide integrated strategy. German presence in Asia will undoubtedly grow in the future. Since 1990 Volkswagen is investing heavily in the expansion of its joint ventures in China. Last year the Group created a new Board of Management responsible for the Asian region, reflecting its important role in corporate strategy. The main motivation for investing in Asia is the enormous growth potential of the Asian market. Volkswagen expects China, presently its tenth largest market, to move up to third place as early as 1996.

Textiles and clothing

The emergence of new important players in the textile and clothing industry has completely disrupted the world market. Countries located in South East Asia (Taiwan, Hong Kong, and South Korea) emerged as major textile producers in the fifties at a time when they were implementing an export-oriented industrialisation strategy. In the 1980's these countries' industrial strategies shifted towards higher technology and skill intensive activities. The NICs were replaced by countries like Indonesia and the Philippines and more recently by China, Morocco, Turkey and Bangladesh.

These new producers made large inroads in the world's market by selling cheap textiles and clothing products. To remain competitive, EC manufacturers reacted by either increasing their flexibility and diversifying their product ranges, and by transferring part of their activities towards low-wage countries. The Germans were first to adopt this strategy, and started sending semi-finished products to neighbouring countries presenting low wages (Turkey, Yugoslavia in particular). In a first stage, this led clothing producers located in other parts of Europe to relocate in order to maintain competitiveness. In a second phase, the phenomenon of relocation started to be implemented in upstream sectors, such as textiles, despite their higher capital intensity than clothing.

This relocation strategy, developed on a large scale, has major consequences on the EC's trade balance. Europe's textiles and clothing industry nets a trade deficit in both textiles and garments, though the latter account for the bulk of the deficit. This witnesses large flows of trade between Europe and low wage countries, where either subcontractors or European firms located there produce garments from raw materials or semi finished products exported from Europe. This activity then gives rise to further imports into the European market. EC know-how exerts an influence on EC imports which include products designed in Europe, and marketed under EC brand names. A report by Texco/KSA for CEC estimates that a third of EC clothing imports are controlled by EC manufacturers.

Whereas the textiles and clothing industry has long been involved in foreign operations in developing countries (far more pervasive in clothing than in any other segment of the industry), FDI was never significant in the first place. The bulk of investment in these countries takes the form of non equity investment such as international subcontracting, followed at a considerable distance by licensing, which is mostly found in the more fashion oriented products. Textile producers are, however, also involved in these countries via FDI, through the supply of second-hand textile machinery: often, as they have re-equipped their local plants with more advanced machinery, they tend to transfer their older equipment to developing countries through notably FDI, as part of broad strategic considerations.

There is no statistical data available which separates FDI by the textiles and clothing industry from other manufacturing FDI. However, the study of the EC's major trading partners provides additional information on the geographical distribution of textiles and clothing output. While developed countries like Switzerland, Austria or the US rank as the EC's major suppliers of textiles, the EC imports massive amounts of (mainly low-price, mass produced) clothing from the developing countries. Among them are, by decreasing order of importance: China, Hong Kong, Turkey, Yugoslavia, South Korea, Morocco, India, Tunisia, Thailand, and Indonesia. It is noticeable that the EC holds a trade deficit with all these countries (except Hong Kong) in both clothing and textiles. This indicates that the kind of activities developed with these Far east countries is quite different from the trade developed with east European or north African countries, where Outward Processing Traffic (OPT) is the most common form of production organisation.

Pulp, paper and paperboard

In the past, pulp and paper companies have processed FDI in LDCs for several reasons: to enter new markets, to reinforce the company's presence in foreign markets they entered long ago, to be closer to raw materials and to use the lower cost labour to produce pulp and lower grade products for the local and world markets. Since then, host countries have started their own companies or have taken over the foreign-owned firms to compete against the EC (and often the EFTA and North American) companies. EC firms have also made joint ventures, technology and management assistance investments outside the EC. These types of investments are, in fact, the more common ones to take place today. Foreign investment in production aimed at supplying the world market may have hurt EC pulp and paper companies because of the resulting worldwide overcapacity in pulp and paper production. Responses from the pulp and paper industry indeed indicated that recent investments in non-EC countries added to, not detracted from existing EC production. In fact, since many types of pulp are essentially commodities that are traded on a global scale, prices are easily affected by large capacity investments made anywhere in the world.

Another stated reason for foreign investment was to avoid the transportation cost of serving a distant market. To remain competitive with local production firms, EC firms had to relocate production to within a reasonable distance from the customers, particularly for finished paper products. Import tariff barriers have also played a role in encouraging the relocation of production facilities.

For the companies that are re-importing their foreign production to the EC, they do so because of the availability and cost of the raw materials to make pulp. Since it makes more economic sense to ship the semi-processed material rather than logs, EC firms with foreign pulp or paper mills can then benefit from the cheaper labour that exists near the raw material source. Pulp and paper company strategies are not necessarily geared for exploiting cheaper labour forces as the primary reason for investing overseas.

Food, drink and tobacco

The food, drink and tobacco industry in the countries for which statistical information is available (the UK, the Netherlands and France) owned a stock of FDI in LDCs of 2 375 million ECU at the end of 1991. This represents about 10% of total FDI in LDCs by the manufacturing sector.

Food, drink and tobacco companies expand in LDCs for two reasons: to diversify out of the mature European and North American markets into growth areas, and to increase the revenue from their brands by selling them in a larger area.

Expansion in the LDCs usually takes the form of FDI in wholly or majority-owned operating subsidiaries serving the local or regional market. Local production is necessary because food products are difficult and expensive to transport, certainly in LDCs where infrastructure is poor and distances large. It is therefore impossible to serve any sizeable market through exports from Europe. For the same reason, exporting of food products from LDC subsidiaries to Europe is excluded.

Food companies, especially the large ones, prefer to invest in wholly or majority-owned subsidiaries because this enables them to assure a consistent product quality around the world. This is important to safeguard the reputation of their brands. However, when smaller companies set up operations in the LDCs, they are more likely to use joint ventures with limited financial stakes. The preferred way of entering a market in the food and drink industry is by acquiring an existing firm, if suitable takeover candidates are available. The acquired firm offers the acquiring food group immediate access to local distribution channels and locally known brands. The own brands can then be added on.

Asia (China, India and Southeast Asia) is the fastest growing market for food products and cigarettes, and therefore also the most attractive to western food conglomerates. While average purchasing power is very low, this is compensated by the high growth rates of income and the enormous population size. Sales of packaged foods suddenly take off when GDP per person passes the level of 5 000-10 000 USD per year. As more countries cross this threshold food product sales grow faster than income. A small fraction of the population (but in absolute numbers very large) has an affluence comparable to west European countries. They buy the most sophisticated processed foods and are very conscious of the snob value of western brands. To take advantage of these growing market opportunities, British companies, already present in Southeast Asia and India, are now rushing into China.

CONCLUSION

Distinctive sectoral patterns have been identified for FDI strategies of EC firms. This distinction can be made between two sets of sectors based upon the reasons sustaining their investment strategies. The strengthening of the competitive position of firms following the concentration movements in EC industry over the late 1980s, has made EC firms operating in sectors such as chemicals, motor vehicles, food, drink and tobacco or electrical and electronics engineering, more competitive on world markets. This has created an incentive for them to expand abroad to have access to an enlarged market. For these industrial sectors, geographical diversification is seen as a key strategy for future success or even sometimes for survival. Local production will therefore be maintained, or even expanded, so as to achieve substantial market penetration or to avoid tariff or non-tariff barriers.

For other industrial sectors, market liberalisation in Europe has heightened the competitive environment and has sometimes created an incentive for firms to relocate part of their activities abroad to reduce production costs. As a matter of fact, EC firms operating in the textiles and clothing sector, turned to relocation because the competitive climate in the EC had become too strong for them to survive without relocating part of their activity. In the textile and clothing sector however, FDI has never and will not play the prominent role in direct capital formation. Historically, non-equity forms of investment and involvement in the less developed countries have dominated over direct investment. This is also the case in companies operating in other sectors such as mining and metals processing, mechanical engineering or pulp and paper. Prospects for FDI growth will remain relatively low in these sectors, as they will focus their development on a centralised production system in Europe (in the case of mechanical engineering) or will concentrate on their key assets such as management, product development or marketing.

Eco-industries in the EC

INTRODUCTION

The 1957 Treaty of Rome did not confer the competence of environmental policies to the EC. The environmental policy is now enshrined in the Treaty on European Union that came into force on 1st November 1993. However, over the past two decades, the EC has created a number of directives (already 160 have been adopted) to protect the environment. This environmental legislation has fostered the emergence of a new market: the eco-industries. As environmental issues become a major concern worldwide as emphasised by the Rio Summit in June 1992, eco-industries can be considered as a quickly expanding industrial market in this decade.

Eco-industries are not easily defined but may be described as including firms producing goods and services capable of measuring, preventing, limiting or correcting environmental damage such as the pollution of water, air, soil, as well as waste and noise-related problems. They include clean technologies where pollution and raw material use is being minimised by initiatives focusing on quantitative terms. Eco-industry is a diversified industry spanning a variety of industrial products and services which have not yet been statistically classified and for which data are limited. For this reason, the data given in this report should be interpreted as a guide to general trends in the environment industry.

The sector overall is expected to experience strong growth over the next years and well into the future following the foreseeable development of environmental concerns. The situation of the industry is quite different from one country to the other according to the importance given to environmental problems in general and to specific concerns: air, water, waste, noise in particular.

Demand for environmental products and services has so far been mainly driven by regulations. This has had a profound effect on the structure of the industry: a number of firms have been interested in this market but have been reluctant to invest because of the linkage to political decision making. In addition, the growth of the different segments of the market has been erratic: the passing of a regulation spurs new investments and then the market quickly settles down at its replacement level. Consequently, the market has been used to relying heavily on small firms or on bigger firms whose main activities are outside the environmental market. The situation is changing rapidly, however, as polluting firms are changing their attitude towards the environment, shifting from a passive approach dictated by legislation to a more pro-active tackling of the problem, sometimes even ahead of legislation. Moreover, the concentration and the internationalisation of the industry is leading to the emergence of eco-groups in the truest sense.

If we look at the USA, which is amongst the most advanced country in terms of environmental protection, the growth potential of the eco-industry in Europe seems quite significant. The CERCLA (Comprehensive Environmental Response Compensation and Liability Act) voted in 1980 created the Superfund, a mutual fund financed by the polluting industries (mainly chemicals and oil companies) and aimed at reclaiming polluted sites. This fund disposes today of 12 billion ECU. The Environmental Protection Agency (EPA) has recently stated that there are potentially 35 000 sites to reclaim in the USA with an average cost of 31 million ECU per site. In 1990, following the application of the second Clean Air Act, 90 billion ECU have been spent to reduce and control pollution. In the meantime, the Dutch Government stated recently that there are 35 000 sites to reclaim in the EC overall.

LEGISLATIVE ENVIRONMENT IN EUROPE

Environmental action in industry has in the past largely been a result of its effort to comply with legislation. Not only has the awareness grown in industry that a more proactive stance can go a long way in preventing the realisation of new legislation, but also the legislator is acquiring new strategies to ease the implementation of environmental legislation and increase industry compliance to it. The EC's Fifth Environmental Action Programme advocates the use of a wider range of policy instruments to address in a more cost-effective way

the legislative challenges it faces. Policy instruments include, besides the traditional legislative approach, market-based instruments, horizontal instruments, including the provision of information and research and development, and financial support mechanisms.

The proposed Integrated Pollution Prevention and Control Directive (IPPC) embraces the three environmental compartments air, water and waste. In contrast to earlier EC environmental policy that was mostly based on instruments that separately controlled the emissions from industrial sources in each of the three media, the EC proposal on integrated pollution prevention and control introduces permitting systems based on an integrated approach to the three environmental compartments air, water and soil. This type of permitting systems already exists in the UK, France, the Netherlands, and the Flemish part of Belgium. The integrated approach must ensure that none of the three media is preferred or sacrificed. The advocated system would allow the streamlining of the permitting process, as only one authority would be involved. Although the ultimate directive could facilitate the implementation process of adequate environmental standards, the current proposal lacks well established quality objectives.

The Commission wrote notes on Best Available Technology (BAT) for a number of industries and is working on further such notes. The Commission, however, does not intend to write BAT notes for all industries prescribed in the IPPC. The delegation of this responsibility to Member States might be an opportunity missed towards harmonisation of technology definitions and of the related emission limit values.

Air

EC legislation on air has been based on two regulatory approaches, either by setting emission limits to certain components in the flue/exhaust gases to stationary or mobile sources, or by defining air quality objectives for these or other components considered necessary for environmental and health protection. The parallel application of these two legislative principles makes the EC air pollution legislation body complex. EC policy to curb air pollution can be categorised under five headings:

- Air quality objectives: Air quality limits exist for NOx, SOx/suspended particulates, and lead. The Commission is to propose a comprehensive framework directive on ambient air quality, covering the assessment, monitoring and management of air quality, as well as the introduction of new standards covering previously unregulated pollutants.
- Product quality standards: Union legislation imposes limits for certain fuel properties, including the sulphur contents of gasoline. Legislation on the lead in gasoline has allowed the introduction of catalytic converters and the significant reduction of exhaust gas emissions.
- Automotive emission standards: Severe exhaust emission standards exist for gasoline cars, light commercial vehicles and for trucks. Even tighter norms will have to be legislated in the future, fostering therefore technological progress. For passenger cars, the Council adopted in 1991 the so-called Consolidated Emission Directive which covers gaseous exhaust emissions together with particulate emissions for diesel cars and evaporative emissions for gasoline vehicles. The Commission has in the meantime issued a proposal for a further reduction of emissions for the time period 1996/97 and has been requested by the Council to prepare yet another proposal for the year 2000. Similar to cars, the already stringent emission control adopted in 1993 for trucks (CO, HC, NOx and particulates) in line with BATs, will be reduced in two further steps in 1996 and after 1999. This legislative approach is clearly "technology-enforcing".
- Air pollution from industrial plants: The key pieces of legislation in this diverse area aim primarily at the reduction of SOx, NOx, particulates and volatile organic compounds to restore air quality deficiencies and to reduce transboundary air pollution (acid rain). Directive 84/360/EEC requires Member States to authorise new plants from certain industries only when BATNEEC (Best Available Technology Not Exceeding Excessive Cost) measures are taken. This directive will in the future be replaced by the IPPC directive. The "large combustion plant directive" (Council Directive 88/609/EEC) regulates the emission of NOx and SOx and particulates from new and existing plants greater than 50MW thermal input. DGXI is presently preparing equivalent legislation for small combustion units (2MW). The protocols associated to the ECE Convention on long-range transboundary air pollution and the EMEP Protocol on monitoring and evaluating of long range transmission of pollutants, on VOC, SO2 and NOx, represent an additional driving force for the EC to legislate on air quality restoration measures. In addition to the reduction of exhaust and evaporative VOC's from vehicles, specific (draft) directives address VOC emissions of solvents from a range of industrial sectors and the losses experienced during the storage and distribution of gasoline.
- The ozone layer and the greenhouse effect: With respect to the controls on substances that deplete the stratospheric ozone layer, the European Union signed the Montreal Protocol in 1988 which targets the reduction and phasing out of CFCs. In June 1993, the Commission accelerated action on CFCs by a proposal that should cover all the major ozone depleters in one legal instrument. In addition to the phase-out of CFCs, by the end of 1994, marketing of HCFCs in the EC would be banned by the end of 2014. As regards the greenhouse effect, the adoption of the Council Decision on a monitoring mechanism of European Union CO2 and other greenhouse gas emissions will pressurise Member States to adopt specific measures to reduce greenhouse emissions, notably by taking measures to encourage energy efficiency. The monitoring mechanism will be a key information tool for the European Commission to plan for the reduction of emissions in the future. In 1990, the Council had decided to stabilise CO2 emissions in the Union at 1990 levels by the year 2000.
- Since then, a comprehensive strategy has been developed to limit CO2 emissions and to improve the energy efficiency of the European Union. Apart from the monitoring mecha-

nism, a framework Directive on SAVE to promote energy efficiency as well as the ALTENER programme to promote renewable energies, have been adopted. Finally, the carbon/energy tax proposal is still under discussion in the Council and has been incorporated into the tax reform suggestions of chapter 9 of the White Paper on Growth, Competitiveness and Employment.

Water

A basic discussion concerns whether pollution control should be based on BAT (Best Available Technology) standards versus a system based on the respect of water quality standards. In the past a double approach has been followed, namely through quality objectives and emission standards. The present draft of the IPPC Directive finds an excellent compromise. A BAT system should prevail in the absence of environmental quality standards set by the Council, or of equivalent WHO guidelines.

A new emphasis is being given to pollution from diffuse sources. The nitrates and municipal waste water directives, the forthcoming Ecological Quality Directive, the amendment of the drinking water Directive, and a possible new Directive on ground water, are all parts of the increasing realisation that diffuse sources play an as important, if not greater, role than emissions from industrial point sources.

The single most important Directive in terms of market creation for the eco-industry no doubt is the urban waste water directive, that could have a decisive impact on the quality of EC surface waters. It will generate many opportunities for companies involved in the construction and operation of waste treatment plants. Certain industries will be compelled to review their liquid waste management procedures to comply with the requirements of the directive. The new restrictions imposed on the waste water treatment industries will generate more stringent discharge limits for industries, as waste treatment companies will be more careful of accepting waste streams which may contribute to make sludge hazardous, and hence more difficult and costly to dispose of.

The new general approach taken by the Commission towards prioritisation of substances with a view to regulating them, is to prioritise chemical substances from the standpoint of the environmental risk that they may represent. This is happening in the framework of the existing and developing chemical legislation. The novelty of this approach is the usage of exposure and effect assessment to fix priorities rather than prioritise substances simply on the sole basis of their intrinsic properties such as toxicity. Concerning water pollution, the basic reference system remains the list I of Directive 76/464/EEC on the discharge of dangerous substances. The Commission is now also looking at a another list of roughly 180 substances, which were agreed upon by the Members of the 1992 North Sea Conference. It is understood that the Commissions is now working on these two overlapping lists of substances, with the objective of coming up with a list of 20 initially and possibly 80 later. The deadline for completion of this work is the 1995 North Sea Conference.

A final issue concerns the problem of quality standards setting and the its relationship with the future shape that legislation might take. Directive 76/464/EEC left to Member States the responsibility for fixing quality standards only for the list II substances, including, among others, 20 heavy metals, while the Council retained the responsibility to fix standards for list I substances. The IPPC Directive refers in its sixth draft to one single list which includes all list I substances and the heavy metals. For these, the proposed directive implies, standards will have to be set at Union level. Apart from this apparent legalistic contradiction, the final approach is far from clear and only the developments over the coming months will clarify the contents of the proposal. As for the criteria of standard setting the main indications are towards the establishment of a scientific approach based on risk assessment. Another element of the debate stems from the difficulty of measuring individual substances and mixtures in order to control compliance. The final shape that the IPPC Directive, and the Ecological Quality Directive will take, together with the conclusions of the discussion on the amendment of the Drinking Water directive, will certainly contribute to setting the scene for future legislative development.

Waste

The Commission has had in place since the 1970s a basic waste management regulatory framework. The waste regime required the permitting of a broad range of disposal and recovery activities involving waste, toxic waste and dangerous waste. The EC waste management regulation has entered into a new phase in recent years with the replacement of the old framework legislation with new legislation that seeks (a) to provide more rigorous definitions of waste and hazardous waste; and (b) to specify the disposal and recovery activities subject to permitting.

Directive 91/156/EEC on waste and Directive 91/689/EEC on hazardous waste together create the new basic framework. The definitions under the directives of waste and hazardous waste will determine the scope of the EC waste management regulatory programs. As the waste management provisions will give competent authorities powers to control the import and export of waste for disposal, and arguably, for recovery, this could lead to a fragmentation of the EC waste management market.

The Commission is endeavouring to elaborate the regulatory detail regarding specific waste management activities in subsequent legislation. The most obvious examples are the Hazardous Waste Incineration Directive and the proposed Landfill Directive. The proposed IPPC Directive should however not be overlooked.

An important area of legislative activity is the Packaging and Packaging Waste directive, containing important targets for recovery and recycling of packaging waste. Comparable targets could ultimately be introduced for other priority waste streams that the Commission is currently looking into, such as electric/electronic waste, end-of-life automobiles, sewage sludge, hospital waste, used tyres, construction demolition waste, etc. This would represent an ambitious effort to recover and recycle an important part of the EC's waste mountain produced every year.

BUSINESS SECTOR RESPONSE

General response

Environmental concern is no longer the exclusive domain of traditional targets of regulations such as chemical and oil companies. Companies in all industrial and in many services sectors have to cope with diverse environmental issues: complying with ever-changing regulations, marketing environmentally-friendly products and packaging, and integrating environmental risk in their business decisions. The environment has become a key issue for a large number of companies, as demonstrated by the well publicised nominations of top executives to the title of Environment Vice-President.

In response to shifting consumer patterns, companies are required to respond both in terms of their internal procedures and processes but also in terms of the products and service offerings which are developed to meet these environmentally conscious needs. Companies who disregard this evolution are likely to find themselves isolated, if not the focus of adverse media and consumer attention. Managing one's environmental image may indeed become as sensitive an issue as managing the communication of financial performance.

The business sector has quickly understood the profit it could gain from being perceived as environmentally friendly. If demand for environmental products is mainly driven by legislation, "environmentally friendly" products are an exception to this rule: customers directly express a demand which has meant that markets have developed in the absence of regulations.

The EC national governments have tried to rationalise this "green" product offering by issuing "labels": "Blue Angel" in Germany, "White Swann" in Denmark, "Stichting Milieukeur" in the Netherlands and "NF Environment" in France. In March 1992, EC Member States agreed to launch a European Eco-Label. The first European certified eco-products have appeared on the market in the course of 1993.

Specific example of the chemical industry

Seveso in 1976, Bhopal in 1984, Basle in 1986. The chemical industry has earned a bad reputation as far as the environment is concerned. As such, it has been in the line of fire with legal authorities over the past decade. The environmental spending of some of the biggest chemical companies is shown in Table 1. The high point seems to have been reached with environmental expenses amounting to 25% of the capital expenditures of the main chemical companies. Ever increasing volumes of environment-related legislation and bureaucracy weigh heavily on costs at a time when chemical groups are under severe competitive pressures.

The problem is made more acute as environmental legislation can be different from one country to another and thus can create competitive disadvantage. The German chemical companies BASF, Bayer and Hoechst for instance, have complained that the severe domestic environmental legislation they face in Germany could hinder their competitive position worldwide and threatens to cripple German industry. This has created a new concept: environmental dumping which characterises the situation where a company manufacturing in one country could have lower production costs than its competitors producing in other countries only because of less stringent environmental legislation. In this respect, the role of the European Union in harmonising standards through the Member States is becoming increasingly important.

The response of the chemical industry to growing environmental pressure is "corporate environmentalism": self regulation is best because each company knows its own processes and the most effective way of reducing emissions. A move from a command and control phase to a voluntary phase is thought to be necessary. In this respect, the industry has launched a programme of Responsible Care. This involves measuring emissions in a credible way, improving environmental performance and then communicating that performance to the public. The programme was initially created by the Canadian chemical industry but has since been adopted worldwide.

ECONOMIC IMPORTANCE OF ECO-INDUSTRY IN THE EC

Overall market size

According to the OECD, the worldwide market for eco-industry amounted to 200 billion ECU in 1990. The largest national market was that of the USA and accounted for 39% of the total. The EC represents 24% of the world market with

Table 6: OECD trade in environmental products, 1990

37 billion ECU. Table 2 shows the structure of environment output by region.

Within the EC, the market is dominated by Germany which represents 36% of the market, followed by France (21%), the United Kingdom (15%) and Italy (11%). If we look at the pollution abatement and control expenditure by country as a percentage of GDP (see Table 3), we can characterise 3 different groups: the first one comprises Germany and the Netherlands with environmental expenditure representing respectively 1.6% and 1.4% of GDP. These countries have environmental standards which are already highly developed and they aim to introduce more stringent regulations ahead of the EC; the second group comprises countries which spend between 1 and 1.2% of GDP on pollution abatement and control. These countries have less rigorous environmental policies, often accompanied by a lack of administrative and legislative structures for enforcement - Belgium, France, Ireland, Denmark and the UK; finally, the third group comprises the southern Member States which spend less than 1% of GDP on environment. They are lagging behind, in particular the new entrants to the EC : Spain, Portugal, Greece which face a major task in achieving compliance with EC environmental legislation.

Over three-quarters of industry output is made up of equipment produced for environmental purposes, primarily end-of-pipe pollution abatement equipment. The rest includes general environmental services largely based on engineering and consultancy services for solving specific environmental problems. Environmental equipment and related services can be subdivided into four main categories according to end-use:

- water and effluent treatment;
- waste management;
- air pollution control and;
- other (mainly contaminated land reclamation and noise reduction).

The structure of environment industry output differs by region as shown in Table 4 and reflects local environmental concerns as well as variations in environment legislation. Water treatment equipment for instance is highly developed within the EC, while waste management now accounts for the largest share of industry value in the USA and Japan is more concerned about air pollution.

Economics of market segments

The production of equipment for water and effluent treatment is a mature market using well established technologies. With 34% of the eco-industry output in the EC in value term in 1990, this is the largest segment of the eco-industry, principally due to the fact that EC governments have targeted most of their investments at this area. Control of water distribution and waste water treatment in the EC is still largely in the hands of public monopolies although following the French example, where already 75% of water distribution is in the hands of private operators, private companies are gaining ground. The most radical change of ownership occurred in the UK in 1989 with the privatisation of the 10 water authorities.

Waste water treatment tends to use mature, non-proprietary technology, the aim being to speed up the natural processes which reduce contaminants to an acceptable level for discharge to the environment. Equipment is generally designed to remove pollutants from an aqueous stream or body of water or to convert the pollutant to a non polluting or less polluting form prior to discharge or use. Products consist of primary treatment equipment to remove solid particles (filters, clarifiers), secondary treatment equipment to remove bacteria (biological treatment, chlorination) and tertiary treatment equipment to remove chemical or metal compounds (reverse osmosis, chemical recovery system).

Expenditure on waste water treatment is principally being driven by three factors. Higher standards on water released to the environment, stricter controls on sludge disposal, growing volume of waste to be treated. The largest sector is the secondary treatment area which is currently dominated by the biological processes.

The market is dominated by a few large players having the financial means to invest in and run big treatment plants. The European firms are at the forefront in this segment led by Alfa Laval of Sweden (turnover of 2.3 billion ECU in environment in 1990) and Bilfinger and Berger (2.3 billion ECU) and Steinmuller (2.2 billion ECU) from Germany. An increasing number of water utilities (like Générale des Eaux and Lyonnaise des Eaux in France with respectively 2 and 1.6 billion ECU in the sector) are becoming involved in the development and supply of water treatment technology. The main UK firms involved in this segment are John Brown Engineering (780 million ECU), Portals Water Treatment (700 million ECU) and Biwater (470 million ECU). The Netherlands is also active in that segment with Esmil Water Systems (78 million ECU) and Jansen Vanneboer (39 million ECU).

Waste management has been one of the key environmental issues within Europe since the mid 80's, following in particular the growing concern among public opinion about hazardous waste. The segment includes products and services to collect, transport, treat and dispose wastes from homes, municipalities, commercial establishments and manufacturing plants. It covers equipment for management of solid waste (compactor trucks, separation methods), liquid waste (tank trucks, treatment chemicals) toxic or hazardous waste (landfilling, incinerators) and waste recycling (valorisation process). It represents 15% of environment industry output in 1990.

European waste equipment companies are led by Edelhoff and Hoechst of Germany with an estimated environmental turnover of 780 million ECU in 1990. Most solutions are developed at a local level resulting in a fragmented market with companies specialising in specific materials handling or recovery markets such as chemical waste treatment (Leigh and Rechem in the UK) or hazardous or toxic wastes (France Déchets). The large French water utility Lyonnaise des Eaux is also present in this segment through its subsidiary, Sita. Large conglomerates have also targeted this segment as an area for diversification (Hoechst in Germany, BET PLC in the UK). The world market is dominated by Waste Management from the USA (turnover in that segment of 3.5 billion ECU in 1990) which has recently reinforced its position in the EC with the acquisition in November 1991 of the waste treatment division of Wimpey (UK) and of Environnement Services (F) in December 1992 and the joint venture with CFF (Compagnie Française des Ferrailles, F) in 1993.

Equipment for air quality control, which is estimated to account for 17% of environment industry output, is designed to remove

pollutants from a gaseous stream or to convert pollutants to a non polluting or less polluting form prior to discharge into the atmosphere. Pollutants include solid particulate (dust, metallic fumes), gases (carbon monoxide, nitrous oxides, sulphur dioxide) and liquid fumes (sulphuric acid, hydrocarbon solvents). Air pollution control equipment may thus address particulate (fabric filters, electrostatic precipitator, mechanical collectors), acid emissions from power stations and other large scale combustion plants (scrubbers, catalytic reduction, electron beam methods) and emission of gases and vapours (desulphurisation, oxidation, carbon absorption). Particulate emissions collectors are estimated to account for about 60% of the market.

The EC firms involved in that market are mainly subsidiaries of larger conglomerates: Handel is part of Deutsche Babcock, Lurgi of Metalgesellschaft and KWU of Siemens. Air pollution appears as the most mature segment of the environmental market as enforcement of emission standards is relatively simple and technologies most often used are well developed. Suppliers tend to provide systems rather than simple devices. Large suppliers concentrate on major areas such as Flue Gas Desulphurisation (FGD), where internationalisation and globalisation have been key. The major air pollution control companies have been highly acquisitive and have set up partnerships with local companies to gain a presence in many markets. The world market is dominated by the Japanese firms Mitsubishi and Hitachi, followed closely by Flakt of Sweden, the environmental control subsidiary of Asea Brown Boveri and one of the largest purely environmental companies in the world.

The market for product and services for remediation or reclamation of contaminated land represents, together with noise control equipment, 10% of the total market and is in an emerging phase in the EC countries at the moment. Products for excavating, transporting, incinerating and treating contaminated soil as well as covering, sealing, stabilising and enhancing land sites are in increasing demand. Equipment for noise control is designed to either eliminate the source of noise or to contain a muffle noise. These include mainly integrated encapsulations, acoustic products, soundproofing and buffers for industrial equipment. This market is also an emerging niche, driven mostly by labour safety and health regulations which are often followed by environmental regulations.

General environmental services currently represent some 24% of the eco-industry output. They regroup three main types of activities: technical engineering (site assessment, process design, control specifications, project management), environmental consulting (impact assessment, environmental audits, environmental monitoring, risk management) and management services (expert system, financial analyses, data base management). The market is dominated by large engineering firms providing technical engineering and construction services, many of which have formed special subsidiaries for the environment. These include Foster Wheeler and Davy Corporation in the UK, Philipp Holzmann and Preussag in Germany. There are additionally numerous smaller specialist environmental consultancies. A growing segment is "environmental audit" with companies like Taylor and Woodrow Plc (UK).

Number of companies/employment

The structure of the environment industry is highly contrasted, with a small number of large players accounting for more than half of the market alongside a very large number of small firms (half of them employ less than 50 employees). The number of firms involved in eco-industries in Europe is estimated at 20 000 (against 30 000 in North America and 9 000 in Japan). This industry employs directly 600 000 people in Europe. Table 5 shows an estimate of the number of firms in that sector in the main EC countries as well as an estimate of the number of people it employs. Eco-industries have hence become a significant force within the EC.

Trade in eco industries

Trade data on Eco-industries are limited but estimates are shown in Table 6. Germany leads in trade in environmental products and appears as the world's largest exporter, currently exporting about 40% of the value of production. Exports are largely of water treatment equipment (40%) and air pollution abatement products (35%). About half of exports are to other European countries with the remainder divided evenly among North America, Eastern Europe, the Middle East and Africa. Import penetration is less than 5% of the market. Overall, Europe maintains a trade surplus in environmental products with the UK, France, and the Netherlands as net exporters in addition to Germany. An increasing share of international exchanges is through technology licensing rather than imports and exports of equipment.

Customers

The main purchasers of environmental equipment and services are municipalities, power and water utilities, the mining industry and the manufacturing sector. Expenditures for environmental equipment are almost evenly divided between the public and private sectors in the EC. The public sector spends mostly on water treatment investments (an estimated 65%) and least on air pollution control equipment (an estimated 5%). The private sector spends a larger share of its total environment outlays on air pollution control equipment (about 40%). For waste management equipment, the allocation from the public sector tends to be greater than that from the private sector. Table 7 shows a comparison of the environmental expenses of the public and private sector.

The share of investment expenditure for pollution control is estimated at between 2% and 4% of total manufacturing investments in the EC. This percentage varies significantly across the different manufacturing sectors, however, as shown in Table 8. Typically, there is a small number of manufacturing sectors, in particular chemicals and iron and steel, which account for fairly large proportions of private sector spending and have the highest share of expenditures relative to total investment (respectively 7 and 8% for chemicals and iron and steel).

FUTURE TRENDS

Future legislation

The Commission will overhaul its existing environmental legislation on water and air, adapting EC legislation to subsidiarity. The European Commission envisages to replace several directives on water, but will delay a review of existing air pollution legislation until EC-wide quality objectives have been defined.

On water the Commission intends to reorient rules and regulations towards compliance with essential quality and health parameters, leaving Member States free to add secondary parameters as they see fit. Water protection policy will essentially be based on two sets of directives:

- New framework directives that would replace existing water quality legislation. A drinking water quality directive would define general parameters, with some defined at the EC level and others at the national level. This directive will ultimately replace the existing drinking water directive (Council Directive 80/778/EC) and perhaps part of the directive on surface water intended for the abstraction of drinking water. The directive would cover the water for use in the home, and water used in the food industry that can affect the health properties of the final product. Another framework directive would concern the ecological quality of surface water, laying down the general objectives to be fleshed out by national or regional authorities. A directive on bathing water quality would simplify the existing one (Council Directive 76/160/EEC) and adapt it to new scientific knowledge. Other planned directives, on freshwater management and groundwater protection, would replace the existing directive on protection of groundwater from pollution by dangerous substances (Council Directive 80/68/EEC), integrating it into a general freshwater management policy.
- Directives to control water pollution at the source, which would not be changed. These include the urban waste water directive (Council Directive 91/271/EEC) and the nitrates directive (Council Directive 91/676/EEC)

On air, the Commission intends to work for an EC agreement on the definition of air quality objectives before embarking upon a review of existing air pollution legislation. At present only five air pollutants are regulated by specific directives, and there is no definition of objectives or of harmonised monitoring criteria for Union air quality standards. After defining the objectives, the Commission believes it will be possible to rationalise and simplify a body of legislation that tackles air pollution in a general way.

The withdrawal of several directives on water and air and their replacement with more general or framework directives could lead to a weakening rather than a reinforcement of standards in several Member States and in some areas. Changes intended by the Commission will indeed require the approval of the Council, and it is very well possible that the Council will try to relax standards proposed by the Commission. Whether this would effectively slow the tightening of EC environmental legislation is not altogether clear, since the Commission has recently admitted that some of the legislative pieces to be withdrawn and replaced have not been fully successful.

Growth prospects

According to the OECD, the world market for environmental products and services is forecast to grow at a real rate of 5.5% per year to the year 2000. Growth will be different from country to country. Within the Member States, Germany, Denmark and the Netherlands have developed comprehensive environmental policies over the past two decades and are therefore forecast to have lower than average growth within the environmental sector in their relatively mature markets (growth rates from 2.2% to 4.1%). The UK, France, Italy, Ireland and Belgium offer moderate growth potential as new European Union standards are introduced, thus encouraging market growth in some sectors (growth estimates range from 5.5% to 6.5%). Southern European countries such as Greece, Portugal and Spain are projected to have the highest growth rates reflecting the expected investment effort they will have to make to achieve compliance with EC environmental legislation (growth estimates range from 7.4% to 8.3%). Table 9 shows the market size and growth of the EC countries.

Within the equipment and related services market, the share of the waste management and land reclamation sectors is expected to increase, while the share of the water treatment and air pollution control equipment sectors may decrease. These trends will vary considerably by geographic region depending on local environmental problems and regulatory frameworks. Table 10 shows OECD estimated forecasts of market trends for environment industry by segment.

Technology trends

Many of the technologies used within the pollution control sector have remained basically unchanged for 30 years or more, for example those of electrostatic precipitators, sedimentation systems, chlorination treatment. With some notable exceptions, European suppliers have lagged behind in the development and assimilation of new technologies, compared to their counterparts in the USA. This has largely been due to the absence of legislation as a market driver. The situation now is changing: the environmental market is increasingly technology-driven and technology is used more and more as a competitive tool.

Research and Development in eco-industries has been particularly high, with the large multinational environment com-

Table 10: Forecasts of market trends for environment industry by segment

panies spending 8 to 10% of their turnover on R&D. This has fostered the emergence of new technologies with significant growth prospects. In water and effluent treatment for instance, aerobic methods, ion exchange and membrane technologies are being developed. In waste management, new technologies are being developed for the physio-chemical treatment of hazardous waste, including neutralisation, detoxification and evaporation. Air quality control techniques increasing in importance include biological scrubbers and filters to treat flue gases, activated charcoal and catalysts to reduce organic emissions and combined particulate and acid gas control through electrostatic methods.

Concentration in the environmental sector in the EC

One of the most significant trends to be foreseen in the eco-industries is that of increasing concentration. A study on mergers and acquisitions in the US in the environmental industry shows that scale benefits and customer preference favour large players. Throughout the environmental industry, larger companies appear able to achieve higher returns. Table 11 shows the profitability by size of USA companies in the environment industry. Customer preference is also an important factor favouring size. In solid waste, more stringent regulations are inducing municipal firms to use fewer environmental service suppliers in order to more easily monitor compliance and trace liability.

Technology development also favours larger groups, with environmental processes becoming more complex and integrated. While new firms are constantly being created, small firms will find it increasingly difficult to fund the equipment investments necessary to remain competitive. Advantages enjoyed by large firms with significant resources are becoming more critical for achieving profitability.

As a result of such developments, spending on environmental acquisitions in the USA surged from 1.2 billion ECU in 1987 to 2.9 billion ECU in 1991, the number of mergers and acquisitions in that period increasing at an annual rate of 56% to reach 223 transactions in 1991.

Over the same period 1988-1991, the actual number of publicised mergers and acquisitions in the EC has been low. The number of deals completed grew slightly from 1988 to 1989 (from 22 to 25) but fell dramatically in 1990 (to 6). This was caused primarily by the UK recession: prior to 1991, the majority of firms acquired were British. The renewed acquisition activity in the first nine months of 1991 (23 deals) was driven by the emergence of Germany as the major market for acquisitions : German reunification was expected to lead to large growth in the German environmental market as the extent of the pollution problems in East Germany was discovered.

Mergers and acquisitions in the EC were carried out by a limited number of firms, with the 10 most active accounting for over 60% of all deals in the period. The two largest acquirers were British : Leigh Interests (including HT Hughes, acquired in 1990) and the Caird Group. The next largest were German: RWE and VEBA. In fifth and sixth place were Shanks & McEwan (UK) and Compagnie Générale des Eaux (F), the latter being the group out of the top six to be active in cross-border takeovers. Table 12 shows the environmental acquisition activity of the major EC acquirers over the period.

The development of clean technologies

Waste minimisation is the new credo in the industry. Treating waste is expensive, hence the industry is responding through the development and adoption of cleaner technologies (process modification, raw material substitution, process equipment changes) reducing the requirements for end-of-pipe pollution control equipment. In Germany, where emission standards are the most stringent in Europe, the industry is already looking to move away from traditional end-of-pipe abatement techniques to pollution prevention at source. This is due primarily to the steadily growing investment costs and energy consumption resulting from the increasing requirements made on the pollution control units concerned.

CONCLUSION

Being a relatively young industry, the EC eco-industry has developed strongly in the last two decades. Although an expected overhaul of EC legislation may lead to a somewhat lower pace with which environmental standards are harmonised, future prospects for the industry remain bright. In the more classical areas that are more mature, such as air pollution control and water treatment, further growth can be envisaged. On air, attention will focus on the reinforcement of the Large Combustion Plants Directive and the upcoming directive for small combustion plants. The recent directives on incineration of waste and of hazardous waste will also spur important investment. On water, the urban waste water treatment directive will generate an important investment programme that will last for two decades. Besides the more classical areas of air and water, waste and soil will increasingly gain attention. National initiatives on waste recycling have recently been followed by the Commission in its Directive on Packaging and Packaging Waste; the effort to recycle household waste that will follow from the application of this directive might go as far as doubling the EC waste management market over the years to come.

Social and economic cohesion within Europe

Europeans living in the Member States of the European Union do not as yet enjoy equal levels of wealth or equal opportunities for improving their economic prosperity.

A levelling-out of health standards...

Over the last decade, national and Community policies can be credited for eliminating some of the worst inequalities between European nationals, those pertaining to health and life expectancies. Between 1984 and 1989, Portugal and Greece came closer (1.2% and 1.0%) to the EU's mean rate of infant mortality (0.8%). In addition, there is limited variance in the twelve countries around the average life expectancy of both men (72.8 years) and women (79.4) whereas, some thirty years ago, the less favoured (the Portuguese) could expect to live ten years less on average.

...but a persistence of economic disparities between countries...

However, the sharing of the same basic rights to life is not matched by a similar freedom of access to the riches of the modern world. The six founding members of the EC, plus the UK and Denmark, clearly constitute a centre of superior prosperity, with a GDP per head at least 50% higher than that of Spain, Ireland, Greece and Portugal. The spread is reduced by 25% when taking into account actual purchasing power standards (PPS) in each country. Nevertheless, even allowing for the difference in the cost of living, a Greek citizen is ECU 11 000 per year poorer than his fellow European from Luxembourg.

...and between regions

The traditional GDP/head measurement at national level does not fully represent the wealth differentials. Significant deviations around the national averages are observed at regional level: in Germany, the Hamburg area creates 85% more value per head than neighbouring Schleswig-Holstein; in Italy, Mezzogiorno's output is half the level of Lombardia and Emilia-Romagna. Throughout the European Union, the two regional extremes (Bundesland Hamburg and Northern Greece), as measured by Eurostat in PPS-weighted Gross Domestic Product per capita, are separated by factor 3.5, i.e. a catching-up period of 30 years at a steady growth rate of 4.26%.

Impact of income disparities on individuals

Other per capita indicators give a more daily account of uneven economic conditions among Europeans:

- a Greek, Portuguese or Irish citizen owns less than 5 meters of national motorways whereas a Belgian, Danish, German, French, Dutch or Italian national can boast more than 10 meters already invested on his behalf;
- international trade amounts to more than one tonne per year/head for the second group, less than 200 kg for the first;
- 40 or more access telecommunication lines are at the disposal of 100 businessmen or private citizens in Denmark, France, UK, Germany, Benelux and Greece, 35 or less in Spain, Ireland and Portugal;
- each inhabitant of the ten richest regions of the Union (Hamburg, Ile-de-France, Bruxelles, Bremen, Hessen, Lombardia, Emilia-Romagna, Hoverstadsregion, Luxembourg, Baden-Württemberg), with an average PPS of ECU 20 512 per capita, uses 1 339 kWh/year, compared to only 796 kWh in the four countries with PPS below ECU 11 000 (Spain, Ireland, Portugal and Greece).

Geographic inequality of unemployment

The problem of unemployment in the early nineties does not affect all Europeans in equal fashion: in 1992, one out of ten (9.1%) residents under the age of 25 of the ten richest regions was out of a job, against one out of five (18.3%) in the four poorest countries. Overall, it is estimated by the Economic and Social Committee that 20% of the EU's population, (i.e. more than 60 Million people) live in areas with

revenue per capita below 75% of the Community average and unemployment as high as 30%. A large majority of these less favoured Europeans live in the Mediterranean areas, but not all: 16 million East Germans were recently added to that group and many areas undergoing industrial conversion in northern France, northern England or the Basque Country are zones of similar imbalance. The above figures (from Eurostat Regio and International Telecom Union) concern the continental territories of the Member States. They leave aside the specific economic problems in overseas territories (France's DOM-TOM, Canarias, Azores, Madeira).

Risks of social disruption at regional level

Over the last decade, wealth disparity between countries has decreased slightly owing to a certain amount of redistribution (e.g. delocalisation) of industrial production in favour of Spain, Ireland, Portugal and Italy. However, the overall spread of wealth between *regions* has increased steadily, thus widening the gap between the poorest and richest areas. This growing discrepancy results from the economic specialisation of poor regions in labour-intensive, low technology or low value-added sectors. Introducing medium or high technology industries in these areas requires heavy conversion costs, which can only be carried out through public investment. In the meantime, the worsening situation in regions lagging behind or affected by industrial decline is reflected in above average unemployment (4 times higher in South than in North Italy) with particularly severe prospects for certain social categories (young unqualified; aged; long-term unemployed). Such a situation leads invariably to social and racial tension, criminality and the increase in drug use. Hence, the socially and politically disruptive impact on the EU cannot be underestimated.

Social and economic cohesion is a fundamental goal of the Community.

A political principle since the inception of the Community

Ever since the founding of the Common Market, the narrowing of economic gaps between Member States has been a constant principle as declared in the Rome Treaty of 1958 (in Article 2 of its Preamble). Structural Funds were established to add Community subsidies to national investment policies:

- European Regional Development Fund (ERDF)
- European Social Fund (ESF)
- European Agricultural Guidance and Guarantee Fund (EAGGF)

Overall funding of structural investment was also helped through loans granted by the:

- European Investment Bank (EIB)
- European Coal and Steel Community (ECSC)

New perspective for cohesion in the Seventies

The extension of the Community to Greece, Portugal, Spain and Ireland during the Seventies and Eighties gave new force to the issue of cohesion. The reduction in income disparities had formerly been an agreement between similar economies: overall growth fuelled by a common market was to be used to channel more prosperity to those parts of the Founding Member States that were less well developed (e.g. Mezzogiorno, Corsica). The new membership of countries that were globally behind the Community average brought about a review of the programmes and instruments of such a policy. Moreover, a new focus was imposed by the economic disaster brought to previously prosperous regions (e.g. Lorraine, Borinage, Saarland, Lancashire) by the restructuring of whole industries (steel and coal, textile, shipbuilding). Individual membership agreements as well as Community treaties reflected the growing determination of the EC political and administrative bodies to use industrial policy for the fostering of economic and social cohesion within the twelve Member States.

A turning point in 1987

The Single European Act of 1987 embodies this evolution. The concept of solidarity and its corollary of voluntary action aimed at removing economic disparities has moved from a general statement of intent (Rome Treaty) to a specific commitment in Article 130 of the new Treaty: "the Community shall develop and pursue its actions leading to the strengthening of its economic and social cohesion...reducing disparities between the various regions and less favoured regions". This article has also been inserted in the 1992 Treaty of the Economic and Monetary Union (Maastricht Treaty). There is now official recognition that the total opening of markets (Single Act) as well as the voluntary convergence of monetary and

economic policies (Union) may impose severe constraints on less developed countries or regions in the EC, which will be confronted to free competition without the safeguard of independent budgetary and monetary policies. The Community (now Union) is committed to alleviate the cost of these constraints.

Renewed industrial policy instruments

Given the high priority accorded to economic and social cohesion in the Union, the Commission has sought to adjust its industrial policy to reflect this. An important reform of the Structural Funds was carried out in 1988 to provide the Community with an effective instrument to enact the corollary objectives of the 1993 Single Market: to coordinate macroeconomic policies, to improve the technological base of industrial sectors, to strengthen economic and social cohesion. Five policy objectives have been set out to enhance the efficiency of the various funds; the precise funding mechanism has been revised; targeted programmes (Community Initiatives) have been established across the Funds; the overall budget dedicated to the Funds has been doubled.

In 1993, while the Union Treaty was being ratified, a five-year plan was adopted for the allocation of ECU 141 billion through the Funds. A specific Cohesion Fund (cohesion financial instrument), planning to spend ECU 15 billion over seven years, was set up "to provide financial contributions to projects in the fields of the environment and trans-European transport infrastructure networks in those Member States which have a per capita GNP of less than 90% of the Community average, i.e. Greece, Spain, Ireland and Portugal".

The European Union aims at reaching a better standard of economic and social cohesion by reducing the structural deficiencies that hinder local industrial policy

Main role for local authorities

Primary responsibility for progress in backward areas rests with regional and national authorities, as underlined by the "subsidiarity" principle in the Union Treaty. EC economic and industrial policy is indeed not entirely appropriate for tackling the underlying causes of backwardness (e.g. under-education, overpopulation, poor housing conditions, political corruption and criminality). Local government is better equipped to design the general infrastructure layout, to set up efficient services (legal help, professional banking), and to implement the cultural changes that can foster regional development. EC industrial policy should therefore complement and accelerate Member States' own economic policies. However, the financial weight of Community instruments, as well as their careful application, are becoming an increasingly powerful tool in bringing about social and economic cohesion between regions.

Four general principles for EC intervention

The guidelines for EC funding of structuring investment have been clarified and reinforced since the policy reviews that followed the Single Act and Union treaties. Four general principles govern possible EC subsidies for investment projects:

- concentration on a short list of objectives and regions with a pre-allocation of global budgets by objective
- partnership with local authorities or the professional bodies they nominate
- programming of funding within specific Community Support Frameworks (Cadres Communautaires d'Appui) that set out the duties of involved partners
- "additionality" of Community subsidising to a matching investment effort by national governments

Five selected objectives

Community decisions to participate in the funding of investment projects have to fit one of the following objectives:

- Objective One: "to benefit the development and structural adjustment of regions whose development is lagging behind".

Eligible regions are defined as having a per capita GDP of less than 75% of the Community average, i.e. the whole of Greece, of Portugal, of Ireland, half of Italy, French DOM-TOM and Corsica, Northern Ireland and northern areas of the UK, about two thirds of Spain and the new Länder of Germany. Those regions represent 27% of total EU population. 96 Billion ECU (70% of total budget for the Structural Funds) will be devoted to attainment of Objective One between 1994 and 1999.

- Objective Two: "to convert regions or parts of regions seriously affected by industrial decline".

Source: EUROSTAT REGIO

Regions are made eligible for support every year according to their average rate of unemployment and the extent of restructuring forecasted in the area. ECU 15 billion ECU (i.e. 30 % of remaining Structural Funds' budget after programmes funded under objective one) is allocated to Objective Two until 1999. Specific projects to be financed are to be proposed by Member States.

- Objective Three and Four: "to combat long-term unemployment" and "to facilitate the occupational integration of young people under 25".

ECU 17 billion will to this end be budgeted by ESF.

- Objective Five: "to speed up the rate of adjustment in agriculture" and "to promote the development of rural areas".

This objective is closely associated with reform of the CAP. The EAGGF is the main provider of support to eligible regions of Objective Five.

Modus operandi of industrial policy

Within the overall framework of the above objectives, the EC has developed two main methods of programming the funding of its industrial policy:

- the Community Support Frameworks are agreements bilaterally signed with each Member State to lay out projects and areas that will benefit from an application of funds; the CSFs also state the extent and programming of the Member State's commitments according to the additionality principle.
- the Community Initiatives (9 % of total budget) are targeted programmes initiated by the EC around a specific industrial sector (coal mining, energy networks, telecommunications, services to business) or a transversal economic goal (protection of the environment, cross-border cooperation, integration of remote regions, new skills and qualifications, equal opportunities for women, access of handicapped to the labour market, diversification of regions dependent on textile or military industries); present discussions between EC, governments and trade associations examine a possible concentration of Community Initiatives on industrial conversions.

A new tool: the Cohesion Fund

Together with the Union Treaty, the Member States have created a new fund to promote social and economic cohesion (art. 130 D of Maastricht Treaty). The Cohesion Fund is aimed at financing projects in the sectors of environment protection and transport infrastructure. It stands to receive ECU 15 billion over the period 1993-1999.

Beneficiary regions are restricted to those located in countries with GDP below 90% of Community average; this means that the Fund is oriented towards programmes in four countries only: Spain (52 to 58% of total allocations), Greece (16 to 20%), Portugal (16 to 20 %) and Ireland (7 to 10 %). The purpose of the Fund is to speed up the basic equipment of the beneficiary Member States in transports, telecommunication networks, research and development, protection of the environment. Backwardness in such infrastructures is considered a sign (and a cause) of their relative poverty.

The financing principles are more flexible than those applied to the Structural Funds. Additionality, for instance, is only marginally requested since 85% of the projects and 100% of the feasibility studies can benefit from the Fund. Another feature of the Fund is that it will examine projects separately, not within bilateral agreements on joint programmes (although the projects should be part of national global planning). Key criteria that will be considered for funding are the impact of transport infrastructures on regional ease of access the rest of the Union ("désenclavement") and the catching-up of environmental protection standards applied in the most advanced Member States.

The future achievements of economic and social cohesion will depend on answers given by the Union to strategic issues facing economic policy

Towards a more active industrial policy?

Up to now, the Commission has been constantly involved in industrial policies: setting out Community rules for free markets, facilitating industrial conversions, supporting job creation and the transfer of technologies, cofinancing infrastructures. However, implementing a global industrial strategy and coordinating national policies with that strategy has not been a role assigned to the Commission. The issue is still debated within the framework of a monetary and economic union, as laid out by the Union Treaty.

Irrespective of the uncertainty of the time-frame for achieving monetary union, the indirect industrial policy implied in the present monitoring and support roles of the Community (through Directives, Funds, Initiatives, Support Frameworks) will be greatly expanded by the Single Market programme: a stronger and freer competition in the marketplace will emphasise the regional needs for adjustment and restructuring. Free competition, protected as such by the treaties, has to be made consistent with the cohesion principle. A Community industrial policy, if accepted at political level, would have to define the delicate balance between fighting state aid to individual firms - to maintain fair competition between players, and increasing state/Community aid to regions (i.e. regional players) impoverished by stronger international competition - to prevent the widening of income differentials.

Towards more coordination of social policies?

The Member States so far have failed to agree on what should be the implications of the single market and economic union aiming at cohesion for the convergence of social policies. The stakes are high for several reasons. First, differentials in social spending are important: 13% of GDP in Portugal against 32% in the Netherlands; 30% of hourly labour cost in Ireland against 47% in France. These differentials create distortions among the cost structures of free competitors; they also distort the logical link between the need for protection and actual social protection (the poorest populations have less access to collective economic protection).

Second, many economists deem that significant progress towards European cohesion cannot be achieved without some degree of convergence of national social policies. The movement of labour-intensive, low-technology industries to regions where competitive advantage is based on low wage and social costs rather than on actual productivity, leads to a situation of unstable growth:

- job creation is vulnerable to competition from countries with even cheaper labour.
- there is little impact on elements of long-term development (such as education and qualification of workers, sophistication of banking and services to business, the acquisition of diversified managerial know-how).

For these reasons, it is likely that the Council will have to address the social issues not settled in the Maastricht Treaty and give direction to the Commission in such areas as education and vocational training, immigration control, collective industrial agreements. These are all key ingredients of an overall industrial policy and essential to future social cohesion within the Union.

Towards a deeper reform of agricultural policies?

The Common Agricultural Policy (CAP) has long been a controversial factor in the social and economic cohesion of the Community. It reflected the initial fear of the founding Member States that unrestrained market forces would disrupt large segments of European farming.

The intricate policy instruments of the CAP (intervention purchasing arrangements, export refunds, monetary compensatory amounts, quotas and subsidies) as well as the growing amounts of Community spending on agriculture (EAGGF spent ECU 4.5 billion in 1975, 11.3 in 1980, 31.5 in 1991) did not achieve any meaningful progress towards improving the purchasing power of farmers, nor did it reduce the inequalities between northern and southern farming. Critics of the CAP point out that the artificial support of the market has led to over-intensive production, benefited the large units more than the medium and small size-farms, and favoured cereals and meat producers of northern states over the fruit and vegetables producers of the South (in 1989, Dutch farmers - 4.7% of population - received ECU 3 751 million from the EC, their Portuguese counterparts - 20.7% of population - only ECU 174 million).

The recent reform of the CAP aims at progressively alleviating the artificiality of the present management of markets. It probably will be accelerated by the Uruguay Round of GATT. Maintaining the living standards of northern farmers, converting non-viable units, integrating the agriculture of the new Länder into a market-oriented economy, upgrading the productivity and market access of southern farmers will therefore constitute one of the toughest challenges for the Union if it is going to apply the cohesion objective to the agricultural sector, which presently has the highest standard deviation of all economic sectors in value-added per production unit.

EEA and single market progress

INTRODUCTION

The completion of the Internal Market did not come to an end at 1 January 1993. This date marked rather the beginning of a new stage in the development of the Single Market as an ongoing dynamic process. By the deadline, embodied in the Single European Act of 1987, 95% of the basic legislative programme foreseen in the Commission's 1985 White Paper had been adopted by the Council. The objective set out in Art 8A (now 7A) of the Treaty has largely been achieved to assure the free movement of goods, services and capital. Whilst customs controls on persons have disappeared, the removal of identify controls on persons at all the Internal Borders is still outstanding. However, the entry into force of the Union Treaty has already enabled the Commission to tackle this problem with new initiatives. Additionally, the Schengen Group of countries has decided to abolish identify controls on persons in the near future after having installed the Schengen Information System (SIS).

The objective is now to ensure the efficient and proper functioning of the Internal Market. To benefit fully from the opportunities of the Single Market, national administrations, enterprises and consumers have to adapt their attitude and behaviour to the requirements of an "open" Internal Market. Thus, in 1993 the focus was shifting away from the adoption of legislation towards enforcement of the new rules and the management of the new business framework. The European Council on 10/11 December identified the full exploitation of the possibilities of the Internal Market as a major asset in the fight against unemployment. After having undertaken wide consultations over the past six months, the Commission presented a Strategic Programme "Making the Most of the Internal Market". The document maps out the priority actions which have to be taken by the Union in order to fulfil these expectations and to contribute to economic growth, competitiveness and employment.

By 1 January 1994 the European Economic Area had became reality. This development creates a free trade area covering some 375 million consumers by extending the relevant Community legislation with regard to the free movement of goods, capital, services and persons to the EFTA States except Switzerland. The EEA will cover most of the "aquis communautaire" including most Internal Market measures (e.g. public procurement and financial services) except those dealing with abolition of border controls. However, the EEA will not bind EFTA States to participate in the Common Agricultural Policy. There are special arrangements for certain sectors, such as food, fish, energy, coal and steel. A special EFTA Surveillance Authority will ensure that the EFTA Countries abide by the rules and that the same competition rules as applicable within the European Union are also applied by the EFTA Side. For some EFTA States the EEA will be a stepping stone towards full membership. Membership requests have been received from Austria, Sweden, Finland, Switzerland and Norway. Enlargement negotiations are being expedited with Austria, Sweden, Norway and Finland with the objective of completing the negotiations by 1 March 1994 so that these countries can accede on 1 January 1995.

SINGLE MARKET DECISIONS

The basic legal framework for the Single Market was agreed by 01 January 1993. Out of the 282 White Paper Measures required to eliminate remaining physical, fiscal and technical barriers, 95% measures have been adopted by the Council. Important progress concerning the outstanding measures, particularly in the field of intellectual property, has been made during 1993. Furthermore, the Council has adopted a wide range of additional measures to complement the original White Paper Programme and others are under discussion. In certain areas not covered by the White Paper Programme, particularly energy and telecommunications services, considerable work has to be undertaken. What does this impressive Internal Market statistic mean for the companies and consumers in the Internal Market area?

The entry into force of a series of measures, particularly reorganising tax, veterinary, plant health, safety and statistical controls eliminated systematic controls at the intra-EC frontiers. These measures opened up Community markets to the free circulation of goods, services and capital and reduced trade costs. It also allows firms to work towards achieving technically efficient capacity and increases competitive pressure on complacent enterprises. The traditional bureaucratic burden in terms of paperwork, imposed upon enterprises involved in Intra-EC trade, is now a thing of the past. The last symbol, the Single Administrative Document, has been axed. Cross-border deliveries are now as time and cost efficient as shipments within a member state. Additionally, the transitional VAT system provides purchasing firms with a cash flow improvement since the VAT is no longer deducted at the border and reclaimed later but is deferred until the company submits its regular VAT declaration.

The harmonisation of national technical specifications required for the operation of the Internal Market is under way and is widely seen as being one of the most significant benefits to be derived from the Internal Market Programme. The Community has applied three principles to achieve this objective: Firstly, the mutual recognition of national technical regulations is being applied where possible. As follow up to a communication on the management of the mutual recognition of national rules after 1992 (Art 100B), the Commission presented recently a proposal for a decision on the establishment of a a procedure for the exchange of information on national measures derogating from the principle of the free movement of goods. Secondly, detailed harmonising legislation was adopted where necessary. Entire sectors such as agriculture and food products, pharmaceutical products and motor vehicles are now covered by this kind of legislation. Thirdly, a "new approach" for the approximation of national legislation by establishing only essential requirements is being employed, backed up by ongoing provision of European standards (CEN, CENELEC, ETSI). In addition, the Community has established a global approach to testifying and conformity which paves the way towards recognition by national authorities and institutions for conformity assessment results. Enterprises will progressively be able to sell their products, produced according to one set of technical specifications, all over Europe. Potentially

significant cost savings result from cutting out the need for product redesign and adaptation to different national requirements.

The public procurement legislation opens up previously sheltered markets for government supplies, works and services contracts in all sectors, notably energy, telecommunications, water and transport, to European-wide competition. However, it will take some time before this legislation becomes fully effective since most of the legislation entered into force recently or has yet enter into force as far as public utilities are concerned (July 1994). In order to ensure that national administrations become familiar with the new legislation, the relevant directives provide provisions for enterprises to seek financial compensation and legal redress if they feel that a public contract has been unfairly awarded.

In the field of free provision of services, directives and regulations on transport, financial services, telecommunications, recognition of diplomas and the equivalence of professional qualifications have been adopted entering gradually into force. A breakthrough was the final decision in October paving the way for the liberalisation of road cabotage by 1997. Particularly in the financial services field the removal of controls on capital movement and the "European" passport providing financial institutions with access to partner countries has contributed to a qualitative increase in the degree of EC financial services integration. Insurance companies can provide services on a pan-European basis once the third non life insurance and life insurance directives enter into force by 1 July 1994. This will create sufficient benefits for consumers.

Since the companies have to adapt to the new conditions of the Internal Market through corporate restructuring and the restructuring of their business strategies, the proposals on company law, company taxation, and industrial and intellectual property formed an integral part of the White Paper Programme. As regards intellectual property, most of harmonisation measures (software, term of copyright protection) have been adopted. An important step was the decision of the European Council at the end of October on the location of the Community Trade Mark office in Spain (Alicante) which paved the way for the adoption of the Regulation on the Community Trade Mark. This will allow for the registration of Community trade marks, design and industrial models and thus remove the current requirement and costs for registering separately in each Member State. The political agreement on the legal protection of biotechnological inventions will foster the innovatory potential and competitiveness of Community science and industry in this field of modern technology. However, the ratification of the Community Patent Convention is still outstanding. In the field of company law and taxation important decisions are still outstanding concerning a European Company Statute, the harmonisation of laws relating to take-over bids and the elimination of double taxation (taking into account of losses suffered abroad and withholding of taxes on interest payments and royalties).

With regard to measures accompanying the abolition of Internal Market border controls, the Council has on its table proposals concerning VAT on gold transactions and transport of passengers, hall-marking of precious metals, controls on export of dual-use goods and on measures to prevent the putting into free circulation export and transit of counterfeit and pirated goods. The 7th directive on harmonisation of VAT rules concerning the second hand goods, antiques and works of art is expected to be adopted soon since major problems have been solved recently.

FUTURE PRIORITIES

The priority is now to pursue the overall approach contained in the Strategic Programme to foster the ongoing process of ensuring and reinforcing the effectiveness of the Internal Market. The Programme contains several lines of action:

The first part concerns the completion of the outstanding basic legal framework, particularly the adoption of the 17 remaining White Paper proposals, action to ensure the free movement of persons under Title VI of the Treaty on European Union and measures to introduce competition into the regulated sectors of energy, telecommunication and postal services.

The second part addresses the task of managing the Internal Market, covering several areas. First of all conformity and transparency in the transposition of Community legislation into national law as well as quality of enforcement has to be ensured to create confidence of business and consumers in a fair and convergent European-wide application of this framework, which does not distort competition between different Member States. This need can be illuminated by an analysis of transposition by Member States and sectors. Out of the 265 adopted White Paper measures 231 require currently transposition. By 20 January 1994, 83% of the total number of necessary transposition measures have been taken with Denmark in the lead (92%) followed by UK(88%), Italy and Portugal (85%). The most delays are in Spain, Greece (80%) and France(79%). Broken down by sectors, transposition has been completed or is above average in the areas of free movement of capital, in elimination of physical barriers, in financial services (excluding insurance), in the elimination of technical barriers, company taxation, VAT and excise duties. The Commission remains concerned about substantial delays in the areas of insurance (49%), company law (60%), intellectual property (60%) and public procurement (61%). To solve this problem, the Commission seeks to develop closer administrative cooperation between Member State administrations and between them and the Commission. Action is also envisaged to prevent the emergence of new barriers to trade by reinforcing and extending procedures for prior notification of new national rules concerned. Special assistance for enterprises and consumers will be provided by initiatives to improve the information on their rights under Community law, to facilitate recourse to the national courts in cases of violation of these rights and to improve judicial cooperation.

The third part deals with developing the Internal Market. A coherent communication strategy will provide individuals and enterprises with the necessary information to benefit fully from the Internal Market. Action is needed to improve the environment for enterprises by further extending Community direct and indirect taxation provisions, eliminating obstacles to cooperation and cross border activities (company law, cross border payments, European standardisation and certification, legal protection of intellectual and industrial property, transport). Special efforts will be made, in line with the multiannual programme for SME's for 1993-1996, to assist SME's in adapting to the possibilities offered by the Single Market. To gain the necessary participation of the consumer in the Internal Market measures are envisaged in the areas of legal and commercial guarantees, financial services and information for the consumer. Another important point for smoothing the Internal Market machinery is the promotion of Trans-European Networks.

The fourth part outlines the objectives of the Union's external policy in terms of management of the external frontier and completion of the common commercial policy.

CONCLUSIONS

The Internal Market is now in its second stage. The already well established legal framework provides the basis for the elimination of non tariff trade barriers. The Strategic Programme identifies new ways for managing this area without internal frontiers. As far as it can judged by now, the Single Market is operating without major difficulties, apart from transitional problems for small and medium sized enterprises. It is still to early to assess the full economic impact of the Internal Market, as firms have not yet had sufficient time to adjust to the new legislation and the process of transposition

is still going on. The Internal Market Programme is also not being constructed in an economic vacuum. The current recession and the world-wide economic situation has overshadowed the process of adaptation to the emerging single market framework. Nevertheless, there are indications to believe that restructuring and investment undertaken during the late 1980s in anticipation of the Internal Market have helped to mitigate to a certain extent some of effects of the current downturn. In this context, the successful completion of the GATT-Uruguay round has improved the economic outlook.

The Internal Market legislation has injected new dynamism into key industries and services by providing open and therefore increased cross-border competition. The key competitive yardsticks are price and quality. The transformation of this competitive environment forces enterprises to adapt to the new conditions by increasing their efficiency. The process of the completion of the Single Market has already strengthened mutually profitable economic and commercial links between the Member States. This has been reflected in a steady increase in the proportion of intra EC-Trade as a component of industrial and services output. The share of Intra-EC trade in total trade in percent has grown on the import side from 49% in 180 to 59% 1992 and on the export side from 55% to 61% during the same period. A Europeanisation of company corporate and investment strategies to allow firms to take advantage of newly accessible commercial opportunities in other Member States has been indicated by an increasing number of mergers and acquisitions as well as foreign direct investment, in anticipation of the effects of the Internal. Market.

The 1st January 1993 was a deadline for the establishment of the legal framework for the Single Market removing the physical, fiscal and technical barriers. It has been largely respected. It marked a high point in the life of the Internal Market but neither the end nor the beginning of an ongoing, dynamic and irreversible process. This legislation is coming on stream and opens up new possibilities for trade and investment. The challenge is now to realise the full potential of the Internal Market. Other Union policies also contribute to the proper functioning of the Internal Market by providing appropriate complementary measures concerning competition policy, consumer policy, special initiatives for SME's and the establishment of Trans-European Networks. The Single Market framework provides a positive environment within which to do business. But it is also up to firms and consumers to take advantage of the new possibilities and to draw attention to cases where they have experienced problems in availing of Single Market freedoms.

Written by: European Commission, DGXV

The world's largest industrial groups

This article compares the relative performance of the top 200 European companies with that of the top 200 US and Japanese firms, and describes the past trends in key financial indicators of Europe's top 200 companies by sector. The data is extracted from the Commission's database on large enterprises (DABLE), with all figures reported in current ECU. The data published only goes to 1992, as it relies on official figures from the companies' annual reports. 1993 figures were not yet available at the time of writing.

THE WORLD'S TOP 200 COMPANIES

Overall performance

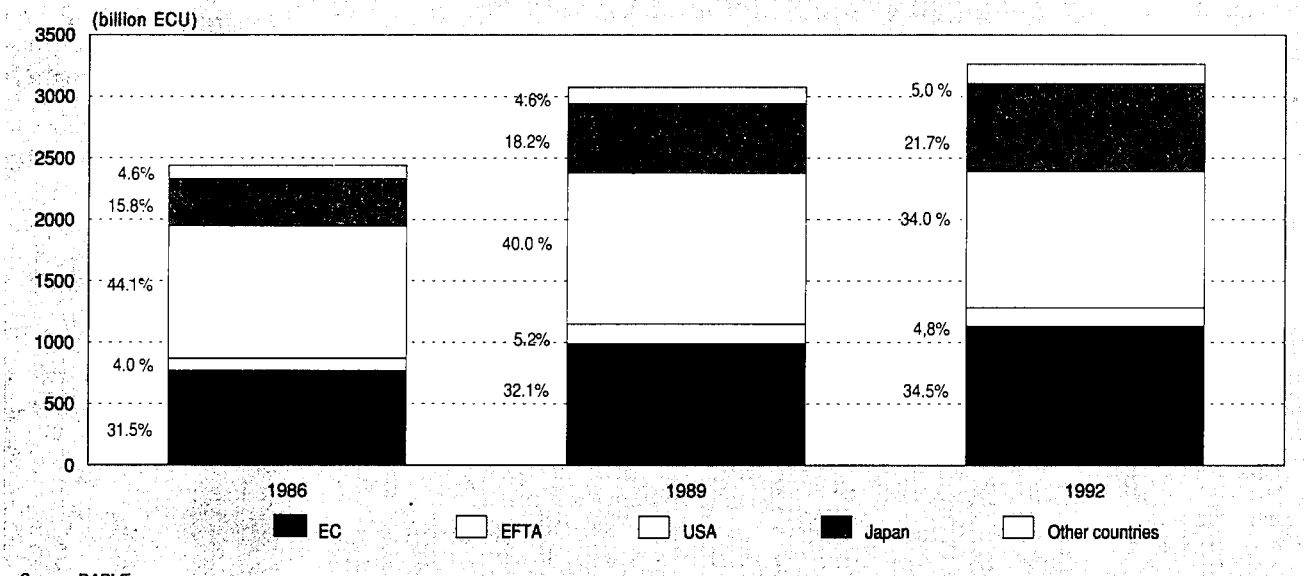
Between 1989 and 1992, the total turnover of the world's top 200 companies increased by 6%, about half the rate recorded over the previous 3 year period (Figure 1). The best performances were recorded by the top companies in Japan and in the EC, who saw their share of the turnover of the world's top 200 companies rising from 18% to 22% and from 32% to 34% respectively. In comparison, the share of turnover by the top EFTA companies and by companies from the "rest of the world" remained stable, at about 5% each. All of the improvement in the EC and Japan's positions was thus at the expense of the large US firms, who saw their share of the total turnover falling from 44% in 1986 to 40% in 1989 and to 34% in 1992.

The weak relative sales performance of the large US companies reflects more than just the downturn in the US economy in the early 1990s. On the one hand, concentration movements within the EC in the late 1980s led to a steady increase in the average size of EC firms, including of the larger ones. More EC firms thus entered the list of the world's top 200, replacing several US companies which fell back in the ranking (Table 1). After 1990, however, the number of EC firms ranking amongst the world's top 200 started to decrease, falling from 67 in 1990 to 62 in 1992. Over the same period the number of US firms continued to decline sharply (from 68 to 63) while 9 Japanese firms were making their entrance into the world's top 200 list.

To some extent, the changes in the world ranking in the early 1990s reflects exchange rate movements acting in favour of the Japanese firms, as the progressive appreciation of the Yen between 1986 and 1988, which was interrupted only for a short period in 1989 before resuming from 1990 onwards, has translated into an even stronger growth in their turnover in ECU terms than that observed in local currency.

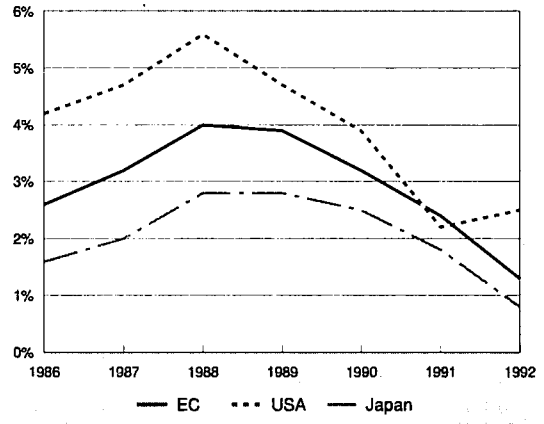
A comparison of the trend in the profit ratio of the top companies by region over the period 1986-1992 also shows an interesting pattern (Figure 2). Whereas profits were distinctly upward oriented over the period 1986-1988, thanks to policy moves aimed at restoring the profitability of firms, the trend reversed after 1988. In 1992, the profitability ratio in all three regions had fallen back below its level in the mid 1980s. This fall in average profits resulted both from the slackening

Figure 1: The 200 largest industrial groups in the world
Turnover growth at current prices



Source: DABLE

Figure 2: The 200 largest industrial groups in the world
Net profit / turnover



Source: DABLE

of economic activity in the early 1990s, which led to a decrease in sales volume, and from the increase in competition which resulted from globalisation and deregulation in many country markets. The rise in competition negatively impacted margins as companies were trying to keep prices down to retain market share. In order to limit the fall in profits, companies then started reducing employment levels and engaged in a second wave of rationalisation and restructuring moves. This, however, did not prevent the number of companies reporting a loss to increase between 1990 and 1992. In 1992, although the profit ratio was still falling in the EC and Japan, a small improvement was observed in the US (Figure 2): between 1991 and 1992, the number of US companies reporting a loss fell by 6, from 18 to 12.

What is interesting is that this fall in average profit ratios took place in all three major world regions. It can thus not be attributed to adverse movements in exchange rates in a given region, nor to the faster moves towards deregulation in the EC after 1986. In fact, the fall in average profitability was stronger in the US than in either Europe or Japan over the period.

The improvement in the profit ratio of US firms in 1992 was particularly important in the food & drink and in the aerospace industries. The automotive sector also saw an improvement in its overall financial situation, although this was not sufficient to return the sector to profit. Whereas the average profit ratio of the US automotive sector hovered between 4-5% between 1986 and 1988, it fell to zero in 1990 and to -3% in 1991 before recovering partly to -1% in 1992.

In Europe, the average profit ratio of the 200 largest firms, which had increased from 2.6% in 1986 to 4% in 1988, has since fallen back to 1.3%. The decline spared no industries, but a few were more badly hurt than others. The only sector in Europe to have reported an aggregate loss (based on the financial performance of the companies in the top 200 Europeans' list) in 1992 was the ferrous metals sector. This sector had already reported a small loss in 1991. In other sectors, the profit margins of firms in the EC also decreased but somewhat less than that of their US counterparts. Europe's largest automotive companies for instance saw their aggregate profit margin falling from a little over 5% in 1989 to just over 1% in 1992 (in the US, the top automotive producers were in deficit in both 1991 and 1992), while the European chemical firms saw their profits falling also from close to 5% in 1989 to a little over 1% in 1992.

Japanese companies, which traditionally operate with smaller margins than their European and US counterparts, also experienced a squeeze in margins between 1988 and 1992, although to a lesser extent: their average profit ratio fell from 2.8% in 1989 to 0.8% in 1992, half the 1986 level of 1.6%.

The three main causes of the deteriorating financial performance of the large US and European firms in 1991 and 1992 are weakened world demand, heightened competition leading to price wars in certain sectors, and sustained high real interest rates which weigh strongly on capital costs and negatively influence profits.

In 1991, 36 of the world's top 200 companies reported a loss (Table 2). Half of these were US firms, 10 were from the EC, 2 were from EFTA and 4 were Japanese. In 1992, although the total number of firms in the top 200 which reported a loss increased to 45, these were more evenly split across regions: there were with 16 EC groups reporting a loss in 1992, alongside 12 US groups, 11 Japanese and 5 from the EFTA region.

Within Europe, the largest groups in terms of turnover are from Germany, France and the UK, in that order. Together, the top companies of those three countries accounted for two thirds of the total turnover of Europe's top 200 firms in 1992, the same share as in 1989. This compares with a share of 71% in 1986. Two other EC countries which also host a large number of Europe's top firms are the Netherlands and Italy, followed by a non-EC country, Switzerland. The Netherlands is, in fact, home to a number of Europe's top oil and chemical companies (Royal Dutch Petroleum, Unilever, Akzo, DSM), as well as to other giant corporations such as Philips (electrical engineering), Hoogovens (metals) and Heineken (food and drink). Switzerland hosts two of the world's best known companies, Nestlé and ABB, as well as several large chemical firms such as Ciba-Geigy, Sandoz, and Roche, amongst others.

The breakdown of turnover of the world's top 200 industrial groups by sector in both 1986 and 1992 is shown in Figure 3. As expected, the sectoral shares in Figure 3 are highly related to the average degree of concentration in the industry. Thus, in 1986, oil companies accounted for 21% of the total turnover of the world's top 200 firms, followed by the motor

vehicles and parts sector, electrical engineering producers and chemical companies. The computer and office equipment sector, which represents less than 2% of total value added in the industrialised countries, has a share of the turnover of the world's top 200 firms' which is comparatively much higher (3% in 1992).

Between 1986 and 1992, however, the weakening in oil prices limited the growth in the turnover of the oil and chemical companies and made these firms lose their first place in the ranking. The motor vehicles and parts sector thus became the sector with the highest turnover within the world's top 200, despite a relatively poor financial performance over the period 1990-1992. In 1992, the motor vehicles and parts producers generated more than one fifth of the total turnover of the world's top 200 firms (Figure 3). Next came the petroleum refineries (19.5%), electrical engineering firms (15.8%), food, drink and tobacco (9.9%) and chemical companies (9%). The ferrous metals industry, which has seen many concentration moves between 1986 and 1992, had more firms in the top 200 list in 1992 than in 1986, and its total share of turnover also increased over the period, from 4.1% to 5.4%.

Table 3 shows the 25 largest profit earners at world level. The first is an EC firm, Royal Dutch Shell. In total, 8 EC and 2 EFTA companies rank amongst the top 25 largest profit earners, alongside 14 firms from the USA and only 1 from Japan. Most of the companies which rank in this list are from the oil, chemicals and food and drink sectors, alongside a few equipment producers such as Toyota. Toyota is, in fact, the only Japanese firm in the list.

It is interesting to compare the list of largest profit earners with that of the most profitable companies at world level (Table 3). Again, only one Japanese company ranks amongst the 25 most profitable companies at world level: Fuji Photo Film (in 23d place). Fourteen of the world's biggest profit earners are also amongst the 25 most profitable firms: these are all the pharmaceutical companies in the list of largest profit earners, along with a few diversified chemical companies such as Johnson and Johnson and Procter and Gamble, and the giant soft drinks company Coca Cola. None of the oil companies which ranked amongst the largest profit earners are amongst the "most profitable" firms, as the average profit ratio in the petroleum refinery sector is generally low. The regional distribution of the most profitable companies is similar to that of the largest earners, with 13 US companies, 9 European and 1 Japanese. The last two are Canadian and Australian.

Below, we look at the overall performance of the world's top 200 firms by main sector of activity.

The next section will then focus on the relative performance of the largest European companies, both by country of origin and by sector.

Sector profiles

Petroleum refining

The world energy sector is dominated by large companies, many of which are either still fully state owned or largely controlled by government. Industrial restructuring, combined with a healthy demand growth leading to improved sales and profit performance during the 1980s, have led to a gradual increase in the number of energy companies in the world's top 200 and in Europe's top 200 list: the number of petroleum refining companies in the world's top 200 increased by 2 between 1986 and 1990, from 28 to 30, despite extensive restructuring in other sectors which had as an effect to increase the average size of firms in these other sectors.

Between 1990 and 1992, however, the total turnover of the world's largest petroleum refining companies decreased by 0.2%, due to a combination of falling oil prices and weak demand. This followed a period of healthy growth between 1986 and 1990, when the total turnover of the world's top refineries had increased by 21.2% in total, or 5% per year on average.

Measured in terms of turnover, the share of EC companies in the total turnover generated by the world's top petroleum refineries increased from 34% in 1986 to 36% in 1992 (Figure 4). In general, USA companies suffered the most from the hard times in recent years. Most saw their turnover decreasing in absolute figures between 1990 and 1992, some even posting a lower turnover in 1992 than in 1986. This was the case for instance of Mobil, Texaco, Atlantic Richfield, Philips Petroleum, Sun, USX Marathon Group, UNOCAL and Ashland Oil. In fact, all USA companies in the list except Exxon, Chevron and Amoco had a lower 1992 turnover than in 1986.

In the fight for leadership that Royal Dutch Shell and Exxon have been fighting over the past years, 1992 saw the victory of Exxon, whose turnover exceeded that of Royal Dutch Shell by 6.5%. (In 1990, Royal Dutch Shell's turnover exceeded that of Exxon by 0.4%). The turnover of the world's third largest petroleum refinery, British Petroleum of the UK was, at ECU 45.2 billion, 43% less than that of the first largest, Exxon. In 1992, British Petroleum indeed gained one place in the ranking at the expense of Mobil of the USA.

The new features of the 1992 ranking of the world's largest petroleum refining companies are the arrival of two Korean companies, Ssangyong and Sunkyong, respectively ranked 17th and 18th, and the entrance of Nippon mining in 26th position.

The overall improvement in the turnover and profits of the world's top US industrial firms in 1992 was not shared by the companies in the petroleum refinery sector. Indeed, in 1992, most USA oil companies continued their descent in the rankings, many of them losing four to eight places. In fact, the best performers in this sector in 1991 and 1992 were Japanese (Nippon oil gained three places compared to 1990, Idemitsu Kosan gained one from 1990, Showa Shell Sekiyu gained 4 and Mitsubishi Oil gained 2) and the already mentioned two Korean companies. Most EC firms basically moved by one rank at most in either direction in the rankings.

A direct result of the above developments is that, although the average size of the USA's top refineries has remained virtually stable between 1986 and 1992, at around ECU 23 billion, that of the average EC refinery in the world's top 30 has increased significantly, from ECU 28.14 billion in 1986 to ECU 34.93 billion in 1992 or nearly 1.5 times the size of the top USA company. The Japanese top refineries are in

comparison much smaller, at ECU 11.4 billion or one third the size of the EC companies.

Iron and steel

The world ranking of the largest metal producers is dominated by EC and Japanese firms. In 1992, six EC companies and 8 Japanese firms featured in the world's top 17 list in this sector, the remaining three being respectively US (Aluminium company of America, in 14th place), Korean (Pohang Iron and Steel, in 17th place) and Australian (Broken Hill Proprietary, in 10th position) (Figure 5). The major restructuring moves which took place in this sector between 1986 and 1992 in Europe and in Japan are evidenced by the strong increase in the average size of firms in this sector. In the EC, the average company size of the top metal producers increased from just under ECU 8 billion in 1986 to a little over ECU 12 billion in 1992, whereas in Japan the average size of the top companies increased from ECU 8 billion to ECU 10.5 billion between 1986 and 1992. This growth was essentially achieved through acquisitions. Metallgesellschaft of Germany for instance nearly tripled in size over this 6 year period through a set of acquisitions, moving into 4th place in world rankings, whereas VIAG, also of Germany, climbed into fifth place also as a result of a series of acquisitions.

Metallgesellschaft AG indeed acquired, together with Deutsche Bank AG and Dresdner Bank AG, 98.8% of the shares in Buderus AG plus 100% of the shares in both Dynamit Nobel AG and Cerasiv GmbH via MG Industriebeteiligungen. These acquisitions substantially boosted Metallgesellschaft's sales volume in the industrial sector, from DM 1.9 billion in the 1990/1991 fiscal year to DM 5.6 billion in 1991/1992.

1993 may, however, prove to be a black year for Metallgesellschaft, as the company is in the throes of serious financial difficulties. As it reported large losses for the year to September, the conglomerate unveiled a deep restructuring plan which may lead to the sale of many of its 258 subsidiaries worldwide. Such internal restructuring should lead to a lower sales performance for the German group in 1994 and after.

The other German company which posted significant turnover growth in the early 1990s was VIAG. VIAG group sales measured in DM indeed grew by 21% in 1991 and by a further 3% in 1992, through the inclusion of newly acquired companies. Among the foremost acquisitions reported during this period are the purchase of the CCE group in 1991, along with the purchase of a 33.3% interest in Kuehne & Nagel International AG and the takeover of Eisenwerk Bruehl Aluminiumtechnik GmbH and its subsidiaries in 1992.

One Korean metal producer has joined the ranking of top metal producers: Pohang Iron and Steel, which ranked 17th in 1992.

A notable feature of the sectoral growth between 1986 and 1992 is the continued decline in both the share of turnover and the number of US firms in the world ranking: whereas in 1986 the three largest USA metal producers accounted for nearly one fifth of the total turnover of the leading firms in this sector, in 1992 this share had fallen to a mere 4%, as both LTV and USX - US Steel bailed out of the ranking of the world's top 200 firms, based on turnover.

Chemicals

The chemical sector is a very heterogeneous sector, with large corporate giants dominating the basic chemicals segment and SMEs accounting for the bulk of output in many segments of the specialty chemicals sub-sector. In the pharmaceuticals industry, although no single company clearly dominates the world market, the size of the key pharmaceuticals players who fight for leadership is such that many of them are well placed in the world's top 200 list. Amongst the world top 200 firms in 1992, 25 are chemical companies, of which 10 are key players in the pharmaceuticals market.

Europe is a major player in the world chemical industry, with six of the world's top 10 chemical companies being European firms (5 from the EC and 1 from EFTA).

After 1986, the removal of intra-EC barriers to trade reinforced the on-going trend towards increased concentration in the industry, as basic chemical producers sought to diversify both geographically and across product lines to spread risk over a broader market base. The fall in the dollar exchange rate in the second half of the 1980s also encouraged EC firms to undertake major investments in the US. Large European chemical groups such as Hoechst, BASF or Bayer have thus become key players in the US chemical market, ranking respectively as the 5th, 6th and 11th biggest company in that market.

As a result of this move towards increased concentration and geographical diversification of EC firms, the total turnover generated by the largest EC chemical firms increased by 20.5% between 1986 and 1992, rising from ECU 106 billion to ECU 128 billion, while the number of EC firms in the world ranking of top chemical companies increased from 9 to 10. Over the

same period, the number of US firms in the ranking decreased by four, such that the share of turnover generated by the largest US firms actually fell by about 7 percentage points over the 6-year period (Figure 6). Two of the USA firms which disappeared from the list were basic chemicals producers (Monsanto, and Union Carbide which was taken over by Rhône-Poulenc), and the others were specialty chemicals producers (Colgate Palmolive, American Home Products and Pfizer). Another basic chemical firm which disappeared from the list is DSM of the Netherlands.

The geographical expansion and product diversifieation strategy of the largest world chemical companies also translated in a significant increase in the average size of the top firms within each region. Whereas in 1986 the top 9 EC companies generated an average turnover of ECU 11.8 billion this figure had increased by 8.4% by 1992, to ECU 12.8 billion. In comparison, the 7 USA chemical producers which remained on the list of world top 200 firms in 1992 had an average turnover of ECU 14.3 billion, a 21% increase from 1986. In fact, between 1986 and 1992, although the overall performance of US chemical firms was dismal, the larger ones were able to maintain their position and expand their turnover through a series of acquisitions. Procter and Gamble, Johnson and Johnson and Bristol Myers Squibb - which was formed by the merger of Bristol Myers on one side and Squibb on the other side - were particularly successful over the period, gaining 3, 3 and 11 places respectively in the ranking of the top 25 world chemical producers.

The new entrants in the world ranking over the period were mainly pharmaceutical or specialty chemical companies: two from the EC (SmithKline Beecham and Henkel), Roche Holding from Switzerland, and Merck from the US. The last entrant, is Sumitomo Chemical of Japan. The dominance of pharmaceutical companies in the rankings of top world chemical producers is in line with the fact that the sector has posted much faster growth than the rest of the chemical industry over the past decade, thanks to rising demand for health care from an ageing population. This trend was exacerbated in the early 1990s when demand for basic chemicals started falling, while pharmaceuticals production was still on an upward trend.

Electrical and electronic engineering

The high degree of concentration of the electrical engineering sector is illustrated by the large number of electrical engineering companies in the world top 200. In 1986, 29 of the world's biggest companies were electrical equipment producers. Although in 1992 this number had come down to 27, the share of global turnover by the world's top 200 firms which was accounted for by these companies had increased from 15.0% to 15.8%. In fact, over most of the six year period, the sector experienced healthy growth with the total turnover by the leading firms growing from ECU 349.4 billion in 1986 to ECU 493,6 billion in 1990, a 9% average annual growth. After 1990, however, the growth in turnover slowed significantly, to less than 2% per year on average between 1990 and 1992.

The world ranking of the top electrical engineering firms is dominated by Japanese and Korean companies. In 1992, 11 of the top 27 electrical engineering companies at world level originated from one of those two countries. Together, these two countries accounted for 53% of the total turnover of the top 27 companies in this sector. Japan's share alone rose from 35% in 1986 to 41% in 1992 (Figure 7).

Rationalisation and restructuring moves amongst the top electrical engineering firms has led to significant changes in the relative position of these companies in the rankings, not only between 1986 and 1990 but also after 1990. Over the past 2 years, thus, Westinghouse Electric of the US has lost 6 places in the ranking while General Electric also of the US lost its leadership position, falling in third place behind Hitachi and Matsushita Electric of Japan. In fact, most of the Japanese companies significantly improved their position in the ranking during the past two years, with Sanyo Electric for instance rising from 22d to 17th position between 1990 and 1992 thanks to a 16% increase in turnover, and Sony rising from 12th to 8th position on the back of a 24% growth in turnover between 1990 and 1992.

Several EC firms have also improved their relative position, the most notable performance being recorded by the European leader Siemens, which ranks 4th at world level and whose turnover grew by 25% between 1990 and 1992. Alcatel Alsthom of France also posted remarkable growth in turnover, (+14%) over the same period. In both cases, growth was largely external. Divestments by Philips, on the other hand, resulted in a comparatively low overall sales growth over the period, of 7% in total over the two years. The first EFTA company, Asea Brown Boveri, saw stagnating sales (+1.2% between 1990 and 1992) which have brought the company back to 11th position in the world rankings, from 8th position in 1990.

Computer and office equipment

The world computer and office equipment sector is dominated by a very small number of large companies, with IBM as the unchallenged leader in terms of sales: in 1992, IBM's turnover was close to ECU 50 billion, nearly 2.5 times the turnover of the next largest company in this sector, Fujitsu

of Japan. Between 1986 and 1990, intense competition and ownership restructuring moves in this sector led to further increases in industry concentration, such that the number of computer and office equipment producers in the world top 200 list fell from 7 in 1986 to 6 in 1990 and to 5 in 1992. Olivetti's poor sales performance since 1990 has eliminated it from the world top 200 companies' list, such that in 1992 there were no more EC (nor EFTA) companies in the world ranking of this sector. Of the five firms on the list in 1992, four were US firms, accounting for close to 80% of the combined turnover of the top 5 firms, the last one being Fujitsu of Japan, which ranks second.

The difficulties experienced by this sector over the past years as intense competition in world markets triggered price wars are illustrated by the fact that the joint turnover of these five companies only increased by 1.8% over the past two years, following a growth by 15.4% between 1986 and 1992. The only change in the relative position of companies on the list between 1990 and 1992 has been the fact that Hewlett-Packard moved from fourth to third position, thanks to a turnover growth of 17.7% over the 2-year period, the second best performance after Fujitsu (+35% turnover growth).

The crisis in the mainframe market is also evidenced by the strong fall in the global sales of Unisys (-18% between 1990 and 1992) and IBM (-8% over the same two-year period).

Motor vehicles and components

Growing concentration in the European motor vehicles and components sector over the past 6 years brought the share of world turnover which is accounted for by the largest EC firms in this sector from 27% to 34%.

Eight firms from the EC rank amongst the world's top 200 companies, alongside four firms from the US, 9 from Japan and one from EFTA. This distribution of top companies by country/region of origin in 1986 was essentially the same, with 3 US firms, 8 EC, 8 JPN and 2 EFTA companies. The sector as a whole experienced such rapid growth in the late 1980s that, despite the recent downturn in production and sales, the total turnover of the 22 largest companies in this sector was 41% higher in 1992 than 6 years earlier. The fastest growth over the 6 year period was recorded by BMW (even before its recent acquisition of Rover), which more than doubled sales to ECU 15.5 billion, closely followed (in terms of turnover growth) by Mitsubishi Motors, which posted a ECU 22.2 billion turnover in 1992 against ECU 10.6 billion in 1986. The worst performances were posted by General Motors, which remains the unchallenged leader in the sector but saw its turnover shrinking by 3.6% in total over the 6 years, and Volvo, whose turnover fell by close to 8% between 1986 and 1992. With a few exceptions and despite somewhat varying sales performances over the period, most large motor vehicles and components producers maintained their place in the rankings between 1986 and 1996.

Thanks to the concentration moves within Europe, the average size of European motor vehicle companies is now more in line with that of the other world giants: from an average size of ECU 16.5 billion in 1986, compared with ECU 63.7 billion for US firms and ECU 14.7 billion for Japanese companies firms, the top EC firms now have an average turnover of ECU 27.3 billion, which compares to ECU 52.0 billion for the US companies.

Aerospace equipment

The aerospace industry has been seriously affected by the downturn in air traffic demand in the early 1990s and the deteriorating financial situation of most of the airlines. As orders for new civilian aircraft and defence budgets were cut, the aerospace equipment producers experienced falling sales and profits. Between 1986 and 1992, the total turnover of the top 11 companies increased by a mere 8.8%, less than 1.5% per year on average. Four companies on the top 11 list recorded negative growth in turnover between 1990 and 1992: British Aerospace (-8%), Allied Signal of the US (-4%) General Dynamics, also of the US (-15%) and Lockheed (-0.1%).

A new feature of the 1992 ranking is the entrance of a Japanese company in 9th position worldwide: Kawasaki Heavy Industries, with a total turnover of ECU 6.8 billion, 30% that of the industry's world leader, Boeing.

Source: DABLE

France's Aérospatiale, which had disappeared from the world Top 200 list in 1990, has returned in the ranking in 1992 and is the world's 8th largest aerospace equipment producer.

In fact, the improved overall performance of EC aerospace equipment producers is probably the most significant feature of the 1992 figures. Whereas in 1986 the combined turnover of the top EC aerospace producers only represented 9% of the total turnover generated by the firms in the world top 200, in 1992 this share had increased to 25%, with British Aerospace moving from 11th position to third place and Deutsche Aerospace, which was not in the 1986 top 200 list, now featuring in 6th place behind Allied Signal of the US. Over the same period, Aérospatiale of France moved up from 10th to 8th position.

Food, drink and tobacco

The agri-food sector is much less cyclical than most of the other sectoral markets which have been considered until now. Between 1986 and 1990, the total turnover generated by the top 25 world companies in this sector increased by 32.5%, a 7.3% average annual growth. In the two years to 1992, the turnover generated by these 25 companies increased by another 6% in total, in current ECU.

Concentration movements within the EC following the launching of the Single Market programme, combined with the fast expansion of a number of Japanese food groups, translated into a significant increase in the share of world turnover which is accounted for by EC and Japanese firms, mainly at the expense of the US. In 1992, the share of turnover accounted for by US firms in this sector had come down by 7 percentage

points, from 58% in 1986 to 51% in 1992, whereas the share of turnover of Japanese firms had increased from 3% to 9% thanks to the entrance of three additional Japanese agri-food producers in the world top 200.

Over the period 1986-92, the average size of the top EC firms in this sector also increased significantly, from ECU 10.2 billion to ECU 14.1 billion, a figure even slightly higher than the top US firms in 1992, at ECU 13.8 billion.

Between 1990 and 1992, there was no major change in the relative positioning of the large food producers in the world ranking, with the exception of RJR Nabisco and BSN, both of which recorded strong growth in turnover (+11.6% and +35.6% respectively), thus gaining 2 (respectively 4 for BSN) places in the world ranking. BSN is, in fact, the company which recorded the fastest growth in turnover in the early 1990s, followed by Coca Cola (+25.7%), Ferruzzi Finanziaria (+14.3%) and Nestlé (+14.2%). Much of this growth was through acquisitions. In 1992, however, although the number of M&As in the European agri-food sector continued to increase, the size of deals was somewhat smaller. Both the number and size of deals came down further in 1993. Between 1990 and 1992, only one company experienced negative sales growth: Grand Metropolitan of the UK.

EUROPE'S TOP 200 FIRMS

Overall performance

In 1992, the total turnover of Europe's 200 largest companies amounted to ECU 2028 billion, i.e. about 42% of EC's GDP. Table 5 shows the distribution of Europe's 200 largest companies by country, in 1986 and in 1992 respectively. Important rationalisation and concentration movements in France, combined with the recession in the UK which eroded the net results of British firms, have resulted in the reversal of France and UK's positions in the ranking between 1986 and 1992, based on turnover.

The most notable trend in Table 5, however, is the Europeanisation of markets after 1986, as concentration and rationalisation moves amongst companies which were previously constrained to relatively small, national, markets resulted both in a considerable increase in the average size of Europe's giants, and in an increase in the share of companies from the "smaller" EC countries in Europe's top 200. In 1986, thus, 72.5% of the companies in Europe's top 200 list were from one of the three largest EC economies (Germany, France and the UK). In 1992, this share had fallen to 67%, with countries such as Spain, Italy, the Netherlands or Belgium increasing the number of firms that are placed in Europe's top 200 list.

Compared to the rest of the world, the breakdown of Europe's largest companies by sector is much more varied - implying that many sectors which are highly concentrated in the rest of the world have not yet reached the "critical size" in the EC (Figure 13). Petroleum refining companies for instance, which account for nearly one fifth of the total turnover of the world's top 200 firms, account for less than 13% of the global turnover of Europe's top 200 companies. And indeed, excessive fragmentation is one of the factors frequently quoted as negatively influencing the relative competitiveness of Europe's petroleum refineries compared to their competitors in the US of Asia.

In the motor vehicles sector also, the relative fragmentation of the industry in Europe (mainly of the automotive components part of the industry) is reflected by the fact that the "large" motor vehicle companies only account for about 12% of the total turnover of Europe's top 200 firms, whereas the equivalent share at world level is more than 20%.

Comparing the sectoral distribution of companies in the top 200 list in Europe between 1986 and 1992 shows no major difference (Figure 13). The telecommunications sector and the industrial conglomerates were able to post a better overall performance over the period than the average for European industry, whereas in three sectors (chemicals, petroleum refining and mechanical engineering) the sales performance of the larger firms was less than average, so that their share of the total turnover generated by the top 200 European firms decreased significantly.

Table 6 present Europe's 25 largest profit earners, the most profitable and the richest firms, along with Europe's 25 biggest employers. As in the rest of the world, the list of most profitable companies is dominated by companies from the pharmaceutical industry, alongside a few electrical equipment companies. Amongst the biggest EC employers we find a very diverse mix of companies, many of which are fully or partially government owned, and some of which may not keep their place in this ranking in future years as they are on the list of companies to be restructured or privatised.

Below, we look at the relative performance of EC firms in each of these sectors over time.

Sectoral performance

Petroleum refining

The total turnover of Europe's 10 largest petroleum refining companies represents 19.5% of the total turnover of Europe's 200 largest firms, but the employment share is much lower, reflecting the fact that petroleum refining is not a labour intensive activity.

1993 was not a very good year for petroleum refineries, which saw profits tumble as a result of weak demand and oil prices. Even those companies that were able to maintain their turnover in 1992-93 saw profits squeezed by the dollar effect. Elf Aquitaine for instance saw its net profit falling by 40% in 1992 compared to 1991.

Of Europe's 10 largest petroleum refining companies, eight are in the world's top 200 ranking. The last two, Compañia Española de Petroleos and Ultramar PLC, are from Spain and the UK respectively. All 10 companies were already in the 1990 top ranking, in the same place except for Petrofina who lost two places in the ranking, falling from Europe's 7th biggest oil refinery to 9th place.

The total turnover of Europe's 10 largest refineries fell by 1.5% between 1990 and 1992, following a total increase of 37% between 1986 and 1990, or 8.2% per year on average. The companies which reportedly suffered most in terms of turnover over the past two years were Veba Oel (whose turnover fell by 17% between 1990 and 1992), Petrofina (-11.6% in turnover over the same period) and Royal Dutch Shell (-10% in turnover). In contrast, Repsol, Elf Aquitaine and Total registered healthy rises in overall turnover between 1990 and 1992, their increase in turnover ranging from 7.7% for Total to 15.7% for Elf Aquitaine and 28.6% for Repsol.

Source: DABLE

Iron and steel

The total turnover of the top 10 European metal producers increased by 66% between 1986 and 1992, an 8.8% growth in annual terms. Much of this reflected growth through acquisitions, however, as overall market demand growth was subdued, especially in the early 1990s. Of the top 10 European metal producers, five are German, the remaining five being respectively French, British, Luxemburguese, Belgian and Swiss.

The combined turnover of these top 10 companies grew from ECU 81.6 billion in 1990 to ECU 90.4 billion in 1992, a 10.8% growth in nominal terms. Although there has been no major change in the ranking of the top European companies in this sector over the past two years, the relative performance of individual producers has been quite varied, with Krupp Stahl growing by a factor of 3 through the acquisition of Hoesch, whereas VIAG and Metallgesellschaft were respectively growing by 28% and by 30%, both through a series of acquisitions. Apart from these three companies, and with the exception of Alusuisse-Lonza which recorded stable turnover at about ECU 3.6 billion, all the other top European metal producers experienced a decrease in turnover over the past two years, the worst performance being recorded by British Steel whose turnover measured in ECU fell by 20% between 1990 and 1992.

Chemicals

Amongst the top 15 European chemical companies, four are German, three are Swiss and three are British. Italy, France, Norway, the Netherlands and Belgium only have one representative on the list, and Spain has as of yet none.

The total turnover generated by these top 15 companies in 1992 amounted to ECU 168.5 billion, about 20% more than that generated by the top European chemical companies in 1986. Although there have been much changes in the ranking of the top European chemical producers, all but 2 of the top 15 in 1986 were still among the top 15 in 1992. The two that had disappeared are Montedison - whose basic chemicals division has in fact been merged with ENI's chemical division to form Enimont - and DSM of the Netherlands. The two new - one of them a false - entrants are Enichem and SmithKline Beecham.

Rhône-Poulenc, Sandoz and Henkel are the three companies which posted the best performance in terms of turnover between 1986 and 1992, growing by more than 50% in total over the 6-year period, sometimes through acquisition. The companies which showed the worst performance were Norsk Hydro, whose turnover measured in ECU actually shrank in ECU by 3.5% between 1986 and 1992, along with Bayer and ICI. The latter two companies reported an average annual growth in turnover of only 1% per year or so over the six-year period.

Mechanical engineering

The European mechanical engineering sector is much less concentrated than its Japanese and US counterparts, such that the largest EC producers in this sector rank fairly low in the world Top 200 ranking.

Table 9: Chemicals
Turnover

(million ECU)	1986		1992

Thyssen Industrie	2 215	SKF	3 553

Source: DABLE

Between 1986 and 1992, the sector had mixed fortunes, as a period of fast growth between 1986 and 1990 was followed by falling investment and fixed capital demand. Whereas total sales by Europe's top 10 mechanical engineering firms increased by close to 47% between 1986 and 1990, or 10% annually, the total turnover generated by these top 10 firms then contracted by 0.4% between 1990 and 1992. The best sales performance was posted by Linde (whose turnover grew by 26.5% over the two years to 1992) and Mannesmann (+19.3% in turnover), whereas SKF experienced a decrease in turnover by 3.5% and MAN only grew by 1.5%.

Thanks to its takeover of Hoesch, Fried-Krupp Hoesch climbed to second place in the top 10 European ranking, despite a 16.4% decrease in the combined turnover of the two companies. The main change in the rankings between 1990 and 1992 were the improved position of AGIV, which now ranks as Europe's 5th largest mechanical engineering producer, and the continued decline of SKF which now only ranks as the 8th largest European producer, behind Sulzer of Switzerland.

Electrical and electronic engineering

The rapid growth of the electrical engineering sector over the eighties has masked highly diverse performances by market segment, which had major implications on the relative ranking of firms in this sector. In Europe, thus, there have been notable changes in the rankings of the top 10 firms due to contrasted performances of companies involved in the production of electrical equipment for consumers (a segment which has been faced to growing competition on world markets and where EC firms have been losing market share) and electrical equipment for industry (which includes telecommunications equipment, an area where EC firms are world leaders).

Siemens, which had already overtaken Philips as the European leader in this sector in 1990, has since largely confirmed its position thanks to a 25% growth in turnover between 1990 and 1992, compared an average turnover growth of the European top 10 of only 9.4%. The second and third largest European firms in this sector are respectively Philips of the Netherlands and Alcatel Alsthom of France. The EFTA countries are very present at world level in this sector, with three companies in the top 10: Asea Brown Boveri (CH/S) in 4th position, Electrolux (S) in 5th position and Ericsson (S) in 10th place.

Compared to 1990, three companies saw negative growth in turnover: Thomson (-4.7%) from France and Electrolux of Sweden (-2.0%), and General Electric of the UK (-13.2%). The best performance was that by Siemens (+25%) and Alcatel Alsthom (13.6%), both of which partly grew through acquisitions.

Motor vehicles and components

The combined turnover of the largest 10 European motor vehicles and components producers amounted to ECU 246.3 billion in 1992, a 57% increase from 1986. Most of this growth was achieved during the first part of the period, however, as falling new car registrations in the early 1990s has resulted in cutbacks in sales and turnover. Nevertheless, although overall market demand growth was slowing down significantly in the early 1990s, the total turnover generated by the 10 largest European companies in this sector continued to increase, from ECU 214.9 billion in 1990 to ECU 246.3 billion in 1992, a 7% average annual rate of growth. Much of this was external growth.

The largest European automotive producer is Daimler-Benz, with a total turnover in 1992 of ECU 48.8 billion, 15% more than the next in line, Volkswagen. Daimler-Benz is, in fact, the third largest European industrial company and ranks 11th world-wide. Fiat, which had risen to second place in the European ranking in 1990, has since fallen back into third position behind Volkswagen. Volvo, which reported an 8% fall in turnover in the 6 years to 1992, was the worst performer of the top 10 in terms of turnover growth, although a cooperative agreement with Renault has made the Volvo/Renault group

Table 11: Electrical and electronic engineering

Source: DABLE

the world's largest truck producer. The involvement of several of the large automotive producers in other markets, such as aerospace (for Daimler-Benz and Fiat) can in fact make comparisons of relative performances based solely on turnover somewhat misleading. Nevertheless, Volvo's sales performance was in sharp contrast with the overall growth of 50% and above posted by all the other top 10 European vehicle manufacturers over the same period.

Compared to 1990, the best performance in terms of turnover was that of Volkswagen (+27.9%), which absorbed Audi, followed by Daimler-Benz (+17.5%) and BMW (+17.1%).

Two groups saw negative growth in turnover over the past two years: Fiat (-1.4%) and Peugeot (-1.6%). Saab Scania, which sold a big part of its car division to General Motors a couple of years ago, has since disappeared from the top 10 list. Opel has made a notable entrance in 8th position in the top European list, just behind BMW.

Food, drink and tobacco

The total turnover of the top 10 European agri-food producers increased by 51.6% in total between 1986 and 1992, a 7.2% average annual increase.

Although most of the sector's production is accounted for by small and medium-sized firms, there are a number of major European giants operating in this sector which have recorded healthy growth in turnover and posted high profitability over the past years. As these major groups adjusted their strategies in the late 1980s to prepare for the single market, there have been significant changes in the list of companies which feature in the top 10 ranking as well as in the country of origin of the leading European producers. Whereas in 1986 seven of Europe's top 10 agri-food companies were from the UK, in 1992 this number had fallen to five, alongside two Italian companies, two French and one Swiss firm. Ferruzzi Finanziaria, Beghin Say and Eridania Zuccherifici were not in the 1986 list of top 10 agri-food businesses, and neither was Hillsdown Holdings, while companies like Dalgety, Guinness, Associated British Foods and Jacobs Suchard either disappeared from the list or were acquired by one of the other top players.

Unilever of the UK/Netherlands remains the unchallenged leader in this sector, closely followed by Nestlé of Switzerland. The next in line, BAT, has a turnover which is less than half that of the European leader in this sector.

Services

The above sections mainly looked at the relative performance of Europe's top manufacturing companies over the period 1986-92. Below, we briefly review the trends in turnover in Europe's key services companies, in those sectors which are most concentrated: the distribution of energy, telecommunications services, transport services and distribution.

The sector accounting for the largest share of turnover is the utilities sector, with 15 companies accounting for a turnover which is, at ECU 142.1 billion, equivalent to 90% of the turnover generated by the top 10 European electrical engineering companies. The next largest services sector in terms of turnover, and also the fastest growing sector, is the telecommunications services sector. Because of the major changes in the organisation of this sector in Europe in the late 1980s and early 1990s, however, the sector's growth must be appreciated by adding the "postal services" sector to the telecommunications services sector. The average annual growth of the combined "communications services" sector between 1986 and 19892 was nevertheless impressive, at +87%.

Energy

Table 14 presents the top 10 European utilities, ranked by turnover. The largest is EDF of France, with a turnover in 1992 of ECU 25.9 billion, followed by the German utility RWE AG. All the companies on the list of top European utilities are still essentially national companies, so that it is not surprising to find the French, German , Italian and UK distributors at the top of the list.

Telecommunications

The liberalisation of the European telecommunications services market and the transformation of the key national players into companies capable of competing at the EC level has changed the names and relative ranking of the top 8 companies operating in this sector in Europe, without fundamentally changing the nature of their business.

Between 1990 and 1992, the combined turnover of the 8 companies in the 1992 top European companies' list increased by 8.1%, or just over 4% per year on average. The period was characterised by the consolidation of Deutsche Telekom, and the privatisation of parts of British Telecom which would explain a fall in turnover by 6%.

The fastest growth in turnover between 1990 and 1992 was reported by Telefonica de España from Spain (+48%), followed by STET (+30%) and SIP (+23%) from Italy, and France Telecom (+13%).

Transport services

The list of top 10 transport companies in Europe is, unsurprisingly, dominated by airlines. Of Europe's top 10 companies, half were airlines, three were railways and the remaining two were shipping companies.

Table 17: Europe's 200 largest manufacturing and service groups, 1992

Rank	Name	Country	Turnover (million ECU)	Profit (million ECU)	Net worth (million ECU)	Employees	Return on assets (%)	Sector

Between 1986 and 1992, the total turnover generated by the top 10 European transport services providers increased by 42% in total, a 6% increase in annual terms. Most of the companies maintained their place in the ranking between 1990 and 1992, with the exception of Lufthansa which gained four places to become the European leader in the sector. Nedlloyd, the shipping company which was in 9th place in the 1990 ranking, has since disappeared from the top 10 list, whereas Delmas of France has entered in 10th position.

The on-going rationalisation and the restructuring moves which are under-way in this sector as market liberalisation proceeds will undoubtedly lead to further changes in the ranking of top firms in this sector over the coming years.

Distribution

Europe's largest distribution companies are listed in Table 18. Tengelman of Germany is by far the largest European distributor, with a total turnover in 1992 of ECU 26.1 billion. It is also the largest employer on the list, with employment of close to 200 thousand in 1992.

Although cross-European concentration movements have taken place in this sector in the late 1980s and early 1990s, the size of the top players is still mainly determined by the size of their national markets, with the exception of the second group on the list, Spar International of the Netherlands. Among the list of top 10 European distributors, three are German, five are French, one is from the UK and one Dutch.

A comparison of the turnover generated by these top firms in 1986 and 1992 respectively shows major changes both in the average size of the groups and in their relative position. Carrefour of France for instance saw its turnover nearly doubling over the period, rising from 6th to 4th position, bypassing Leclerc (also of France) which had posted a 58% cumulative growth over the same 6-year period.

The relative concentration of the distribution sector in the Netherlands is evidenced by the fact that this country has four companies in the top 50 list, three of which are in the top 20. Belgium only has two top distribution companies in this list, Delhaize Frères and GIB, ranked respectively 19th and 30th. In comparison, there is only one company from Spain on that list (Centros Comerciales Pryca, in 44th position), and there are no Italian companies.

European social economy undertakings (cooperatives, mutual benefit societies and associations)

FOREWORD

The term social economy, while still a controversial subject in some Member States, embraces throughout Europe cooperative, mutual benefit and associative undertakings as well as organised social movements of men and women who create, inspire and are members of these economic entities.

These three forms of undertaking have been grouped under a common title because they are based on specific principles and conform to specific modes of organisation which reflect legal rules different from those governing companies with share capital.

Social economy undertakings are characterised by great diversity as regards status, size, sector of activity and location. They are, however, present in all the Member States of the European Community and often play an important economic and social role nationally, regionally or locally.

A common feature of these kinds of undertaking is that they all require personal commitment by their members and thus make an essential contribution to the dynamism of a democratic society which attaches paramount importance to pluralism and to the blossoming of the spirit of initiative of its citizens.

Beyond the statutory differences between the various kinds of legal status, the specific feature of these economic entities lies in the constraining nature of both democracy ("one person, one vote") and organised solidarity - at least internally, within the group of members - resulting in particular from the indivisible nature of the reserves.

The importance of these structures is not confined purely to their economic weight but also relates to their social and cultural dimension. Thus the position assigned in each Member State to these economic structures - ratified by the rules and regulations - harks back to the history and culture of each nation.

In view of the revival of interest in the social economy during the present recession, it should not be forgotten that the period of economic expansion of the "magnificent thirty" occurred within a protective framework of regulations which made possible the institutionalisation, consolidation and expansion of cooperatives, mutual benefit societies and associations.

This is particularly true of the provident mutual benefit societies and associations in the welfare-health sector which found a reference framework when, in the post-war period, countries made social protection for everyone one of the pillars of our European societies.

It is equally true of the cooperatives in the agricultural sector (agricultural processing and distribution of the interest subsidy on loans), where the authorities made them a preferred vehicle of the modernisation of European countryside.

One could give many examples of this: Credit Unions in Ireland, Charities in the United Kingdom, the Mondragon Group in Spain, etc. These economic entities and movements thus constituted a founding and federating element in our different European societies, affecting their structures in depth.

The major changes which have taken place in our European societies over the last two decades have had a far-reaching effect on the various cooperative, mutual benefit and associative movements in the Member States.

The cooperatives

The sociological effects of the recession (fewer farmers, manual workers and traders, the tertiarisation of the economy) have had far-reaching repercussions on cooperatives. Their reaction to these changes in the European production system and to the transformations in society, as well as in patterns of consumption, has not, however, been the same everywhere.

The traditional social basis of co-operation is shrinking but some social groups belonging to the new, expanding social classes are receptive to cooperative organisation. Thus, whereas the number of farmers is falling dramatically, farmers' cooperatives are holding their own rather well, by restructuring

and merging, despite some spectacular bankruptcies (Feder-Consorzi in Italy, ULN in France, SüdMilch in the Federal Republic of Germany).

Workers' cooperatives are losing ground in their traditional sectors (clothing, building, printing) but are growing in the intellectual services sector (design and consultancy firms, data processing and software, audio-visual activities and cultural activities, welfare-health services).

Faced with the crisis of the "classical undertaking", the fast-growing social frameworks and categories seem to be tending to rediscover this form of undertaking, which is fairly well matched to a service economy.

Consumer cooperatives have been drastically cut down in size in some countries (Federal Republic of Germany, France) because they did not know how, or were unable to adopt the organisational and management methods of the big distribution chains.

On the other hand, in some countries (Italy, the United Kingdom, Spain) these groups have succeeded in consolidating their position in the commercial and distribution sector by adapting themselves to the new consumer behaviour. Paradoxically, whereas traders and craftsmen are two occupational categories which have been strongly affected by the changes which are taking place, cooperative groupings of craftsmen and traders have been formed to carry out certain functions such as supply and marketing and various collective service functions in order to defend their earnings and market shares more effectively.

Lastly, maritime co-operation, which used to play a role similar to that of agricultural co-operation for the prosperity of non-industrial fishermen, is now feeling the full force of the structural fisheries crisis.

Mutual benefit societies

Whether centred more on health (so-called provident mutual societies) or on insurance (insurance mutual benefit societies and cooperatives), mutual benefit societies are undoubtedly parts of the traditional "institutionalised" sector of the social economy. But this does not prevent them from being affected by the recession, like the other categories, while at the same time, some of them at least are providing support for innovation projects which are worthy of interest from the point of view, for instance, of their impact on employment.

Mutual benefit societies are having to contend with the major challenge of the relationships between their activities and public action. But this is a constant historical feature of this sector, which, except during periods of authoritarian regimes, has displayed its capacity for independence, anticipation and formulation of social needs, and also for exerting flexible pressure and adapting itself to government action. Admittedly, the outstanding fact is the Government's disinvolvement in the social field and particularly in that of social protection.

As harmonisation of the legal systems of social protection is henceforth ruled out, while the convergence of policies and - why not? - practices is encouraged, undertakings of the mutual benefit type should be well placed to meet the challenge of the establishment of this coordination in practice at, or indeed beyond, Community level. The essentially bilateral trans-border experiments now in progress ought to be further pursued in such a way as to involve mutual benefit undertakings in large-scale practical Europeanisation, which is so necessary for their durability and the preservation of their jobs.

The sector's reaction to the decline of the 'welfare state is not the same from country to country' its role and its place in relation to profit-making initiatives are, however, an essential subject of political debate everywhere. It is generally recognised that this sector has three main assets in this connection:

- its partnership characteristics (economic democracy, employment of practices based on solidarity, physical proximity...), coupled with a natural propensity towards organisation in networks;
- its particular ability to exercise concerted and lasting control over costs, thanks to the greater responsibility entrusted to everyone involved, especially members and consumers;
- lastly - a point which is noteworthy but not unanimously recognised - its role as a recession-damper, at least through an approach to welfare which does not regard it as a burden but, on the contrary, sees it as a wealth-generating and demand-stimulating investment.

Table 3: Employment and turnover growth in the 20 most dynamic social economy undertakings

	Full-time employment, 1988	Full-time employment, 1992	Employment growth 1992/88, (%)	Turnover 1988 (million ECU)	Turnover 1992 (million ECU)	Turnover growth 1992/88, (%)
Sample	1 354	1 572	16.0	385	594	54.0
20 most dynamic	994	1 492	50.0	232	492	111.0

Source: DGXXIII

The power of these assets differs, however, according to the sector's degree of "institutionalisation" and the status of its activity in relation to public intervention ("independent" sector, third sector, ...) and according to whether provident-society undertakings tend rather to be "providers of services" for the public sector, to "plug gaps" or to specialise in certain types of products and services in fields where the exclusive presence of private undertakings might lead to some malfunctioning of the market.

True, the impact in terms of employment differs in the same way. What matters in the end is to find out whether this sector's reactions do not involve substitution for other jobs elsewhere or reduction of the quality of content (qualifications, pay).

As is shown by the example relating to mutual benefit societies in the two classifications presented below, they can plan an active part in the effective creation of quality jobs. Effective because what they have to do, by a major effort to train and retrain workers, is both to preserve jobs which would otherwise be threatened and to help create others. This job creation, entrusted to experienced and for the most part financially sound institutions, should also ensure that these jobs are socially useful, permanent and reasonably well paid. It is thus necessary to avoid the risk of their developing into just "little jobs".

Associations

There are three different categories of associations, depending on their activity:

- Those which employ paid workers, which have grown very greatly over the past decade both in number and in budget. Part of this growth is due to a semi-privatisation by the Government of activities which were previously performed by the public authorities. Consequently, as is shown by the figures set out below under the various headings, employment is growing fast in this sector, even though it is difficult to obtain any financial information from associations. Furthermore, the growth of this sector seems to be entirely endogenous, as no mergers or acquisitions appear to be taking place within it. It should be noted, finally, that very little capital needs to be raised.
- The voluntary work which is done in most associations shows that it is possible to organise and harness people's good will in order to render genuine services to society.
- Training of unemployed persons and, more generally, all schemes for reintegration into the economy of persons who have been marginalised are, unfortunately, a fast-growing sector: out of the ten cooperatives, mutual benefit societies and associations which showed the greatest growth, three belong to this category!

This apparent stability of the association sector - if we disregard the sudden disappearance of some structures which were apparently unshakeable - is attributable to the status of these enterprises, which protects them from hostile take-over bids and damps down the recession by smoothing out its effects. A second explanation lies in the links which this "institutionalised" category of the social economy has forged with that economy's credit institutions.

THE AVAILABLE MATERIAL

Two classifications have been produced at the request of the European Community.

The purpose of the first is to bring together the 500 biggest European cooperatives, mutual benefit societies and associations (CMAs).

The aim of the second is to find 500 cooperatives, mutual benefit societies and associations which have shown dynamism and achieved growth over the last five years (1992 compared with 1988).

These two classifications will be finalised by the end of March 1994; at present we only have very partial results so that we cannot yet say for sure that the names of the cooperatives, mutual benefit societies and associations listed will appear in the final classifications.

These two classifications have been compiled:

- To gain a better knowledge of the major European cooperatives, mutual benefit societies and associations and thus acquire a panel of representative CMAs which can be used to study how their development and Europeanisation should be promoted.
- To determine which are the most dynamic cooperatives, mutual benefit societies and associations in order to study the financial requirements created by their development and the sectors and forms in which organisations of this type are to be found.

THE METHODOLOGY USED

Our first difficulty was to determine why a particular entity does or does not belong to the world of cooperatives, mutual benefit societies and associations.

With a view to avoiding inaccuracy and arbitrary judgements and ensuring that each entity can recognise itself and accept the classification made, we decided to adopt each entity's membership of a recognised federation as the single and sole criterion for belonging to the world of cooperatives, mutual benefit societies and associations.

Secondly, as this approach involves sending each entity a questionnaire specifying all the general and financial data so that they can be validated, each entity is free to participate

Table 4: Employment and turnover growth by sector

or refrain from participating in the classification by returning or not returning the questionnaire sent to it.

It must be possible for the classification criteria to be applied to all cooperatives, mutual benefit societies and associations, which means that they must be simple, and homogeneous for the whole of the population studied: it is not possible, therefore, to use the sophisticated criteria which are fashionable in most of the classifications produced, because they would not apply to the whole world of cooperatives, mutual benefit societies and associations.

At the present stage the scope of the two classification bases is confined to a study of the magnitudes described below.

Firstly, the number of persons employed has been chosen as the main criterion for classifying the largest CMAs. It indicates the extent of contribution made by the entity analysed to the employed labour force and hence the size of its share in the working population. This concept does not create any particular problem, as we decided to observe the following principles:

- to take average employment in the year as the basis, in order to prevent certain activities using a substantial amount of seasonal labour from being overrepresented in the sample;
- to calculate on the basis of full-time equivalent jobs, because CMAs have many part-time jobs;
- to record only paid jobs, as the calculation base must exclude charitable services which do not really participate in the economy and which it would be difficult to monitor (because there is no reference wage) in terms of time actually spent.

Secondly, the change in turnover or its equivalent (comparison between 1992 and 1988) has been chosen as the main criterion for classifying the most dynamic undertakings because it gives a correct idea of how much the activity has grown in relation to other firms. In the individual cases turnover has been deemed to be equivalent to the following value:

- for cooperatives, to total proceeds (amounts invoiced + change in work in hand + other proceeds);
- for banks working in and belonging to the world of CMAs, to financial proceeds and other proceeds (and not to outstanding balance sheet items, which do not correspond to this concept);
- for insurance undertakings, to premiums received;
- for mutual benefit societies, to premiums distributed;
- for associations and the like, to the budgets for the year;
- in order to have CMAs which are large enough to justify being considered at European level, a minimum clause has been imposed, requiring that the CMA must have employed at least 50 full-time-equivalent persons during the last year (1992).

Owing to its different forms and to the difficulty of calculating it in the twelve countries of the Community, it was unfortunately not possible to use value added, which is usually the reference value because it represents the entity's contribution to the creation of the nation's wealth (the sum of values added constitutes the country's gross domestic product) and because it is entirely due to the factors of production (labour and capital).

As cooperatives, mutual benefit societies are to a great extent integrated and associated with each other, it had to be asked openly what level of consolidation should be adopted in recording the entities' financial data; an excessively high level of consolidation would have entailed the following major disadvantages:

- carried to the extreme, it would give 11 entities per country, corresponding to the following sectors of the social economy: cooperative banks, production cooperatives, consumers' cooperatives, agricultural cooperatives, social pharmacies, social tourism organisations, social housing and accommodation organisations, purchasing groups, craft cooperatives, recognised mutual benefit organisations, cooperative insurance companies, associations;
- it would give the advantage to large countries (at the expense of small ones) by allowing consolidations between regions and thus systematically increasing the entities' market share at national level;
- it would make it difficult to obtain and check the financial data for the consolidated entity, in terms of the three values adopted for reference purposes (turnover, value added and employment).

In view of the foregoing we thought it best to limit the concept of entity to the existence of a legal structure requiring accounts to be kept (consolidated, if appropriate).

The basic financial year is a 12-month year; if the reference period is more or less than 12 months, the figures given by the entity will be reduced, by rule of three, to a 12-month equivalent.

In the questionnaire, the respondents were asked to provide the monetary information in national currencies; this was then systematically converted into ECU.

STAGES OF THE STUDY

The first stage was to obtain the particulars of the cooperatives, mutual benefit societies and associations potentially eligible for inclusion in the two classifications. For this purpose:

- Nearly 500 federations in the 12 countries were personally contacted and asked to give the particulars of the member undertakings which, in their opinion, were eligible for inclusion in the classifications;
- Use was made of around ten existing financial databanks to select the undertakings which meet the conditions for participation in the classifications;
- A search was made for other sources of various origins.

Table 6: Large CMAs in the EC

Name	Country	Employment in 1992
Rabobank	NL	36 258
R+V Versicherung	D	11 635
Croix Rouge	F	10 160
United Northwest	UK	8 881
SODIAAL	F	8 639
Mutuelle Générale de l'Education Nationale	F	8 125
Standard Life Insurance Company	UK	7 795
Co-op Schleswig Holstein	D	7 048

Source: DGXXIII

In the second stage a questionnaire, accompanied by the rules for classification, was sent to these 3 000 CMAs for completion. It comprised the following eight sections:

- The undertaking's identity card;
- The financial data for the undertaking: the closing months and accounting periods of the financial years 1987 to 1992; total proceeds (for cooperatives and banks) or the budget for the financial year (for associations) or total premiums (for insurance companies and mutual benefit societies); the average number of paid employees in each financial year (full-time equivalent); it was decided not to ask for the number of voluntary unpaid persons because this box was rarely completed in the questionnaire sent to associations by the EC; the number of members of the undertaking;
- The financial data for the group, if any, to which the undertaking belongs: if there is such a group, changes in the proceeds received by that group; if there is such a group, changes in the number of its employees;
- The undertaking's financing capacity and requirements: the amount of its long-term debts (at over one year); its requirements as regards additional permanent capital (own funds plus long-term debts) during that period;
- The undertaking's involvement at international level: the present distribution of sales within the EEC countries and outside the EEC should make it easy to assess how open the undertaking is towards other countries; the undertaking could also state whether it has any branches and, if so, in which countries; it could also state whether it has alliances relating to these various countries (association with other undertakings, without the acquisition of any interest); lastly, it could mention any countries in which it proposes to pursue an active development policy;
- An open question concerning international development, in response to which the undertaking was free to comment on factors connected with its international development (plans, constraints, ...);
- A request to be supplied with the articles of association and documentation concerning the undertaking;
- The questionnaire ended with the date and the signature of the responsible person, indicating that he/she acknowledges the figures shown and agrees to their publication as part of the classification.

ANALYSIS OF RESULTS

This covers the first results for the first 150 questionnaires received. The elements at our disposal at the time of writing this article are therefore, once again, very partial and the analyses are still liable to be changed.

For the time being, the average CMA which has responded to our survey, employed, on average, 1 572 persons (full-time equivalent) in 1992, against 1 354 persons five years earlier, which represents a growth in employment of around 16% in five years or of 4% per year. With regard to turnover, its average invoicings total ECU 594 million in 1992 against ECU 385 million five years earlier, representing a growth of 54% in five years, corresponding to a growth in turnover of 11.3% per year.

Table 1 shows that, in our sample, mutual benefit societies are of roughly the same size as cooperatives, but slightly bigger, and, on average, three times larger than associations.

With regard to the rates of growth of both employment and turnover, it should be noted that the undertakings selected in the classifications are not very representative of all CMAs but constitute two selected samples, either because they employ over 500 persons or because they have undergone significant growth during the last five years.

On the basis of our present information, it would appear that mutual benefit societies - although large - have the largest growth in employment, followed by associations and then by cooperatives.

This finding that large cooperatives, mutual benefit societies and associations grow at least as fast as, if not faster than, their smaller counterparts is confirmed by the following table, in which we have included, from the 140 questionnaires received to date: the 20 largest CMAs, the 50 largest CMAs, the 50 smallest CMAs, the 20 smallest CMAs.

This finding is contrary to what might have been expected a priori, since, for a small undertaking with a turnover of ECU 26 million in 1988, an increase of 32% brings this figure up to ECU 34 million in 1992, thus requiring, in all, the achievement of a rise of only ECU 8 million.

The turnover of the large undertakings increases, on average, from ECU 1 614 million in 1988 to ECU 2 662 million in 1992, so that the growth is 61% over five years (or nearly 13% per year), representing a growth effort of ECU 1 048 million of additional turnover in five years.

At this stage, with such a small sample, it seems too early to draw any final conclusions, but we can offer the following hypotheses in explanation of what has been happening:

- CMAs operate in sectors where their growth is the result or product more of take-overs and mergers than of endogenous growth of the structure itself;
- CMAs work in fields where economies of scale are considerable beyond a certain size, and this would appear to be attributable to the following factors: large CMAs are capable of tapping financing sources enabling them to undertake investment in development; smaller CMAs are reduced to making sure that they can survive and find it difficult to develop and grow to a size allowing them to undertake similar investments;
- Small CMAs have become established in sectors or under conditions such that they do not seek to grow.

Consequently the two classifications of the largest and the most dynamic undertakings) are liable to include a significant number of CMAs appearing in both classifications and, as Table 3 shows, the average size of the most dynamic undertakings is relatively large.

The number of employees of these 20 most dynamic CMAs appears to have increased by over 50% (making an average growth in employment of over 10% of the workforce per year!). They alone created 9 960 jobs in five years (or 498 jobs on average per CMA in five years).

In comparison with our total sample of 140 undertakings creating 30 520 jobs, these 20 CMAs represent 14% of the sample

in terms of number of CMAs, account for less than 10% of jobs in the 1988 sample, and have created nearly a third of the jobs.

This finding is identical in terms of turnover, which grows by more than 20% per year (against only 11% for our sample as a whole). The analysis by sector of activity is summarised in Table 4.

One of the explanations for the low growth of the small entities would thus appear to lie in the sectoral logic, since small sectors (production, building, social) show low growth rates while other sectors in which the entities are larger (insurance, purchasing, agriculture) show higher growth rates.

Another factor explaining this relatively lower growth of small CMAs would appear to relate to the countries concerned, with expansion taking place only within the national frontiers, and small entities in smaller countries having more modest possibilities of growth. For the five countries dealt with up to the present, the growth rates are described in Table 5.

Although it is still too early to give any definitive findings, the CMAs which can be named as being very likely to be included in the final classification of large CMAs are listed in Table 6. The most dynamic CMAs are named in Table 7.

SUMMARY

The way in which the European production system has developed and operates has created a paradoxical situation: on the one hand, unprecedented levels of production of goods and services in terms of quantity and quality and, on the other hand, an uncontrolled increase in unemployment and social exclusion. It is not the particular vocation of the undertakings and movements of the social economy to solve these problems, which are primarily the responsibility of governments, the guarantors of social cohesion, and which therefore require the resources of the national or Community authorities to be used in implementation of economic and social policy.

However, the three families of the social economy do have a particular ability, which history has amply demonstrated both during recession and in periods of economic growth, to wage an effective battle against social exclusion and for economic integration. The revival of interest in this sector is largely attributable to the renewed initiatives and participation of civil society, of which it has acted as the driving force, in conjunction with bodies such as trade unions, the churches and local communities.

This finding emerged very clearly at the fourth Social Economy Conference and was illustrated in detail at the various symposiums around which it was organised (apart from two other political demands of the sector: the setting up of a consultative committee and the need for the early adoption of European articles of association).

The traditional undertakings of the social economy, which today account for the greater part of this sector's employment and turnover, will not remain outside the processes of economic restructuring. And the new wave of social economy undertakings cannot find the resources they need for development within the standard pattern of aid for the creation of enterprises if the difference in the size of projects is ignored. There is therefore a danger that entire sections of this sector will be wiped off the map, while the new forms cannot blossom, despite the fact that this sector displays a great ability to create permanent jobs (the study of the 500 largest undertakings and the 500 most dynamic undertakings shows an increase in employment of 16% over the last five years).

It is not necessary to start from scratch to meet the sector's needs: what is required, rather, is to step up certain existing lines of action and solutions.

In Europe a network comprising over thirty-five financial organisations, of all sizes and all kinds of legal status, has been created to participate in the funding of this new social economy: to collect joint savings in order to promote projects involving micro-undertakings, women, environmental groups, etc. which do not have access to the traditional banking system. Financiers of this sector are responsible for the establishment of SOFICATRA, the first European financing mechanism for social economy undertakings. However, with a few exceptions, these financial organisations based on solidarity do not have the status of banks and their development and impact, although significant, are only limited.

A first answer would therefore be to support this collective saving for the creation of socially useful undertakings employing young people and the unemployed by the establishment of a European network of solidarity risk capital funds.

The other main lines to be pursued in the work at national and/or European level in order to support this economy which may be referred to as "solidarity" or "social", are as follows:

- The promotion of socio-economic innovation. Failure to recognise economic experimentation is holding back people who are prepared to work for innovations. It must be possible to finance the design and contracting period which is essential for the success of projects, whether personal or collective.
- Increasing the supply of consultancy and training services for the parties responsible for projects. Within this framework, various associations which bring together staff performing consultancy services on an ethical basis could be effectively mobilised. The organisation and management

of these joint neighbourhood service undertakings, which are particularly complex structures, call for the dissemination of appropriate methodologies which take account of their original character.

- The establishment of mediation and/or regulation between administrations and actors. This is to remedy the inequality of approach to initiatives. This "facilitator" could speed up the innumerable procedural steps and give assistance in arriving at clear contractual arrangements including provision for a posteriori assessment and monitoring.
- The establishment of a genuine monitoring of participation in and access to the structural funds by the social economy entities, as this sector has been found to be the preferred interface for Community policies (training, regional and rural development, welfare, research and development). In particular, it will be necessary to induce the Member States and the regions to find practical ways and means of establishing a genuine partnership with the cooperative, mutual benefit and associative networks with a view to the drawing up and gradual implementation of operational programmes.

Adoption of these main lines of approach could be the prelude to the establishment of a genuine system for promoting and supporting this sector, which could then create and preserve permanent jobs.

Lastly, the organisation of undertakings open to users and to charitable contributors would provide new opportunities for participation in and assumption of responsibility for projects dealing with social problems close to everyday life. At a time when European political citizenship seems to have ground to a halt, working at European level for the recognition of a social citizenship is a challenging enterprise which is coupled with the creation of jobs.

Service industries in a changing EC economy

Introduction

The significance of services for the economy is generally acknowledged; in 1990 the service industry accounted for over 62% of both EC-total production (in value added) and employment. Technological development, particularly information technology, and deregulation in view of establishing the single market have already changed and will continue to change the service industries considerably. Change will not only occur in terms of implications for legislation, but also for employment, trade and government policies.

This chapter describes the major issues and problems that influence the trends in service industries. An outline will be given of the problems to measure service activity, the importance of the service industries in the EC-economies and the transborder provision of services. Then, the major developments in concentration, technology, market structures, deregulation and harmonisation will be described. Next, the implications of privatisation will be dealt with.

Regarding the achievement of integrated liberalised markets, in particular of relevance to internationally traded services such as transport and financial (banking and insurance) services, the most important problems still have to be solved. It concerns the harmonisation of these services in order to avoid differences in the competitive conditions by Member State. Cabotage in transport and the single licence principle in the financial and business services are the mechanisms which have to bring about this goal.

In the short, run the single licence principle will give rise to mixed regulatory frameworks by Member State: those prevailing for their own national financial enterprises, and those prevailing for foreign service providers. Harmonisation of systems is expected to occur through competition between systems; these mixed systems will converge to the most liberal one in the European Community. However, this is a long-lasting process. In the meantime financial and business services may be provided under a variety of (market) conditions within Member States and across the European Community. This may impair market transparency and so harmonisation will be in jeopardy. Hence, measures to increase market transparency are required.

Another area of legislation is to cope with externalities. These problems are of particular relevance in the transport sectors. They concern rules for various forms of pollution.

Further, despite considerable expansion of service employment it turned out that this occurred not always in the regions, which were most severely hit by loss of employment in manufacturing and agriculture. In addition, the more advanced and dynamic services such as financial and business services are not evenly distributed over the Community; advanced services tend to concentrate in the northern Member States, whereas basic services can be found specifically in the South of the European Community. These disparities in the growth and regional distribution of the services may not automatically be solved by the market mechanism and active (regional) employment policy may be required.

Another area of new legislation is in the field of privacy protection. This legislation should be aimed at limiting the possibilities to exploit databases containing confidential per-

sonal information of citizens. Additionally, further regulation would be required concerning the liability of service providers.

Privatisation may also give rise to problems. The particular concern is the market entry of services and the service level. Before privatisation pricing and policies for such services as banking, (public) transportation and telecommunication were often aimed at general accessibility irrespective of income. Moreover, the services had a wide geographical coverage. If economic (profitability) rather than social (general market entry) criteria are underlying prices and service levels, accessibility will be impaired, whereas peripheral -unprofitable- regions will not be serviced.

Services and statistics

The most that can be said on the general level is that services encompass a very heterogeneous group of economic activities often having little in common other than that their principal output and are, for the most, part intangible products. It is difficult to have a good definition and categorisation of service activities and a consistent way to measure it.

Traditionally, services, unlike physical products, were considered not to be transportable and storable. Hence, production of services was also considered to be the immediate consumption of services. They required face-to-face contact. They were labour intensive. They were generally tailor-made for the client. Further, they were unsuitable for capital intensive, continuous and standardised production.

The 'traditional' borderline between physical products and services has become less clear over time. Physical products sometimes also contain service features, such as after-sales service; services go together with all kinds of physical products, such as computer services requiring adequate hardware. In the production of services, face-to-face contacts are required less and less. Large scale capital intensive and standardised production have become possible. Service products have been standardised considerably. Further, new technologies allow a certain kind of storage for services, causing a disengagement of production and consumption.

Measuring service activities is problematic. Various causes underlie this. Firstly, it is not always easy to have a good indicator for service output. Secondly, there is not always a clear link between revenues and service output. And thirdly, there are difficulties in where to get the information. Most problems can be attributed to the invisibility of service transactions and the difficulties of measuring 'stored' or 'embodied' services.

Various indicators can be used to measure output. In manufacturing, output is simply the number of physical products delivered. In services, however, output is not physical, which makes counting the number of services difficult. For example, in insurance one could consider an insurance policy to be a unit of output, but one could also argue that the repayment of claims on those policies is also output. In banking, output may be the number of loans, but also the amount of loans issued can be an appropriate indicator. It is this heterogeneity of output definitions and the impossibility to derive adequate indicators which hampers measurement of service output most.

When output is already difficult to define, it is also difficult to establish a proper link between output and revenues or service income. In banking, the actual revenues come from interest margins between money lent and money borrowed. How does this relate to the number of loans made, or the number of savings accounts opened? In distributive trades, a similar problem exists: revenues generally come from sales margins on products sold. But margins differ from product to product and also from company to company.

Similar problems exist in measuring international trade in services. The invisibility of many services inhibits the establishment of when the service has crossed the border, as there is nothing physical crossing. Indicators for services trade can refer to the use of the infrastructure, such as the number of data transmissions or trucks crossing the border. Other indicators are the number of passengers or tons of goods crossing borders and the distance over which they are transported. Invisible international trade is measured financially in the balance of payments as are here the financial flows resulting from cross-border service provision are registered.

Due to the above difficulties in measuring service activity national statistical offices have had little opportunity to develop a consistent set of statistics for service industries. If offices have engaged in measuring this, there is little international comparability. It is in view of these problems that EUROSTAT has made some efforts to develop a harmonised system of information collection in services through initiatives taken in the Framework Programme for Priority Actions in the Field of Statistical Information 1993 to 1997, 93/464/EEC, OJEC L219, 28.08.93.

The source of information, i.e. the unit underlying the statistics, is the enterprise. In an enterprise, usually a set of actions are undertaken to come to a result: either a product or a service. This set of actions consists of both manufacturing activities and service activities. Enterprises are classified according to their main economic activity. Hence, the current classification systems are on an institutional rather than on a functional basis.

The most appropriate way of collecting data would be on a functional basis. This would imply that companies provide information specified according to all manufacturing and service activities within it. Gathering statistical information from an enterprise for all separate activities undertaken would be far too costly. Therefore, the data obtained from an enterprise can only be classified according to their main type of activity. Hence, statistical data on services only relate to companies with service provision as their main line of business. Data on service activities in manufacturing industries are not included in service data.

Efforts have been made to allow for functions within institutional classification frameworks. An example of such a functional classification system follows. It distinguishes five functions and their service branches: (1) transformational services (construction, public utilities), which are capital intensive and comparable with the manufacturing sector; (2) distributive services (transport and storage, communications, wholesale and retail trade) which are spanning time and place; (3) commercial services (financial, insurance, real estate, engineering/architecture, accounting/book-keeping and miscellaneous business services) which are provided to companies and governments; (4) personal services (domestic services and personal care, hotel/catering, repairs, leisure and recreation and miscellaneous personal services) which are oriented towards the individual consumer; and (5) collective services (health care, education and research, social welfare and government services) which are not provided at market prices as they are generally provided and subsidised by government authorities.

EUROSTAT's National Accounts also distinguish service functions in its institutional NACE-classification system. It identifies the following industries in services:

- building and civil engineering (NACE 5) (are transformational services, but are not always considered a service. Transformations can also be considered as a manufacturing activity).
- market services such as: distributive (wholesale and retail) trades, hotels, catering, repairs (NACE 6); transport and communication (NACE 7); banking and finance, insurance, business services, renting (NACE 8); and other market services (part of NACE 9); and
- non-market services (part of NACE 9).

Aggregate importance of services

Despite the registration problems some broad indications of the magnitude of service industries can be obtained. For this, generally, such data as turnover, value added and employment from the National Accounts statistics are used.

In terms of value added, the services industries constitute nearly two thirds of the EC-economy in 1990. Three quarters of this relates to market services, of which the grouping of repair, wholesale and retail trade takes the largest share. The remainder comes from non-market services.

Compared to 1980, value added in services grew at a rate of 8.7% per year, whereas total value added in the EC augmented at an annual rate of 7.8%. This has led to an increase of the share of service industries in total value added by 5.6 percentage points. Within services the share of market services has increased slightly during the 1980s to the detriment of non-market services. This increase is mostly due to the increasing share of other market services.

Similar tendencies are shown in terms of employment. In 1990 nearly two thirds of EC-employment related to services labour (about 80 million in the EC10). The composition is however different from that in value added: two thirds of service employment is employed in market services and the rest in non-market services.

In comparison with the situation in 1980, total employment in services grew by 13.5 million (1.9% per year), whereas in agriculture and manufacturing it decreased by 3 million (3.1% per year) and 4 million (1% per year) respectively. As a result, the share of services in total employment has increased by 7.8 percentage points, which is a stronger growth than in terms of value added. The structure within services employment remained virtually unchanged during the 1980s. However, within market services there seems to be a substitution of employment to the benefit of other market services.

The importance of the service sector in the national economies of the Member States varies from one country to the other. Most of the northern EC-countries have shares well above 60%, whereas most southern EC-countries have shares below this percentage. Germany and Italy are the exceptions to this rule. Germany, with its long tradition in manufacturing industries (especially in metal products, machinery and electrotechnical products), shows shares below 60% for value added and employment. Italy, as the most developed economy in southern Europe (especially in the northern part), has percentage shares above 60%. In Portugal services employment makes up less than 50% in total employment. This is due to the importance of the agricultural industries in this country.

The structure of the service industry varies. In Southern Europe the more basic services, such as hotels and catering and other activities associated with tourism have expanded most. In the North, other types of service activities, in particular, the high value business services, have become more important.

Since 1980, the service sector has gained in importance in all countries, both in terms of value added and employment. Especially, in Italy, Luxembourg and the United Kingdom, growth has been particularly strong. Shares increased by some 10 percentage points in these countries. The augmenting shares of services in both value added and employment reveal a structural transition from a manufacturing (and agricultural) orientation towards a service orientation in the EC-economies.

Measured as value added per employee, labour productivity in services in 1990 is hardly different from overall labour productivity. During the 1980s however, labour productivity in services has deteriorated versus productivity in agriculture and manufacturing. In agriculture, labour productivity increased by 7.9% on average and in manufacturing by 7.4%. For services, an increase of only 6.7% occurred, on average. This also confirms the stronger transition towards services

Table 4: EC service sector foreign direct investment

in terms of employment in the EC-economy than in terms of value added.

Within the service industry, there are considerable differences in labour productivity. For repairing, wholesaling and retailing, hotel, and transport industries and for non-market services productivity levels are below the overall average. The hotel industry and the non-market services appear to be very labour intensive. In communication and, in particular, banking, insurance and other market services, productivity is high, although the banking/insurance sector experienced a productivity decrease of 28%.

During the 1980s the productivity of non-market services developed at a slower pace than that of market services: 5.9% and 7.0%, respectively.

Transborder provision of services

Basically, there are three modes to provide services across the border. These are: international trade; foreign direct investment; and cooperation agreements.

In the first mode, international trade in services, the service is provided from a resident in one country to a resident in another country. This mode can be found particularly in tourism and consultancy.

In the case of foreign direct investment, the second mode, a company from one country establishes an entity in another country, which provides the service to residents in the other country. Especially in banking and insurance, this mode is very popular. Establishing an entity across the border can be done by either creating a new company abroad (greenfield investment) or by taking over an existing company in the foreign market (merger and acquisition). The latter has the advantage that no new capacity is created and that the existing company already has a market share and knows the ways in the market.

The third mode is cooperation agreements, which is very similar to foreign direct investment. An entity is created in the foreign market without the initiating company taking control of this entity. Such agreements can take various forms, such as licensing, minority equity participation and franchising or even the creation of a strategic alliance. Effectively, a network is established in which services are provided under the same brand name. Examples can be found in accountancy, consultancy and retailing.

With a share of about one third in both extra-EC imports and exports, services are relatively less important in foreign trade than in production; for manufacturing the opposite applies. This may be due to the way in which services are provided across the border. The ratio of foreign direct investments to imports in the European Community reveals that service industries differ significantly from manufacturing. On average, during the period 1984-1988, the ratio of foreign direct investment inflows to imports was three times larger than for manufactured products. Traditional barriers, such as the need for face-to-face contacts, cultural differences and national regulations forced service providers to engage in foreign direct investment rather than in trade. Within foreign direct investments, the most important way of going international has been mergers and acquisitions rather than greenfield investments. As investments were targeted at the local market, this type of internationalisation was called internationalisation of a 'multi-domestic' nature.

When considering the importance of services in total direct investment flows, different pictures emerge. For intra-EC investments about two thirds of the total relate to investments in service industries. The same is true for non-EC investments into the European Community. For investments by EC-companies outside the European Community however, the share in the total is only about one third.

Intra-EC foreign direct investment in services amounted to ECU 21.3 billion in 1989. With this figure these investments outnumbered both inward investments from outside the European Community (ECU 16.8 billion) and outward investments from EC-countries (ECU 11.9 billion).

Between 1984 and 1989, all three types of investment have gone through a strong growth process. Intra-EC investments have grown tremendously by ECU 18.4 billion. Inward non-EC foreign direct investments have increased at a similar pace by ECU 13.2 billion. For outward non-EC investments, the increase amounted to ECU 6.3 billion.

In intra-EC investment and in inward extra-EC investment the banking sector plays a major role with some 40% of the total. This sector has also contributed most to the increase in foreign direct investments. Non-EC banking groups have increased their investments into the European Community by nearly ECU 7 billion between 1984 and 1989. This implies that these banking groups consider the EC-market important enough to establish subsidiaries. EC-banking corporations have also increased their investments abroad, particularly within the European Community. Intra-EC investments in banking have grown by ECU 9.6 billion between 1984 and 1989. Apparently, they are building large EC-conglomerates in order to meet the challenges of increased competition in the single market and to become a global player in the world market.

The remaining sectors reveal considerable annual fluctuations. This is particularly true for the grouping of trade, hotels and catering, and the total of other services, with shares of 9% and 21%, respectively, in 1989. The large 1989 foreign direct

investment shown in transport and communication is remarkable in view of the investments in the preceding period 1984-1988: in 1989 the share was some 25%, whereas the average for 1984-1989 was only 3%.

Total M&A-operations increased significantly between 1987 and 1989. The total number of deals increased from 2190 to 5455; this number declined to 4553 by 1992. M&A-operations in services followed a similar pattern. However, the services share in total M&A-operations decreased from 46.0% in 1987 to 36.4% in 1992.

Mergers and acquisitions in service industries from 1987-1992 were mostly of a domestic nature. However, the share of domestic mergers and acquisitions, in the total declined from 87% to 74%, indicating the increasing importance of cross-border mergers and acquisitions. In international mergers and acquisitions those within the European Community are most significant. Remarkably, however, after 1990 intra-EC mergers and acquisitions became relatively less important, whereas the significance of extra-EC operations increased. In 1992, both types of mergers and acquisitions were about equally important.

Most of the intra-EC mergers and acquisitions can be found in Northern Europe. Germany, France and the United Kingdom together account for some 60% of the total number of deals and for two thirds of their value. Further, the relatively high shares in the number and value of operations in the Netherlands is remarkable. The central position of Germany and France within the European Community, and the open nature of the United Kingdom and Dutch economies together with the presence of multinational companies in these countries have most likely determined this situation. Within the southern economies Spain stands out as a favoured target. Spain's relatively larger size and higher degree of development together with its proximity to the more prosperous centres of the EC could explain this. Spain is also a more favoured target than Italy, which would suggest that ownership structures in Spain are more favourable to M&A-operations than in Italy. Characteristic for the Italian economy are few massive companies (partially state-owned enterprise groups in both services and manufacturing) together with an overwhelming number of small family-owned firms.

For outward M&A-activities, the intra-EC purchases, particularly from the United Kingdom, are highly relevant. Nearly 50% of intra-EC mergers and acquisitions, both in number of operations and in value, originate from this country. France follows at a distance with 20%. Germany is relatively much less important as a buyer in the European Community. Most Spanish service firms seem to have little resources to invest elsewhere. This is also true for Greece and Portugal.

In the European banking and insurance industry, domestic and international M&A-activity has been particularly strong. In 1988 and 1989 alone, there were around 3 000 mergers, acquisitions and strategic alliances in this sector. These were mostly aimed at strengthening their market positions to respond better to the challenges of internationalisation in the sector.

Various factors underlie the strong M&A-activity in the European financial sector. Economies of scale and scope are important, but do not seem to be major factors. More importantly though, is the integration of the banking and the insurance business enabled by new regulations on financial and insurance control.

Concentration and cooperation

Competitive forces may cause national, intra-EC or even global consolidation pressures. Competitive pressure as a stimulus to consolidation is closely related to the need to cooperate in order to increase productivity through economies of scale and scope. Examples of global co-operation are to be found particularly in international air transport and shipping. Co-operation to counter competitive pressures are further to be found in banking and insurance.

EC-airlines operate on global, increasingly deregulated markets. Their strategic response has been cooperation, mainly between established European carriers and major non-European carriers. At the same time, cooperation is sought with regional airlines. Cooperation may involve partial financial participation or may be limited to commercial agreements.

A remarkable example of cooperation in the financial service industries, enabled by new regulation, is the emergence of 'bancassurance' companies, or mergers of banks and insurance companies. Although these mergers permitted economies of scale and scope, they were primarily induced to cope with competition and stagnating markets. Bancassurance enables banks to increase the potential of fee-based income (particularly from life insurance) as a relatively risk-free way of increasing revenues and profits. Conversely, the insurers have been attracted towards bancassurance primarily to solve their problems of inefficient distribution along with their need to enlarge their customer base. Moreover, insurers have used bancassurance as an entry strategy into growing markets like

Table 5: Intra-EC mergers and acquisitions

the Spanish and the East European markets with the intention of gaining significant long-term growth at a relatively low price.

Concentration can further be the result of the changing position of services within value chains. Information technology induces service firms to aim at more strategic positions within chains of business activities; a great deal of competition is currently going on between firms trying to reach and preserve logistical control positions. By controlling the distribution channels and the necessary extended and complex information systems, companies have the possibility to dominate the way transactions are taking place, for instance with regard to timing, quality control and profit margins. Particularly, companies in wholesale and retail outlets, transportation and banking and insurance engage increasingly in inter-firm networks.

The crucial role of chains is very clearly revealed by the grocery retailing sector in the Netherlands and the United Kingdom. In these Member States, the grocery retailing sector is heavily concentrated; supermarket chains hold such strong market positions that they have taken over various functions of the manufacturing industry, including product development and marketing. Additionally, supermarket chains also increasingly form alliances on a European scale in order to be able to concentrate their power vis-à-vis the large food manufacturing companies.

Hence, service producers (and distributors) are trying to cooperate, although competition is intensifying. As concentration is aimed at market control, diminishing competition, restricting market entry and price agreements, strong competition policy by European authorities is required to prevent incumbents to deter entry. The concentrations of ownership in the service industry may be detrimental to free competition.

Notwithstanding that EC-competition policy is strongly geared towards ensuring the forces of the market economy and to prevent dominant market positions, cooperation and concentration are allowed if they do not harm competition. This calls for a strong competition policy by European authorities. EC-competition policy will become increasingly involved with the service industries. The dilemma between competition and concentration has to be solved by defining the relevant market in each particular case in accordance with Article 2.1 (a) of the EC-Merger regulation.

Technological development

The emergence of information and communication technology can be considered as the most significant technological development with respect to the service industry. A lot of service activities deal with the processing of information, both in terms of transformation (arrange information in appropriate ways) and communication (forward information to appropriate destinations). Information and communication technology by way of automation and computerisation enables the digitised processing of information. Hence, improvements in information and communication technology have a considerable impact on service activities, as substantial progression in economies of scale and scope can be accomplished.

New technologies have led to strong increases in office automation and transportability of information. It changed the nature and form of existing services in such a way that services are delivered more efficiently and more easily. However, service industries are not similarly affected. Industries where information and communication functions are more important and where automation and standardisation of methods and procedures to process and deliver services are most promising to achieve, economies of scale will be more affected. For example, in distribution, transport and communication as well as in banking, insurance and producer services, information technology allows firms to develop standard infrastructures to facilitate document handling, administrative processing, billing, etc. Ad hoc procedures are replaced by pre-specified methods.

New technologies have also led to new types of services. This is especially obvious in telecommunications. Apart from traditional telecom-services (e.g. telephone) new telecom-services have emerged due to the technical developments in telecom-infrastructures. New service types relate to the so-called 'value-added network services' like videotext, databank services and the like.

Introducing new technologies has had a major impact on employment. Office automation caused considerable productivity improvements, which meant that the same service could be provided with less personnel. However, the remaining personnel had to cope with the more complex aspects of the service and the maintenance and repair of the technologically advanced equipment. This implied an increased demand for better skilled personnel. Furthermore, the demand for existing services has increased in line with the growth in overall economic activity. Also, the creation of new service activities gave way to new employment opportunities. The negative employment effect in terms of redundant low-skilled labour from productivity increases could therefore be (partly) compensated by positive employment effects in terms of more need for higher-skilled labour from increased demand for existing and new services.

The improvement in service provision enabled by new information and communication technology also has relevance for manufacturing activities. As was indicated previously, services activities are also necessary for manufacturing a product. Hence, improvements in services can enhance the strategic position of manufacturing industries. For example, the development of new logistic concepts in transportation and distribution services has created the possibility for just-in-time manufacturing, which has become a major asset for the competitive position of leading manufacturing industries in the EC.

As a result of technological development, new areas of concern have emerged, such as privacy protection and liability with regard to services. The EC will take increasingly responsibility for the enforcement of rules and regulations with respect to these problems. In 1991, therefore, a directive was introduced, stipulating that liability cannot contractually be excluded or limited by the service provider in any way. As to privacy protection, new policies are aiming at limiting the possibility to exploit databases containing information on the features and behaviour of individuals, such as those held by banks, insurance companies and credit card organisations.

Market structures

Until the mid-1980s, lack of mobility of services across markets and of firms within markets had resulted in a fragmented EC service industry. Markets were generally protected against competition. This was not only due to government regulations, but also to natural entry barriers. Entry barriers can best be assessed by looking at determinants of market structures.

Firstly, if the service requires a high capital intensity for its provision, new service providers may not be able to get the necessary funds to become a competitor. This may result in a high degree of concentration and considerably high sunk costs.

Secondly, for some services (telecommunications) the creation of new capacity (e.g. a new network) next to existing capacity one would be economically inefficient. Therefore, governments have created national monopolies not allowing competition in the market.

Thirdly, governments may decide to arrange a monopoly in order to make sure a service is provided. Without such a monopoly competition would cause the service to disappear. This is the case for a lot of non-market services.

Table 6: Market structure in services

Sector	Determinant of Market Structure						
	Degree of product differentiation	Degree of concentration	Sunk costs	Regulatory measures	Degree of competition Actual	Potential	Type of market structure
Banking	High	Medium	Medium	High	Low	Medium	Oligopolistic competition
Insurance	High	Medium	Medium	High	Low	Medium	Oligopolistic competition
Road transport	Low	Low	Low	Medium	High	High	Pure competition
Airlines	High	High	Medium	High	Low	Medium	Oligopolistic competition
Telecomm.	Low	High	High	High	Low	Medium	Regulated monopoly
Distribution	High	Low	Low	Medium	Medium	High	Monopolistic competition
Hotels	High	Low	Low	Low	High	High	Monopolistic competition
Business services	High	Low	Medium	Low	Medium	Medium	Monopolistic competition

Source: Commission of the EC, European Economy, Supplement A, No. 5, May 1993.

Fourthly, the industry itself may want to keep certain standards of service quality. Then, a branch organisation may be established controlling the service quality of new entrants. Further, service companies may invest heavily in creating brand names with a stature of good quality and reliability.

Governments in all Member States play an important role in regulating service markets. Regulations can be subdivided into structural and behavioural regulations. Structural regulations particularly influence entry of new suppliers on service markets; behavioural regulations are aimed at controlling the conduct of existing firms.

Basically, only in road transportation (and in construction) are the markets are purely competitive. For telecommunication, the market can best be described as a regulated monopoly. In all other markets for services, the structure of the market can best be qualified as oligopolistic or monopolistic competition.

Deregulation

EC-policies force national governments to aim at more liberal regulatory frameworks with regard to service markets. Economic incentives rather than direct government intervention should induce economic behaviour in compliance with market forces. The resulting changing role of government regarding the outcome of economic processes, is underlying deregulation policies.

Market incentives are considered to be the basis for economic behaviour. All obstacles impairing the proper functioning of markets, therefore, should be removed, both from the private sector and from governments. If regulations are not meant to counter market failure and are not detrimental to the common interest or the achievement of government goals, they should be abolished. Not all regulations will have to disappear. On the contrary, where necessary, governments will have to take responsibility and introduce new regulations.

In view of the EC Treaty, it is envisaged to allow the free provision of services within the Community. Restrictions on the free provision which currently exist, will be abolished in the coming years. Deregulation in transportation and in banking and insurance considerable has already been achieved. In other service industries, however, regulations restricting the service market to national economies, still prevail.

For most service industries government intervention is likely to remain. Nevertheless, such intervention would require a careful analysis to determine the appropriate level of authority (Community, national, regional or local). It is likely that in several instances, national regulations should be replaced by EC-wide interventions. In addition, whatever the appropriate level of intervention, more room should be made for market-based regulations.

The Articles 52 to 58 allow companies in one Member State to supply services in another Member State by establishing branches or subsidiaries. These establishment directives have enabled companies to intensify their foreign direct investment under the prevailing regulatory system of the host country, which, therefore, needed not to be adjusted. Companies wishing to set up branch offices in other EC-countries would have to adhere to the same regulatory framework and market practices as local companies. This has been most applicable in the banking and insurance industries.

The introduction of Directives referring to the Articles 59 to 66 of the EC-Treaty, dealing with the intra-EC cross-border provision of services, required much more time than expected. National frameworks had to be adjusted. For example, in insurance, governments in a number of Member States had to find new mechanisms to collect taxes on premiums.

The deregulation is of particular relevance to the transport sector. The Commission is aiming at an integrated EC-transport market, implying a completely deregulated market for all modes of transport. Although much progress has been made in the deregulation of the international transport markets, their pace of liberalisation is very different.

One crucial issue is still to be solved in all transport sectors i.e. cabotage: the freedom of a non-resident haulier of one Member State to provide transport services within any other Member State. Cabotage is the natural outcome of Articles 59 to 62 of the Treaty, stipulating the free provision of services and elimination of competition distortions.

Although cabotage is a prerequisite to achieve competitive and integrated transport markets, it is not yet fully allowed for any mode of transport. Transitional systems and periods have been established. For example, cabotage in road freight transport, where it is most advanced, is still subject to significant restrictions. Firstly, it is based on a licensing system; as of July 1990, the number of licenses has increased by 10% per year. Secondly, cabotage may not cause serious disturbances on a national road haulage market. For example, non-resident hauliers are not allowed to reach a 30% share in the road haulage market concerned.

In air transport, the liberalisation process started in 1987. During the period 1987-1992, three sets of proposals were accepted each representing a stage in the liberalisation process. Currently, the package for the third stage is operational. It is the most far-reaching programme so far, but still it will not bring about a completely deregulated EC-air transport market, as full cabotage will only be introduced in 1997. In

the meantime, 'consecutive' cabotage will prevail: in other words, cabotage under conditions.

Further, it is intended to complete the liberalisation process in the shipping industry by 1999. This is particularly relevant to the short-sea shipping among Member States. Long-haul shipping is to a much larger extent subject to competition on the world market.

The current absence of full cabotage, the different transitional measures and the different pace of deregulation of the various transport modes are detrimental to a rapid creation of an integrated transport market across the European Community. This implies that for the time being the providers of transport services are still coping with rules distorting full competition.

Deregulation and the subsequent increased competition may tend to put too much emphasis on efficiency and profitability. As a result, other aspects related to service production such as health and safety conditions as well as externalities like environmental pollution may not get the proper attention.

This is of particular relevance in the transport sectors and in public utilities. For example, health and safety conditions in road transport may be put in jeopardy by neglected maintenance, overloaded vehicles and excessive working hours for drivers. Also, little attention for environmental pollution due to competition pressures can be added to this list.

Harmonisation of systems

Harmonisation of markets within the European Community is also a pre-condition to the creation of integrated EC-markets. Harmonisation of systems means on the one hand that the service sectors across the European Community are operating under the same conditions; lack of harmonisation gives rise to different competitive positions by Member State. This is especially important to internationally tradable services such as transport, banking, insurance and business services. The international intra-EC deregulation framework is most advanced for these sectors, but domestically a variety of regulatory systems prevails.

The most recent directives aim at providing one single legal framework for business conducted on an establishment and on a cross-border basis. The most significant feature of these directives is the acceptance of the principle of a single licence valid throughout the European Community. A company with a head office in one Member State would, for its international operations within the European Community, only have to comply with the supervision within its own State for both establishment and services.

The focus in the directives has moved from the regulatory framework of the host (importing) country to that of the home (exporting) country. Governments' acceptance of the principle of mutual recognition of existing regulatory systems is underlying these directives. Although they encourage greater liberalisation within Member States, national regulatory systems will still be allowed to exist.

As the degree of regulation varies sharply across the Community, regulation can remain an important source of competitive distortion. However, subsidiaries abroad that are controlled by the home country start to compete with local companies controlled by domestic regulation. This incurs a competition in regulation, which will trigger a process of automatic convergence in regulatory systems over time.

This policy to harmonise regulatory systems differs from the previous more static view that harmonisation of national regulation should be a precondition of fair competition and hence, cross-border business should not be allowed until harmonisation is achieved. It is the implicit dynamic character within the single licence principle to resolve this dilemma. Under the current approach, it is envisaged that if national governments have onerous regulations, this will penalise the companies licensed within their own countries, and over time there will be pressure from the local industry to moderate those areas of regulation impairing their competitiveness.

Consequently, the regulatory systems would converge to the most liberal one. However, the single licence principle will give rise to a variety of products for which, depending on their country of origin, different conditions may prevail. This will impair market transparency, which may eventually not bring about the required harmonisation through competition between systems, and competitive distortions will subsist.

For transport, apart from cabotage, the intra-EC road freight industry is largely liberalised. As of January 1st, 1993, quantitative criteria to market access (bilateral Community licenses and quota) have been abolished. With the exception of cabotage licences, they have been replaced by quality criteria such as entrepreneurial competence and a solid (financial) reputation. Despite the advanced international deregulation, most of the domestic markets are still subject to a variety of rigid regulatory systems. In addition to the absence of full cabotage these - often very different - systems have given rise to highly fragmented national markets, impairing the creation of a common EC-transport market.

Other important harmonisation issues relate to the need for uniform technical standards and equal quality standards. Uniform technical standards are of particular relevance for the creation of an integrated EC-telecommunication market. In banking, due to different payment clearing systems, it is still difficult and expensive to transfer money across borders. Further, uniform quality standards for services throughout the European Community are required. Already a stimulus can be observed for the certification of quality standards in service firms and professions.

Privatisation

Governments are increasingly trying to end their ownership of manufacturing and service companies thus, privatisation throughout the EC (and other West European countries) is developing fast. Both practical and ideological factors underlie the rush to privatise. Practical considerations refer particularly to the need for additional government revenues to counter the rise in public debt and budget deficits. More of an ideological nature is the cultural change in corporate management at the wake of increased competition from private companies. Governments now generally consider the involvement in companies as a less important and even an inappropriate task. Additionally, private sector solutions are increasingly sought to cope with government financial problems; there is a growing need - also reflected in deregulation - to let market forces allocate resources in such a way that services are provided to the consumer most optimally. Finally, the introduction of the EC-competition policy has also encouraged privatisation. State subsidies have become prohibited or are much less amply allowed. In order to get access to private investment capital companies are urged to privatise.

Over the next five years there are 70 potential candidates to be privatised in the EC, of which 43 or 62% are service firms. The amount involved with the privatisation of the EC-service industry is at least ECU 85 billion. Most of the service companies to be privatised fall into four sectors: telecommunication, utilities, energy and banking. For example, state banks had to provide unprofitable banking services and uneconomic financing for state industries. Privatisation will enable these banks to be more selective rather than acting as a government banking agency.

France, where the government has declared privatisation as a top priority, the prospects for privatisation are currently the best. As a result, with 11 privatisation candidates in the service industry, France is going to be at the centre of the next wave of privatisation. Italy follows suit with 10 candidates; the amounts involved are ECU 36 billion and ECU 12

Table 7: Number of potential privatisation projects as of mid-1993

Services	Total	Total Services	of which: Utilities	Transport	Telecom	Banking/ Insurance
Belgique/België	1	1	N/A	N/A	1	N/A

(1) Total value of projects in billion ECU; ( ) Number of projects for which the value is known.
Source: NEI and Cambridge Econometrics, based on Financial Times of 24 June 1993.

billion, respectively. In both countries, State holdings are predominantly in financial services (banking and insurance); together France and Italy account for 15 of the 19 financial companies to be privatised in the European Community.

In the remaining Member States, the telecommunication sector is the main privatisation candidate, particularly as far as value is concerned. In this respect, it is worth to note that the German telecommunication sector alone is valued higher than all the Italian privatisation candidates together: ECU 19 billion versus ECU 12 billion.

For a successful privatisation policy a number of requirements must be met. Firstly, interest rates must be low enough to encourage economic development and the subsequent investments in equities. Secondly, the company must be fully or at least nearly restructured to improve its profitability. Thirdly, prices should be set correctly in order to maximise receipts and encourage investment. Finally, regulations and legislation, including those affecting ownership must be clear.

Privatisation will put a strain on the finances of domestic investors in Europe. Domestic institutions and individuals in continental Europe hold only up to 20% of their assets in equities. They must be persuaded to switch money from fixed-income securities into variable-income equities. Lower interest rates could play an important role here.

Privatisation will have an important impact on the size of government debt and the performance of the economy. The impact will not always be positive. In particular, unemployment will rise since many redundant employees will be sacked. Further, receipts from selling government shares are important in the reform and fiscal programmes, but they will be relatively small in relation to the size of the overall government debts. Finally, the sale of profitable state companies is detrimental to the government budget, as the stream of contributions from profits (if any) by state-owned companies to state revenues disappears.

The experience from the 1980s UK privatisation programme clearly reveals the various consequences. The number of private shareholders increased five-fold as compared to the pre-privatisation period. The return on these stocks were well above the market average. Government received about 50 billion pounds in revenue. Productivity rose in the privatised companies, but employment decreased.

Privatisation along with deregulation may reduce the access to services and the service levels. This can, in particular, relate to services which were provided by state-owned or state-controlled companies and agencies prior to privatisation. The regulatory framework, as imposed by national governments, was mostly based on the need to set standards for safety, to secure the adequacy of service provision and the accessibility of the services to all citizens.

For example, pricing policies and levels of service provision, like in banking, public transportation and telecommunication, were often aimed at ensuring that everyone could have access to, and benefit from, the service irrespective of their income or the remoteness of their residence. If this social goal of general accessibility is replaced by the economic goal of profitability, possible price increases may reduce or prohibit service demand. Unprofitable service activities will be abandoned completely. As a result, deregulation and privatisation may impair the service level and quality in peripheral regions, particularly when local infrastructure is needed, for example for telecommunication and public transport services.

Government measures would secure general access to the services concerned. The Community policy regarding telecommunications has taken these regional effects into consideration, resulting in measures to stimulate investments in peripheral infrastructure and value added services. This may also be necessary in other sectors in the future: for example, when railway companies are privatised.

Additionally, the service markets that are directly linked to specific population groups should be considered. Examples are to be found in the media and entertainment sectors (movies, television, newspapers, magazines, books, etc.). Measures may have to be taken to cope with the threatened future of small, local newspapers, TV-stations and publishers representing a specific population group.

The above shows that the involvement of other dimensions, like culture and region, will lead to a more complex decision-making process. The free market focus will have to be balanced against other considerations, because of its undesired side effects.

Written by: Netherlands Economic Institute

Employment and structural change in the EC

INTRODUCTION

This article summarises the key findings of a study on "Employment and Structural Adjustment in EC Industry and Services", undertaken by DRI at the end of 1993, in association with Bernard Bruhnes Consultants, BIS, Databank, Eurostaf, IDC, KSA and WS Atkins. The study reviewed the main factors underlying structural change in 17 industrial and services sectors in the EC (see list in annex), and discussed the extent to which these factors will influence employment in Europe over the short and medium term. Among the key structural factors that were considered in the analysis are:

- competitive challenge (at the national, European and international level);
- the completion of the Single European market;
- re-location factors;
- the role of SMEs and their relationship with large companies;
- technological and organisational change;
- environmental requirements and concerns;
- the potential for innovation, including R&D activities;
- existing levels of skills and qualifications of the labour force in relation to the projected needs;
- socio-economic factors;
- the general character of relations between social partners;
- the geographical concentration of sectors in regions.

The outlook for employment in any given sector in Europe depends upon:

- future trends in demand, both in qualitative and in quantitative terms;
- changes in supply and in the competitive environment;
- the strategic response of firms to the above changes.

Future trends in demand can reflect normal cyclical developments in the economy, but can also be influenced by changes in the regulatory environment, such as a tightening of environmental protection regulations, or market liberalisation. The companies themselves can to some extent force change in consumer choices, for instance through product innovation.

Changes in supply conditions and in the competitive environment also find their origin in a number of different situations.

- In some cases, the heightening of competition can result from a sudden and largely unexpected fall in world market demand, which causes a temporary situation of excess-supply in the market.

- The increase in competition can also result from other factors, such as an unfavourable trend in production costs in Europe compared to competing countries, or a certain weakness shown by EC firms in innovating or developing new products.
- Changes in the degree of competition on the market can also result from changes in the regulatory environment (market liberalisation as part of the European integration process, for instance) or in trade agreements, and from the supply strategies of non-EC countries. In particular, the transformation of the economies of Eastern and Central Europe into market economies has greatly contributed - and will continue to contribute - to the changing competitive environment for EC steel producers, vehicle assemblers and ship yards, amongst others.
- A final factor which has recently played an important role - and which will continue to influence the competitive environment of firms - is the greater emphasis given to "non-price" competitiveness factors such as after sales services, product customisation, timeliness of delivery and, of course, overall product quality. Shifts away from purely price-driven competitiveness factors to more qualitative competitiveness factors can change the balance of power among the different actors on the market and thereby drive change in the industry. This then spills over to employment.

Companies respond to these challenges in different ways. The strategies that they choose to adopt are, however, instrumental in influencing future trends in employment. Possible strategic responses to the above challenges include:

- re-locating production facilities within the EC or in non-EC countries;
- increasing product automation;
- changing the organisation of production and management within the firm, adjusting to new concepts such as JIT, TQM, QC etc.;
- emphasising new aspects of product development to take into account environmental concerns or other customer needs;
- changing the nature of relationships with the suppliers or with the customers;
- re-organising supplier and distribution networks;
- increasing the rate of innovation or R&D;
- changing the level and/or nature of employment and training.

Depending on the nature of the challenge and on the degree of success firms have in adapting, the impact on employment varies.

Below, we first review the main factors influencing demand over the short and medium term. The following section analyses the factors influencing supply and the competitive environment. We then review the different ways firms in each sector are addressing these challenges, and discuss the implications for employment over the short and medium term.

FACTORS INFLUENCING THE OUTLOOK FOR DEMAND

The factors that influence the changes in demand by sector can be grouped in three main categories:

- overall economic developments, both within the EC and at world level (i.e. the influence of the business cycle);
- changes in the regulatory environment;
- changes in the nature of demand.

Within each of these categories, there are a number of distinct factors influencing future demand patterns, whose influence is briefly reviewed below.

Influence of the business cycle

Table 1 presents the factors that dominate trends in demand in 17 sectors of EC industry and services.

Economic growth in the early 1990s has slowed down considerably from the rates achieved in the second half of the 1980s. In some sectors, the slowdown in demand growth is the principal factor which is driving the change in employment in the EC. This is the case, for instance, in the petrochemicals, machine tools and pulp and paper sectors. In the petrochemical sector, the strong rates of growth achieved during the second half of the 1980s combined with improved profitability led to decisions to expand capacity. However, when these new capacities came on stream, world economic growth had slowed considerably. This created a situation of overcapacity and led to downward pressure on prices. Low industry profitability and the poor demand outlook within Europe will result in major job reductions in this sector over the coming years.

Another sector for which the present difficulties largely originate from an unexpected fall in demand is aerospace, as falling demand for commercial aircraft has combined with shrinking military orders to create the worst crisis in the history of the sector.

Elsewhere, the slower growth in demand is rather playing the role of an accelerator of change, as it combines with other supply constraints, such as enhanced competition on world markets, to reduce the sector's medium and long term growth potential. This is the case in the consumer electronics sector, where the penetration rate of many types of appliances in EC households has reached very high levels, as well as in shipbuilding, air transport and textiles and clothing. Although the textiles and the clothing sectors are accustomed to experiencing only slow growth in demand, the heightening of competition at world level still makes them extremely vulnerable to an even small deceleration in demand from their traditional markets.

There are, nevertheless, a number of sectors which will continue to benefit from fast growing demand in the medium and long term. These are mainly services sectors, among which software and computer services, and telecommunications services. Another sector benefiting from fast demand growth in the outlook is the telecommunications equipment sector.

Changes in the regulatory environment

Alongside those sectors whose outlook will be dominated by the trend in the business cycle, there are a number of sectors for which the future trends in demand will essentially result from changes in the regulatory environment. There are essentially two categories of regulatory changes that are likely to influence future trends in employment. These are environmental protection regulations and the demand effects of the completion of the Single European Market.

Demand effects of the completion of the single market

The Cecchini report outlined the potential benefits of the Single European Market. These were to be achieved through a combination of a demand and a supply effect in the EC economy. This section only looks at the impact on EC employment of the demand effects of the Single Market. The supply effects are discussed in the section "Changes in supply and in the competitive environment".

In raising expectations and giving access to both consumers and producers to a unified market of 340 million inhabitants, the creation of a Single European Market and the unification of Germany had important consequences on demand trends within the EC.

The demand effects of the Single Market which currently dominate are for the most part second round effects of over-investment in the late 1980s on equipment demand, and of the ongoing deregulation of several services sectors. In air transport, for instance, the progressive liberalisation of European skies will continue to influence both the level of demand for air travel and demand for new aircraft.

In many manufacturing sectors, however, a lasting and not entirely positive effect of European integration on demand trends has been to increase the cyclicality of markets, as the European economies move more closely together. Downturns in one market are thus not offset any more by relative strength in other EC countries.

However, as stated in the White Paper "Growth, competitiveness, employment", it is impossible today to measure the full effects of the single market, as the latter is not yet complete. There are indications that the internal market is acting as a catalyst for a change in the competitive environment: these include, among others, the removal of border formalities, the removal of controls on capital movements, the increase in intra-EC trade and in the flow of FDI into the Community.

Environmental regulations

The impact of a tightening of environmental regulations depends on the sector and on the type of product considered, and on the policy measure envisaged. For some sectors, in particular for capital goods producing sectors, a tightening of environmental regulations taking the form of tighter standards or reduced emission limits can translate into increased demand, by forcing an accelerated replacement of the existing equipment or encouraging the use of new products to substitute the less environmentally friendly ones. In the shipping sector, for instance, the envisaged tightening of environmental regulations aimed at reducing pollution at seas would have a beneficial impact on EC ship yards by raising demand for new ships built according to the recent US and IMO legislation. In the aerospace industry, an increased demand for Chapter 3 compliant aircraft would have resulted from the implementation of the Directive concerning noise, had this proposal for Directive been adopted in its original form.

New environmental regulations can, however, also translate into reduced market opportunities for existing producers. Established automotive component suppliers for instance have had to re-equip their facilities and retrain their workforce to meet the changing market requirements: the introduction of emissions legislation in the EC in 1989 indeed made it essential for the component manufacturers to incorporate closed loop catalysts and electronic fuel injection systems; carburettor producers had to adapt and accelerate the development and production of such fuel injection systems, in order not to be forced out of the market.

Amongst the 17 sectors analysed, however, it appeared that past changes in environmental protection regulations either had no significant effect on demand, or only had an indirect effect due to increased production costs resulting in losses in competitiveness for EC producers. A further tightening of environment protection regulations could, however, change this situation.

Changes in the nature of demand

A fundamental change underway on the demand side, that will have major implications for employment in Europe, is the higher rate of innovation and the resultant shortened product life cycle.

Shortened product life cycles is a typical feature of most high-tech sectors, and has been particularly important in explaining the performance of EC companies in sectors such as telecommunications equipment, consumer electronics or electronic components. On the employment front, the challenges that result from the increased rate of innovation and shortened product life cycles result in increased emphasis being given to highly skilled, flexible workers in research and development and in production, and to individuals with strong marketing and distribution expertise on the sales front.

Technological progress can also lead to a more rapid turnaround of products, as the new technologies are being deployed, in some cases by prompting an early replacement of the existing equipment. Increasing technological sophistication, however, demands high levels of customer support, both at the point of sale and after the sale. The roll-out of new technologies and their adoption by the markets thus have a major side-effect which is extremely important from an employment standpoint: they increase the importance of the service dimension of products. This, again, calls for changes in the types of skills that are required in the EC. In particular, this calls for distribution and marketing expertise within the firms, along with increased emphasis on customer support.

CHANGES IN SUPPLY AND IN THE COMPETITIVE ENVIRONMENT

Changes in the competitive environment can result from:

- temporary situations of excess supply in the market;
- unfavourable trends in production costs in the EC compared to its main competitors;
- increased importance of non-price competitiveness factors;
- changes in the regulatory environment, and privatisation;
- changes in supply strategies of other world countries.

Temporary situations of excess supply in the market have been discussed earlier. Here, we focus on the other major forces which have influenced and will continue to influence the competitive environment of EC industry and services companies, and which effect employment.

Price-competitiveness factors

The unfavourable trend in production costs compared to the EC's main competitors is often considered to be the main cause for the deteriorating external competitiveness of EC industry. Such deterioration in the EC's relative price competitiveness is said to result from:

- too high labour costs in Europe;
- excessive industry fragmentation;
- too high capital costs;
- unfavourable trends in exchange rates, environmental costs, input material costs,
- lack of appropriate basic infrastructure (transport, communications), etc.

As indicated in the White Paper on Growth, Competitiveness and Employment, however, the key elements in competitiveness that are now of greatest importance are no longer confined to the relative level of direct costs of the various factors of production. They include education and training, the efficiency of industrial organisation, the capacity to make continuous improvements in production processes, the intensity of R&D and its industrial exploitation, the fluidity of the conditions under which markets operate, the availability of competitive service infrastructures, product quality and the way in which corporate strategies take account of the consequences of changes in society, such as improved environmental quality.

The relative importance of the "traditional" cost elements in explaining the present situation and the outlook for employment in Europe is nevertheless briefly discussed below.

Labour costs

In most sectors, labour costs in the Community are significantly higher than in its main competitors. Despite this, in

the sectors considered in this analysis, labour costs were not perceived as the key factor explaining the lack of competitiveness of EC producers in domestic and world markets. More important were the organisational structure of firms, their relationships with suppliers and customers, and the duplication of R&D efforts which can result from a lack of co-operation between firms. The only sectors amongst those considered in which labour costs did play an influential role were the labour intensive textiles, clothing and consumer electronics sectors. In these sectors, the high level of labour costs in Europe was in fact reported to be the main reason for the re-location of EC production outside the Community.

There is, however, some concern that labour market regulations in the EC are more rigid than in its main competing countries, thereby reducing the industry's flexibility to adjust to changing market conditions. Increasing labour flexibility should not necessarily be achieved by making it easier for firms to adjust employment levels, but could be achieved by allowing more flexible reviews of holiday pay, health insurance, bonuses and other variable costs, for instance.

Furthermore, statutory charges on labour (i.e. the sum of taxes and obligatory social security contributions) in the EC are much higher in the EC than in the USA or Japan, thereby hampering the competitiveness of European enterprises. This explains the general trend among Member States to stabilise or reduce statutory charges as a proportion of GDP.

Another source of concern is the fact that, in eight out of the twelve countries of the European Union, social security contributions are relatively more onerous on low incomes (White Paper on "Growth, Competitiveness and Employment", COM(93) 700 final). Studies have been carried out in countries with very high levels of social security contributions, which show that a reduction of 30-40% in social security contributions for low-paid workers would increase employment by 2%. The Commission has therefore made the suggestion that the Member States find ways to reduce the relative cost of unskilled and semi-skilled labour, in order to facilitate job creation.

Industry fragmentation

Despite the surge in concentration which was observed in the late 1980s/early 1990s following the launching of the Single European Market programme, there are still sectors for which the excessive fragmentation of the industry is an important element of the unfavourable cost structure in Europe compared to non-EC countries. In the petrochemical sector, for instance, the relatively high fragmentation of the industry imposes a fixed cost penalty to EC manufacturers, which negatively weighs on their relative competitiveness vis-à-vis emerging producers in the Middle East and the Asia/Pacific region. Other sectors in need of further concentration include telecommunications equipment and aerospace.

In contrast, in sectors such as machine tools, automotive components and textiles and clothing sectors, which are also dominated by small and medium sized companies, economies of scale are only relevant in selected market niches, which are generally characterised by relative concentration. In machine tools, for instance, economies of scale in production are only relevant in the mass-products market segment, which represents no more than 30% of the total market for machine tools.

In sectors where economies of scale are limited and firms operate more efficiently as small units, consortia can represent a possible answer to the issue of fragmentation. Indeed, inter-firm co-operation is still important in these sectors in order to ensure both the efficient allocation of the R&D spending and to maintain the balance of power between these SME-dominated sectors and their global, often highly concentrated, industrial clients.

The cost of credit

The high cost of credit in the EC at present is a third factor negatively influencing competitiveness, as it slows the rate of corporate fixed investment and thus the penetration of new technologies. Small and medium sized firms are particularly vulnerable, as they suffer from a difficult access to credit. It is, however, the small-sized firms which would benefit most from the introduction of new technology, as they suffer both from the increased competition and from the increased concentration of their customers as the larger firms are putting downward pressure on their suppliers' margins, thus reducing their profitability. As a result, SMEs often lack the funds for investment or do not have the financial base to appear creditworthy.

Environmental standards

Regulatory changes in environmental and safety standards, customer demands for "clean" products, "clean" production processes and production using "clean" inputs can result in increases in production costs and losses in competitive position, or to re-location moves. Both of these have obvious (negative) implications for employment. Among the 17 sectors analysed, however, the only ones in which this factor seemed to have been important enough to significantly impact employment are automotive assembly, electronic components production (mainly the printing of circuit boards) and shipbuilding.

In shipbuilding, health and safety issues are gaining importance and legislative measures to improve the environment in ship yards are raising costs substantially, affecting the EC industry's competitiveness with respect to non-EC ship yards. The EC industry's answer to these cost pressures has been to specialise in niche markets where they can exploit the Western industry's technology leadership.

Exchange rates

Past unfavourable movements in exchange rates have aggravated, rather than being a cause of the difficulties experienced by sectors such as aerospace equipment, consumer electronics or electronic components manufacturing. The problem has been particularly acute for the European aerospace industry, due to the high share of total production costs that are in local currencies, when the final products are mostly priced in US dollars. Given the very long lead time between the development of a new product and actual sales, usual hedging techniques are of limited help.

Other factors

Other factors hampering the expansion of EC industries and services sectors in domestic and world markets reflect the lack of appropriate infrastructure for production, transport or distribution in certain countries/regions, or the unavailability of key natural resources for production at reasonable prices. In the petrochemicals sector, for instance, naphtha is still used as the principal feedstock and the lack of appropriate infrastructure in certain regions imposes a fixed cost to EC producers.

Changes in the regulatory environment

The completion of the Single European Market had major supply-side effects on industry in Europe, through the moves towards a common trade policy, the rulings on state aids, the liberalisation of public procurement markets and other similar measures. In influencing production and the competitive environment, these changes have lasting effects on the levels and nature of employment.

The harmonisation of standards

The harmonisation of standards had a double effect on EC industry, whose net impact on employment was not always positive. On the one hand, the standardisation of components used by industry broadened the market base, enabling a more

rapid write-off of R&D costs. For the end-user sectors, the standardisation of components significantly reduced the production costs as manufacturers were able to use standardised components from a limited number of supply sources. Inevitably, however, such standardisation also led to strong increases in the level of competition on the components market, putting downward pressure on prices. As access to technology for the end user (on the applications side) become even cheaper, this changed the nature of competition further downstream as companies started to fight for market share by developing customised applications to better meet the needs of their customers. The net result was a shift in development costs from up-to down-stream.

Ownership restructuring

The harmonisation of standards and liberalisation of markets had other effects on the industry structure in Europe, also with major impacts on employment. In facilitating intra-EC trade it set the stage for movements towards concentration in the industry and services sectors. These movements often translated into job reductions. Although the Europeanisation of the EC industry and services sectors through M&A is now largely completed in downstream sectors such as automotive and consumer electronics, further concentration movements are expected (and, in some cases, needed) in sectors such as machine tools, telecommunications equipment, and aerospace. This in itself will lead to further job losses in those sectors in the short and medium term.

In favouring concentration movements in the wholesale and retail sectors, and more generally in nearly all downstream sectors, the completion of the Single Market also had important indirect effects on employment in EC manufacturing, in particular in SMEs. Indeed, the growing concentration of these purchasing sectors has changed the balance of power between the large retailers and their suppliers, with the latter being forced to squeeze prices and margins. The implications on profits were disastrous and forced many SMEs out of the market. This process is still on-going in many of the equipment manufacturing sectors.

Market deregulation

In many services sectors, it is through market deregulation that the Single European Market process will have the most effect on employment. Amongst the markets that have been or are in the process of being deregulated are air transport, telecommunications services, banking and insurance. In each of these sectors, market deregulation translates into an increased competitive climate, often through the entrance of new, more commercially oriented producers in the market. In challenging the existing suppliers which were accustomed to operating in an essentially closed market and which often benefited from a quasi-monopoly situation, these new entrants usually force radical change onto the industry. This typically results in increased emphasis on productivity enhancements through the integration of new technologies and production automation, and downward pressure on prices and margins creating a need for organisational changes, rationalisation of production and restructuring.

Another market which is in the process of being deregulated is the public procurement market. The liberalisation of public procurement is having an important impact on all those sectors for which the government sector represented a major client. One of these is the telecommunications equipment sector. Market liberalisation has forced prices down in this sector and is increasing the costs associated with creating products of superior quality (quality being an important factor of competitiveness in this sector), in addition to creating needs for a more commercially oriented work-force (i.e. with marketing skills). Many of the vendors were indeed used to selling to government specifications processes which involved little competition and required no showrooms.

Free movement of persons

The completion of the Single European market has, finally, also had a more direct effect on the labour market by removing many of the barriers to the free movement of persons. As the EC manufacturers' selection policies are also becoming less nationalistic and more international, and as pressures to reduce costs and improve productivity have reached unprecedented levels, manufacturers increasingly look beyond their local region or country for suppliers and employees who are more competitive and have the requested skills. Aerospace equipment manufacturers for instance are amongst the first to stress the importance of geographical mobility of labour to maintain a leadership position in world markets.

Privatisation

The privatisation moves that are in the pipeline will have a major influence on future trends in employment, both in the sectors in which there are companies to be privatised (in petrochemicals, air transport, telecommunications services, or banking, among other) and in upstream sectors. Indeed, the privatisation of companies in sectors such as airlines, telecommunications services or banking will change the nature of relationships between these firms and their upstream suppliers (the aerospace equipment producers or the telecommunications equipment manufacturers, for instance).

Whether in the air transport, petrochemicals or telecommunications services sectors, public-owned companies indeed tend to be much slower in adjusting employment levels to changing economic conditions than their privately-owned counterparts. In the air transport sector, in particular, the privatisation process can have a bigger aggregate impact on employment than deregulation, which is implemented only gradually and is carefully monitored in order to avoid the adverse effects on the industry which were experienced in the US.

This is less true in the telecommunications services sector and in banking, where the opening of the market to private operators and the liberalisation of public procurement can contribute to the development of new products and services. This could result in such a faster overall growth in demand in these markets that it would partly offset the negative effects of privatisation on the employment front.

Changes in supply conditions in the rest of the world

Eastern Europe and the CIS

The development of both demand and supply in Eastern Europe and the CIS is still a major factor of uncertainty for EC producers. On the one hand, the East European countries have the potential to become major competitors in sectors such as petrochemicals, automotive assembly, automotive parts and components, and some segments of consumer electronics.

On the other hand, however, these regions also represent important export market opportunities for western producers in certain market segments, which could lead to job creation within the EC. Examples of such market segments include electronic components, a product whose manufacturing requires a degree of technical skills and expertise not presently available in Eastern Europe, as well as software and computer services. It is, however, important for the EC producers to take appropriate measures to ensure that it is they and not non-EC based producers who take advantage of the new market.

Far East Asia & the Pacific Rim

Being a fast growing demand region, Far East Asia and the Pacific Rim represent a major opportunity for EC producers which they do not appear to be exploiting. Contrary to Japan or the US which have undertaken major investments in the region and from which they export at competitive prices, West

Europeans have remained very timid in their outward investment strategies. This limits their potential for participating to the fast growing markets in this region but leaves intact the competitive challenge. Competition from firms located in the Far East and Asia is thus expected to intensify in the following sectors:

- petrochemicals (if demand in the region falls short of expectations);
- consumer electronics;
- vehicle assembly;
- electronic components.

Textiles and clothing are two other sectors in which emerging producers in the rest of Asia, as well as in low labour-cost countries such as China, Pakistan, India, are expected to continue making strong inroads into the EC market.

US & Japan

Last but not least, the US and Japan are of course the EC's traditional world competitors in many key, fast-growing demand sectors. Generally speaking, the competition from the US is largely felt in sectors where research and/or development costs are important and can only be written-off rapidly through access to a large, unified, market. In the film and video sector, for instance, language and cultural differences between the Member States prevent the European producers from having a rapid rate of return on their investment. In aerospace, electronic components and software and computer services, the problems for EC companies are less insurmountable as they could be offset by an increased collaboration of firms across countries.

Within manufacturing, the sectors in which the US will continue to represent a major challenge for the EC over the short and medium, and in some cases also over the longer term, are mainly the aerospace, telecommunications equipment and electronic components sectors, but also software and computer services, telecommunications services and films and videos. US competition is much less of a threat in the financial services sectors, in textiles and clothing, or in shipbuilding.

Japan, on the other hand, ranks amongst the EC's main competitors in a number of high-technology sectors such as machine tools, electronic components and consumer electronics. These are sectors in which product innovation is important and where the control of the new technologies and processes is key to market leadership. The Japanese competitive challenge is also important in other capital intensive sectors, where they have been able to retain a leadership position thanks to shift to new forms of production organisation and distribution. These are automotive assembly, parts and components, and shipbuilding.

In the services sectors, Japanese and US competition is generally more moderate than in manufacturing. Still, in the insurance sector, the financial strength of the Japanese companies is such that it is generally believed that they could easily control significant shares of the EC market if the barriers to entry in the EC market were reduced a little further.

Both US and Japanese companies are also highly competitive in software and computer services. In fact, in this sector, the highly focused US companies are market leaders worldwide. They are often able to move faster and more adeptly than their Japanese and European rivals. However, they lack the in-depth knowledge and understanding of the local markets within Europe. Such in-depth knowledge is, however, key to success in a market which is putting increased emphasis on customised applications and on close relationships between the software developers and the end-users. US companies are likely to respond to these challenges through external growth operations.

THE STRATEGIC RESPONSE OF FIRMS

Re-location strategies

As reported in the article on "Past and Future Trends in EC Foreign Direct Investment in the Less Developed Countries" which is presented elsewhere in this Panorama, the re-location of EC production in low-wage countries is much less pronounced than is usually believed, and remains the fact of a limited number of sectors. In fact, as globalisation proceeds and the fastest growth markets are displaced to the Far East, China and the Pacific Rim, some sectors naturally tend to re-locate the centre of their production activities into the newer markets. The global tendency to manufacture PCs outside Europe and the US for instance is thus not strictly the result of a production cost disadvantage, but reflects a shift in market demand growth in these regions. The same applies to petrochemicals. This, however, also tends to displace the production of up-stream sectors which are heavily dependent on these end-markets, such as semi-conductors.

It is nevertheless important to note that foreign investments only lead to reductions in employment in Europe if the production in the non-EC region is then re-exported to substitute past production within the EC. To date, there is little evidence of this happening on a large scale.

The sectoral concentration of re-location movements, however, causes concern. Such moves are indeed mainly observed in the textiles, clothing, consumer electronics and electronic components sectors, and are becoming visible in the motor vehicle sector. In the few sectors where such movements are being observed, they reflect one of the following:

- the desire to take advantage of lower production costs in the region to remain competitive at world level; this is the main reason for the re-location of the textiles, clothing and several consumer electronics firms, for instance;
- a tightening of environmental regulations in Europe which raise production costs to a level that is deemed intolerable for survival within Europe; segments of the EC manufacturing industry which have re-located their production facilities to non-EC regions for environmental reasons include the printing of circuit boards.

Production automation

The introduction of new technology in response to increased competitive pressures has been an essential factor influencing the development and structure of employment in Europe. Apart from generally resulting in absolute reductions in the numbers employed, increased automation also results in important shifts in the nature of employment. New automated equipment has typically been introduced in those areas which represent the hardest and most repetitive working conditions, and has also replaced certain craft skills. By executing the more repetitive tasks, the use of automated equipment has changed the nature of work carried by men and women. This, in turn, has resulted in important changes in the types of skills required from the employees, as will be discussed in more detail in the section "Labour Market".

Changes in the organisation of production and management

Growing competitive pressures have increased emphasis on productivity gains and production efficiency within the firm. In particular, the shortening of product development cycles and the more widespread adoption of "lean" production philosophy are generally perceived as an appropriate way to reduce costs, increase productivity and improve production efficiency. This generally implies the re-organisation of product development and management functions to maximise personnel utilisation and synergies across departments, and the introduction of new techniques such as simultaneous engineering. Such consolidation and centralisation of personnel

typically results in job losses at all levels and requirements for new skills, both in terms of organisation so that information is fed across all departments from design and development to purchasing and production and in terms of the new equipment which has come into use.

The adoption of management systems which involve Total Quality Circles (TQC), Total Quality Management (TQM), Statistical Process Control (SPC) and Quality Function Deployment (QFD) thus places new demands on production line employees. These are now expected to take greater responsibility for the quality of their work, and for stopping production if pre-programmed tolerances are exceeded. Increased responsibility is also placed on the employee by the suppression of inventory which is associated with JIT manufacturing, since any fault in the system has to be corrected quickly and with minimum disruption.

Sectors which have experienced radical changes in their approach towards organising design, development and production as well as in their relationships with suppliers and customers are the vehicle assembly, automotive parts and components, aerospace and shipbuilding sectors. In all these sectors, the re-organisational changes have had far-reaching effects on the nature of employment and has created a need for continued education and training, as well as re-orientation of displaced workers.

Increasing the rate of innovation or R&D

The previous sections have emphasised the increasing importance of new technologies in today's markets. Companies have come to realise that those producers that are first into the field with new technologies are in a position to control the market for the systems or products using those technologies. This has contributed to accelerating the turnaround of new products and increasing the importance of R&D as a factor of competitiveness. The implementation of - or increased importance given to - the new technologies should therefore cease to be viewed as a negative factor influencing employment in the long term, but rather as a prerequisite to future growth in employment in Europe.

Frequently, however, spending on R&D in the EC is still low compared to competitor countries, and so is the rate of innovation. In sectors dominated by SMEs, the fact that efforts are scattered across a large market base also involves duplication of efforts. Increased co-operation of European firms is essential to the survival of several high-tech sectors of EC manufacturing. This is true at all levels: co-operation between SMEs is essential to avoid duplication of efforts in R&D and better anticipate market needs, whereas co-operation between multi-national firms on the technology front is important to share knowledge in design or manufacturing, and develop industry standards at world level.

In the electronics sector, for instance, the dominance of Japanese producers in component technologies for the consumer sector is presently unchallenged. The Japanese producers control more than 70% of semiconductor production, 95% of imaging devices, 95% of miniature LCD displays, 70% of laser diodes and 70% of video heads. This dominance explains the dis-integration of the EC's consumer electronics producers more than any labour cost disadvantage. Inter-national co-operation of European and US firms in this sector, appears to be the only way to break the Japanese dominance. In other areas, increased co-operation between firms from all Members of the Triad would have a beneficial effect on employment, as the development of new markets relies on the maintenance of a continued rapid pace of technological development.

Emphasis on new aspects of product development

As a result of the growing concern for the environment, firms have started to develop environmentally friendly products and have tried to make this a new factor in consumer choice. They have made efforts at designing equipment or products that are recyclable and non-toxic, and have widely advertised their shifts to clean production processes and to non-polluting input materials. These moves, however, generally only have a limited direct effect on employment.

Another important change encouraged by companies in Europe has been the increased emphasis on timeliness of deliveries and close contact with the customers. Domestic (EC) players indeed have a strategic advantage in servicing customers, and are attempting to exploit this in most areas of EC manufacturing and services by putting great emphasis on:

- customised products and applications for products (or services);
- end-user support;
- after-sales service;
- timeliness of delivery.

Convincing customers that this is what they need would indeed give a leading edge to EC producers in sectors such as machinery and equipment production, but also in services sectors such as software and computer services and telecommunications services.

Changing relationships with suppliers and customers

The relationships between EC companies and their suppliers and customers are changing rapidly, for a number of reasons. End markets have become more concentrated, changing the balance of power between firms up and down stream; competition has increased due to market de-regulation and privatisation; and, markets have become more open.

In such rapidly changing markets, a producer's ability to respond to changing regulatory and market trends is key to its success as well as to its ability to create employment. SMEs, however, generally lack the resources to anticipate such trends and implement appropriate strategies for change. They can therefore be regarded as most vulnerable to change of this nature.

The concentration movement among EC industries, which was accentuated with the creation of the Single European market, has indeed fundamentally changed the structure of many "downstream" sectors such as the automotive industry, the retail sector or clothing. As companies in these sectors restructure in order to adjust to a larger (more homogeneous) market and to increased competition, they are also putting greater pressure on their customers to squeeze margins, reduce delivery time, take responsibility for product and component development and customise products. Their suppliers, many of which are SMEs, are finding it increasingly difficult to survive without undertaking a major structural re-organisation of production. In a few cases, this has the effect of causing the dis-integration of the upstream sectors into a set of increasingly independent sectoral specialities. This has for instance happened to the software and computer services sector, and is bound to happen in the aerospace industry, in shipbuilding and in the automotive components sector.

Another factor driving changes in relationships between suppliers and customers is market de-regulation and the changes in ownership structure within EC industry. Indeed, in this increasingly global world, and also due to de-regulation, captive markets are dis-integrating. The long-term relationships which existed for instance between the telecommunications equipment manufacturers and the services operators, and more generally between up and downstream producers in many equipment manufacturing sectors, have had to be replaced by new forms of relationships, often creating a need for different types of skills on the vendor side.

Finally, competitive pressures to reduce lead times and costs are leading to major changes in the structural organisation of sectors such as automotive, aerospace and shipbuilding, as well as telecommunications equipment and software and computer services. As vehicle assemblers delegate an increasing volume of component development and production to their traditional suppliers, for instance, radical changes in the interaction between these manufacturers and the component suppliers occur:

- suppliers are being structured in different levels or tiers, graded by the nature of their connection to the final user, their level of product technology and their overall role in controlling and co-ordinating the production and supply functions;
- there are stronger and more co-operative vertical relationships between customers throughout the supply chain;
- there are also stronger horizontal relationships between suppliers, through strategic alliances, joint ventures, technology partnerships and supply agreements;
- first tier suppliers concentrate on core activities, whereas non-core products are being externally sourced.

Such developments lead to smaller suppliers becoming increasingly divorced from the ultimate source of the changes, and it becomes increasingly difficult for them to understand the ultimate requirements of their final users of their products - the assembly plants or the customers.

The effect on employment is the transfer of certain component functions from the equipment manufacturer to their traditional suppliers. Not all jobs are transferred, however, and some disappear as this increased reliance on supplier technology is usually accompanied by strong downward pressure on component prices, forcing component manufacturers to further enhance productivity in order to remain profitable.

There is also an implied need for suppliers and manufacturers to cooperate on training in new technologies or R&D, in view of the design delegation trend.

SMEs, which are particularly vulnerable to such changes, could be helped to reposition their organisation through support in the following areas:

- increasing the awareness of the nature and extent of the forthcoming changes, and assessing the implications on their own company;
- implementing plans to reposition their company; this would involve the provision of appropriate resources in such areas as business planning, management and marketing techniques;
- identifying international opportunities for licensing, strategic alliances or joint ventures;
- having access to technical advice and support, in particular to continually enhance existing skills and develop new skills in product design and development;
- providing access to financial and technological expertise to support investments in new equipment and manufacturing systems, and to support start-ups.

Re-organising supplier and distribution networks

In markets previously dominated by public procurement contracts, the liberalisation of markets creates a need for the suppliers to build distribution networks where these were previously virtually non-existent. This is the case for instance with telecommunications equipment manufacturing and with the development of commercial applications for what were primarily defence markets in the past. The same is true in those sectors which were previously highly vertically integrated (automotive, consumer electronics, electronic components) and where the dis-integration of formerly captive markets creates a need for new services (marketing & distribution) functions, as well as in the sectors presently in the midst of organisational change, such as the EC software and computer services sector.

THE LABOUR MARKET

Changes in employment levels

A main result which emerges from the sectoral analyses is the significant change in employment levels which is expected to take place over the coming years. In nearly all the sectors considered, the overall trend in employment is downward oriented.

Among the few factors that will have a positive effect on employment in the medium and long term are:

- fast demand growth for many services sectors that are also high technology users, such as telecommunications services, and software and computer services;
- continued rapid growth of demand and activity in the labour-intensive banking and insurance sectors.

In most cases, however, the net effect of structural change on employment levels will be negative. The reasons are:

- increased emphasis on labour productivity to protect margins;
- increased cyclicality of markets;
- insufficient funds for SME's capital investments;
- privatisation;
- on-going concentration movements;
- increased automation;
- advances in production processes and management.

Changes in the nature of employment

Existing levels of skills and qualifications in relation to projected needs

The above-mentioned structural factors, and the strategic responses of firms to these factors, will imply major changes in the structure of employment in the EC, as well as in the required skill mix.

In manufacturing, for instance, the changes in production organisational structures and in managerial styles, aimed at reducing development cycles and increasing both productivity and production efficiency, lead to a new human resource configuration:

- increased emphasis is given by management to employee motivation;
- employees are organised into teams, which share a variety of jobs that are fully cross-functional;
- these teams are expected to take responsibility for the quality and efficiency of their work, and to be able to offer suggestions for improvement;
- traditional skilled jobs are being replaced by new skills and multi-skilling;
- employee flexibility has become of uttermost importance;
- and so has commitment to employer;
- dynamic and continuous improvements are expected.

The implication of these changes is a somewhat flattened hierarchy, with major changes in job nature and responsibility structure for middle management.

Another implication of the changes in the nature of demand and increased emphasis on the service dimension of products is that new demands are placed on the industry and services

sectors. Most companies are unable to respond to these challenges with the existing in-house skill mix. Such demands can indeed only be addressed with a more flexible and multi-skilled work force. With an unemployment rate in the two-digit range in the EC, one can not speak of a labour supply shortage, however. The problem thus arises from insufficient labour mobility and inadequate qualification and appropriate skills of the labour force in unemployment in relation to the projected needs. Such inadequacies can be addressed by an anticipatory approach, with appropriate training, and policy moves facilitating a greater mobility of the work force.

There are, nevertheless, certain sectors which do suffer from a labour-supply shortage. These are sectors which suffer from a bad image due to the past recession and to imminent (or past) layoffs, which is discouraging potential entrants into these sector's labour pool. This effect is sometimes compounded by unattractive working conditions (shift work and noisy production, for instance), by the low technological image of the industry or environmental criticism. Such sectors then fail to attract young, ambitious and highly qualified people. Up-grading the image of these sectors would make it easier for the companies within these sectors to hire personnel with the required skills and ability. Among the sectors concerned by the above are textiles, shipbuilding, and software & computer services.

Impact on the geographic distribution of employment in the EC

The structural changes underway in many manufacturing sectors in Europe will lead to important changes in regional employment distribution. In those EC regions which are characterised by a heavy concentration of production in a limited number of sectors, the structural challenges to which the firms in these sectors will be confronted over the coming years should be a major source of concern. Indeed, in these regions, additional restructuring will need to take place in order to generate employment outside the critical sectors. Many of the small and medium-sized textile companies for instance are established in structurally poor regions and are at the same time important employers. Another sector in which regional employment is at risk in certain countries is the automotive sector (particularly in Germany and Italy).

With the heightening of competition throughout the EC, company/plant location decisions based on comparative regional analysis are also increasingly common. This is particularly apparent in the telecommunications equipment and consumer electronics sectors, and, increasingly, in software and computer services. As competitive pressures increase, a trend becoming visible throughout industry in Europe is to undertake effective and careful evaluations of the savings that would be realised if production were relocated elsewhere in the EC.

Trends in production and employment by region will thus have to be monitored very closely in the coming years, as actions may be needed to accompany the structural changes underway and to minimise the problems that heavy concentrations of unemployment can mean for a region.

Training needs

The need for more or better training is apparent throughout the EC industry and services sectors. Such need for a well-trained work force is also stressed in the White Paper on Growth, Competitiveness and Employment published by the Commission in December, 1993.

Training is needed both to enhance the technical skills of the workforce in some sectors of EC manufacturing and services, in order to teach existing employees to use the new technologies, and to increase the marketing and distribution skills of vendors. Indeed, in those sectors whose end-markets were largely secured through some types of regulatory arrangement (as in banking) or because of the existence of privileged links with the customers (national champion policies in telecommunications and defence), there is presently a lack of commercially oriented staff. Increased distribution and marketing expertise has now become a major requirement for both manufacturers and services providers in these sectors.

Production line employees also have to be trained (or re-trained) at a number of levels in order to fulfil the increased requirements placed on them. This includes preparing workers to take more responsibility on the shop floor, to adapt to the new environment, to become multi-skilled and more flexible. On the production side, emphasis should also be put on training middle management in order to enhance communications skills and team motivation, and to improve team performance and effectiveness further. Finally, training is also needed in new technologies and R&D related fields.

In most small and medium-sized firms, it is mainly the upper management which requires better training, as it is mainly the internal organisation of the firms which needs to be changed to further enhance productivity and reduce costs. Also, barriers to co-operation within and among sectors dominated by SMEs often lie in the culture of management. There is no question that a better educated management would be more open to innovation and would feel less threatened by co-operation.

In those sectors such as the equipment manufacturing sectors where new management concepts are being introduced or extended, important criteria for the selection and employment of people have become the acceptance of the need to be flexible; aptitude for versatility; aptitude for learning; good level of basic education; attention to quality. This is generating a demand for a lower age profile of the work force. In those sectors where the median age of the work force is in the mid-40s and higher (in shipbuilding, for instance), the development of training programmes specifically designed at addressing this problem and enhancing the work force's aptitude for learning is particularly important.

Finally, with the likely increase in job mobility in the EC manufacturing and services sectors, there will be increased needs for re-training and re-orientation of displaced workers. Most of the employees with a job position in 10-15 years time will have gone through a second or third level training.

Job sharing, part-time work, etc.

The recent recession has highlighted the need for retrenchment in most sectors of EC industry and services. Part-time work is one response, but is commonly used only in situations perceived to be temporary, due to the high costs involved.

The extension of part time work is, however, not always possible, as it does not necessarily fit well with the production line work. In the consumer electronics and aerospace equipment sectors, for instance, job functions are by nature constrained by continuity requirements and are difficult to divide. In addition, workers in these sectors are not very keen to work on a part time basis.

In the telecommunications services sector, in contrast, interesting shifts in working patterns are emerging from the heightened competitive climate. The majority of operators now provide 24 hour customer service, which has resulted in the introduction of shift-based working schedules. In the financial sectors also, increased competition in the market has lead to increased flexibility of working hours, with late opening hours, etc.

Some telecommunications operators have been exploring the use of "teleworkers", a technique which keeps operators in their homes connected to virtual offices by computers and telephone lines. Although the participants to the first of such experiments have reported positive results, a broader application of this technique in EC firms is limited to the services functions, for obvious reasons; also, the implications for labour costs are still uncertain.

Early retirement programmes

Early retirement programmes have been largely used by EC industry and by several services sectors to gain increased labour flexibility in periods of cyclical downturns. Examples of sectors which have made an extensive use of such schemes include aerospace and shipbuilding, as well as banking and insurance. Such schemes have served part of their purpose, which was to reduce labour costs at times of falling demand and production activity, but not sufficiently as the perceived bulk of over-employment is generally concentrated in the 40-50 age range and corresponds to the massive employment increases in the 1960s and early 1970s. Where retirements schemes have proved most effective is in the services sectors where they were aimed at middle and upper management levels, where the smallest level of staff reduction could be made for the largest financial benefit.

Increasing job mobility

As stated in the White Paper on Growth, Competitiveness and Employment, labour flexibility has to be analysed under its two main aspects: external flexibility, i.e. on the external labour market, and internal flexibility, i.e. within the company. Improving external flexibility means to make it easier for unemployed people to meet the requirements of the labour market, while a better internal flexibility can be obtained through an optimisation of a company's management of human resources.

Increasing external job mobility in the EC is viewed as important in those industries for which the maintenance of a leadership position in world markets is contingent upon international co-operation, or where skill shortages are likely to develop over the medium term. International co-operation is extremely important in aerospace and in vehicle assembly, for instance. The increased geographic mobility of workers across the EC is seen as one of the ways to make it possible for the industry to benefit from all the synergies that can be achieved through multinational partnerships.

Among the practical measure that would contribute to increase the geographic mobility of the European work force are the development of a common system of references for competencies, a harmonisation of social systems and regulations related to health care, pension schemes and the like, and a greater harmonisation of direct taxation systems.

Economic aspects of quality

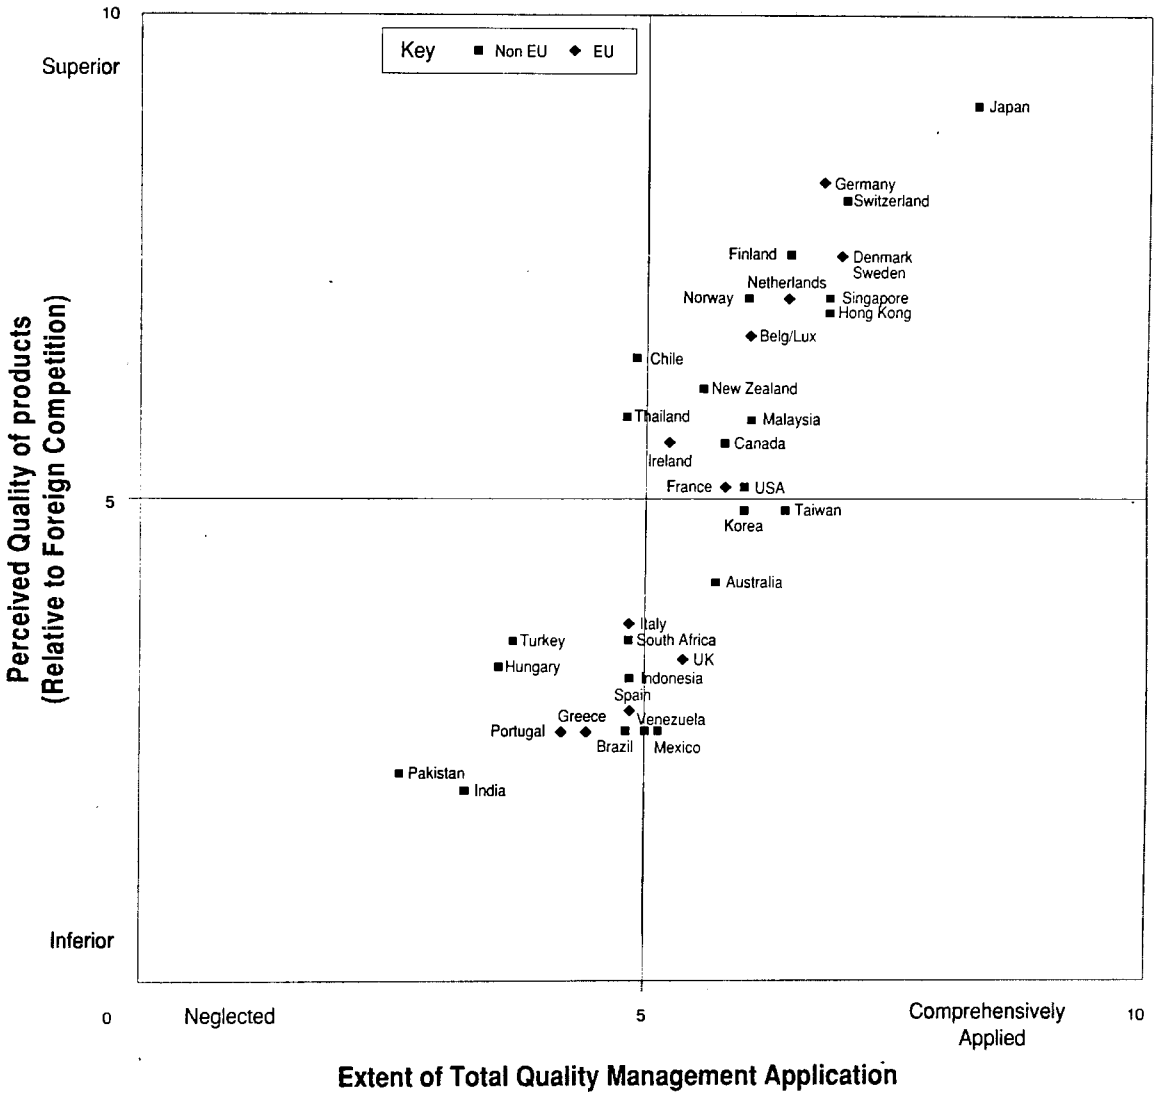
INTRODUCTION AND SUMMARY

There is mounting evidence that Quality Management improves the financial performance of European business. The following quote is typical of the commitment and enthusiasm of leading European practitioners: "We have overwhelming evidence to support that this (Total Quality Management) is an investment which is repaid many times over." - Milliken (1993 European Quality Award winner).

The term Quality Management groups a set of socio-technical theories and practices related to quality into a management discipline. Quality in this context measures the extent to which organisational outputs (products or services) satisfy "customers". The purchaser of any product is a "customer" in the publicly accepted sense, but Quality Management extends this to the notion of shareholders (e.g. via dividends), employees (e.g. via satisfying work) and society as a whole (e.g. via pollution).

Such enthusiasm from leading European organisations appears to justify formal public encouragement for the widespread adoption of Quality Management in Europe to the benefit of

Figure1: Correlation of total quality management Application & product competitiviness



Note: Readers are advised to refer to the World Competitiveness Report 1993 for the precise definition of Total Quality Management employed and the scope of the products surveyed for each company

companies and public bodies. Yet such encouragement needs to be underpinned by more than anecdotal evidence. The costs and benefits of Quality Management are debated widely (especially ISO9000 quality standards), with detractors often balancing the enthusiasts.

There is a clear need to quantify the costs and benefits to companies of Quality Management. It is also important to assess the macro-economic and associated social effects in Europe. Addressing these issues is essential to securing government promotion and adoption of Total Quality Management.

Against this background, Directorate General III of the European Commission has supported the European Foundation for Quality Management (EFQM) in performing a short study into the economic aspects of Quality Management.

The short study

The EFQM has worked with Coopers & Lybrand on a short study which aimed to identify significant studies completed in the last ten years (with specific focus on the past five years) that have attempted to assess the costs and benefits of Quality Management from the perspectives of:

- individual European organisations in a global context;
- the wider social costs of Quality Management.

The findings in this article are based on:

- database searches, contact with quality promotion organisations and current researchers;
- responses to a questionnaire sent to EFQM members and followed up with key personnel in selected companies.

In the article, the authors put Quality Management into context and identify some of the developing themes and issues in Europe; highlight the initial findings on the evidence of economic costs and benefits; and draw together conclusions on what further work is needed.

We would like to acknowledge the support we received from Directorate General III and the EFQM companies which responded to the questionnaire and in particular to ICL, Bull, Groupe Caisse Des Depots and AT&T.

Why is Total Quality Management relevant to Europe?

European global competitiveness in key sectors is being widely debated. Further there appears to be mounting evidence of the correlation between the adoption of Total Quality Management and improved competitiveness (see Figure 1).

The findings from the short study and leading European practitioners suggest Total Quality Management is one of the most effective ways to improve competitive position of European business during the 1990s.

The findings so far

The findings need to be taken in the broader context of European Quality Management which is summarised in Section II. The important messages are:

- Europe has a well established and strengthening infrastructure for the on-going development of Quality Management;
- Total Quality Management adoption in Europe continues to lag behind the US and Japan. Similarly the quantification of costs and benefits appears less developed in Europe;
- doubts are being raised over the true economic benefits of the widespread use of the ISO9000 series of standards.

There are very few up to date, wide-ranging studies on the economic aspects of Quality Management across the European Union. Despite this, the authors have identified 89 relevant, publicly accessible studies dealing with the economic aspects of quality in Europe, the US and Asia. These are summarised in Table 1. The key points from these studies are analysed in Section III. A number of consistent and positive messages emerge:

- There is evidence that Total Quality Management improves competitive position. One US study in the mid 1980s showed that businesses with products or services rated as "superior" quality may achieve a significant increase in market share over those with "inferior" quality;
- A small number of studies shows that Total Quality Management improves financial results. A major study from 1980 to 1990 showed that the stock prices of a portfolio of Total Quality companies significantly outperformed the index;
- Continuous improvement in cost-competitiveness is a natural part of Total Quality Management for the leading practitioners.

However:

- There is no generally accepted framework to measure and communicate the bottom-line impact of Total Quality Management;
- A key issue is to demonstrate the causal impact Quality Management has on economic performance as opposed to correlating it with improved business results;
- The full social impact of Quality Management has not been quantified.

Section IV highlights the further work needed. This includes the need to:

- develop a robust framework to support the collection of economic and competitive position data in relation to Quality Management practices;

- collect more up to date pan-European data on the costs and benefits of Quality Management in the private and public sectors;
- identify the most appropriate methods for using this data to promote Quality Management in Europe.

What are the expected benefits to European organisations and economies?

Existing work provides persuasive evidence that Quality Management could improve substantially the global competitiveness of European business.

The application of Quality Management practices is likely to benefit European business by sustaining competitiveness through:

- improved customer satisfaction;
- integrating the concept of continuous improvement into company activities;
- fully harnessing learning and innovation capacity to make step changes in performance;
- continually upgrading the satisfaction and skills of all employees;
- and improved financial performance

As financial institutions and government gain confidence in Total Quality Management, it is believed this will engender a longer term view of business and associated interventions and investment.

If this is true for the private sector, then the public sector could also benefit. The application of Total Quality Management within government and the public service sector could lead to improved efficiency and effectiveness in setting and implementing policy.

The potential impact of the benefits is far-reaching, but to what extent are they attainable? The initial findings are encouraging and the enthusiasm and commitment of the leading practitioners is beyond question. However, the study reveals uncertainties and gaps in the economic data. There are also gaps in the understanding of the indirect impacts of Total Quality Management in Europe.

The next two sections put Total Quality Management into historical context and discuss the detailed findings of the short study.

TOTAL QUALITY MANAGEMENT IN PERSPECTIVE

History

There is no single definition of Total Quality Management which is the name commonly given to the most advanced forms of Quality Management. Figure 2 shows the origins of Total Quality Management practice from 1920 to the present day. Figure 3 shows the body of theoretical work (mostly American) upon which this practice has been based. The approaches depicted have not entirely supplanted each other over the years. Rather, theoreticians and practitioners have built on the more effective elements of each and amalgamated them into the evolving best practice models for Total Quality Management (such as the European Quality Award Assessment Model, shown in Figure 4).

Until the 1950s the focus remained on technical issues such as improving inspection (Quality Control) using statistical techniques. This was associated with the introduction of planned, preventative measures (Quality Assurance). Although there were benefits from these approaches, the role of the worker was largely ignored, quality remained the domain of the "Quality Department" and improved quality was associated with increased cost. The spectacular success of certain Japanese companies in key economic sectors damaged the credibility of traditional Quality Control and Assurance. Much of this success centred on the idea that improved quality leads to reduced costs, a message promulgated by the late Dr W Edwards Deming, a leading American industrial academic.

The Japanese achieved their success with a combination of US economic and technical aid. In particular Company Wide Quality Control (CWQC) programmes were developed drawing on leading-edge Western thinking. Such programmes included the rigorous, on-going application of statistical techniques to critical processes (not just outputs) and the development of employee empowerment strategies. Indeed, the development of empowerment strategies (e.g. using Quality Circles) signalled a fundamental change from the era of Quality Control to Quality Management, and a shift in the role of managers that the US and Europe have been slow to emulate.

In the 1960s and 1970s a small number of large Japanese manufacturers fully exploited their lead by working with US and Japanese academics (amongst others) to develop innovative approaches to production. These innovations dramatically reduced lead times, inventory and cost whilst reducing defect levels (e.g. Lean Production), non-bureaucratic, empowering management systems for implementing policy (e.g. Policy Deployment) and a range of techniques for quality improvement. Concepts like 'zero defects' and 'right first time' became a reality. Few US and European companies followed suit.

It is important to keep this in perspective. Published information suggests that the Japanese experience continues to be dominated by large manufacturing companies (particularly in the automotive and electronics sectors with their supporting infrastructure). Indeed, there are reports of significant problems with white collar productivity in Japan. By contrast the European experience has been that Total Quality Management can be applied equally successfully to service industries (examples include British Airways, SAS, Avis Europe).

Considering the degree of maturity of Total Quality Management in Japan and the rate of implementation in the US over the past decade, there remains considerable scope for further adoption of Total Quality Management in European private and public organisations.

Recent approaches to implementation in the US and Europe (such as Business Process Re-engineering and Mass Customisation) are showing great promise by producing radical im-

provements in performance without the development lead-time required by the Japanese.

Current trends

Quality Management continues to grow as a discipline and there is a number of trends which are likely to raise specific issues for the European Union:

- increasing focus on individual customers by Total Quality organisations is helping to create fragmented, heterogeneous markets through the introduction of customised products and services. For example, one leading European washing powder producer now offers over 30 different products based on their analysis of specific customer requirements. Five years ago this figure was less than five.
- the role of management changes as Total Quality Management is adopted: requiring coaching, team skills and associated competencies rather than traditional management skills associated with command and control. There is a significant training and education implication;
- re-engineering organisations to focus on the core is leading to new ways of organising to provide products and services which in turn will dramatically change employment patterns. In particular this is likely to accelerate the rate of growth of small and medium-sized organisations as the corporates shrink and reorganise themselves into smaller business units. This has implications for the interaction of government and the private sector;
- increasing competitive pressures on service providers (across Europe and globally) is accelerating the adoption of Total Quality Management;
- accelerating application of Total Quality Management in government itself may improve efficiency and effectiveness, while increasing focus on excellent service delivery within the EU.

Additionally, there is a number of issues in Europe which presents both opportunities and threats to improving competitiveness. These include:

- increased competition as a result of the recent GATT round;
- the evolution of a single market in the EU;
- rapidly changing European social conditions and demographics;
- the recession and current high levels of unemployment in the EU; and
- regional differences in European business performance.

Infrastructure to assist the growth of Quality Management

Quality practices are well developed and supported by the European Organisation for Quality (EOQ). Formed in 1957, the EOQ originally acted as a focus for discussion and experience-sharing regarding Quality Assurance. The development of the EOQ has reflected the evolution of quality management and it now addresses broader aspects of quality management.

The EOQ currently represents the national quality organisations of 25 European countries and involves over 50 000 people via individual or corporate memberships (see Table 2). Importantly, the EOQ actively supports the establishment of professional Quality qualifications across Europe. Full member organisations are active in the areas of publications, research, education and training, testing and certification, conferences, national prizes and awards. In addition they liaise with other organisations in the Quality Assurance field (for example, standardisation organisations, societies, testing and certification bodies).

The multicultural nature of European business demands flexibility that is less apparent in the US and Japan. The existence of well-organised national quality organisations has meant that support and promotion for a variety of model approaches has been available to European businesses (e.g. publications, working groups, national quality awards and prizes). At the same time membership of the EOQ has tended to promote a degree of commonality as practice is disseminated.

In 1988, the European Foundation for Quality Management was established in recognition of the strategic importance of Total Quality Management to the competitive position of European businesses. Fourteen leading European total quality companies are founder members. The EFQM has developed a best practice Total Quality Management Assessment Model (Figure 4) which is used as the basis of The European Quality Award. The model is gaining wide acceptance as a framework for self-assessment and the implementation of Total Quality Management. The model is being adopted by some national quality organisations as the basis for all new national awards and revisions to existing ones.

A key feature of the EFQM's approach is its non-prescriptive nature. Also The European Quality Award differentiates itself from the US Malcolm Baldrige National Quality Award by overtly including the assessment of Business Results as a criterion.

The first European Quality Award was awarded in 1992 (see Table 3) In contrast the first Japanese Deming Prize was

awarded in 1951 and the first US Malcolm Baldrige National Quality Awards in 1988.

The extent of EFQM membership indicates the status of Total Quality Management in Europe. By July 1993 there were more than 280 members (see Table 4). These figures suggest that active promotion of Total Quality Management is mostly confined to larger European corporates. This is likely to influence the standards and management of smaller companies. There is relatively little representation for small to medium businesses in Europe and manufacturers still predominate. Service organisations do not appear to be adopting Total Quality Management at the expected rate despite accounting for more than 60% of Europe's GDP. The reasons for this are not entirely clear.

In comparison there are an estimated 30 000 ISO9000/EN29000 certified organisations in Europe, with potentially 50 000 by 1995. Although growing, a small proportion of European business has announced interest in Quality Management in these two most common forms. The majority uses ISO9000/EN29000 as a vehicle which, at best, accounts for about, only a third of the features of the best practice EFQM assessment model.

Companies that have embraced Quality Management as an integral part of their management processes are likely to meet ISO9000 requirements. However it is possible to adopt a quality standard without being a follower of Total Quality Management principles.

The ISO9000 series of Quality Assurance standards have been widely adopted (by manufacturers, service providers and government). Many organisations appear to misunderstand the relationship between Quality Assurance and Total Quality Management.

What issues affect Quality Management development in Europe?

Total Quality Management remains top of many European management agendas. However, the impression gained is that CEO's are not effective at translating their proclaimed commitment into actions (even amongst EOQ and EFQM membership).

Despite the enormous strides in harmonisation of standards across Europe, some standards are still barriers to trade. This creates an unnecessary overhead for European industry in the international arena.

Other issues affecting Quality Management development include:

- many small and medium sized organisations have been ineffective at pursuing Total Quality Management because the initial training and education commitments are inconsistent with their short-term financial needs;
- training and education to support Quality Management remains a significant issue in Europe. Government incentives for training to support Total Quality Management implementation are highly variable across Europe. Small and medium sized organisations are particularly vulnerable. A recent EC working paper on 'Total Quality Management Education and Training in Europe' concluded that higher educational institutions "must urgently adapt their current curriculum" to meet training needs;
- government promotion of the proven benefits of Total Quality Management is less apparent than in the US, where the National Institute for Science and Technology actively communicates the value of adopting Total Quality Management;
- government incentives for implementing Total Quality Management (e.g. grants or economic aid) are highly variable across Europe;
- the benefits to individual companies and to European economies of research work currently underway in European management schools, universities and other seats of learning has not been quantified;
- little has been publicised of the benefits of the application of Total Quality Management within government in Europe.

WHAT ARE THE FINDINGS SO FAR?

The studies show a widespread, growing belief in the benefits of Total Quality Management. The evidence ranges from detailed and rigorous to circumstantial. In the observations presented in this section we have drawn conclusions from fact-based studies. It is worth noting that in many cases faith in a successful outcome has been a more effective driver for change than an understanding of the causal link to bottom-line improvement.

Total Quality Management improves competitive position

Michael Porter clearly demonstrates that the ability of organisations to compete more effectively in local and global markets has a significant, beneficial macro-economic impact. Understanding and measuring this ability, and the resultant competitive position, is complex and uncertain.

For example, in Table 5 competitive position is broken down into components that are commonly accepted as having a significant influence on profitability. Each component has associated measures which combine the quantitative (e.g. return on sales) and qualitative (e.g. relative quality index) aspects of competitive position. It is important to note that US experience shows that properly constituted relative quality indices have been one of the most consistently reliable measures in assessing competitive position over the 1980s and early 1990s.

Comparable data are not available for the performance of European organisations but several studies have been performed in the US. Figure 5 shows results from a recent Profit Impact of Market Strategy (PIMS) survey of more than 1 000 US companies. This relates return on investment (ROI), market share and relative quality index for a wide range of products, services and market sectors. Although a causal link was not established, the inference is that organisations which pursue quality strategically (as indicated by a high relative quality index) will secure market share and improved financial performance. A US Government Audit office report supports this

and observes that these findings apply to almost all service providers, producers and market situations.

Bottom-line impact of Total Quality Management

There is no single universally recognised approach to collecting the financial data needed to demonstrate the effectiveness of Total Quality Management. Where quality costs have been collected and analysed there are major doubts over the accounting involved and the extent of comparability between organisations. This is particularly apparent when pan-European studies are involved.

Quality Management specialists tend to use collection and analysis methods that do not always have accountants' endorsement (e.g. 'Cost of Quality' measurement). Would this situation persist if quality costs were a substantive item in management accounts (a common response to the questionnaire issued to European total quality companies as part of this short study)?

There remains an overwhelming reliance on traditional quality measures to measure effectiveness (such as productivity, defect levels, lead times etc.). The prime motivation appears to be ease of data collection. Current financial systems do not generally support the collection of quality costs or, more generally, activity costs. One study notes that the Japanese have made excellent use of Information Technology to aid in the collection of financial data to support their quality improvement efforts. Conversely, in US and European examples parallel cost collection systems have been established to provide the information. However, the general trend towards the provision of management information from activity-based costing systems could reduce the need for parallel data collection.

The replies to the EFQM's questionnaire serve to highlight the cost collection and analysis dilemma. Of the 57 EFQM members that contributed, 26 declared they had conducted studies into quality costs (either the costs of investment in quality, cost benefits from that investment or the cost of non-quality). These ranged between:

- pilot studies of the cost of non-quality using a national standard-based approach;
- full systems or the detection and tracking of non-quality costs; and
- formative attempts to introduce cost of non-quality into the normal profit-centre cost management structure.

Total Quality Management improves financial results

There is a body of fact which indicates that Total Quality Management is strongly associated with improved financial results. If profitability and competitive position of European companies are enhanced by widespread adoption of Total Quality Management, there will be a beneficial macro effect on European economies.

In the US, a study of Total Quality Management initiatives during the period 1980 to 1990 showed that the stock prices of a portfolio of Total Quality companies significantly outperformed the index (see Figure 6). The companies achieved a compound annual growth rate of 16% per annum compared with 10% for the Standard & Poor's 500 by the end of the decade.

The responses to the questionnaire (sent to EFQM members in November 1993) show that the costs of non-quality are significant and the impact of Total Quality Management on these costs is equally significant.

Typically the data are presented as the 'Cost of Quality' (i.e. costs associated with non-quality in terms of the prevention, appraisal and failure activities. Quality improvement is then represented as a reduction in 'Cost of Quality.' Note that there is no single agreed definition of the 'Cost of Quality'. The ECQ has a definition but companies often use their own.

The scale of quality costs is rarely reported as less than 25% of operating costs. For example, a UK utility responded that its annual 'Cost of Quality' is 53% of employment costs or £6.3 million per annum. Similarly, a textile manufacturer has estimated its 'Cost of Quality' to be 52% of employment costs or £3.6m per annum.

Hence, small improvements in 'Cost of Quality' will impact annually on the bottom-line and translate into added-value for the customer and profitability.

Table 5: Components of competitive position

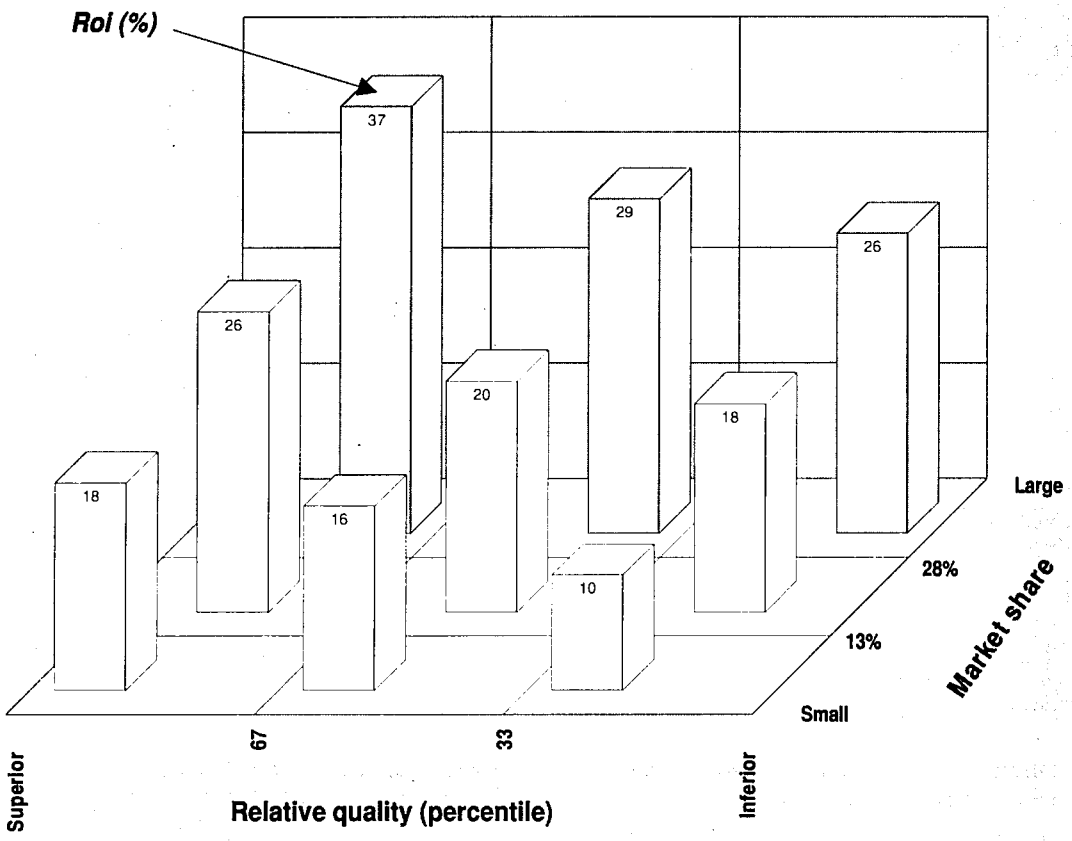
Figure 5: The interrelationship between quality and financial performance



Source: EFQM

Specific examples from our survey of the impact of quality management on EFQM members include:

- Honeywell S A Europe has achieved between 8 and 35% reduction per annum in Cost of Quality across its business;
- Automobile Citroën has reduced its quality costs by 50% in 10 years. This was achieved whilst improving productivity (cars per employee per year), by 88% in the same period, reducing customer claims by 50% and reducing inventory levels by two-thirds.

A multi-sector survey of British business in 1989 showed that 75% of businesses increase their profitability within three years of introducing Total Quality Management. Fifty-three percent have achieved "good" results within a year of starting. The subjective nature of replies means that the extent of improvement is difficult to assess, but the overall conclusions remain.

A key methodological issue is to demonstrate the causal impact of Total Quality Management on economic performance, as opposed to correlating the adoption of Total Quality Management with improved business results.

There have been pioneering studies on this difficult area by Bradford Management Centre and by Smith. The Bradford research, covering 29 European Total Quality companies asserts that 72% of companies show above average financial performance.

A 1993 study by Smith seeks to establish causal links between improvements in Total Quality enablers and subsequent financial performance by eight European Total Quality companies. One untested hypothesis in this study is that minor improvements in key decisions (which impact elements of the enablers) could result in significant improvement in profits. However the financial performance criteria in these studies were very broad.

Measurable targets are key to Total Quality Management success

Cost reduction allows a company to improve competitiveness by lowering prices or by creating more value for customers through a more effective customer-focused use of resources.

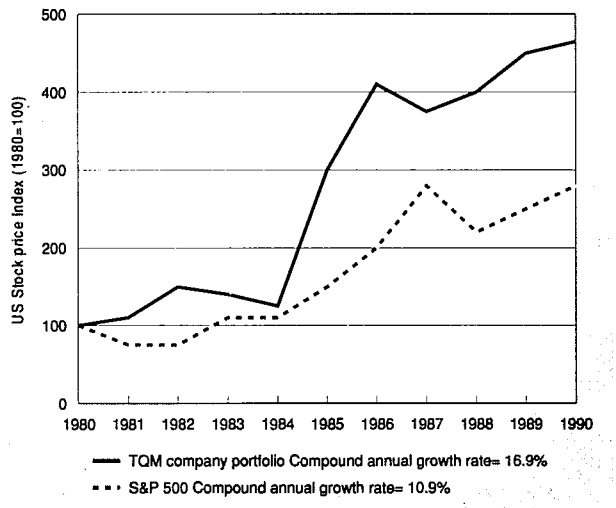
Cost reduction is an integral part of Total Quality Management. Japanese experience suggests that stretching financial targets are more likely to lead to success. This aspect of Total Quality Management is more likely to gain shareholder and senior management backing for quality improvement activities.

Cost reduction strategies are still viewed as important for maintaining competitiveness, particularly since overheads remain a significant proportion of most European organisations' operating costs.

Other critical success factors for Quality Management include:

- active customer focus along the value chain. Several surveys show Total Quality Management initiatives which are completely inward facing fail to achieve the performance improvements already discussed (from anecdotal evidence this may be particularly true of ISO9000/EN29000 initiatives).
- quick results which can only be achieved if the right approach is chosen (particularly those which initially re-engineer core processes). However, the major benefits occur over periods which are much longer than US and some European management teams are comfortable with. One affect of Quality Management is to extend management's planning horizon. Such an approach is entirely consistent with the long-term creation of value desired by many investors.

Figure 6: TQM companies outperform industry's leaders



Source: EFQM

A mix of financial and non-financial performance measures is key to Quality Management

Performance measures extend to a greater range of subjects than just financial performance as illustrated by ICL's Manufacturing Division's response to the EFQM's questionnaire. ICL has developed performance measures to cover: competitiveness; customer satisfaction; productivity; employee satisfaction.

Examples of ICL's performance measures include:

- Competitiveness: contract wins to bids, market share, customer retention;
- Customer satisfaction: customer driven indicators such as: technology performance, support performance, delivery performance;
- Productivity: value added per employee, return on capital employed;
- Employee satisfaction: annual employee opinion surveys

The business began adopting Total Quality Management techniques in 1984/5 and has achieved some remarkable results:

- Cost of non conformance reduced by a factor of 8;
- Process yields up 30/35%;
- Product costs: 10% reduction still being achieved annually;
- Time to market reduced from 2 years to below 3 months;
- Delivered quality improved by a factor of 10;
- Employee turnover reduced from 5% pa to 1% pa.

To drive through financial performance improvement, adoptees of Total Quality Management need to manage the business through a variety of non-financial performance measures.

The full social impact of Quality Management has not been quantified

There is evidence to suggest that aspects of Total Quality Management in Europe and the US have led to job losses in the short term. A possible explanation is that organisations are concentrating on core functionality and re-engineering processes to radically improve performance. This clearly implies less resources required to achieve the same or higher outputs, but this may often be balanced by an increase in contracted out services. However, a focus on cost reduction may lead to export of jobs from the EU to lower wage economies such as Eastern Europe and China. This implies that government policy will have an important role to play as European competitiveness improves

A high proportion of overhead costs is tied up in administration. Administrative functions across Europe employ a significant proportion of women. Hence, overhead reduction strategies may lead to unexpected changes in employment patterns for female workers.

There is also increased awareness of the need for European management thinking to incorporate a fuller understanding of the wider social implications, benefits and pitfalls of operating in such a culturally diverse and rich environment. The inclusion of an 'Impact on Society' criterion in the EFQM Model is a practical example of how total quality principles are increasingly being applied to the social dimension. A characteristic of Total Quality companies is that they view performance comprehensively and not from the narrow view of a single group of stakeholders.

Typically companies do this by demonstrating to the public how they are implementing environmental policies, acting as 'good neighbours', actively investing management time in the local community and by handling job losses to minimise damage to the community (e.g. outplacement counselling, relocations etc.).

Some academics consider Total Quality Management as a market de-stabiliser. They believe it creates market turbulence by shortening lead times to market, increasing diversity of organisational form and outputs to meet individual customer needs more closely. However, we believe that the benefits outweigh the disadvantages.

CONCLUSIONS AND FURTHER WORK NEEDED

The evidence examined in this short study shows that applying Quality Management principles effectively yields superior business performance. However, the short study has also confirmed that significant work is still needed to demonstrate the extent and range of benefits of Quality Management in Europe. Further study is required to:

- develop a framework to support the collection of economic and competitive position data across Europe in relation to Quality Management practices. This should aim to: test whether causal links between Quality Management practices (enablers) and business results can be demonstrated; understand clearly how individual European organisations should set performance measures, collect and analyse performance data to reveal the effectiveness of Quality Management implementation; develop a framework to assess the macro-economic effects of Quality Management on the EU economies;
- collect more data on Quality Management in the private and public sectors, for national and pan-European organisations. This will provide an up-to-date and ongoing assessment of the costs and benefits (including the impact on competitive position) of Quality Management. In particular, this should include assessment of: the extent of Quality Management adoption; the criteria for successful implementation; a comparison of implementation methods; the micro and macro-economic effects of widespread Quality Management adoption; the impact of Quality Management on small and medium-sized organisations; the impact of Quality Management in different sectors and regions; the impact on service and manufacturing industries; costs/benefits of ISO9000 (EN29000); the impact of Quality Management within government agencies;

- identify the most appropriate methods for using these data to promote Quality Management within Europe. This should aim to: quantify the costs and benefits of existing national and pan-European government promotion of Quality Management; assess what types of future national and European government interventions, if any, would be most effective to support Quality Management development in Europe;
- quantify the socio-economic impact of Quality Management application across the EU. This would: assess the social impact of Quality Management (e.g. in terms of changes in employment); explore the implications of demographic changes (especially the increase of women in the workforce) for Quality Management;

In conclusion, this short study confirms that widespread adoption of Quality Management is likely to advance the competitive position of European business. However it also shows the need for further, more detailed study.

We have identified key gaps in the information which should be closed to make this possible. It is now necessary and timely for the EU to take a more active role in developing a richer understanding of the economic aspects of quality to enhance European business performance.

SMEs and internationalisation

INTRODUCTION

The importance for the European economy of small and medium-sized enterprises (SMEs) is now universally recognised, as is proved by the direction in which economic policy has been moving recently: the White Book of the Commission of the European Communities on growth, competitiveness and employment suggests a number of measures to promote the development of SMEs and the way in which they function.

At the same time, internationalisation is gaining more and more ground. States are more economically and politically interdependent than ever, particularly in the Community.

As there is relatively little documentation on the subject, we thought it might be worthwhile to look at the role of European SMEs in internationalisation.

A survey of European SMEs is followed by a look at the internationalisation of enterprises now taking place and finally by a description of how European SMEs are responding to internationalisation with special mention of a new Community instrument for transnational cooperation adapted to the needs of SMEs: the European Economic Interest Grouping (EEIG).

We have drawn from four main sources:

- the publication "Enterprises in Europe - Second Report, produced jointly by Eurostat and Directorate-General XXIII of the Commission of the European Communities (Enterprise Policy, Distributive Trades, Tourism and Cooperatives) which contains statistics of workforces, employment and production for enterprises in the Community and certain EFTA countries, broken down by size of enterprise (in terms of jobs).
- the first report of the European Observatory for SMEs, produced at the request of Directorate-General XXIII by the European Research Network for SMEs, which analyses the present position and prospects of Community SMEs under various headings such as spirit of enterprise, dynamism, markets and sales, jobs, capital and funding, followed by strategic recommendations;
- the research on "Les PME et l'internationalisation - La PME belge à l'aube du grand marché de 1993" (The SMEs and internationalisation - Belgian SMEs on the threshold of the single market 1993", undertaken by the Centre d'étude PME of K.U. Brussels and covering over 1000 SMEs in the secondary and tertiary sectors;
- the document "GEIE - L'émergence d'une nouvelle coopération européenne - Bilan de trois années d'expérience (EEIG - The emergence of a new form of European cooperation - Assessment of three years of experience" produced by Directorate-General XXIII on the basis of a survey of 194 EEIG.

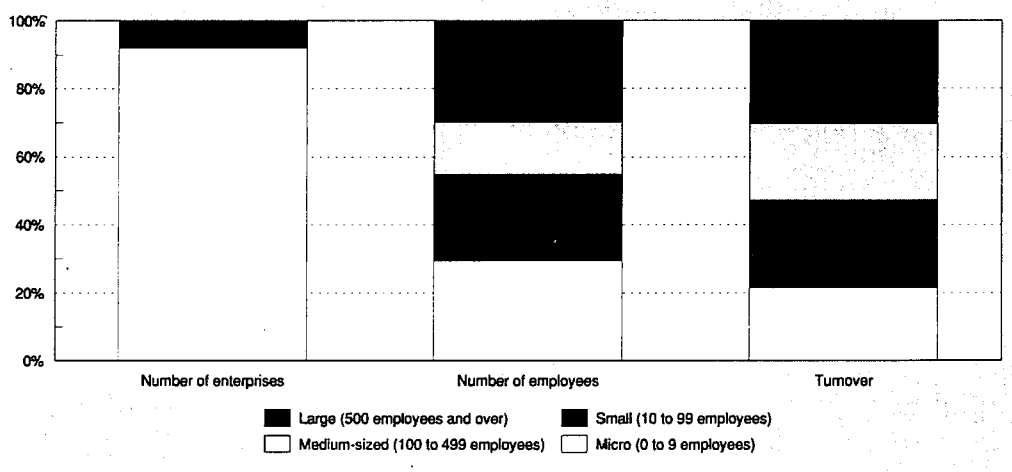
EUROPEAN SMEs

SMEs in the broad sense (0 to 499 employees) account for 99.9% of the European Community's 11.6 million enterprises (1988), not counting enterprises in the agriculture, hunting, forestry and fishing and other services sectors (NACE 0 and 9). They employ 70.2% of the 80.7 million persons employed by all enterprises and generate 69.7% of total turnover amounting to ECU 10.7 billion.

SMEs in the broad sense can be divided into three categories:

- micro-businesses (0 to 9 employees);
- small enterprises (10 to 99 employees);
- medium-sized enterprises (100 to 499 employees).

Figure 1: Breakdown of EC enterprises according to number of enterprises, employees and turnover, 1988



Source: Eurostat

Table 1: Extent of forms of internationalisation of SMEs in Belgium, 1991

Form of internationalisation	% of enterprises involved
Exports	89
Subsidiaries	29
Production units	17
Licensing of foreign firms	13

Source: Centre d'étude PME of K.U.B.

The second and third categories constitute SMEs in the strict sense (10 to 499 employees).

As figure 1 shows, micro-businesses are the most numerous, accounting for 92% as against 7.4% for small enterprises and 0.5% for medium-sized enterprises. They also have the biggest proportion of employees (29.4%; small 25.3%; medium-sized 15.5%). By contrast, their share in turnover is the lowest, standing at 21.4% as compared with 25.7% and 22.6% respectively for small and medium-sized enterprises.

As compared with large enterprises (500 and over employees), micro-businesses are still the most numerous (large enterprises: 0.1%) but their percentage figures for jobs and production are lower (large: 29.8% and 30.3%).

The percentages for SMEs in the strict sense are 7.9% for the number of enterprises, 40.8% for numbers employed and 48.3% for turnover. Community enterprises have an average of 7 employees.

As regards the weight of SMEs in the broad sense, the picture is much the same as for the Community and all the Member States. Apart from Denmark, the same is true for the average size of enterprises, 80% of which have less than 10 employees.

The position does, however, vary from country to country in the case of micro-businesses and SMEs in the strict sense, with the southern countries having proportionally more micro-businesses than the northern, except for Belgium. In Italy, this category is of exceptional relative importance in terms of jobs and production (almost 25% of the active population and over 20% of GDP, as against less than 20% and 15% respectively in most of the other countries). One-man businesses (0 employees) are most numerous in France and Spain (over 50% of all enterprises) and fewest in Germany and Luxembourg.

In Spain, Germany, Luxembourg and Denmark, SMEs in the strict sense lead with 47 to 56% of employees and from almost 30% to over 40% (Luxembourg) of the active population. The figures are lowest for Italy and France (less than 40% for employees and less than 25% for the active population).

The sectors with most SMEs in the broad sense are building and civil engineering (NACE 5) and services (NACE 6 to 9) at both Community and national level.

Micro-businesses are particularly numerous in the "distributive trades, hotels, catering and repairs" sector (NACE 6) which accounts for over 40% of all enterprises in that category, as can be seen from figure 2. They are also numerous in the "transport, credit institutions and business services" sectors (NACE 7 and 8) and in building.

The "energy, metal manufacture, intermediate goods and equipment" sector (NACE 1 to 3) is characterised by large enterprises but also has medium-sized enterprises, more particularly in the manufacture of intermediate goods and equipment.

Other manufacturing industries, i.e. consumer goods industries (NACE 4), tend to be medium-sized or small.

The not-insignificant presence of large enterprises in the "transport, credit institutions, business services" sectors (NACE 7 and 8) is explained mainly by the importance of the credit institutions, which may be very large.

For some analyses a distinction may usefully be made between "small" and "large" sectors. A sector is described as "small" or "large" according to whether it is dominated by SMEs and large enterprises respectively in terms of jobs or number of enterprises. For example, the "consumer goods" (NACE 4) and "distributive trades, hotels, catering and repairs" (NACE 6) sectors are made up exclusively of small subsectors while the "transport, credit institutions and business services" sectors (NACE 7 and 8) have a majority of large subsectors.

THE INTERNATIONALISATION OF ENTERPRISES

Internationalisation, also referred to as "globalisation" has been going on for a long time, as differing resources have very quickly led States to establish trading relations. It has,

Figure 2: Breakdown of EC enterprises according to sector, 1988

however, picked up speed over recent decades, in terms of both quality and quantity, and is bound to increase in Europe with the completion of the single market. Indeed, as Figure 3 shows, world trade in goods has grown more than world production since the sixties. This acceleration is due mainly to technical advances in the fields of transport and telecommunications, which have changed very significantly the link between the place of production and the places of supply and sale, with a consequent spectacular growth of the service sectors.

For enterprises, "internationalisation" means "extension to international level of their activities at national, regional or local level".

Currently, there are four forms of internationalisation of enterprises, often constituting successive stages: exports, cooperation with foreign enterprises, licensing of foreign firms and direct investment abroad.

Exports

With world flows amounting to ECU 2665 billion in 1990 and ECU 2742 billion in 1991, accounting for over 30% of world GDP for goods, the oldest form of internationalisation through exports is still the most important. More than two-thirds of trade is accounted for by the industrialised countries and, in particular, the Community with almost 41% in 1991. In 1990, world trade in goods accounted for 81% of world exports, chiefly of manufactured products (57%).

In the Community, exports of goods represented 22% of GDP in 1991 and amounted to ECU 1136 billion in 1992. Of this figure, only 38% related to trade with third countries, led by the United States and Japan. The most dynamic Member States measured by the ratio value of goods exported to population are Belgium, the Netherlands, Denmark and Ireland.

Cooperation with foreign enterprises

Cooperation with foreign enterprises can take various forms with differing degrees of formality, ranging from a verbal agreement to the creation of an EEIG or a joint undertaking; it can cover various areas such as "research and development" (R&D), marketing or production. This method enables the parties involved both to widen their field of action, by reaching new markets, distribution networks, customers, products, technologies, capital ... and to improve their performance particularly as regards management and productivity.

Such cooperation leapt ahead during the eighties. For example, between June 1985 and May 1992, the number of joint enterprises created annually in Community industry and services (by the 1000 biggest industrial enterprises in the Community, the 500 biggest world industrial enterprises and the biggest enterprises in the distribution, banking and insurance sectors ranked by turnover) rose from 27 to 54 for creations involving different Member States and from 28 to 46 for those involving Member States and third countries, with the United States and Japan as leading partners. These operations involve chiefly the industrial sector, and chemicals in particular, while banking dominates in the services sector.

Licensing of foreign firms

Licensing of foreign firms has also grown considerably over the last ten years. As it is directed to a product, brand or technology, licensing is more successful with Swedish, American or New Zealand enterprises than with their European counterparts whose Governments' balance of payments is even in deficit.

The situation differs widely between the Member States of the Community; while Belgium has been losing ground for twenty or so years, the Netherlands have seen their influence rise by 70% between 1984 and 1990. This influence is chiefly with European countries to the extent of 60% in the Community and EFTA. Furthermore, by contrast with the other Member States, Germany exports many more licences than it imports, even though its balance of payments is in deficit.

Direct investment abroad

Direct investment abroad can be defined as the use of capital by enterprises to finance the purchase, creation or development of subsidiaries abroad or to acquire holdings in foreign companies giving them powers of decision in those companies. The reason may be a desire to escape from protectionist measures, to take advantage of attractive local conditions (fiscal, legal, financial) or to move closer to customers.

Over the last ten years this type of internationalisation has gone ahead without a break at an average annual rate of 29%,

Source: Eurostat, GATT

thus greatly exceeding the rates for production and trade, to attain world flows of ECU 147 billion in 1990. As in the case of exports, most of the operations take place in the industrialised countries (82% in 1990). The Community, the United States and Japan together accounted for 77% of flows from 1985 to 1989 and held 81% of total world direct investments abroad in 1988.

In 1989, Community investments amounted to ECU 33 billion in third countries and ECU 32 billion in Member States (by countries of destination). The main receiving third countries were the United States (72%), the EFTA countries (7%) and Japan (2%). The United Kingdom is a very substantial investor accounting for almost half of Community investments in third countries and over a quarter of Community investments in Member States. France is also a major intra-Community investor with 26% of the total. In the Community, as in Japan and the United States, a major proportion of direct investments abroad go to the service sectors, and to the financial sector in particular. Acquisitions of subsidiaries accounted for around 85% of United States investment abroad and 60% of such Community investments over the last ten years.

INTERNATIONALISATION OF SMEs

This section examines in turn the way in which SMEs have dealt with the four forms of internationalisation, the EEIG, the indirect effects which internationalisation may have on SMEs and the organisations and bodies available to them in this field.

Response of SMEs to the four forms of internationalisation

Although to a lesser extent than large enterprises, European SMEs are also involved in the process of internationalisation, chiefly through exports as shown by table 1 for the 52% of Belgian SMEs which operate internationally.

Table 2 shows that for all sectors of the economy in 1988, shares in foreign sales were estimated at 5% for micro-businesses, 10% for small enterprises and 13% for medium-sized enterprises as against 22% for large enterprises. The lead adopted by the latter did not extend to all sectors, however; in the commerce sector, small and medium-sized enterprises led with 9% and 7% respectively, compared with 6% for large enterprises.

The SMEs' share in international trade seems to be growing faster than that of the large enterprises. In the Netherlands

industrial sector, for example, the growth rate for SMEs was more sustained than that of large enterprises between 1980 and 1991 when the figure was ECU 26 billion for the former and ECU 36 billion for the latter.

Three small sectors (NACE 31 "Manufacture of metal articles (except for mechanical, electrical and instrument engineering and vehicles"), NACE 45 "Footwear and clothing industry", NACE 46 "Timber and wooden furniture industries") and three large sectors (NACE 25/26 "Chemical industry"/"Manufacture of man-made fibres", NACE 33 "Manufacture of office machinery and data processing machinery", NACE 35/36 "Manufacture of motor vehicles and of motor vehicle parts and accessories"/"Manufacture of other transport equipment") were compared in order to determine the respective performances of SMEs and large enterprises with regard to international trade. It was found that there was no great difference. At European level in 1990, each of the two groups sent about 60% of their exports to Community countries. From 1988 to 1991, however, the growth of exports to these countries was much greater than that of exports to non-Community countries, for the small sectors as compared with the large sectors. This leads us to consider the "Europeanisation" of SMEs.

A further point is that SMEs export more than large enterprises to neighbouring countries. More than 70% of Irish exports go to a Community country, with the United Kingdom taking 27%. For micro and small enterprises the United Kingdom figures are 45% and 36% respectively. Belgian SMEs export mainly (61%) to neighbouring countries and in descending order of sales to France, the Netherlands, Germany, Luxembourg and the United Kingdom as shown in table 3. Reasons given by SME heads include a wish to gain experience before trying to win distant, less well known markets, ease of trading in countries which often have a familiar language and similar mentality to their own, unwillingness to risk change and fear of running up against obstructive regulations in countries which are not members of the Community.

The superiority of large enterprises over SMEs, as confirmed by the foregoing comparison (the share of exports in gross output in 1990 was slightly lower for the small sectors than the large sectors) is attributable to the sectors to which the SMEs belong (as can be seen from Table 2 the sectors where they are numerous are less export-oriented) but also to their inherent characteristics. These include mainly inadequate financial resources, lack of time and an internal structure which does not allow the enterprise to trade internationally. In addition, some SMEs do not export because their heads overestimate the problems involved or because the home market is sufficient for them. Table 4 illustrates the difficulties created for Belgian entrepreneurs by internationalisation.

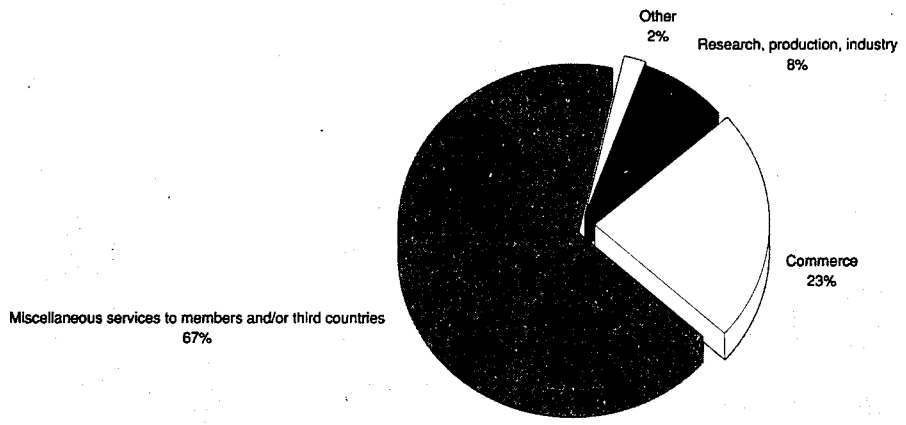
The second stage of internationalisation - cooperation with foreign enterprises - is of special interest for SMEs whose size often restricts their possibilities. Nevertheless, a European survey of transnational cooperation covering 5000 firms showed that large enterprises seem to be more active in this area than SMEs. The explanation again lies in the inherent characteristics of SMEs already mentioned and also in their wish to remain independent or their being satisfied with their present situation.

Those who decide to risk cooperation look by preference for a partner with a profile similar to their own particularly as regards sector, customers and size. In 1988, however, 45% of agreements in the biotechnology sector where cooperation is chiefly in R&D, linked SMEs with large enterprises. In most cases, collaboration is limited to two partners.

The preferred countries are in Northern Europe with Germany as favourite, followed by France, Belgium and the United Kingdom. The countries to the south suffer particularly from their remoteness, the weakness of their economies and lack of information about their markets.

Cooperation agreements mainly relate to sales but in some sectors they are concerned primarily with production and R&D. In Belgium they relate to production for 24% of SMEs, to commercial representation for 16%, to marketing for 15%, to distribution for 13%, to personnel for 12%, to R&D for 9% and to the provision of services for 7%. Cooperation is usually more formal and longer term in the case of production than in the case of sales and services.

Figure 5: Breakdown of EEIG in the EC according to main activity, 1991



Source: European Commission

Very little information is available about the licensing of foreign firms by SMEs. It may be noted, however, that as table 1 shows, Belgian owners have little enthusiasm for this arrangement. The reason given is that the laws on industrial and intellectual property, which still have gaps at both national and European level, do not afford adequate protection. This attitude is confirmed by a survey showing that only 6% of 240 industrial SMEs had granted licences abroad.

The information concerning the licensing of foreign firms must be interpreted with caution because many operations of this kind involve enterprises linked through subsidiaries.

Direct investment abroad is the prerogative of large enterprises. In the Netherlands, ten big multinationals share 40% of this activity. Smaller enterprises are not, however, standing still and are moving more and more in this direction, even faster than the large enterprises; still in the Netherlands, over the periods 1984-1987 and 1988-1990 direct investment abroad by smaller enterprises rose by 163% as compared with 110% for large enterprises.

63% of investment by small Netherlands enterprises went to Community countries from 1984 to 1987 and 67% from 1988 to 1990, as compared with 42% and 48% respectively for all enterprises. In Italy, many (50%) SMEs with subsidiaries abroad invested in the developing countries in the same way as firms with over 2000 employees. Enterprises with 500 to 2000 employees tend more towards the developed countries.

Owners of Belgian SMEs may prefer the setting up of a subsidiary abroad to the other forms of internationalisation for certain types of activity and more particularly for service activities, for which proximity to customers is important. It is indeed essential when the country of destination is a long way from Belgium. Some of them, however, consider the establishment of a production unit abroad to be very risky because of the sums involved and the unreliability of market studies; they intend to give first consideration to collaboration with an importer.

An article reporting interviews with them indicates that heads of French parent SMEs with a subsidiary abroad experience difficulties with managing from a distance. They quote obstacles resulting from differences of language, currency, tax and welfare legislation and culture. They stress problems arising from the need to have adequate local management and an effective system for monitoring management, as parent SMEs cannot guide their subsidiaries effectively for lack of time and resources. It is often very difficult to find men and women who can be relied on and are competent, perfectly acquainted with the country and capable of adapting to the methods and culture of a French group. Most enterprises take on nationals in preference to expatriates who are generally not as close to the culture and market of the country; they do so by referring to local recruitment agencies. Personal contacts with the local management are of special importance; they supplement the information provided by the management system and give a better picture of the subsidiary's position.

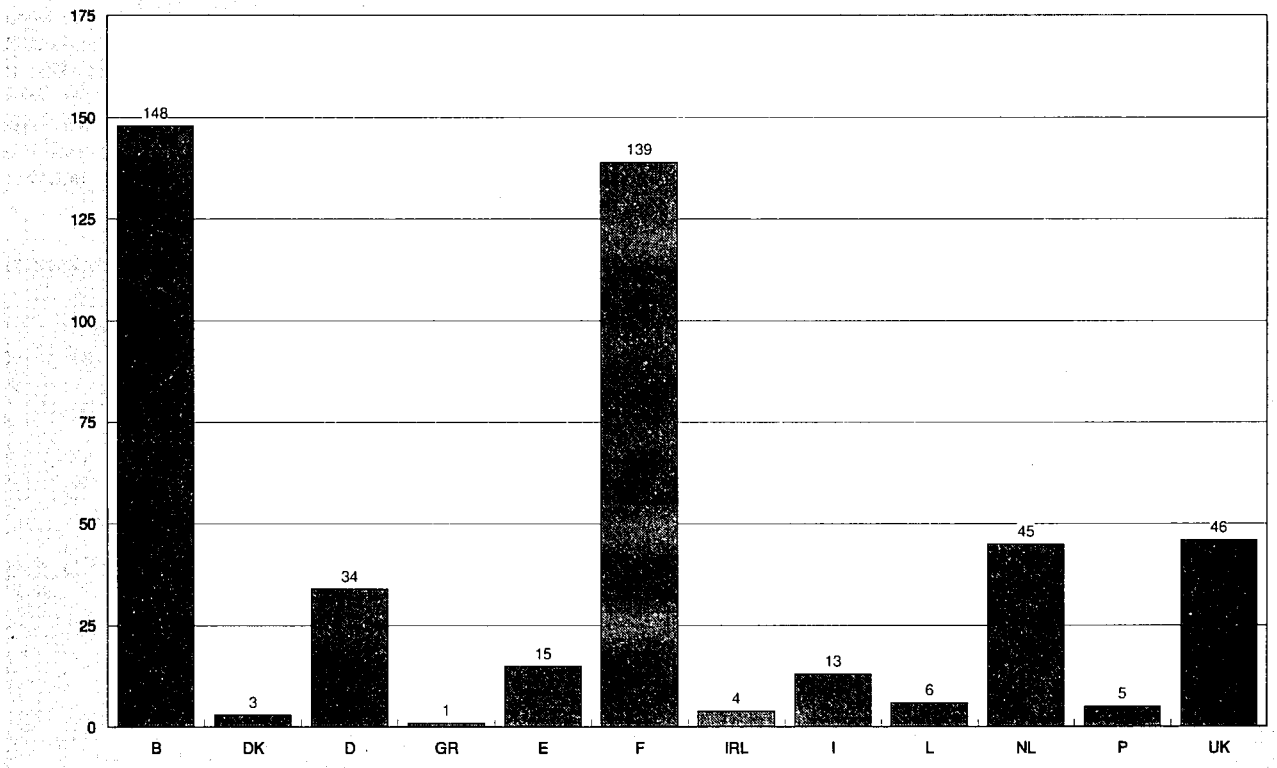
The EEIG

Formed in 1985, by regulation 2137/85, the EEIG is so far the only instrument operating under Community law which provides a legal framework geared to transnational cooperation between enterprises in different Member States.

The EEIG formula meets the special needs and circumstances of SMEs by:

- preserving the economic independence of the partners. Outside the actual arrangements for cooperation, each retains control of its economic activity and development strategy;
- ensuring great flexibility in the organisation and internal working of the EEIG. The contract of association allows the members considerable freedom to fix its internal regulations. A contribution to seed capital is optional. Members can contribute in cash, kind or know-how or by other forms of funding as they choose. Matters not covered by the EEC Regulation or by the contract are governed by the law of the Member State where the EEIG has its headquarters;

Figure 6: Breakdown of EEIGs by Member State, September 1993



Source: European Commission

- allowing a wide measure of freedom for the proposed activity. Cooperation can be developed in all sectors of the economy;
- providing a structure open to many other partners: SMEs' craft workers, tradesmen, public or private enterprises, research bodies and possibly government agencies. Cooperation can therefore be horizontal (associating partners from the same sector of activity to exchange know-how, for example) or vertical (pooling of complementary resources);
- offsetting the possible handicap of small size of the partners in the case of SMEs by cooperation on a group basis.

The findings of a survey of 194 EEIGs conducted in June 1991 by the Commission of the European Communities show that this formula meets SMEs' expectations. Several interesting results came to light:

- the members of EEIGs are predominantly SMEs (mostly medium-sized) but the public sector and large enterprises participate in many groupings;
- the service sectors, and in particular commerce, predominate, followed by the industrial sector (see figure 4);
- the members of each grouping have similar profiles: in most EEIGs they engage in the same type of professional activity;
- in over half of the cases, members of the grouping were collaborating before the EEIG was formed. Their collaboration had usually been informal in the form of an exchange of services or follow-up in professional relations and the partners had decided to make it official;
- the grouping is used predominantly to provide various services for its own members and/or non-members. Commerce stands second among the activities entrusted to EEIGs followed by research and production (see figure 5).

Notifications of formation show that by early September 1993, there were 459 EEIGs distributed among Member States as shown in figure 6. As they are a new instrument, this number indicates that enterprises are definitely interested in the EEIG thus confirming its ability to meet the cooperation needs of SMEs.

The indirect effects of internationalisation on SMEs

Internationalisation concerns not only enterprises which are actively involved but others, including sub-contractors. For all enterprises continuing to operate in the home market, the entry of foreign enterprises increases the range of goods and services on offer, with a consequent increase in competition and lowering of prices, often combined with better quality. This is to the good on the supply side but sales are likely to be adversely affected. In addition, SMEs are a favourite target for enterprises wishing to acquire a subsidiary abroad. Belgian, German and Italian entrepreneurs expect a fresh burst of takeovers with the completion of the Single Market. Some are even looking actively for possible buyers both within and outside the Community where European enterprises are highly prized.

Sub-contractors who make products for inclusion in goods or services sold abroad by their clients are forced to adapt to current standards in the countries of destination. In addition, when a direct investment abroad is accompanied by the shutdown of a domestic enterprise, that is in case of "relocation", sub-contractors have to face stronger competition from their "abandoned" colleagues who survive the departure of their customer. Lastly, the increased competition met by customers is also detrimental to sub-contractors; clients are forced to rationalise their production, become very demanding towards their suppliers and often try to cut down their numbers. Suppliers then have to improve performance, particularly as regards prices, quality and delivery times and sometimes even have to change their strategy, for example by ceasing to be direct sub-contractors and becoming indirect sub-contractors (making only part of the product originally supplied). The secondary effects on sub-contractors affect SMEs in particular, as the majority of sub-contractors are SMEs.

Organisations and bodies available to assist SMEs with internationalisation

The SMEs are not left on their own to face internationalisation. At both Community and national level their are public and private sources of assistance. At Community level, enterprises can apply, in accordance with their requirements, to various services managed by the Commission of the European Communities:

- the Euro Info Centres or EICs, operating within 211 host organisations and well-established at local level in the 12 Member States; they are supplemented by Correspondence Centres located in the countries of Central and Eastern Europe, EFTA members and the countries round the Mediterranean and are linked electronically with each other and with the Commission; they provide SMEs with assistance, information and advice relating to matters within the Community's competence.
- the Business Cooperation Network, or BC-NET, is a computerised network covering a number of third countries in addition to the Community; it brings together 600 company consultants, whose function is to identify quickly and confidentially, SMEs suitable for cooperation on the basis of proposals submitted by enterprises;
- the Bureau de rapprochement des entreprises (BRE), is a service which collects offers of cooperation from SMEs, passes them on to correspondents in 50 countries who publish them, and briefs potential partners.

In addition to these services, there are other Community instruments designed to support the international activity of SMEs. They include:

- Europartenariat which is a programme to promote contacts between enterprises in regions which are underdeveloped or in industrial decline and other regions;
- Euromanagement, which is a programme in three parts; the first is the training of SME executives and heads for the Single Market, the second is concerned with standardisation, certification, quality and safety at workplaces and the third is concerned with "technological research and development" (TRD);
- the special programmes of the 3rd and 4th outline TRD programmes, such as BRITE/EURAM or ESPRIT, which offer opportunities to SMEs wishing to collaborate at European level with large enterprises and research institutes;
- the VALUE and SPRINT programmes, concerned respectively with encouraging innovation and technology transfers and making profitable use of the results of Community research, by helping SMEs with funds to acquire new technologies developed in the Community.

57% of Belgian SMEs wishing to extend their activities to other countries apply to information and consultancy agencies located in Belgium. 34% turn to organisations located abroad. Professional and interprofessional organisations are among those most frequently consulted and their assistance is greatly appreciated. The EICs play an important part in establishing relations with Central and Eastern Europe. Through them and with the support of the Belgian government, contacts have been established with firms in Poland, former Czechoslovakia, Hungary, Rumania, Bulgaria and the former USSR.

The survey of cooperation mentioned earlier showed that in most Member States very few enterprises make use of public or private initiatives to promote internationalisation and, except in Denmark, are even aware of their existence. The Community instruments, including Europartenariat, BRITE/EURAM, ESPRIT and SPRINT are the most appreciated, and attract the majority of enterprises which generally take the view that such types of action should be extended at both Community and national level.

CONCLUSION

The presence of SMEs on the international economic scene is a reality which is daily gaining ground faster than the reality of the large enterprises. This is happening mainly through exports, most often to neighbouring countries. But SMEs are also active in other areas including direct investment abroad, principally to Community countries. The extension of SMEs' activities to other countries is held back rather by their intrinsic characteristics than by external obstacles. Some of these difficulties can however be overcome through a legally established instrument for cooperation such as the EEIG, thanks to the new opportunities it provides for users. Internationalisation is also affecting SMEs which still operate on the home market particularly in the case of sub-contractors of international companies. Lastly, for sources of assistance, enterprises refer mainly to professional organisations but favour the development of national and Community public initiatives.

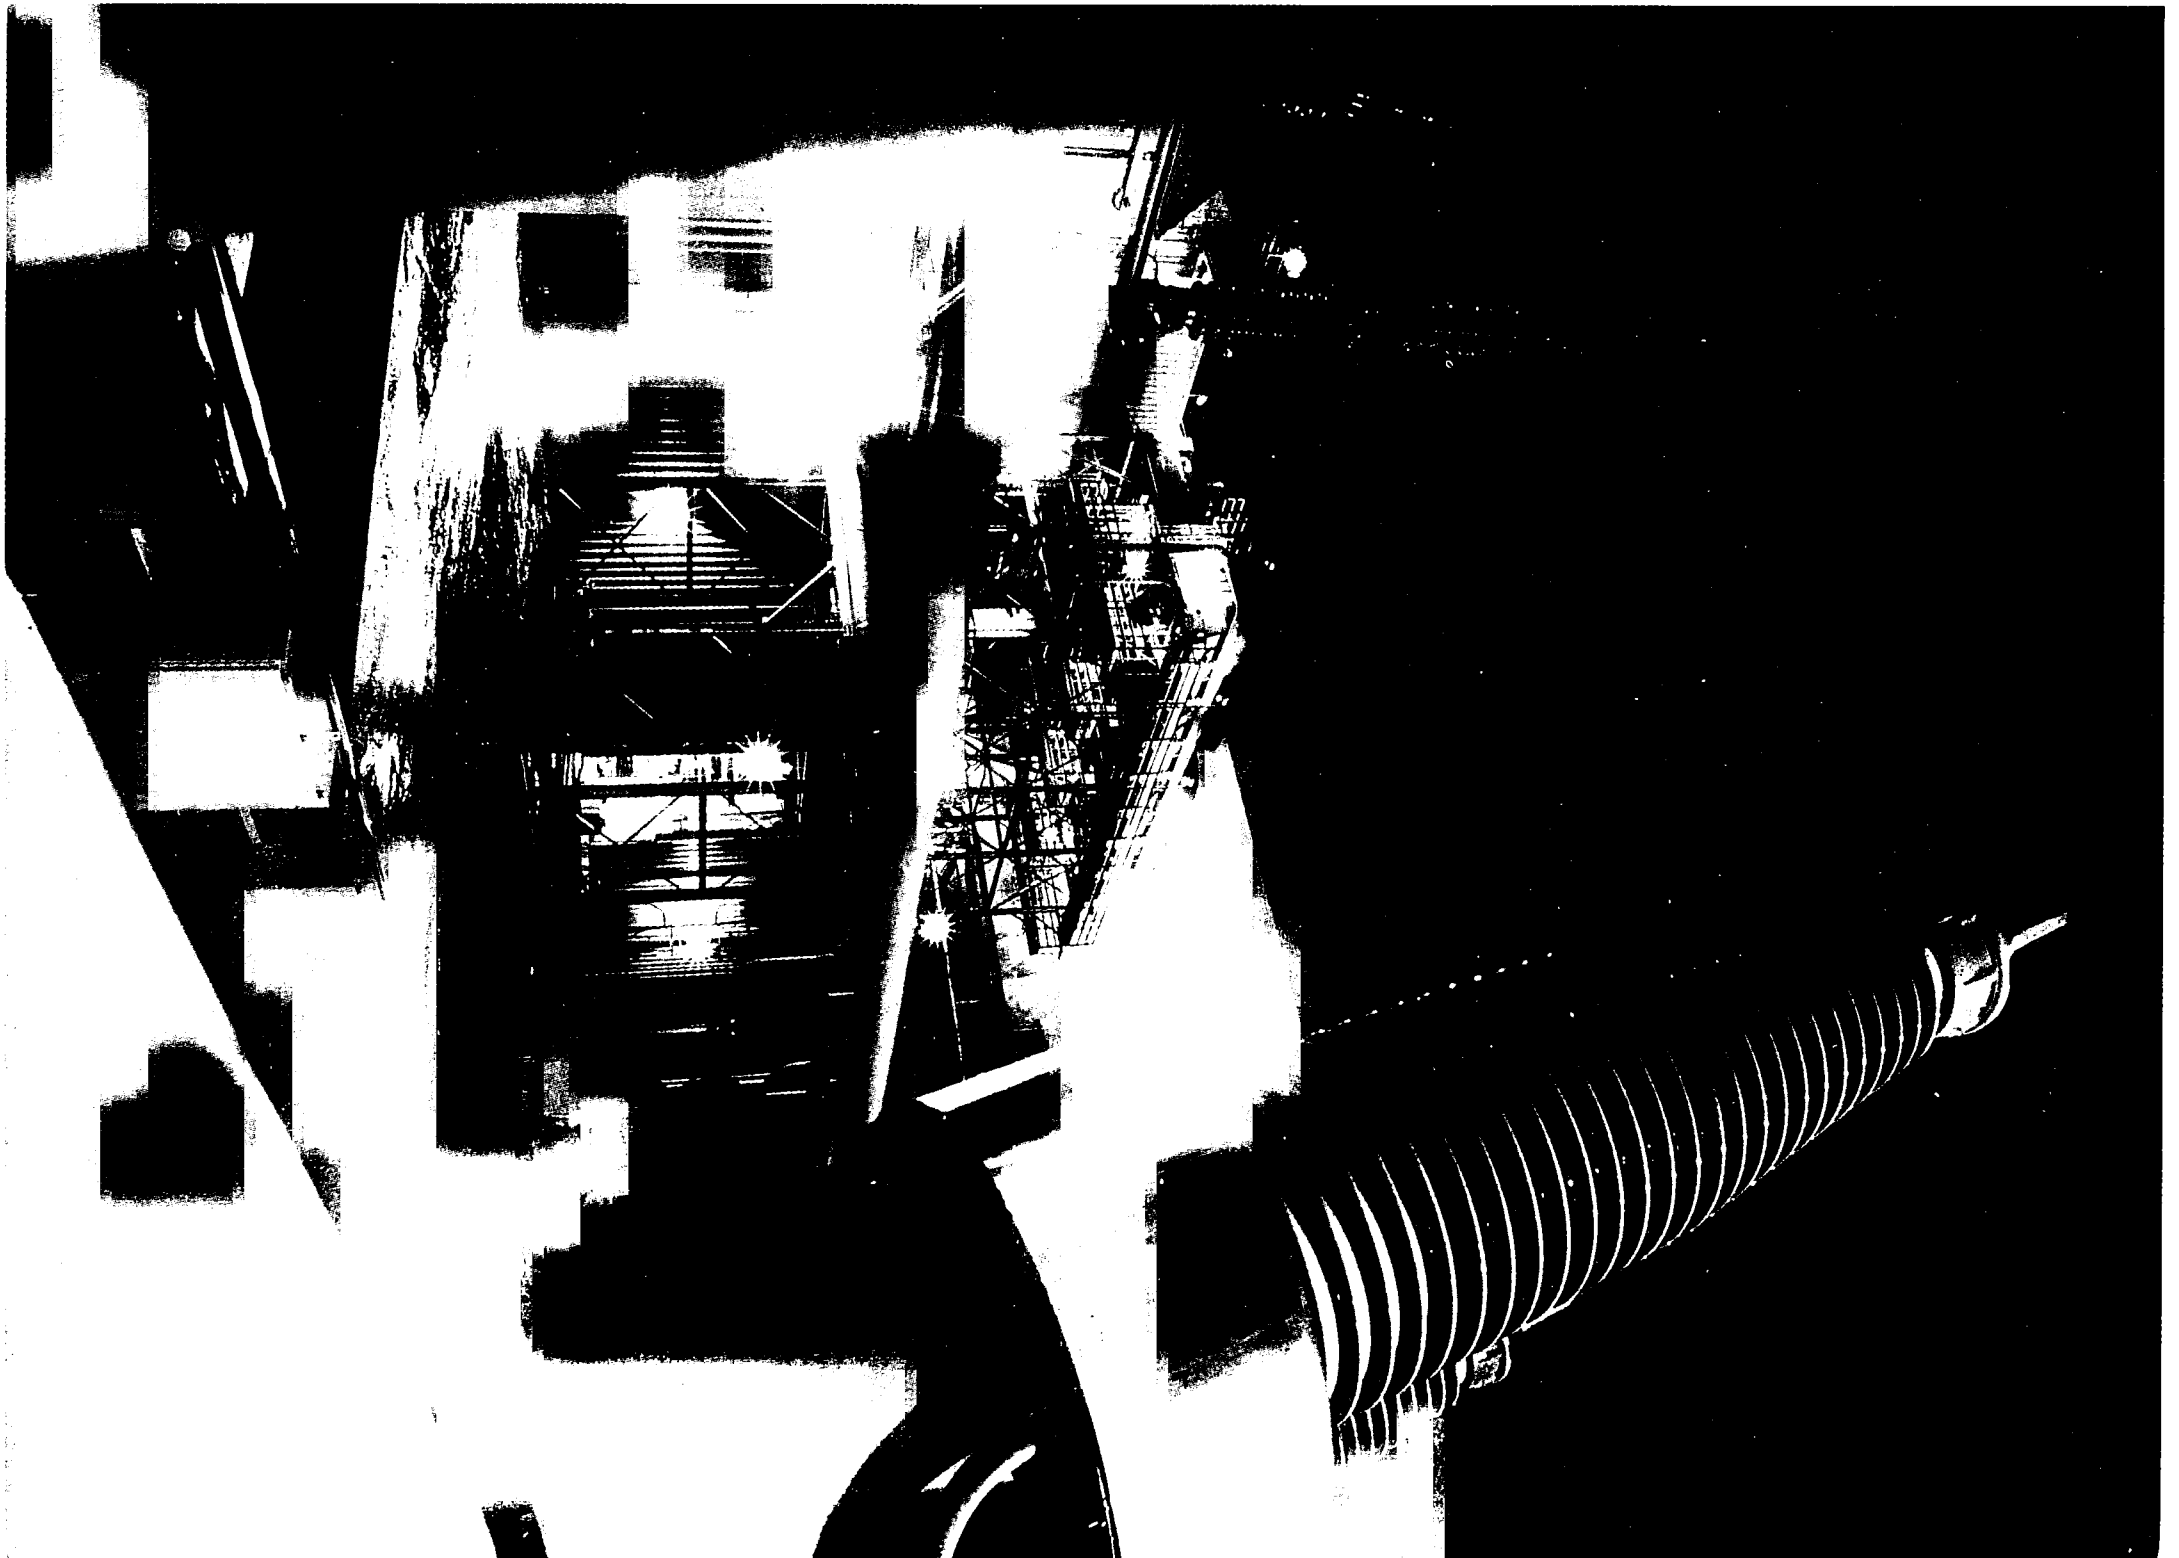
Reviews and Forecasts: Industrial Sectors



Overview

NACE 11, 12, 13, 14, 15, 16

In 1992, primary energy consumption in the EC was about 1.2 billion tonnes of oil equivalent (toe), which corresponds to 15% of total world energy consumption. On the supply side, the EC contributed about 8% of total world primary energy production. EC primary energy production is dominated by the United Kingdom which accounts for 32% of the total. The EC is a net importer of energy; in 1992 net imports amounted to 612 million toe.
The primary energy mix is still dominated by oil, which accounts for almost 45% of primary energy demand. Natural gas consumption is increasing fast. By the year 2000, gas is expected to account for about 23% of EC primary energy requirements, overtaking coal to become the second largest energy source in the demand mix.

INDUSTRY PROFILE

Description of the sector

The energy industry is composed of the following activities: extraction and briqueting of solid fuels (NACE 11); coke ovens (NACE 12); extraction of crude oil and natural gas (NACE 13); refining and distribution of oil products (NACE 14); the nuclear industry (NACE 15); and the production and distribution of electricity, gas, steam and hot water (NACE 16).

In addition, a description of the renewable energy industry is given in this chapter (not defined by NACE). Renewable energy still has a relatively minor role in energy supply, but should grow in importance as their environmental benefits are promoted at EC and national levels.

Throughout the discussions of the various energy industry sectors contained in this and following chapters, we have followed normal industry practice in ensuring comparability between different energy sources by the use of common units of measure, the toe.

It is also important at this stage to define the difference between primary energy consumption and final energy consumption, both of which are referred to in the following chapters. Primary energy consumption refers to the sum of all energies either used by consumers or used as an input to the production of other energy forms. For example, the production of electricity requires the input of such fuels as coal, natural gas and heavy fuel oil. Final energy consumption refers to the sum of all energy used by consumers, and thus excludes transformation and distribution losses.

Energy intensity is defined as the amount of primary energy consumed per unit of gross domestic product (GDP). Energy intensities vary from country to country and over time depending on the economic background, national energy policies and sectoral and industrial structures.

Recent trends

Between 1985 and 1992, primary energy consumption increased by 16.4%: an average annual increase of 2.4%. Over the same period, primary energy production increased by only 5.1%. These two factors resulted in an increase in EC net imports of energy of 34% between 1985 and 1992.

During the period 1973 to 1985, energy intensity decreased by more than 20%. The EC objective was to reduce energy intensity by a further 20% by 1995. In 1992, the energy intensity of the EC was 9% below the 1985 level, less than half way towards the target.

Overall, energy intensity in the EC showed a had a negative development from 1985 to through 1990. Intensities began increasing again in 1991 for most Member States. The largest increase indicated by the 1991 data occured in Germany; however, since it contains data for the former East Germany for the first time, it is not comparible to previous years.

International comparison

The EC is a relatively large consumer of energy. Primary energy consumption in the EC in 1992 was just under 1.2 billion toe (see Table 7): almost 15% of total world primary energy consumption. The USA, the largest energy consumer in the world, accounted for over 24% of total world primary energy consumption. The only region other than the USA that consumed more energy than the EC was the former Soviet Union with nearly 17% of total world consumption.

In demographic terms, the EC consumes roughly 3.5 toe per capita. This corresponds to that of Japan, where energy consumption was a little over 5% of world consumption. The USA has the highest ratio at 7.9 toe per capita per year, the former USSR consumed around 4.7 toe per capita per year.

The proportion of total primary energy requirements accounted for by oil in the EC was 43.9% in 1992. In Japan, 56.2% of primary energy consumption was derived from oil. The proportion of oil consumed in the USA was slightly less than the EC at 39.5%.

Natural gas, currently undergoing rapid expansion in the EC, still occupies a relatively low proportion of EC primary energy consumption in an international perspective. In the EC, natural gas accounted for 19.3%, compared to 24.9% in the USA. The USSR, home to the largest proven gas reserves in the world, consumed a massive 42.2% of total primary energy consumption as natural gas. In Japan, natural gas took a 10.3% share in primary energy consumption.

In the EC, 1992 coal consumption had a 21.5% share of primary energy consumption. The former USSR consumed a similar percentage. The USA, however, had a coal share in primary energy consumption of 24.2%, reflecting the greater emphasis of coal in the power generating sector. Japan was less coal intensive, with coal accounting for 17.2% of total energy consumption. China, on the other hand, as one of the world's major producers, is extremely dependent on coal which contributes a huge 76.7% to primary energy consumption, though inefficiency in combustion processes is a major factor contributing to this high percentage.

Hydroelectric power in the EC took a relatively low share in the fuel mix. At 3.4% of total primary energy consumption, hydroelectric power had a lower share than the USA (3.6%), the former Soviet Union (4.2%) and Japan (4.8%). There is limited scope for expansion of hydroelectric power in Europe as the most attractive sites have already been developed and environmental concerns are likely to inhibit further large-scale projects.

The EC contributed 7.8% to total world primary energy production. The country contributing the largest share of production was the former USSR with 22.2%. The USA followed close behind with 19.4%. EC primary energy production was dominated by the United Kingdom which accounted for around 32% of the total.

In global terms, the EC is not a significant energy producer and has been in decline since 1987. It is, however, a significant consumer. This resulted in the EC being 48% dependent on imports for its energy supplies. Oil production, 80% of which came from the United Kingdom, was modest in an international context. EC oil production was 27% of that of the USA and only 4% of total world oil production.

The EC was a rather more significant producer of natural gas with over 7% of total world natural gas production (74% of which came from the Netherlands and the United Kingdom). The former Soviet Union was the world's largest producer of natural gas; Soviet natural gas production in 1989 came to over 5 times that of the EC.

Coal production in the EC (45% of which came from former West Germany and the United Kingdom in 1989) was around 170 million toe in 1992, less than a third of the output of the world's largest coal producer, the USA (closely followed by China).

Primary electricity production in the EC accounted for 17% of the world total. The USA accounted for over 20% of world primary electricity production. This was 4.9% of total US energy production. Japan on the other hand, with very small indigenous reserves of fossil fuels, had 73.5% of its total energy production as primary electricity.

Foreign trade

The European Community showed a deficit in the energy trade balance. Net imports were estimated at 617 million toe in 1991, or 51% of gross internal primary energy consumption.

EC energy imports have increased since 1988, this was due to a slight increase in energy prices and a renewed start up of economic activity. The Gulf War increased crude oil imports for EC refineries that were working close to capacity. This in turn led to an increase in exports of refined oil products which explained the upturn in exports which took place in 1990.

In 1991, around 38% of extra-EC crude oil imports came from the Near or Middle East. Overall, since the end of 1987, extra-EC crude oil imports from OPEC countries have been increasing by 3% per year. The percentage of extra-EC imports coming from the former USSR and eastern Europe fell by 4.2% between 1989 and 1991.

MARKET FORCES

Demand

Energy demand by sector

Conservation and structural changes in the 1970s had a great impact on the industrial sector, particularly in energy intensive industries. Industrial energy consumption (including non-energy use) declined 21% between 1973 and 1985. By 1986 in the residential and commercial sector, energy consumption had increased almost 10% on 1973 levels despite improvements in the efficiency in end use equipment and in the use of insulation. Since then energy consumption has declined in the residential and commercial sector and in 1989 consumption was down to almost 1983 levels. In 1990, consumption increased slightly, though it remained at roughly the same share of final energy consumption. Energy use in the transport sector increased 24% between 1980 and 1988, an average annual increase of 2.7% despite improvements in vehicle fuel efficiency. Since then, energy consumption in the transport sector has increased at a rate 1.5% per year above this, reflecting large increases in the vehicle population.

As a result of these trends, the share of industry in EC final energy consumption declined from 32% in 1980 to 20% in 1988. Since then the share has remained fairly stable, and in 1992 was at 19%. The transport sector share in final energy consumption has overtaken industry, accounting for about 28% in 1991. The residential and commercial sector remains the largest energy user, accounting for 36% in 1991.

Energy demand by fuel type

Oil is still the dominant energy source in the EC, mainly because of continued strong growth in the transport sector where substitute fuels have yet to make a major impact. The share of oil in gross inland energy consumption has declined only slightly since 1985, standing at about 44% in 1992. The main shift away from oil took place in the early 1980s fol-

lowing the oil price shocks of the mid and late 1970s. The share of oil in primary energy consumption declined almost 9% between 1980 and 1985. The share of oil in the industrial energy demand mix has been declining more rapidly than that of the residential and commercial sector. In 1992, oil shares in final energy consumption for these sectors were 30% and 32%, respectively, while the transport sector was still nearly completely dependent on oil.

The contribution of natural gas to gross inland consumption has been steadily increasing. Over the last decade it increased its share of primary energy demand by 2%, rising to over 19% by 1992. The share of electricity has increased greatly over the decade from just over 6% in 1980 to almost 15% in 1992. The growing role of electricity in meeting end-use energy requirements was largely met by an increasing penetration of nuclear power in the early 1980s, which tailed off in the latter half of the decade as nuclear construction programmes were halted following increasing public concern over the perceived risk of accidents and nuclear waste disposal problems. Nuclear energy and hydropower accounted for around 44% of electricity generation in 1992.

In the EC industrial sector, fuel consumption in the 1980s saw a marked increase in the share of natural gas accompanied by the decline in the use of refined oil products. Residual fuel oil consumption has declined by almost a third over the last decade. In 1980, the share of petroleum products and natural gas in industrial final energy consumption were 37% and 21%, respectively. By 1985, the shares had evened up to roughly 24% each. In 1991, natural gas had gained the larger share with 30% of industrial final energy consumption, leaving oil products with just over 19%. Consumption of solid fuels has increased only slightly over the decade with a share of 19% in 1991. Electricity consumption has seen a high rate of growth: an average annual rate of increase over the decade of 1.8% (0.5% per year below the average annual growth of GDP).

Energy demand by region

There were regional differences in the consumption of fuel types. The region that was over 50% dependant on oil in 1992 was the southern EC region including the Members States of Greece, Spain, Italy and Portugal. The area least dependent on oil was the north-western region including the United Kingdom, the Netherlands, France, Germany and Belgium. These regional disparities in oil dependence are due to a number of factors such as: reliance on oil fired electricity generation, the size and age of the vehicle population, the penetration of oil used for space heating and process requirements and their associated efficiencies. Industry has tended to switch away from heavy fuel oil for its heating requirements over the past decade, so that this factor is becoming less significant.

Regional differences in the consumption of solid fuels can almost exclusively be explained by the share of solid fuels in the power generation sector. As a result of this, Denmark, Greece, Ireland, Germany (including the new Bundesländer) and the United Kingdom all have a significantly higher share of solid fuels in the fuel mix than the EC average. France, noticeably, has a very low coal dependence due to the small share of coal fired electricity generation in its nuclear dominated power sector. Italy, though it has no nuclear generation, relies more on natural gas and oil for power generation than solid fuels.

Supply and competition

EC primary energy production increased at a lower rate than consumption, resulting in greater net imports. Production increased by just over 5% between 1985 and 1992 to reach a total of 619 million toe.

The EC coal industry, facing foreign competition with far lower costs, tough environmental legislation increasing its own costs and moves by EC and national governments to reduce subsidies, has been in steady decline in recent years. Between 1985 and 1992, hard coal production declined by 17.7%. Solid fuel production as a whole increased slightly, due to the inclusion of the new Bundesländer in the statistics, pushing up lignite production which had declined by over 4% to 1990, but which in 1992 was 75% above its 1985 level across the whole of the EC.

Oil production, principally from the United Kingdom North Sea oil fields, declined by 20.5% between 1985 and 1992. This meant that the share of oil in total primary energy production declined from 26% in 1985 to 18.6% in 1992. Natural gas production, principally from the United Kingdom and the Netherlands, increased by 13.7% over the same period. This has resulted in a slight increase (to over 23% in 1992) in natural gas' share in primary energy production.

Primary electricity production, mainly due to nuclear power stations coming on-line towards the beginning of the period, increased its share in primary production from 24% in 1985 to almost 29% in 1992.

INDUSTRY STRUCTURE

Companies

The EC energy industry is still dominated by a small number of very large companies that are both state and privately owned. Some Member States have made significant moves towards

privatisation, deregulation and liberalisation of their energy markets allowing new opportunities for investment by non-traditional companies. For example, the independent power generation sector is a major growth area in which oil, gas and industrial companies are planning an important presence.

REGIONAL DISTRIBUTION

In the EC as a whole, energy intensity has declined by almost 9% over the 1985-1992 period. Examination of the regional contributions to this reduction in energy intensity reveals marked differences between Member States. Leading the way in energy intensity reductions were former West Germany, Denmark and the United Kingdom. In the Mediterranean countries, where there are less opportunities for efficiency gains in space heating (such as through improved insulation), energy efficiency gains have been less marked and intensities have, in some cases (Greece and Portugal), increased. What is apparent in all countries where improvements in energy intensity have been made is the recent slowdown in the rate of energy intensity decline that resulted from the easiest improvements being completed and lower energy prices that reduced the incentive to invest in more energy efficient technology.

ENVIRONMENT

The issue of global warming has been in the forefront in the public debate and in the environmental activities of the EC. As a first step in the preparation for the Rio de Janeiro conference on global warming the joint Energy and Environment Council decided in October 1990 to stabilise the Community's CO_2 emissions in the year 2000 at the 1990 level. No specific measures for achieving this target were adopted by the Council.

Following this, the Commission outlined in October 1991 an EC strategy to limit CO_2 emissions and to improve energy efficiency. The Commission believes that a CO_2 policy is needed and that such a policy would work out more efficiently if adopted on the EC level than adopted on the national level. A coordinated carbon tax policy will be critical avoid distortions in the internal market for energy as well as for trade within the EC. The Commission outlined three sets of measures to control CO_2 emissions: specific measures, including R&D programmes, sector measures and other types of regulatory and voluntary measures; fiscal measures; and complementary national programmes.

The fiscal measure suggested by the Commission is a tax on energy use corresponding to USD 10 per barrel. The carbon tax element of the total tax should not exceed 50%. The Commission was invited by the Council to present a formal tax proposal. In this proposal (submitted to the Council in May 1992), the Commission foresees that the new energy and carbon taxes will be national taxes levied on top of already existing energy taxes. The new tax policy should only be implemented if other members of the OECD adopt similar taxes or other measures having similar effects, following the principle of "conditionality". The proposal from the Commission foresees that energy intensive industries may obtain tax refunds if they are confronted with serious difficulties because of competition from non-OECD countries not having imposed carbon taxes or equivalent measures. These measures have still not been adopted by mid-1992, nor have any of the EC's major trading partners adopted reciprocal measures. It is, therefore, unlikely that such taxation will be adopted on an EC level before the mid-1990s, although some individual states, such as Denmark and the Netherlands have already imposed taxation based on the carbon content of energy sources.

REGULATIONS

In order to promote an integrated internal energy market, the Commission is pursuing two lines of action. On the one hand, the Commission is enforcing the existing EC legislation and treaty obligations, the free trade provisions of the EEC treaty in particular as well as competition and state aid provisions.

On the other hand, a strategy involving regulatory changes and new EC legislation started being seriously envisaged in the June 1987 Council. At that time, energy ministers asked the Commission to identify the remaining obstacles to the functioning of the internal market for energy and to make proposals for their progressive elimination before the end of 1992. The subsequent Commission report (COM(88)238) was followed by a first set of proposals which have been adopted by the Council and constitute what is referred to as Phase 1 of the creation of an internal market for energy. The measures concern only gas and electricity and are the June 1990 directive on price transparency for gas and electricity, the October 1990 directive on transit of electricity, and the May 1991 directive on natural gas transit.

The directive on price transparency provides for collection of information on electricity and natural gas prices for final consumers across the Member States. It is, first of all, a statistical instrument which allows comparisons of price levels. The two transit directives give access to the electricity and natural gas transmission grids for transport across a Member State on certain conditions.

Early in 1992, the Commission made another series of proposals for Phase 2 of the energy internal market. These proposals have not yet been adopted by the Council. They include three sets of measures: the liberalisation of electricity generation and the freedom to construct transmission lines for both gas and electricity; the unbundling of production, transmission and distribution activities for vertically integrated gas and electricity companies (unbundling is an accounting concept and does not require changes in the ownership structure); and the introduction of limited third party access to the gas and electricity networks. Eligible customers will be industrial companies whose annual electricity or natural gas consumption exceeds a specified threshold (100 gigawatt hours for electricity and 25 million m^3 for gas). Distribution companies with a market share above a threshold (3% in the case of electricity and 1% in the case of gas) will also have third party access to transmission grids.

The introduction of these Phase 2 proposals has been considerably delayed from the original timetable because of the debate arising from the potentially radical consequences for the structure of Europe's energy supply industries.

The historical improvement of energy efficiency in industry is characterised by several phases that are listed below.

First, there have been changes in the structure, technology and management of energy saving measures. Implementation took place with the advent of higher energy costs in the 1970s. These measures did not require large capital investments and can be termed a stage of rationalisation.

Second, investments were instigated by improvements in energy performance through design changes. These were made by the energy intensive industries, mainly because market prospects in the 1980s, which were mediocre at the turn of the decade, did not encourage them to make investments in capacity increases. Industry consolidated and centred on inward investment with a view towards reducing costs.

Third, investments were made in wide ranging projects that took into account energy efficiency, capacity increases, product quality improvements and the reduction of other operating costs.

Since the first of the oil crises in 1973, energy efficiency has been one of the principal elements of the EC's energy policy. The EC's commitment to energy efficiency has been evident in the many measures adopted by energy ministers since 1974 aimed at improving the rational use of energy. Most notable examples are the Joule Thermie and SAVE (Specific Actions on Vigorous Energy Efficiency) programmes. The effects of these policies, indicated by a tailing off of the decline in energy intensity, have been waning partly as a result of lower crude oil prices. The SAVE programme was designed to give new impetus to progress in energy efficiency.

SAVE consists of three elements. First, legal and administrative measures are aimed at creating a more positive environment for energy saving. The legal aspects take the form of a single directive encompassing those measures without bearing on the internal energy market. A large measure of freedom is left for Member States to implement the directive with developments being monitored by the EC, as under the principles of subsidiarity. Second, a support programme is available to assist in expanding or creating an energy saving infrastructure so as to best utilise Member States' reserves of technical expertise.

Third, a network designed to disseminate information and coordinate activities on a community level concerning energy efficiency activities is also available.

The Thermie programme, designed to promote new and innovative energy technology, was approved by the Council of Ministers in 1990 and will run for 5 years with an estimated total budget of 700 million ECU. Thermie operates in four areas: the rational use of energy in industry, buildings, transport and the energy industry; renewable energy sources (solar, biomass, waste and wind); solid fuels (combustion and waste); and hydrocarbons (safety and environmental protection, exploration and production).

OUTLOOK

In the EC as a whole, gross inland consumption should grow at a rate increasingly below that of GDP as a result of energy efficiency improvements. Total gross inland primary energy consumption is expected to increase by 19% between 1990 and 2005 on this basis. Energy intensity will decrease by just over 20% on 1985 levels by 2005 on these predictions, though increased efforts in conservation on a Member State level and the success of the SAVE programme may speed up this decline.

The future primary energy mix will be characterised by the continued dominance of oil, with its share remaining at over 40% in 2005. This will predominantly be a result of increasing fuel demand from the transport sector. Moderate oil prices in the short term will reduce the incentive for fuel switching away from oil. Demand for oil will be particularly strong in the lower income Member States as stronger economic growth feeds through into energy demand.

Natural gas consumption will increase at the fastest rate of all fuels, at over 1.5% above the annual rate of growth of GDP in the short term to 1% above in the start of the next century. This will result in natural gas occupying the second largest share in the fuel mix, replacing coal in the second half of the 1990s. In 2005, natural gas will have a share of over 22%, 6% more than in 1990. This rapid increase reflects the growing attractiveness of this fuel in terms of environmental and economic considerations. Nuclear power units will be coming on-line in France and the United Kingdom, leading to an expected increase in nuclear electricity production, although all other EC States have frozen their nuclear programme. Renewable energies are expected to triple their share though their contribution in absolute terms will remain modest.

In light of increasing demand and the inevitable natural decline in the resource base, prospects for EC energy production are less favourable. Production costs are relatively expensive compared to other regions of the world, especially for hard coal. As a result, hard coal production levels will decline appreciably to a level which will be primarily determined by the availability of state aid and other policy measures. Oil and gas production from many existing fields may be depleted in 10 to 15 years time, but production from new fields should make some contribution to offset these losses. Consumption will still outpace production, however, and imports will increase as a result. Import dependency in 2005 is likely to increase by around 15% compared to 1990 levels.

In the industrial sector, final energy consumption is forecast to increase at an average annual growth rate of 0.8%. This is 0.4% per year below the annual growth rate of total final energy consumption in the EC. As a result of this, by 2005, the industrial share of total final energy consumption is expected to reduce by 2%.

In the long term, growth in industrial energy demand is forecast to be virtually stagnant. This will result from structural changes within the sector (the industrial base is shifting away from the energy intensive industries towards less intensive industries such as electronics), as well as from further efficiency gains. Energy efficiency measures will occur through both price stimulated behavioural changes and through policy measures taken at a national and EC level.

Solid fuels
NACE 11

Solid fuels accounted for 21.5% of gross EC inland energy consumption and 28.2% of EC primary energy production in 1992. Back in 1980, the share held by solid fuels of primary energy production was about 40%. The decline since then has been wholly attributable to hard coal, while the contribution of lignite has been stable until 1991, when the addition of former Eastern Germany caused lignite output to increase by more than 90%. In terms of contribution to total EC thermal electricity, lignite produced in 1991 about 35% of that produced by hard coal.

INDUSTRY PROFILE

Description of the sector

NACE 11 covers not only hard coal (NACE 111) but also brown coal or lignite (NACE 112). Solid fuels or "coals" are usually classified according to their rank in terms of their degree of maturity. This ranges from peat, the lowest rank, to lignite, bituminous coal and finally hard coal, the highest rank. Although reference will be made to the total contribution of solid fuels to the EC energy balance, the emphasis in the following pages will be on hard coal.

Recent trends

In 1992, indigenous production of hard coal satisfied 57.8% of EC hard coal consumption, well down from 80.5% a decade earlier. Total EC output amounted to 183.4 million tonnes in 1992, 28.6% lower than the 256.8 million tonnes produced in 1982. The three largest coal-producing countries, the United Kingdom, Germany and Spain, together accounted for 94.6% of total output. From 1983 to 1992, hard coal production in the EC declined by 25.1%; over the same period, total imports increased by some 70%. Costs of domestic production have diverged from the international price of coal which has fallen in real terms in recent years. The strategy of coal producing Member States has been to reduce capacity.

International comparison

EC hard coal output has fallen faster than EC hard coal consumption, creating an ever growing need for extra-EC imports. The EC ranks with Japan as one of the two foremost importers of hard coal. The drastic reduction in European production since the 1960s was due to competition from imported coal and, to a lesser extent, to competitive pressure from cheap hydrocarbons since 1986. Indeed, because of unfavourable geological conditions, which among other effects means that European coal is mostly produced from deep underground mines rather then open-cast mines, European coal is expensive to produce and, over the years, its competitive position has grown ever weaker. Less than 10% of European coal is extracted from surface mines, compared to 50% in Australia, 60% in the USA and 85% in Canada. German production costs are particularly high with hard coal deposits at an average depth of 900m.

High production costs affect the competitive position of European coal against imports from abroad. This was exacerbated by the depreciation of the USD compared to EC currencies in the late 1980s which rendered imported coal even cheaper in EC currencies.

The financial losses due to growing competition from imported coal and other sources of energy have forced the European coal industry to rationalise, closing the most uneconomic mines, reducing the work force and increasing productivity. The number of underground mines in the EC fell from 504 in 1982 to 226 in 1992.

Foreign trade

Indigenous coal production accounted for 58% of gross coal consumption in 1992, with the remainder being covered by imports and stocks. Complete freedom in the movement of coal between Member States is ensured by the European Coal and Steel Community (ECSC) Treaty. However, between 1980 and 1992, intra-EC trade fell from 17.2 to 4.4 million tonnes, mainly due to the deterioration in the price competitiveness of EC coal versus coal originating from third countries. Extra-EC trade has increased from 79.5 million tonnes in 1980 to 136.6 million tonnes in 1992.

The USA supplies the greatest volume of foreign imports to the EC, providing 46.9 million tonnes, 34.4% of total extra-EC imports in 1992. Imports from South Africa and Australia accounted for 20.8% and 15.6% respectively. The remaining 29.3% was made up by largely of imports from Colombia, Poland, the former USSR, Canada and China.

MARKET FORCES

Demand

By far the greatest consumer of solid fuels is thermal power generation which, in 1992, accounted for 66% (hard coal) and for 77% (lignite) of consumption, respectively. The volume of lignite used for power generation in the EC increased by 45% between 1990 and 1991 due to the inclusion of the new German Länder. The second largest market for solid fuels is for the production of coke (90% of which is used by the steel industry) in coking plants. The third largest market is the industrial sector.

New and more efficient methods of coal combustion, notably fluidised bed combustion and integrated combined cycle generation (ICCG), are finding a market in the power generation sector. During the period 1985-1992, hard coal consumption by power stations increased in the EC by about 11%, whereas coking plants reduced their hard coal consumption by about 23% during the same period. In addition to declining steel production, development of electric arc furnace (EAF) based steelworks and technological improvements contributed to the reduction in coke consumption and, therefore, in coal consumption in coke manufacturing. EAF based steelworks took a significant share of the European market of low-grade long products, recycling significant quantities of scrap. Estimates by the ECSC suggest that a third of the European gross steel production will come from EAF based steelworks in 1992. This production method does not require coke. Technological improvements aimed at reducing production costs resulted in particular in a reduction in specific coke consumption per tonne of pig iron production in blast furnaces. The major technical change has been the wider use of pulverised coal injection (PCI) in blast furnaces, thereby reducing specific coke consumption: as a result of the PCI technology, there has been a partial substitution of coke by coal in the production of steel. The full potential for use of PCI in Europe has not yet been realised and there is, therefore, scope for further reduction in coke consumption.

The use of hard coal in the industrial sector (which excludes power stations and coking plants) has increased steadily from 16.9 million tonnes in 1980 to 24.7 million tonnes in 1992. The industrial sector includes many small and medium-sized consumers from various industries with varying energy requirements such as cement, chemicals, food, and engineering (for example motive power, high-temperature heat and low-temperature heat). Following the second oil crisis, which demonstrated the need of the EC to reduce its dependence on imported oil and gas as well as to diversify energy sources, there was an upturn in industrial coal consumption. To some

extent, this upturn was prompted by government incentives that were offered to companies to encourage them to switch from oil and gas to coal and also by programmes offered by European coal producers to encourage conversion to coal.

Nonetheless, growth in coal use by the industrial sector was relatively slow and limited to a few countries. An exception was the cement industry, where coal maintains a clear-cut price advantage over other energy sources even without government incentives. Given that coal installations carry a higher capital cost than oil or gas installations, industry will switch from oil and gas to coal only if it expects that the differential of the fuel prices will become sufficiently large. This criterion is reflected in the observation that since the oil price collapse of 1986, conversion from oil and gas to coal has virtually disappeared.

The remaining sector in which significant quantities of hard coal are consumed is the domestic and commercial sector which includes households, services and administrative bodies. Solid fuel consumed in this sector is used almost exclusively for space heating, and its consumption is decreasing. Throughout the EC, environmental concern is expected to leave solid fuels losing ground to natural gas.

As for lignite, because of its low calorific value, transport over long distances is uneconomic. Thus, most lignite is mined and consumed on-site or nearby in power stations or briqueting plants. In 1992, 77% of total lignite was burnt in power stations, while the remainder was used to manufacture briquettes and for the preparation of pulverised lignite for use in the industrial market.

Supply and competition

Coal is the most abundant fossil fuel in the world and within the EC. European proven hard coal reserves are estimated to have stood at 29 billion tonnes at the end of 1992. At current rates of production, this means that hard coal reserves would last about 160 years. France, Germany and the United Kingdom are estimated to account for 93% of Europe's hard coal reserves, some 82% of which lies in Germany.

European reserves of sub-bituminous coal and lignite are believed to have stood at about 68 billion tonnes. Some 83% of these reserves were in Germany. Europe has 13% of world reserves of sub-bituminous coal and lignite. Most lignite mined in the EC is extracted by surface or "open cast" methods, which allow higher productivity than underground mining and yield a fuel that is competitive with other fuels used for electricity generation.

Although the EC is reasonably well-endowed with coal, the majority of remaining reserves are deep deposits that require working at very great depths, sometimes in excess of 1 000 metres with heavy-duty, sophisticated equipment, both for technical and safety reasons. This has led to high production costs and has undermined the financial situation of the coal production industry.

Production process

During the 1980s, mine closures and general restructuring saw the number of workers employed in the extraction of hard coal reduced by more than half. British Coal accounted for most of the decrease. However, the same trend exists in the other producing countries: Belgium coal mining ceased at the end of 1992.

Generally, the marginally least productive mine is the mine that is closed. This has lead to a significant increase in productivity in the EC coal mining industry. During the 1985-1992 period, productivity increased substantially, posting a 58% increase in output per man-hour underground in the EC. Capital expenditure over the past decade has concentrated on developing and implementing the use of new coal mining technology, increasing the share of production held by surface mines, the exploitation of additional reserves, and the closing of uneconomic pits.

Research and development

Investment in the EC coal industry has fallen from 1.0 billion ECU in 1990 to an estimated 0.7 billion ECU in 1993. This has been mainly due to the reduction in the overall size of the industry. As a result the level of investment per unit of production has fallen 32% between 1990 and 1993. Investment

has been high in areas of health and safety concerns. Two key areas of technical research have been in mining technology and product upgrading.

Research in mining technology is concerned with improvement of roadway support techniques (particularly in light of ever greater working depths), monitoring of ventilation, automatic steering of mining machines, and more efficient and safer transport systems for both personnel and materials. Research is also being made into remote control, data processing and modern communication systems, to examine whether and how they can contribute to increased safety, improved working conditions and more efficient mining operations.

Research into product upgrading concerns efficiency and environmental considerations of coal preparation, handling and coking. Both fundamental and applied research is being carried out by mining institutes, universities and laboratories, often on an international level, with ECSC financial support amounting to some 60% of total costs.

After the first oil crisis, in 1974, interest grew in the conversion of hard coal and lignite into other materials as a way of reducing dependence on imported hydrocarbons. As a result, several pilot and demonstration programmes were launched by the EC into:

- gasification and liquefaction of solid fuels (including underground gasification);
- substitution of hydrocarbons by solid fuels with fluidised bed combustion, coal-liquid mixtures and combined cycles as key areas of research;
- utilisation of solid fuels within the framework of the EC JOULE 2 R&D programme into non-nuclear energy and rational use of energy which took over from Joule in 1992;
- energy production from fossil fuels based on advanced technologies, notably combined cycles, within the recent "Framework programme" (1990-94); and
- new and improved clean combustion methods for solid fuels such as fluidised bed combustion, underground coal gasification and use and treatment or enhancement of wastes arising as a result of the use of solid fuels, all within the new demonstration "Thermie" Programme (European Technologies for Energy Management) which was proposed by the Commission to run from 1990-94 and has since been adopted.

INDUSTRY STRUCTURE

Companies

In Belgium, the two remaining mines operated by Kempense Steenkolenmijnen, (a public company in which the state has a majority holding) were closed down in 1992. The central fuel buying agency for the Belgian electric utilities is the Pool des Calories.

Most coal imported by Denmark is consumed by the two Danish power companies, Elsam and Elkraft, which buy coal directly on international markets.

The bulk of French coal production is the responsibility of the nationalised company, Charbonnages de France (CdF). A few small mines are operated by Electricité de France or are privately held. The Technical Association for Coal Imports (ATIC) holds a monopoly over coal imports.

Ruhrkohle, the major shareholder in which is VEBA, is the largest of Germany's coal producers controlling the coal activities of the companies EBV, Sophia Jacoba and Auguste Victoria. Of the others, Reinbraun is owned by the German utility RWE, and Saarbegwerke, is owned 74% by the Federal state and 26% by the German Land of Saarland. The other (small) companies are completely privately owned.

The major producer of lignite in Greece is the publicly-owned Public Power Corporation (PPC). Additionally, there are some small privately-owned mines in northern Greece. Greek lignite is burned almost exclusively in PPC's power plants.

In Ireland, coal mined by the privately-held company Arigna Coelieris is burned in a 15 megawatt (MW) power station that is owned by the Electricity Supply Board.

Italy's modest lignite output is found in Tuscany and Umbria. There is also sub-bituminous coal production in Sardinia. Coal imports are the responsibility of ENEL, ENI and Finsider, the steel company.

Coal is produced in Portugal at only one mine. Most of this coal is burned in a power plant belonging to the state-owned power company, EDP. The mine is set to close in 1994.

Coal in Spain is produced by a plethora of companies, more than 200 in total. The leading company, Hunosa, is publicly owned while most of the rest are held privately. Sales of coal to power stations are made under the auspices of a contract between Carbunion, the association of coal producing companies, and UNESA, the association of electricity utilities.

Finally, in the United Kingdom, British Coal has been undergoing a rationalisation process as part of the British government's preparations to privatise the coal industry. Most underground mines are owned and operated by British Coal. Open-cast mining is undertaken by private operators, mostly under contract to British Coal.

Strategies

The strategies of companies in the EC solid fuels sector are largely shaped by the foreseen decline in EC output, caused

by the EC drive for increased competitiveness within the context of the EC state aid policy. Producing companies will have to diversify and rationalise if they wish to continue to exist in the long term.

British Coal, which the British government is committed to privatising, continues to close pits and reduce staff. In Germany, agreement has been reached between the government and the coal industry to cut subsidised sales of hard coal by 50 million tonnes by 2005, with the possibility of moving this target forward to 2000. In the new Länder, a group of east and west German lignite producers are modernising, rationalising and helping to privatise the lignite sector. Charbonnages de France, which faces similar cuts, is liable by law for the livelihood of its mining employees, and thus is investing in developing alternative employment for them. The Spanish coal industry has accepted to implement a restructuring plan which will result in the closure of the uneconomic underground pits and, hence, a further reduction of the underground workforce. Belgium ceased coal production in 1992 with the closure of their last two mines.

In order to cope with the employment effects of the restructuring process and in order to reinforce the reconversion process in the mining regions affected by pit closures, the European Commission established the Community initiative, RECHAR, which is additional to the other Community financial instruments.

REGIONAL DISTRIBUTION

Hard coal is currently mined in significant quantities in four EC members: the United Kingdom (82.8 million tonnes,) Germany (72.2 million tonnes), Spain (18.6 million tonnes), and France (9.5 million tonnes). Small quantities are also produced in Portugal, though this is due to finish in 1994.

Lignite is mined in the following six EC countries: Germany (242 million tonnes), Greece (52 million tonnes), Spain (15 million tonnes), Ireland (6 million tonnes) and Italy (1.1 million tonnes). The three biggest producers accounted for over 97% of total output in 1992. Lignite production had been stable over the decade before 1991 when lignite production in the new Länder was included. The 318 million tonnes mined in 1992 is expected to fall as lignite production falls in the new Länder.

ENVIRONMENT

As with any fossil-fuel, the production, transformation and use of solid fuels have an impact on the environment. Hard coal and lignite are used mainly for power and heat generation, processes which attract environmental protection measures. In particular, major efforts have been undertaken since the mid-1970s to reduce particulate, SO_2, and NO_X emissions from coal and lignite-burning power plants, albeit at the expense of conversion efficiency and the relative cost of coal-generated electricity. As a result of the installation of flue gas desulphurisation and NO_X removal units, drastic reductions in the emissions of pollutants have already been achieved. Further improvements are expected over the balance of this decade with the development of a large number of pilot plants that employ advanced methods of clean coal utilisation such as fluidised bed combustion.

Compared to other fossil fuels, solid fuels emit the highest amount of CO_2 per unit of energy. In order to ensure that the greenhouse gas emissions from coal use are minimised, it is important that, wherever possible, the efficiency of coal utilisation continues to improve. So far this century, the efficiency of coal-fired power generation has doubled due to technological improvements. Further efficiency gains are expected as combined cycle systems are developed and widely deployed. CO_2 emissions from such plants are as much as 20% lower than from conventional plants. Furthermore, the emplacement of combined heat and power plants offers potential CO_2 emissions reductions of more than over 50%.

REGULATIONS

The Treaty establishing the ECSC stipulates under Article 4(c) that national financial support to the coal industry is prohibited. Decision 2064/86 is the latest in a long series of decisions by which state aid is allowed under strict conditions, to be granted to the coal industry. This decision expires on 31 December 1993.

The form of a new state aid decision from 1984 has been the subject of an in-depth debate. The European Commission has proposed a scheme that would authorise aid until the end of the ECSC treaty in 2002. This will be done on the condition that production costs decrease and better transparency is introduced through the entering of aid into public budgets and their introduction in company accounts as a revenue distinct from their turnover. The draft proposal of the Commission is currently being studied by the Council with the objective of giving its unanimous consent.

The Treaty also stipulates under Article 55 that the High Authority shall promote technical and economic research relating to the production and increased use of coal and to occupational safety in the coal industry. From 1959 onwards, the ECSC High Authority, and subsequently the European Commission, granted financial aid to that end.

The Treaty establishing the ECSC will expire in June 2002. The European institutions have started discussions on the future of the provisions of this Treaty, and their phasing-in to the EC Treaty.

OUTLOOK

Solid fuels face a declining share in both the domestic and industrial sectors. However, as oil and gas prices are expected to rise more quickly than coal prices, the competitive position of coal should improve. Other cleaner fuels are favoured for space heating, while the use of coal in industry is linked closely to the fortunes of the iron and steel industry. Coal does, however, have a future in power generation where its share of the fuel mix should rise into the next century, although lignite consumption in power generation is forecast to drop mainly in Eastern Germany for environmental reasons.

Competition from extra-EC coal exporting countries and the general effort to lessen national subsidies means that, by the year 2000, 69% of consumption is forecast to be serviced by imports compared with about 45% in 1992. Meanwhile, hard coal production should fall by around 38% by the year 2000. Although indigenous energy production can play an important role in terms of security of supply, the stability of the world market for coal with abundant supplies from a wide variety of geographical sources leads to the conclusion that, even in the long term, the risk of persistent interruption of coal supplies is minimal, although it cannot be ruled out completely.

Consequently, major developments are expected in the British, Spanish and German coal markets. In the United Kingdom, a trimmed down British Coal has won a 5 year contract for 160 million tonnes of coal with the electricity generators, without which its privatisation would not be possible. The government intends to subsidise additional deep mined coal for power generation, though this is to be phased out. In Germany, the coal subsidy looks like it will be levied as a general tax, rather than a levy on electricity as is presently the case. Meanwhile, in Spain, a major restructuring of the industry is in progress, along with some improvement of import facilities.

Exploration and production of crude oil and natural gas

NACE 13

Total production of hydrocarbons in the EC stood at 262.5 million tonnes of oil equivalent in 1992, a 7.1% increase over 1991. The United Kingdom and the Netherlands are the two leading hydrocarbon producers within the EC, accounting for 53% and 25% of output, respectively, in 1992.

INDUSTRY PROFILE

Description of the sector

NACE 13 comprises three main activities:

- the exploration of both crude oil and natural gas,
- the production of liquid hydrocarbons (i.e. crude oil), condensates and other liquids resulting from gas processing operations, and
- the production of natural gas.

Recent trends

Over the past few years, crude oil production in the EC had been declining, but the 1992 output posted an annual rise of 2.2% to stand at 113.7.0 million tonnes. This increase was due largely to a 2.7% increase in United Kingdom production to 90.2 million tonnes. The rise broke a downwards trend in output that had occurred over the past few years. The United Kingdom dominates EC output, accounting in 1992 for nearly 80% of total EC oil production. Elsewhere in the EC, output rose in Denmark and Italy, remained constant in Spain and fell in France and the other producing Member States. Total world production of crude oil was 3.1 billion tonnes, in 1991, virtually unchanged from 1990. Iraqi crude remained off world markets and output from the former Soviet Union fell. However, increased output from other producers, both OPEC and non-OPEC made up the shortfall. Provisional data for 1992 point to a 0.9% increase to 3.4 billion tonnes. On current trends, 1993 world output will be about the same as in 1992.

Total proven world oil reserves reversed a three year declining trend during 1992. At the start of 1993 they stood at 134.7 billion tonnes compared with 133.9 billion tonnes a year earlier. The EC's share of total proven world reserves at the start of 1993, was 872.3 million tonnes or 0.6% of the world total, up from 847.1 million tonnes at the start of 1992. At current rates of production and assuming that no further reserves are found, EC indigenous supplies would be exhausted within eight years.

Natural gas output in the EC rose 0.6% to 144.5 million toe (tonnes of oil equivalent) from 1991 to 1992. Meanwhile, total proven world gas reserves climbed 11.6% to 138.5 trillion m^3 (131.6 billion toe) at the start of 1993. At the start of 1992, EC gas reserves accounted for just 2.7% of the world total.

The EC produces about 22% of the oil and about 60% of the natural gas that it consumes. These figures compare to OECD averages of 43% and 87%, respectively. Thus, the EC is relatively dependent upon imports to meet consumption, particularly in the case of crude oil.

Having peaked in the mid-1980s, oil production in the EC has been declining steadily. In contrast, EC natural gas production has been rising steadily since 1988.

The 1986 price collapse led to cutbacks which saw employment in the sector contract by 30% to 35%. In 1989, overall employment within the sector was estimated at 95 000 people. Employment did rise during 1990 and the beginning of 1991, but has since fallen back under the weight of economic slowdowns.

Foreign trade

Extra-EC imports of crude oil stood at 499.4 million tonnes in 1992, 4.4% higher than in 1991. Imports from the Middle East have steadily recovered since falling sharply during the Gulf crisis and Gulf war. During 1991, imports from Kuwait began to recover, but the yearly total was just 8.0% of 1990's level. During 1992, Kuwaiti exports to the EC recovered to nearly 60% of their pre-invasion level.

Natural gas imports to the EC totalled 4.157 million TJ (terajoule) (89.3 million toe) in 1992, virtually unchanged from 1991. The greatest proportion of imports, 44%, were from the former Soviet Union, followed by Algeria and Norway with 31% and 24%, respectively. Despite the continued upheaval in the former Soviet Union, exports to the EC from the region fell back 3.5% from 1991 to 1992. Germany accounted for the greatest proportion of gas imports into the EC in 1992, taking 29.0%, Italy and France were placed second and third, accounting for 26.6% and 25.2%, respectively.

Intra-EC trade in the form of gas imports from the Netherlands showed a strong increase of 25% from 1991 to 1992 to 1.5 million TJ. The majority of this increase was accounted for by increased imports into Germany. Indeed, about 60% of Dutch exports were to Germany. Germany also accounted for all of the 30.0 thousand TJ worth of Danish intra-EC exports.

MARKET FORCES

Demand

Crude oil and natural gas are key energy sources, used to generate power and/or heat. They are used widely in everyday life throughout the power generating, industrial, commercial, domestic and transport sectors. Demand for crude oil and natural gas is characterised by low price and income elasticities because of the lack of competitive alternatives. This characteristic is particularly significant in the transport sector. In recent years, natural gas has tended to replace crude oil and petroleum products largely because of its relatively favourable impact on the environment.

Supply and competition

Nearly 80% of EC production of crude oil originates from fields on the British continental shelf. The high expense of exploiting offshore fields is the main reason why the production cost of EC oil is higher than areas with onshore resources. In 1990, the average cost of producing a barrel of oil from the United Kingdom North Sea was 18/barrel. This figure, which was little changed from 1989, includes the costs of exploration, development, and operation over expected field lifetimes, and assumes a 10% real rate of return before taxes and royalties. The cost of oil fields under development at the end of 1990 was about 12.50/barrel, down from 16/barrel a year before.

In 1990, the total number of wells drilled in the EC rose by more than 21% to 715. This figure represented just 1.2% of the world total of 58 900 wells drilled, although of the world outside the USA, the EC total represents 4.3%. In 1991, 236 exploration wells were drilled in the EC North Sea, 153 of which were exploration wells and the remainder appraisal wells.

Production process

Exploration and production of oil and gas requires a highly skilled and experienced work force. That exploration in the

EC takes place offshore only heightens these requirements. By the same token, the EC is in a position to export highly trained and skilled labour in this sector.

R&D activity in the industry has traditionally been high. The nature of R&D programmes reflect the significant proportion of offshore operations undertaken in the upstream oil and gas sector. The high price of crude oil maintained during the first half of the 1980s encouraged research into enhanced recovery methods. To reduce costs, improvements were made in the tools and operating efficiencies of exploration and production. Most of these programmes produced excellent results and generated significant growth in terms of services and equipment installation within the EC. However, the 1986 fall in crude prices put a damper on much of this research as players in the industry re-evaluated their priorities. Even so, the depth of water and the sometimes harsh operational environment in the North Sea has forced EC companies involved in oil exploration and production in these areas to acquire a wealth of experience in offshore operations. Much of this expertise is unparalleled elsewhere in the world.

Since the late 1980s, the increased emphasis on the development of smaller and deeper fields has led to further technological developments, many of which streamline or increase the efficiency of production. Some of the important technological advances made in the North Sea include: improved and streamlined platform designs; development of sophisticated floating production systems; improved platform safety systems such as interlocking fireproofing panels, multimedia on-platform safety monitoring systems and offshore escape systems; more efficient subsea completion systems such as those with highly flexible and highly durable flowline swivel joints; the development of dynamically positioned drilling vessels capable of operating at depths of 2 000 m; the completion of the first commercial horizontal drilling operation; the development of deep-diving techniques and submarine vessels for underwater activities; improved measurement of static and dynamic statistics; the development of sophisticated pigs such as high friction reversible safety pigs; improved pigging techniques; and better geophysical data acquisition systems such as real-time processing of short offset 3D data.

INDUSTRY STRUCTURE

Companies

During the 1980s, the participation of governments in the upstream oil and gas sector steadily decreased. This trend has continued into the 1990s. In May 1992, the French government announced its intention to reduce its stake in Total to 15% by the end of the year. In June 1992, the state sold 12.4% of Total's share which left it with a direct holding of 12.6%. The government also sold its 6.7% share of the company's capital in the form of petroleum certificates. The state has retained an indirect 2.3% share via two public insurance companies, GAN and AGF. Last year, the French government sold shares representing 2.3% of the company's capital which left it with at 51.5% holding. This year, the new centre-right government has included Elf in the list of companies slated for a round of privatisation set for the last quarter of 1993.

Over the past decade, the oil industry in Spain has been completely restructured. In June 1992, the Spanish government announced that it would give up its majority stake in Repsol through two share sales. The first took place in the Autumn 1992 and was worth some Pta 80 billion. The second phase of the sell-off took place earlier this year (1993) and reduced the governments stake to about 41%. In the long run the government has indicated that it intends to reduce its stake to 33%.

In Italy, AGIP and SNAM are to be partially floated and the remainder of ENI reorganised and privatised later. Some 15-20% of AGIP stock is likely to be floated in the near future, political problems permitting, which should net the Italian exchequer some L 2 trillion.

Competition to obtain exploration licences grew during the 1980s, with increasingly smaller areas being allocated to a

REGULATIONS

The march to the realisation of the Single European Market brought to light several significant obstacles to the free movement of goods and services in the EC. Most of the barriers to trade that were addressed by the Commission were regulations that favoured state-owned companies (i.e. compulsory government participation, reserved areas, local landing obligation) and requirements to procure goods and services locally. In May, 1992, the Commission published full details of a proposal for a Council Directive on the conditions for granting and using exploration and production licenses. This is intended to ensure that exclusive rights to prospect for, explore for and extract oil and gas are granted only on the basis of non-discriminatory procedures that are available to all competing parties that are interested .

growing number of companies, many of which included small independent operators. Nonetheless, the major companies did not relinquish their dominant position in exploration and production. Though this was not entirely due to their own efforts but was also, in part, due to the damage wrought on many small players by the 1986 price collapse. That lead to a concentration of exploration and operating licences, particularly in the North Sea. The majors in the EC include Shell, Exxon and BP, all three of which are very active in the United Kingdom North Sea (with Shell and Esso splitting many joint ventures 50/50), NAM in the Netherlands, BEB in the Federal Republic of Germany, as well as national oil companies such as ELF, DSM, AGIP and Repsol, which are involved in operations both domestically and elsewhere in the EC.

REGIONAL DISTRIBUTION

The production of crude oil and natural gas in the EC is extremely polarised. The United Kingdom dominates EC crude oil output, accounting for nearly 80% of total EC oil production in 1992. As for natural gas, the Netherlands accounted for 43% of EC production, while the United Kingdom accounted for a further 31%.

ENVIRONMENT

Stringent regulations are applied to all offshore operations in the EC. These include regulations concerning oil spills and discharges of cuttings and oil mud. Work is also being undertaken to define rules and standards for the abandonment of disused offshore installations and structures. Safety regulations are also very strict, having been tightened in the wake of several accidents that occurred in the North Sea at the end of the 1980s.

OUTLOOK

EC crude oil production is expected to reflect developments in the United Kingdom sector of the North Sea. Output is expected to peak towards the middle of the 1990s at some 129 million toe as enhanced recovery techniques are applied and small fields are brought on line in the North Sea. Later in the decade and into the next century, crude oil production in the EC is forecast to decline steadily with falling United Kingdom production. By the end of the century, total EC crude oil output should slip to 102 million toe. Moving through the early years of the next century, EC output is expected to drop off even more steeply, falling to just 70 million toe in 2005. Although modestly higher prices should lead to an upturn in exploration activity over the next few years, new finds are considered most unlikely to arrest the long term declining trend in United Kingdom oil output.

The outlook for natural gas is rosier. By the year 2000, Dutch output is expected to have risen 13% from 1992 to 70 million toe, while United Kingdom output is forecast to climb by 8% to 49 million toe. During the decade after 2000, Dutch output is expected to rise a further 5%, but United Kingdom output should decline by 25%.

Declining indigenous crude oil production is expected to lead to an increased reliance in the EC on natural gas and imports of foreign crude oil. A further complication is the expected drift in EC demand towards lighter, low sulphur products. In addition to prompting more refinery upgrading capacity, this should also lead to a shift towards importing ever lighter and sweeter crudes.

Nuclear fuels
NACE 15

The EC's annual nuclear fuel requirement in 1992 was about 15 300 tonnes of natural uranium (tU), a figure which is expected to edge slightly higher by 1995 but decline over the balance of the decade. An increase in the electro-nuclear capacity is expected up to 1995 after which it should remain fairly flat. The widening margin between nuclear capacity and nuclear fuel requirements reflects the employment of better fuel management, the use of plutonium recycling and the recycling of reprocessed uranium.
The EC itself has an annual uranium production of about 3 490 tU, with uranium produced by five Member States: France, Spain, Portugal, Germany and Belgium. France is by far the leading EC producer, with annual production representing 86% of the total EC output. The EC's requirement for conversion is about the same as its need for natural uranium, with current requirement levels representing 73% of the EC's capacity. The EC energy objectives for 1995 take into account the importance of the nuclear industry to the EC's energy supplies and emphasises the need to ensure that all aspects of planning, construction and the operation of nuclear installations meet optimum safety standards.

INDUSTRY PROFILE

Description of the sector

NACE 15 covers all activities relating to the different stages of the nuclear fuel cycle, i.e., from ore extraction (NACE 151) to fuel element production and processing (NACE 152) according to the following sequence:

- Extraction of uranium and thorium ores,
- Chemical concentration of uranium and thorium ores,
- Refining of uranium and thorium,
- Enrichment of uranium in isotope 235,
- Separation of plutonium and uranium through spent fuel reprocessing and
- Preparation of nuclear fuels and fabrication of fuel elements.

Recent trends

Production of uranium in the EC is concentrated in France with 86% of total EC uranium production. France's conversion capacity is now the largest of the OECD countries since capacity in the USA was cut by 42%.

Uranium producers have been hit hard by the present upheaval in the nuclear industry. In real terms, uranium prices for short term contracts have fallen from a peak of 52 ECU/kg in 1975 (when oil prices skyrocketed) to 25 ECU/kg in 1990. During the 1980s, real prices fell steadily due to overoptimistic forecasts of demand for electricity from nuclear sources which resulted in a build-up of uranium stocks. The industry continues to find itself in a situation of over-capacity. Recently, the prospect of military stocks becoming available on the market has dashed any hopes of a recovery in prices.

International comparison

The EC accounted for 18% of OECD production of natural uranium in 1992 with 3 490 tU. Canada is the largest producer with 9 200 tU in 1992. The EC meets 23% of its annual uranium requirements, 4% less than the USA. Canada, the world's largest uranium exporter produces 4.8 times its annual requirement.

USA	4 745	7 386

Source: NEA

The EC has the world's largest uranium conversion capacity at 20 800 tU/yr. Two-thirds of this is accounted for by France and the rest by the United Kingdom. The USA, which until last year had the largest conversion capacity, now has a conversion capacity of 12 700, 42% less than 1991.

The EC had a total enrichment capacity in 1992 of 13 550 tonnes of separative work units (tSWU/yr, which is a measure of a plant's enrichment capacity), 80% of which was by the diffusion process (in France) and the remainder by gas centrifuge (UK, NL and D). The USA with the largest enrichment capacity at 19 300 tSWU/yr in 1992, produces enriched uranium solely by the diffusion process. The EC, therefore, has a slight technological edge over the USA in the enrichment process when it comes to higher electricity prices.

The annual nuclear fuel requirements of the EC are the highest in the OECD with 2 795 tonnes (t) of fuel per year. The USA and Canada have the next largest requirements with 2 200 and 2 150 t, respectively.

Foreign trade

Partly to protect uranium prices, a clause in the START treaty limited the uranium conversion from nuclear warheads to 10t of enriched uranium per year until 1997 and 30t per year thereafter. The USA enrichment Corporation (USEC) is due to receive 500t of weapons grade uranium which the USA has agreed in principle to buy from Russia. The trade in enriched uranium, especially of weapons grade uranium is necessarily highly regulated. In the EC, Euratom regulates both imports and exports of nuclear material. The EC imports 77% of its needs.

Spent fuel from nuclear reactors bound for reprocessing is also traded. In the EC, spent fuel arisings totalled 2 749 t, 11% below the total EC reprocessing capacity. That only France and the United Kingdom are capable of reprocessing intra-EC trade is significant. The only other OECD country with civilian reprocessing capability is Japan. Reprocessing is also practised for industrial purposes by Russia and India. The potentially hazardous nature of spent nuclear fuel rods to the environment and security issues have limited extra-EC trade. If fuel is not reprocessed, direct disposal is the only other long term option available. Of the direct disposal methods, the underground storage option has been the most favoured of proposed alternative.

MARKET FORCES

Supply and competition

Uranium production

The EC itself has an annual uranium production of about 3 490 tU, with the remainder of its requirements being imported. By-and-large, electricity producing companies tend to diversify their sources of supply in order to guard against unexpected interruptions. They have also built-up stockpiles which can vary from two to four years' worth of consumption. According to the latest data from the International Atomic Energy Agency (IAEA), in 1990 the EC paid about 62 ECU per kgU for uranium supplied on long term contracts, down almost 5 ECU per kgU from the 1989 level. In real terms, uranium prices on long term contract have fallen roughly 50% since the start of the 1980's. Prices for short term contracts have fallen 5 fold in real terms, reflecting the oversupply that now exists.

Within the EC, uranium is produced by five Member States: France, Spain, Portugal, Germany and Belgium, with 86% of EC production coming from France. The EC accounts for 18% of OECD uranium production and around 12% of world production.

In France, there are four uranium production locations extracting uranium ore from thirty or so mines. France is by far the leading EC producer, with annual production of 3 000 tU in 1992. It is estimated that the uranium resources that have already been discovered in France, with recoverable costs of up to 72 ECU per kgU, could still maintain production at their present rate for a period of 15 to 20 years. Uranium mining is expected to be boosted in Spain, while France may cut production by around a third. The OECD's Nuclear Energy Agency project a decline in output to just under 2 000 tU/yr by the first decade of the 21st century.

In 1992, Spain's annual production was about 185 tU; a 5% decrease from the previous year. Almost all this uranium (90%) was produced in the Sealices el Chico mine works at Ciudad Rodrigo from ore extracted from the uranium deposits at Fe. The remainder was produced by the small Haba experimental mine situated at Don Benito (which has an annual output capacity of around 30 tU). The government organisation, Empresa Nacional de Uranio SA (ENUSA), owns and manages the uranium production centres. Deposits have been discovered in Spain, which, at a recovery cost of up to 72 ECU per kgU, amount to a total of 27 000 tU. There are plans to increase the production.from Spain's current facilities to about 800 tU per annum by the second half of this decade using credit made available under the EC QUERCUS project.

In 1992, uranium production in Portugal was around 20 tU: a 75% decrease from 1990 production. This uranium was mined from Urgeiria and consists of ore extracted from several deposits in the Upper Beira region. Work has started on a new production centre at Nisa in the Upper Alentejo region, which will process ore from several deposits in the region. Responsibility for uranium production in Portugal lies with the public organisation Empresa Nacional de Uranio (ENU). In Portugal, discovered uranium resources, which can be recovered at a cost of 72 ECU per kgU or less, are sufficient to maintain output at about 370 tU per annum for at least the next twenty years. As Portugal does not have a nuclear power programme of its own it exports its uranium, some of which goes to other Member States. Portugal's uranium output is projected to increase over the course of the next decade, rising to around 150 tU as the new sites start to come on line.

About 232 tU were produced in Germany in 1992 from the underground mine at Ellweiler and from Menzenschwand and Grobschlopen, which are both open cast. This represents an almost seven-fold increase in total production since 1990. Production capacity at Ellweiler is about 125 tU per annum, but limited ore supplies means that capacity is under utilised. There are no plans to increase uranium production in Germany, despite the fact that Grobschlopen deposits could supply a processing facility with 250 tU per annum of uranium ore. The discovered resources, with a recovery cost of up to 72 ECU per kgU, are about 2 500 tU, but the Nuclear Energy Agency believes that German production will be wound down over the next few years and stopped after the year 1995. In former East Germany, there is an estimated 100-500 tU reserves. Production was centred on the Erzgeberge, which straddle the border with Czechoslovakia in the south-eastern part of Germany. Production was undertaken by SDAG Wismut Uranium Combine, which was reportedly once the third largest uranium producer in the world. All output went to the former Soviet Union under an agreement dating back to the immediate post-war period, where the uranium was enriched and made into fuel. Since the beginning of 1991, SDAG has practically stopped mining, with the company's only output coming from slag.

Finally, about 45 tU per annum are produced in Belgium from imported phosphates. Belgium has no known uranium resources and is expected to maintain current rates of production over the foreseeable future.

Competition in the uranium production sector of the EC comes principally from the large surplus remaining from the late 70s, and the reprocessing of military grade uranium. In the long term, the use of plutonium, mainly from reprocessing spent fuel for use as mixed oxide (MOX) fuel, could decrease uranium demand.

Conversion of uranium

The EC's requirement for conversion is about the same as its need for natural uranium, which is about 15 300 tU/yr. This figure is anticipated to increase by around 500 tU by 1995 only to fall back to 1991 levels by the end of the decade. The EC requirement for the conversion of uranium represents 74% of the capacity. Outside the EC, the USA, Canada, Japan, Russia and China have uranium conversion capacity. Canada's own requirements account for only 21% of its capacity, while the USA requires more than it can produce. Together, Canada and the USA have a capacity utilisation rate of 88%.

Despite strong competition, BNFL (UK) and Comurhex (F) have been able to obtain a significant proportion of non-EC European countries' markets and have thus been able to ensure adequate utilisation of their facilities. The EC's conversion capacity is expected to increase to around 25 900 tU/yr by the second half of the 1990s, mostly due to expansion in the United Kingdom, but also in France.

The average conversion cost is about 6.5 ECU per kgU and the turnover in the EC market is about 90 million ECU. The EC attaches more and more importance to the idea of converting reprocessed uranium. In France, Comurhex and Cogema have linked together to form the Urep marketing company with the aim of offering a range of services in this field. In the United Kingdom, BNFL continues to convert reprocessed uranium, recovered from MOX fuel, at its existing installations and hopes to begin conversion at the new THORP plant in 1994.

Uranium enrichment

Uranium enrichment is an important stage, both because it requires advanced technology with a high level of specialised knowledge and because this operation accounts for about 27% of the total cost of the fuel cycle. Production in the EC is in the hands of two multinational groups, Eurodif (F) and Urenco (UK, NL, D).

France joined forces with Belgium, Italy, Spain and Iran in forming Eurodif (F) and also in deciding to construct a large enrichment plant at Tricastin (F) using a gaseous diffusion

process. The decision to go for a large, high capacity plant was taken in order to obtain the maximum benefit from economies of scale, which are considerable in the case of the gaseous diffusion technique. This choice was also influenced by the optimistic climate towards nuclear energy which reigned after the first oil crisis in 1973.

Eurodif's Tricastin plant, which began service in 1979, is one of the biggest in the world, with an annual capacity of 10 800 tSWU. A pressurised water reactor (PWR) with a capacity of 1 gigawatt (GW), has an annual requirement of about 25 tonnes of enriched uranium (i.e. uranium containing approximately 3% U_{235}), which in turn requires about 150 tonnes of natural uranium. Products from the Tricastin plant presently satisfy about 20-25% (including ex-COMECON) of the world's requirements. After the plant reached full production capacity in 1982, it had to trim its rate of output to accommodate a reduction in demand.

Urenco Ltd (UK) was formed on the basis of an equal equity split between Uranit GmbH (D), British Nuclear Fuels Plc (UK) and Ultracentrifuge Nederland (NL). The company was established to develop and apply, on an industrial scale, the technique of enrichment by means of ultra-centrifugation. Urenco Ltd is the central holding company and the parent of the enrichment companies Urenco (Capenhurst) Ltd in the UK, Urenco Nederland BV in the Netherlands and Urenco Deutschland GmbH in Germany. Urenco Ltd has responsibility for marketing, controlling production and planning and arranging and coordinating financing for the Group.

The present output of the Urenco group of plants is around 2 750 tSWU/yr, although a number of projects are currently being undertaken to increase this output to 4 500 tSWU by the end of the decade. The centrifugation technique does not require the construction of large plants; consequently, output can be increased by adding modules when necessary. The new units can be built relatively quickly, enabling investment to be planned in relation to contracts obtained, ensuring a high level of plant utilisation.

Production of the fuel elements

Within the EC, fuel production tends to occur on a national basis. Only the Netherlands has to import all its final fuel as it has no production facilities of its own. Of the other countries, Germany is the only one where production capacity is less than its fuel requirements. For the EC as a whole, fuel requirements in 1992 represented 70% of the EC's production capacity, with the United Kingdom having the largest amount of over-capacity.

The largest producers of fuel rods for light water reactors (LWR) within the EC are Siemens (D), which is capable of producing 1 000 tU of fuel per year; Agip (I), with 200 tU; ENUSA (E), with 250 tU; BNFL (UK) owns a factory producing fuel for LWR, which has an output of 200 tU; finally FBFC factories (F/B) had an overall output of 1 550 tU in 1991. In addition, BNFL (UK) also has 1 630 tU of capacity to produce fuel rods for gas-cooled reactors (GCR). The average cost of producing LWR fuel elements is about 230 ECU per kg, giving an implied turnover of the EC LWR fuel market of about 643 million ECU in 1992.

Because of the development of plutonium reprocessing and recycling, the production of plutonium fuel elements is becoming increasingly important. Special plants in Belgium (Belgonucléar), France (Cogema) deploy a total annual output of about 50 t of MOX. The United Kingdom (BNFL) expects to start production of MOX around 1995, with production rising to 50 t of MOX by 2000. Combining these with increases in France (MELOX: 120t/yr) and possibly Belgium and Germany, would give a total EC MOX production capacity of 300 t of MOX.

Storage and reprocessing of discharged fuels

The majority of EC countries (France, the United Kingdom, Germany, Belgium, Italy and the Netherlands) have adopted fuel reprocessing after an interim period of storing the spent fuel on the power station site, either in special dry storage facilities or in under-water storage tanks. Spain and a number of countries outside the EC have opted for a longer period of fuel storage (from 20 to 50 years), while it awaits either reprocessing or disposal in deep-lying geological formations. Only France and the United Kingdom have any reprocessing facilities at the moment, a situation that seems unlikely to change in the medium-term.

Fuel reprocessing and waste management represent a considerable proportion of the fuel cost, almost 20% if account is taken of the fact that enrichment of the recovered fuel is not necessary, and 30% if this is not taken into account. However, reprocessing is favoured by source countries because of potentials to gain more energy from the spent fuel.

Originally, reprocessing was applied strictly to metallic fuels from gas cooled reactors that were powered by natural uranium. This reactor type was initially adopted by France and the United Kingdom, but no stations of this type are being built at present. Uranium oxide fuel, reprocessed from LWR and advanced gas-cooled reactors (AGR), amounts to around 7 000 t, of which 5 500 t have been processed at the UP2-400 and UP3 plants at La Hague in France, the only commercial plants at present in service. This plant's annual output was 400 t/yr in 1989, but a decision to enlarge the site, with the construction of UP3, has added a further 800 t/yr. In 1995, UP2 plant's output will be increased to 800 t/yr.

In the United Kingdom, BNFL is building THORP at Sellafield which will be capable of reprocessing up to 1200 t of irradiated fuel over the first 10 years of operation and is due to come on line in 1993. Its output is aimed at covering national requirements as well serving other EC and non-EC countries, the latter including Japan, Switzerland and Sweden.

Meanwhile, Germany abandoned its plans to build a nuclear reprocessing plant at Wackersdorf and instead, decided to step up its co-operation with France in the joint processing of spent uranium fuel. At the same time, Germany signed a reprocessing agreement with BNFL to have fuel reprocessed at Sellafield and closed its only reprocessing plant (WAK) in 1990.

Production process

To a far greater extent than other energy sources, nuclear energy has to be backed up by a complex combination of industrial activities. These include mining natural uranium, the preparation of nuclear fuel and the construction of sophisticated power stations. These characteristics are reflected in the structure of electricity costs. Only 17% of total costs is expended on fuel, 7% on natural uranium and 10% on the various processing stages of the nuclear cycle. However, 70% of total electricity costs arises from amortisation of the investment in the power stations, with the remainder (13%) accounted for by the stations operating costs.

The conversion process produces a uranium compound (uranium-hexafluoride) which lends itself to subsequent processing (enrichment and fabrication) and which possesses the required chemical purity. Conversion represents a small (about 3%) part of the total cost of the fuel. At present, two companies carry out conversion operations in the EC, BNFL in the United Kingdom and Comurhex in France. Outside the EC, Canada and the United States also have conversion facilities.

Enrichment is the process in the fuel cycle where the fissile isotope content of the uranium is increased. This stage is necessary in the case of fuel destined for light water reactors (either pressurised or boiling) and for advanced gas cooled reactors. Three processes used for uranium enrichment exist.

Two are currently commercially used. The oldest technology is based on a process known as gas diffusion and is the sole process used in France. In the United Kingdom, Germany and the Netherlands, the gas centrifuge technology is used. Since this technology uses far less power it is the cheapest based on marginal costs. A new process now exists known as atomic vapour laser isotope separation (AVLIS) which could cut costs even further, although this is not yet available commercially. This technology is being considered in the USA, where the old diffusion methods are currently used. This could potentially reduce costs by one third.

Fabrication of the fuel elements comprises the operations during which uranium fluoride, enriched or otherwise, is used to produce the final fuel elements to be introduced into the reactors. This stage represents about 11% of the total fuel cost.

Reprocessing is a complex operation performed on spent fuel discharged from nuclear power stations. This fuel is a mixture of reusable products (unspent uranium and plutonium created during the fuel irradiation in the power station's reactor) and fission products which are highly radioactive and are akin to the ashes from using fissile material. The reprocessing operation enables the various products to be separated. In the medium term, by recycling material recovered from thermal nuclear power stations in the reprocessing process, the amount of natural uranium needed by a nuclear power station is reduced. In the long term, there is the possibility that fast breeder reactors will almost totally eliminate the need for additional natural uranium within the confines of the existing industry structure.

ENVIRONMENT

Environmental considerations of the nuclear fuel cycle stem from the discharges of radioactive liquid and gaseous effluent from nuclear installations. In the attempt to limit these discharges to a small portion of the authorised limit, waste material has been concentrated into solid and solidified forms.

There are three main categories of waste: low level, intermediate and highly active wastes.

Low-level waste forms the vast bulk of waste material, amounting to about 100 000 cubic metres. The material is either held in surface or near surface installations where the composition of the waste is controlled over a maximum period of 300 years. Alternatively, the waste is stored in underground installations where the need for verification and measurement of the waste is considered to be limited. Prior to 1982, some of the low-level waste was dumped in special containers at sea. However, following the adoption of the Convention on the Prevention of Marine Pollution from the Dumping of Waste and Other Matters, the practice was curtailed.

Intermediate waste can be divided into: a) material that has been contaminated by radionuclides which have a long half-life but produce little heat because of their moderate concentration of radioactive elements, and b) material containing and emitters only, but containing intermediate levels of radioactivity that produce a significant amount of heat.

Highly active waste is either irradiated fuel discharged from the nuclear reactor when it has been decided to dump it, or is highly active vitrified waste produced after the reprocessing of the fuel.

Waste from the latter two categories has a very high radioactive toxicity which can persist over thousands of years. Given the length of time that containment of such material will require, disposal systems have to be passive, with the long-term safety not dependent on human control or surveillance. Currently, investigations are being concentrated on the burial of the waste in deep stable geological formations, which offer adequate isolation capabilities. On-land sites are the only ones currently under investigation, although research is also being carried out into the possibility of burial in sub-seabed formations or other geologically stable formations.

REGULATIONS

Another area of concern within the nuclear fuels cycle is to ensure that material is not being diverted for the development of nuclear weapons. Within Europe, the Euratom nuclear safeguards system was established in 1957, with its general objectives defined as ensuring that "nuclear material have not been diverted to purposes other than those for which they were intended".

The Euratom safeguards system is founded in European law, with strong sanctions for infringements. It applies to all civil nuclear materials from the moment they are mined on EC territory or are imported into the EC. Aside from ensuring that the material is not being diverted from peaceful uses, Euratom also checks to see that declarations of specific use are correct and that the suppliers obligations are being respected.

Because the nuclear installations are designed with security and health concerns in mind, the nuclear material is becoming increasingly inaccessible. As a result, Euratom is having to develop advanced measuring instruments and sophisticated computer surveillance systems that record and react to events that may be of interest to the inspectors.

OUTLOOK

By 1995, the EC's annual nuclear fuel requirement is expected to edge slightly higher from its current level of 15 300 tU before falling back over the balance of the decade. Uranium production is forecast to fall to around 1 905 tU by the turn of the century, a decline of 45% from the 1992 level. While Spanish and, to a lesser degree, Portuguese output is anticipated to increase, a drop in French production of 67% is expected to be responsible for the overall decline.

At the same time, the EC's conversion requirement is anticipated to increase by around 0.3% per annum over the rest of the 1990's and enrichment requirements should increase from 9 500 tSWU in 1991 to 9 700 tSWU in 1995 and, by the next century, to over 10 000 tSWU. The EC's total fuel requirements are expected to peak in the mid-1990s and then to fall around 2 500 t by the year 2000. This should coincide with greater decline in fuel production capacities so that overall utilisation rates should increase. In practice, technical progress on better utilisation of uranium in the reactors does not reduce the need for enrichment services as much as it reduces the need for natural uranium. In addition, recycling reprocessed uranium has no appreciable reduction on enrichment requirements. Current expansion plans for reprocessing facilities are set to raise capacity to over 2 225 t in the EC by the turn of the century.

An increase in total output of MOX fuel will gradually increase during the 1990s. MOX production is expected to reach 255 t from capacity increases in Belgium, France and the United Kingdom in order to satisfy the requirements of the plutonium thermal recycling programmes. Total fuel requirements are forecast to peak in the mid-1990s, falling to around 2 500 t by the 2000. At the same time, production capacities are projected to increase to over 5 000 t and, as a result, the utilisation rates should remain at around 50% to the year 2000.

Current expansion plans for reprocessing facilities are set to raise capacity to over 3 000 t/yr by the turn of the century. This should leave about 60% of capacity to deal with the current year's spent fuel and 40% to get through the backlog of material that has been in storage. Taking account of quantities to be reprocessed from countries outside the EC, it is

estimated that interim storage requirements could be about 20 000 tU from 1995 to 2000. The necessary storage capacity to cover these requirements is already in place.

Refining and distribution of oil products
NACE 14

The trend towards lighter products has left the EC refining sector scrambling to install additional upgrading capacity. Meanwhile, the rationalisation of the EC's primary distillation capacity appears to be drawing to a close. After having fallen over the first half of the 1980s, EC oil demand is rising once again despite the economic slowdown. The displacement of oil has occurred in the industrial, domestic and power generating sectors, whereas road transport remains completely dependent on oil. Unleaded gasoline, which is available in all EC countries, continues to gain market share. Its share of the total EC gasoline market has increased from 10% in 1987 to nearly 47% in 1992.

The number of automotive fuel retail outlets has declined rapidly. In 1990, there were 127 000 outlets in the EC, one quarter less than in 1980. Although competition is stiff, the integrated oil companies, especially the majors, are regaining ground in retailing because excess refining capacity has disappeared in some countries. Access to supplies is essential for maintaining and expanding a market position in retailing. Liberalisation of the refining and retailing sectors continues. In Spain and Portugal liberalisation is well underway. Greece, however, remains a laggard.

INDUSTRY PROFILE

Description of the sector

NACE 14 includes the activities of petroleum refining and the processing of petroleum derivatives, with the exception of petrochemicals. The main products of this activity are refinery gas, liquefied petroleum gas (LPG), naphtha, motor gasoline, light distillates, aviation fuels, kerosene, diesel and residual fuel oils.

Recent trends

In 1992, about 23% of crude oil supplies to the EC came from within the EC itself and of that, over 90% was from the North Sea. The remaining requirements were imported from third countries. The volume of these imports has been increasing steadily over the past few years. From 1991 to 1992, such imports rose 4.8%. Total EC imports of crude oil and feedstock (including intra-EC transfers), rose by 21 million tonnes (t) to 499 million t in 1992 from 1991. This reflected higher levels of refinery throughput in 1992.

In 1992, imports of refined products into EC countries fell by 3.9%, or 6.9 million t to 172.2 million t. Extra-EC imports accounted for 52% of total imports into the EC. In 1992, extra-EC imports of petroleum products equalled about one sixth of total inland deliveries of petroleum products in the EC. The volume of these imports fell back sharply (by 8.5%) from the 1991 level, to 82 million t in 1992. Over the past few years, output of refined products from EC refineries has steadily risen, from 437 million t in 1987 to 498 million t in 1991 and 514 million t in 1992.

Refining

The reduction of the total primary distillation capacity in the EC over the past decade reached 573 million t/year in 1989. After another slight decrease in 1990, 1991 capacity rose 39 million t/year to 607 million t/year. The lion's share of this increase is attributable to the inclusion of Eastern German refinery's in figures for the EC from 1991. a significant contribution to increased capacity in western Germany was the reopening of Beta Group's 7.8 million t/year Wilhelmshaven refinery in autumn 1991. In contrast, the move away from heavy end products towards lighter products is forcing refiners to continually invest in upgrade capacity. At the end of 1992, upgrade capacity for the whole of the EC stood at about 31.4%.

Fuel retailing

During the 1980s, the number of petrol retail outlets decreased by 26% over the period 1980-1990. Rationalisation of the retail network did not occur uniformly across the EC; the most drastic reductions in number of outlets took place in the Netherlands (-36%), France (-35%) and Germany (-29%), whereas the networks grew in Greece (+16%) and Spain (+17%). The rationalisation process, which is continuing thus far this decade, has increased the competitiveness of those outlets that remain, in part because of increased throughputs. There is still considerable variation in average monthly throughputs from country to country; the highest are to be found in Spain where there is a small number of outlets per car. In contrast, average throughputs are approximately a fifth of Spanish levels in Italy, Ireland and Greece, where the rationalisation process has been slow. The number of outlets in Greece and Spain has been rising as a growing proportion of the population has had access to cars and as the average car size increased. However, unlike Spanish throughput per outlet, Greek throughput per station is the lowest in the EC after Ireland, suggesting much room for rationalisation.

Among EC Member States, Italy has the greatest number of service stations, 30 400 or about a quarter of the EC total, despite the fact that Italy accounts for only 17.5% of the EC automotive fuel consumption. Germany has only about 14% of EC retail outlets, and yet consumes 26% of transport fuels in the EC. Spain consumes 8% of EC transport fuels, but has only 4% of the retail outlets.

Foreign trade

The Organisation of Petroleum Exporting Countries (OPEC) provided about 34% of extra-EC petroleum product imports in 1992, with the former Soviet Union and Algeria accounting for a further 16% and 15%, respectively. Extra-EC exports of refined products from the EC rose by 5.1% to 161.7 million t from 1991 to 1992. The Netherlands accounts for about one third of these exports with the United Kingdom adding a further 13.5%.

Having risen strongly for a few years, imports of oil products from the USA have stabilised. Such imports stood at 6.9 million t in 1989, 10.8 million t in 1991 and about 10.5 million t in 1992. The USA share of total imports into the EC stood at 6.1% in 1992 compared to 4.1% in 1989. Much of the increase in imports from the USA since 1989 is accounted for by growth of imports of gasoil, particularly in 1991.

Among EC Member States, the trade balance varies widely in terms of volume. In 1992, four countries were net exporters, the Netherlands, the United Kingdom, Belgium and Spain. The Netherlands had the greatest surplus, at about 21.5 million t.

MARKET FORCES

Demand

The product consumption figures in Table 5 represent only inland deliveries, which excludes bunkers' and refineries' own consumption. Between 1973 and 1985, EC oil demand fell by 21%. Since 1985, demand has risen. From 1991 to 1992 the increase was 1.5% to 492 million t. Since the oil crisis in the early 1970s, oil has lost market share to solid fuels, natural gas and nuclear power. From 1973 to 1989, the share of oil in total primary energy demand declined 60% to about 443 million t. Recently, oil's share has crept back up, boosted by low prices and concern about the environmental impact of solid fuels. In 1992, oil's share in total primary energy demand is was about 44%. This rising trend is unlikely to continue.

The long term displacement of oil has occurred in the industrial, domestic and power generating sectors. However, the road transport sector remains completely dependent on oil due to the absence, as yet, of any viable alternative energy source: as a result, some 50% of oil is now consumed in the transport sector, compared to 30% in 1973. These long term trends in energy and oil use have had a dramatic effect on the structure of oil demand, which has increasingly favoured lighter products. The share of heavy fuel oil in inland oil demand has declined from 31% in the mid 1970s, to 29% in 1980 and 15% in 1991 (although, there is a wide varitation by country), while that of light products (LPG, naphtha and gasoline) has increased from 25% in the mid 1970s to 26% in 1980 and about 37% in 1991.

Consumption of middle distillates declined in the second half of the 1970s, but then remained virtually stable throughout the 1980s. The share of middle distillates in inland oil demand has recently been rising. In 1992, it averaged 43% compared to 40% in 1989 and 36% in the mid-1970s. The increase in the share of middle distillates is due to rising demand for middle distillate transport fuels, jet fuel and automotive diesel. Consumption of heating oil has been declining rapidly. From 1991 to 1992, consumption of diesel and jet kerosene rose by 4.6% and 8.1%, respectively, while consumption of other gasoils fell 4.3%.

Supply and competition

During 1992, there was relatively little movement in oil prices compared to 1991. However, 1991 had been an exceptional year with prices moving in wild swings in reflection of the markets' reactions to developments in the Gulf war. Early in 1992, prices showed moderate mixed movement as markets reacted to several matters. During this time, Iraq and the United Nations (UN) Security Council were discussing the "food for oil" deal. Markets talked prices up and down as they reacted to these discussions and also as they mulled February's OPEC meeting. After prices reached a March low, they rallied in June. Markets had found an excuse to send prices higher in the discussion of UN sanctions against Libya. Although an oil embargo was most unlikely given the large volumes of Libyan oil imported by several EC Member States, the discussions marked a turning point in prices. At the same time, fundamentals began to lend modest support. In May, although fundamentals were no longer particularly favourable, the roll-over of OPEC's output ceiling was viewed as bullish for prices as were comments from Saudi Arabia that it would like to see higher prices.

Spot crude oil prices fell back initially during the second half of 1992 but soon drew strength from USA gasoline demand. Towards the middle of the second half they showed some strength, boosted by demand in the Far East. Later in the second half, prices fell back with weak fundamentals and the possibility of a return of Iraqi output to world markets.

During the first quarter of 1992, product prices tracked a downward trend that was reinforced by mild winter weather. High sulphur heavy fuel oil prices bucked the trend to show a net rise. This performance was based on heightened utility demand caused indirectly by drought in France and Spain that hit nuclear and hydroelectric output as well as strong demand around the Mediterranean basin and in the Iberian peninsula. Prices turned around in August after a bearish reaction to weak disappointing summer demand gave way to seasonal buying of middle distillates and, demand for heavy fuel oil emerged in the Far East and North Africa.

The overall effect on refining margins was that they remained fairly flat, changing during the year by USD 2/barrel at most. During the first half of the year there was a general declining trend in margins, broken in May by light crudes such as Brent and Bonny Light. This was due to a strengthening of gasoline prices relative to crude oil prices ahead of the summer driving season. Moving into the summer, the margins of light crudes began a short-lived rise, but those of heavy crudes remained flat. From September into October, margins rose, boosted by higher product prices and the middle and heavy-end of the barrel. Towards the end of the year lower product prices undermined margins.

Consumer prices vary widely across Member States. The major determinant in the differences is the level of taxes applied to oil products. At the Ecofin Council meeting of 19 October 1992, the directive concerning the harmonisation of excise taxes was adopted. The following minima were agreed and applied from 1 January 1993: leaded gasoline 337 ECU/thousand litres; unleaded gasoline 287 ECU/thousand litres; automotive diesel 245 ECU/thousand litres; heavy fuel oil 13 ECU/thousand kilos; and heating oil, 18 ECU/thousand litres. The Member States that, as of the first of January 1991, did not apply an excise tax on heating oil, are authorised to continue to apply a rate of zero on the condition that they pay a control tax of 5 ECU per thousand litres (l) as of 1 January 1993. The minimum rate for LPG and methane used as transport fuel is fixed at 100 ECU per tonne and that on transport kerosene is fixed at 245 ECU per 1 000 litres.

Denmark has a lower rate than the advised minimum on premium leaded gasoline, however, leaded gasoline sold there is a mixture of 33% leaded and 67% unleaded. Luxembourg's excise tax rate falls below the advised minima for automotive

diesel and heating oil. Belgian taxes on heavy fuel oil now exceed the minima as Belgium has abolished the zero rate of tax it formerly applied; however, it's excise tax on heating oil is still below the minima.

For the period from 1 January 1993 to 31 December 1994, Luxembourg can apply a minimum rate of excise of 292 ECU per 1 000 litres for super leaded gasoline, 242 ECU per 1 000 litres for unleaded gasoline and 195 ECU per 1 000 litres for automotive diesel fuel. Greece will benefit from the same treatment for automotive diesel fuel. To a large extent, that these rates fall below the minima is just a reflection of the fall from grace of the currencies of these states within the European Exchange Rate Mechanism (ERM). Because only minima have been set, the final agreement will have only a small effect on consumer prices of oil products in Member States, and therefore on the level and structure of oil consumption.

Differences in excise tax placed on transportation fuels by the each Member States reflects the countries' policies regarding pollution reduction from the use of leaded fuels, by applying less tax on unleaded gasoline, and on gasoline in general, by applying less tax on automotive diesel.

A transitional agreement has been formulated to harmonise levels of value added tax (VAT). Following the adoption of the proposal for directive on the harmonisation of VAT rates at the Ecofin Council meeting of 19 October 1992, petroleum products were submitted to the normal rate, that is, a minimum tax of 15%. Nevertheless, Member States which applied a lower rate on petroleum products as of 1st January 1991 are authorised to apply a minimum rate of 12% from 1st January 1993 to 31st December 1996. The United Kingdom which applies a zero rate on gasoil for heating can maintain this rate until 31st December 1996. However, for domestic economic reasons, the United Kingdom government has announced its intention to introduce VAT on domestic fuel at 8% from April 1994. VAT at 17.5% will be charged beginning 1995 and thereafter.

Production process

Within the EC, each Member State has widely differing production structures. Germany, France and the United Kingdom are characterised by their low proportion of heavy fuel oil and by a relatively high proportion of gasoline output. At the other extreme, Greece, Portugal and Ireland have a refining sector that is characterised by a high proportion of heavy fuel oil production and relatively low light-end output. Over the past few years the move towards increased upgrading capacity and product quality improvement has continued to shift the structure of refinery production away from heavy oil products in favour of the light products.

Any assessment of the utilisation rates of primary distillation capacity poses a statistical problem due to the increase in the share of feedstocks in refinery throughputs. Some of these semi-finished products are re-distilled while others go directly into secondary plants. The problem is that the amounts in either category are not recorded in several EC countries. Because of this, the Commission presented a range consisting of a "maximum" (the relation of total input for transformation in the refineries to distillation capacity) and a "minimum" (calculated solely on processed crude oil) in its communication (Com (88) 491) to the Council on the oil market and the refining industry in the EC.

The variations between these two points differs from country to country and from year to year, because refiners switch from crude oil to semi-finished products depending on their relative prices. These variations are related to the prevailing economic, seasonal and climatic conditions in each country, as well as to turnarounds and the opportunities for exports of key products such as gasoline to the United States. In 1991, EC refineries went into turnarounds in the second quarter, with the utilisation rate dropping to a low of 77% in April and May, before again moving to a summer peak of 89% in August. Many refiners went into turnarounds early in 1992, but others waited until the more traditional second quarter. Consequently the utilisation rate remained flatter than in 1991, touching lows of 83% in February and April. The utilisation rate peaked at 89% in August before falling to an autumn low of 85% in November.

INDUSTRY STRUCTURE

Companies

Refining

Two major problems have afflicted the EC refining industry over the past 10 years. The industry suffered from a chronic surplus of primary distillation capacity due to the decline in overall oil demand in the first half of the 1980s. In addition, the shift toward demand for lighter oil products has forced the industry to invest heavily in conversion capacity to boost production of lighter products and improve product quality.

These problems have been solved by concentrating the industry's activities in a smaller number of refineries that have a more complex structure and are capable of responding to the changing product demand. Consequently, from 1988 to 1992, refineries in most Member States operated without making losses for the first time in many years, however, this was no longer true in the beginning of 1993 in most Member States. Moreover, finished product imports have declined. Currently, planned upgrading capacity in European refineries will help to meet the rise in demand for light products (particularly unleaded gasoline).

In autumn 1991, the 7.8 million tonne/year Mobil refinery at Wilhelmshaven (D) was brought back into operation. The refinery was acquired by Beta Refining & Marketing, a company jointly owned by the trading company Bulk Oil and the French trading firm, Dreyfus. However, in 1992, no new refineries were brought on line.

During the second half of 1993, Elf and Thyssen announced that they will invest in a new refinery as a joint project in Leuna, in eastern Germany. This new refinery, that will replace the existing one in Luena and another in Zeitz, will have a planned capacity of 10 million t/yr and is due to come on line during the first quarter of 1996. Objectives are to produce some 5 million t/yr of middle distillates and jet fuel, 3 million t/yr of gasoline and naphtha and about 300 000 t/yr of LPG.

State monopolies continue to play a significant role in a number of EC countries. However, liberalisation is steadily proceeding. In Greece a three phase plan is being implemented to liberalise markets. This plan removes all remaining controls on prices and margins and allows for the importation of oil products. More recently, the Greek government has indicated that it is keen to move ahead with privatising the refining sector. Both the Asropyrgos and EKO groups of companies are being prepared for privatisation before the end of 1993. The liberalisation of the Greek oil market has stimulated plans for a new refinery. However, new capacity is not expected to come on line before the mid-1990s. In all probability some rationalisation and adaptation will occur in the meantime, since Greece's refining sector is currently ill adapted for a move toward lighter products and a rapid shift into production of large quantities of unleaded gasoline.

In Portugal, the oil product markets were liberalised at the start of 1991, including the system of market quotas. This has put Portugal's three refineries under pressure to modernise and expand their upgrade capacity to enable them to compete with imports. Thus, the three Portuguese refineries, all owned by Petrogal, are to be functionally re-organised. The oldest refinery at Cabo Ruivo no longer distils crude, but is being converted to a distribution centre and batch blending plant.

Source: Eurostat

Work underway includes enlarging and improving liquid fuels and LPG storage facilities and modernising tanker-truck filling facilities. Work on the next oldest refinery at Matosinhos (north of Porto) was completed in 1991 and introduced increased flexibility at the plant and the ability to run imported feedstocks or refine its own crude. The newest refinery at Sines was initially considered a "white elephant", due to its large (10 million t per annum) primary distillation capacity. Efforts to export some of its output have proved successful, enabling the refinery to run at 70% of capacity. Installations of a catalytic cracker, a vacuum distillation unit, an alkylation unit, a visbreaker and an methyl tertiary butyl ether (MTBE) plant are scheduled to be operational by the end of 1993.

Fuel retailing

The major companies continue to have a dominant position, even during years of recession, as they have continued to invest large amounts to protect their market share. They now account for nearly 30% of the EC retail outlets. Shell (NL/UK) has the dominant market share, closely followed by BP (UK). Some of the traditionally national oil companies have now spread their presence throughout Europe: Total is present in eight countries for a market share of 4.4% (1992). A relative newcomer to the European downstream business is Kuwait Oil, which introduced the Q8 brand in 1986 and now owns 4.5% (1992) of the EC retail outlets. Kuwait Oil is now the largest retailer in Denmark and is a major presence in Italy, the United Kingdom, Belgium and the Netherlands. Although competition is stiff, the integrated oil companies, especially the major ones, are regaining ground in retailing because excess refining capacities have disappeared in some countries. Access to supplies is essential for maintaining and expanding a market position in retailing.

Overall, in the countries where regulations permit, supermarkets have an important market share, but nowhere is it as large as in France where a third of automotive fuel is sold by supermarkets (the market share is nearly 40% for gasoline alone). In the United Kingdom, their market share is nearing 15% and is expected to increase to 20% by 1995. The other two countries where hypermarkets have a substantial market share are Belgium and Germany, where it is 10%, though this share is not expected to increase much more in the near future. During 1990, some supermarkets have sold their service stations to oil companies: this is the case of Casino (F) which sold to Shell and AGIP (I).

In parallel with these developments, there has been a trend toward concentration. During 1990, Elf (F) was the most aggressive acquirer, with acquisitions in Spain and the United Kingdom. Shell, AGIP and Norsk Hydro (N) also made acquisitions in the EC retail business.

Liberalisation is also affecting the structure of the petroleum product retailing sector. In Spain, the refinery and product distribution sectors have been liberalised. The structure of its industry has changed in that Repsol (part state owned), Cepsa (part owned by Elf) and Petromed (owned by BP) have inherited the Campsa retail outlets and jointly own Corporacion Logistica de Hidrocarburos (CLH), which inherited the Campsa distribution network. The share of ex-Campsa retail outlets is roughly 60% Repsol, 25% Cepsa and 10% Petromed (some are still unaccounted for). In addition to this is a number of other oil companies have entered the Spanish retail market, most notably Shell and Petrogal. There are now about 750 retail outlets owned by "new" entrants.

Shell recently purchased a 5% share in CLH. This share was purchased from Repsol, reducing their stake in CLH from 66% to 61%.

However the liberalisation of the Spanish oil market has not led to a dramatic increase in imports of oil products. The reasons for this are excess domestic refining capacity, poor access to the CLH distribution system, and the small market share of non-domestic refiners in retail markets. The issue of access to the CLH distribution system, including its pipeline network, has yet to be resolved and is likely to be contentious. This pipeline network gives CLH shareholders a distinct advantage over their future competitors.

In 1992, the first stage of the privatisation process of Petrogal was completed with the sale of 25% of the company's shares to a consortium led by Total of France. The buyers will purchase a further 26% of the company's stock within three years, giving them a majority stake in the company. Petrocontrol was formed as a joint holding company to manage the consortium's stake in Petrogal. The Portuguese investors have a 52% stake in the new company and Total has a 48% stake. Of the remaining 49% of Petrogal's shares, some 20% is expected to go to the employees and small investors, 19% will be sold to "strategic investors" (namely the Calouste Gulbenkian Foundation and Sonangol - the Angolan state oil company). The remaining 10% will be held by the state as a "golden share".

In May 1992, the French government announced its plan to reduce its stake in Total to 15% by the end of the year. In June 1992, the state sold 12.4% of Total's shares which left it with a direct holding of 12.6%. The government also sold its 6.7% share of the company's capital in the form of petroleum certificates. The state has retained an indirect 2.3% share via two public insurance companies, GAN and AGF. Last year, the French government sold shares representing 2.3% of the company's capital which left it with a 51.5% holding. This year, the new centre-right government has included Elf in

the list of companies slated for a round of privatisation that is scheduled for the last quarter of 1993.

AGIP and SNAM (I) are to be partially floated and the remainder of ENI (I) reorganised and privatised later. Some 15-20% of AGIP stock is likely to be floated in the near future, political problems not withstanding, which should net the Italian exchequer some L 2 000 billion.

In Greece, state-owned DEP which among other functions distributes petroleum products, is effectively a monopoly, though its public monopoly status has been removed. Since the "competition" to which the oil market has been opened remains very restrained, DEP continues to control the domestic market

ENVIRONMENT

Environmental considerations have moved to the top of the EC's political agenda, particularly in relation to global climatic change. The EC has committed itself to stabilising CO_2 emissions at the 1990 level by the year 2000 and signed the Climatic Convention at the Rio de Janeiro conference. The energy sector has a key role to play in achieving this target, through improvements in energy efficiency and the promotion of fuels containing less carbon. The mechanisms to implement these changes are primarily aimed at influencing market forces, either directly through fiscal measures or via assistance to R & D projects and the promotion of technological innovation in the energy sector.

During 1992, the EC Commission proposed new taxes which involved an element explicitly linked to the carbon content of fuels. Under these proposals, the tax will be phased in during the 1990s at an initial level of USD 3 per barrel of oil and will reach a level equivalent to USD 10 per barrel in 2000 (50% linked to the carbon content of the fuel, 50% to the energy content). The proviso is that the EC's major trading partners do the same.

Environmental issues are likely to continue to put pressure on refiners to remove sulphur from products and, more generally, to affect the specifications for fuel quality.

An EC directive adopted in 1985 required that unleaded gasoline be marketed in all Member States from 1 October 1989. This date coincided with the date when all large cars produced (2 litres) were to be equipped with catalytic converters. Unleaded gasoline is now widely available in all European countries. Moreover, all cars produced after 1 October 1990, whether they are equipped with catalytic converters or not, must be able to run on unleaded gasoline (Eurograde 95 research octane number [RON]). Although there have been some derogation for old-type engines, 90% of cars produced can run on Eurograde.

An amendment to the directive permits Member States to ban leaded regular grades, which Germany and Luxembourg have done; Belgium is in the process of implementing a ban. The directive encourages Member States to introduce tax incentives in favour of unleaded gasoline in order to accelerate its penetration, which all countries have done. In addition, in order to allow a larger proportion of the existing car population to run on unleaded gasoline, most oil companies have introduced an unleaded fuel with a higher octane level, Super-premium unleaded (98 RON). Super-premium is marketed in most countries, with the exception of Greece, Portugal, Spain and Italy.

The introduction of tax incentives and high octane grades of unleaded gasoline have led to a rapid penetration of unleaded in the gasoline market. Its share increased from less than 10% in 1987 to an estimated 47% in 1992. Concurrently, sales of leaded regular have nearly disappeared in several countries even where they are not banned (United Kingdom, Denmark, Netherlands). Nevertheless, the rate of penetration of unleaded varies widely between member states, because of different tax incentives, government policies and the structure of the car population. The penetration is as high as 84% in Germany but still negligible in Portugal and Greece. In Spain, the share of unleaded is picking up, from less than 1% in 1990 to 6% in 1992.

From the beginning of 1993, all new gasoline-powered cars registered in the EC have to be fitted with three-way catalytic converters to meet exhaust emissions standards. This presages the universal use of unleaded gasoline. However, the speed with which unleaded gasoline gains 100% market share depends on the rate at which owners of pre-1993 cars opt for unleaded fuel and the rate at which old cars, able to use only leaded fuel, are scrapped. The effect will be relatively small in Germany, Denmark and the Netherlands, where the purchase of catalyst-equipped cars has been favoured for some time by tax incentives. However, in other countries, the new emission rules will give a significant push to sales of unleaded gasoline.

REGULATIONS

EC legislation relating to fuel quality addresses the content of lead, benzene and oxygenates of gasoline and the sulphur content of diesel and other gasoils (national standards specify other fuel properties). The European Standard Organisation (CEN) adopted European specifications for unleaded gasoline (EN228), for automotive diesel (EN590) and LPG (EN 589).

The maximum authorised lead level in leaded gasoline is 0.4g/litre, but EC countries are encouraged to use a maximum limit of 0.15 g/litre. All EC countries, except Portugal, have now adopted this lower limit. The maximum benzene content of gasoline is set at 5% for both leaded and unleaded grades.

Source: Eurostat

CEN EN228 specifies the octane quality of Eurograde unleaded (95 RON/85 MON [motor octane number]), the benzene content (5% vol. max.) and the lead content (0.013g/litre). The sulphur content is currently set at 0.1% weight maximum, but will be reduced to 0.05% by 1995. Volatility and density specifications have also been agreed upon.

A directive requires that Member States permit fuel blends containing oxygenates and specifies the maximum content. If this maximum is exceeded, then the pumps must be clearly labelled. Most countries restrict limits below the maximum, with only four countries (Belgium, Denmark, Ireland and Luxembourg) permitting levels equal to, or exceeding, this level.

A 1987 directive specifies a maximum level of sulphur in gasoil of 0.3% weight, except for gasoil used in shipping or further processing; the directive allows Member States to reduce the sulphur content to 0.2% if necessary for environment or health reasons. Five EC countries have already reduced the sulphur content to 0.2%. A directive, adopted in March 1993, calls for a reduction in the sulphur content of all gasoils to 0.2% by 1 October 1994. A further reduction is to be implemented by 1 October 1996 for the sulphur content of automotive diesel (to 0.05% by weight), as this is required to meet the exhaust emissions limits for diesel engines. The Council asked the Commission to propose a further reduction of the sulphur content of gasoil for industry, space heating and shipping, and sulphur limits for aircraft kerosene. This directive also requires that the distributed automotive diesel of 0.05% sulphur be gradually available by 1 October 1995.

Control of reserve stocks

The reserve stocks consist of quantities of oil products which can be called upon at any time by a country to bridge a temporary shortage situation or difficulties in the sourcing of hydrocarbons that occur as a result of an oil supply emergency following rules established by the EC as well as the IEA. Directive 68/414 required the creation and maintenance of reserve stocks at the EC level initially representing 65 days' consumption this was then increased on 1 January 1975 to 90 days' consumption for three categories of product: petrol, jet propulsion fuel and diesel and heating and heavy fuel oils. Since the directive merely imposed the obligation to achieve an end result, the EC Member States have established over the years systems quite different from one another and which can be divided into two categories depending on the existence or non-existence of a centralised stockpiling authority.

EC countries with a central reserves administration

Four countries have a central reserves administration: Denmark, Germany, France and the Netherlands.

Denmark has had legislation governing reserve stocks for over 30 years; the reserves are administered by the Foreningen Danske Olieberedskabslager (FDO), a non-profit making foundation established in 1959 with voluntary membership. The FDO is financed by contributions from its members. The 1959 legislation related chiefly to fuels and was amended when Denmark joined the EC by the law of the 24 May 1972 which widened the stockpiling commitment to the three product categories specified in the EC directive. Currently, Denmark has a 120 day reserve of stocks.

In Germany, the lion's share of the stockpiling requirement of 80 days' consumption is administered by the Erdölbevorratungsverband (EBV), a national body with public corporation status financed by means of a special tax. At least 90% of the reserves stocked by the EBV are its own property. The refineries themselves ensure a mandatory 15 days supply. In addition, the federal government has amassed stocks of crude oil equivalent to a 30 day supply.

France long ago established legislation requiring the stockpiling of oil reserves (the commitments to create and maintain safety reserves can be traced back to the law of the 10 January 1925). More recently (1988) France established a central reserve administration, the Société Anonyme de Gestion des Stocks de Sécurité (SAGESS). This is a private limited company with a special fiscal and legal status. Its shareholders must be all those companies (refiners and independents) who hold a special licence to import and market oil products; its operating costs are defrayed by the contributions paid by the shareholders. SAGESS is responsible for half the total legal stockpiling requirements, i.e. 45 days, twelve of which it actually owns and the balance being covered by allocations; the remaining 45 days are the responsibility of special licensees. As of 1 January 1993, a new law was passed regarding stockpiling requirements.

In the Netherlands the collective administration of stocks is entrusted since 1986 to the Central Organ Vorraadsvorming Ardolie-produkten (COVA), a public body which maintains 70 days of reserves of the light and medium distillation fractions. COVA is financed out of a levy on oil products additional to excise tax. The refineries are required to maintain a 50 day stockpile and sixteen and two-thirds days are maintained by the independents. The stockpiling of heavy fuel oils has been administered since 1 January 1987 by the Union of electricity generators (SEP).

EC countries with no central reserves administration

In Belgium, compulsory stockpiling represents one quarter of domestic supplies made during the previous calendar year; the responsibility is assumed by refineries and importers who are both required to maintain 90 days.

In Greece, the distributors are principally required to maintain 90 day reserve stocks, however this obligation may be assumed by the local refineries which supply the distributors. Distributors only commit themselves to the products which they actually import.

Source: Eurostat

In Spain, the requirement to hold 90 days of oil reserves is spread evenly between the refineries and distribution companies.

In Ireland, stockpiling is ensured by importers by means of coverage contracts signed with the state refinery company located at Whitegate.

In Italy, the compulsory 90 day reserves are administered by various bodies: the refiners, importers, ENEL, the national electricity generating company, as well as the government itself whose strategic stocks are handled by ENI.

The Portuguese oil reserves are administered by import licence holders (refineries, importer-distributors) and represent 120 days of consumption although part of these may be provided by the state corporation Petrogal.

The target of 90 days of indigenous production of oil reserves of every country was cut by 15%. Today, this target is only fully utilised by the United Kingdom and Denmark Two groups of operators are required to maintain reserves: first the refineries (76.5 days); and then the importers, distributors and consumers importing more than 50 000 t per annum for their own account are required to maintain a 66 day reserve.

OUTLOOK

Net back margins are expected to increase. However, as this upward pressure will result from rising operating costs, refiner's net margins are not expected to benefit greatly from the increase in this ratio. Factors pushing up operating costs are principally environmentally related. Increasingly severe constraints will be placed on refiners to abate plant emissions into water (discharges of oil and other products), into the air (principally emissions of SO_2, NO_x and hydrocarbons) and on to the land (liquid and solid by-products of refining). Product quality norms (notably for transport fuels) will become more severe, increasing the complexity of the refining process. The latter factor will be accentuated by the deterioration in the average quality of crudes available to the Western European market.

The structure of oil product demand is expected to shift in favour of middle distillates. The previous move to lighter products appears to be complete while the trend away from heavy-end products is set to continue. By 1995, the share of unleaded gasoline in the EC is expected to exceed 75%. Although there will continue to be wide variations from country to country in the market share, the difference between countries is expected to be far less than that of 1990. Overall, the share

Table 9: Refining and distribution of oil products

of oil in EC primary energy demand is forecast to decline further over the next decade, giving way to natural gas.

The refinery sector is expected to see a very modest expansion of primary distillation capacity. However, upgrade capacity within the EC is expected to increase at a faster rate, reflecting the move towards higher quality products and the shift in oil product demand away from the heavy-end. The retailing market is expected to move into a more sophisticated and increased product specification era, with the emphasis on product quality and performance, as well as on brand differentiation. The trend towards diversification, automation and increased size of sites is also expected to continue.

Written by: DRI Europe
The industry is represented at the EC level by: European Petroleum Industry Association (Europia); Address: Madou Plaza 25th Floor, B-1000 Brussels; tel: (32 2) 226 1911; fax: (32 2) 219 9551.

Electricity generation and distribution

NACE 161

Electricity consumption in the EC grew by 30% in the 1980-1990 period, while the electricity intensity of GDP has been generally stable from the second half of the 1980s.
Nuclear contribution to the electricity sector has risen considerably over the past two decades, but generating capacity is expected to peak in the latter part of the 1990s. The share of nuclear power may then start to decline unless new orders are placed for additional capacity. Electricity production from renewable sources remains very isolated, limited by high investment costs and increasing concerns over siting. Constraints on these primary energy sources will mean that an increasing share of electricity demand is likely to be met by increases in conventional thermal capacity, and in particular gas-fired capacity.
The industry is also going through a period of change with respect to its structure and regulation. At the European level the Commission of the European Communities is continuing discussions on its plans to develop the electricity sector within the framework of the Internal Energy Market, with the proposal for a further two stages to be added to the directives on transit and price transparency. The new proposals include the introduction of third party access on a limited scale. These developments are being complemented at the national level where there is a trend towards greater involvement of independent power producers.
In addition to developments in structure and technology, the industry also has to face the challenge from the environment. The electricity industry should play a significant role in achieving CO_2 emission targets.

INDUSTRY PROFILE

Description of the sector

NACE 161 includes generation of electric power destined for public use from thermal energy (161.1), hydro-electric energy (161.2) and nuclear energy (161.3), transmission and distribution of electricity (161.4), and the generation of electricity by non-public suppliers for their own use (161.5 to 161.7).

The supply of electricity involves numerous activities, including: fuel purchasing and electricity generation; expansion, maintenance and operation of transmission and distribution networks; trading bulk electricity; operation of customer billing and accounting systems.

Recent trends

Three countries account for two thirds of the total EC electricity production: Germany (27%), France (24%) and the United Kingdom (16%). Indeed the top six countries account for over 90% (Italy (12%), Spain (8%) and Netherlands (4%). Over the course of the 1980s, France has dramatically increased its share of total EC electricity production, up from just over 18% in 1980. This increase reflects the French policy aimed at reducing its dependence on imported oil and promoting increased electricity use in conjunction with the development of nuclear power plants. The other countries where there has been a noticeable increase in electricity production over the course of the 1980s have been Greece and Portugal with growth of 4.3% and 5.7%, respectively, (the EC average was 2.5%). The only country to show a fall in production was Denmark, which reflects the increase in imports from Norway and Sweden.

Electricity consumption increased by 30% from 1980 to 1990, an average yearly growth rate of 2.5%, which represents a slow down compared with the corresponding rate of 3.7% from 1970 to 1980. However, the rate of growth of consumption has varied considerably largely due to the strong link between electricity demand and economic performance. Growth was therefore low during the first half of the 1980s, and then much stronger in the second half. The strong growth seen in the later 1980s continued into the 1990s, however the sharp recession of 1993 is expected to make a significant impact on demand.

The electricity intensity of GDP, having increased between 1970 and 1985, has been relatively stable in more recent years, although across countries the trend has varied widely.

Several factors explain why electricity intensity in the EC stopped increasing after 1986:

- the oil price collapse (in real terms the price of oil is now below the 1973 level) and the general decline in fossil fuel prices, while electricity prices remained much more stable, which resulted in electricity becoming less competitive;
- the saturation effects in some applications and some countries. This is most evident in the northern EC Member States, while there is scope left for increased penetration of electrical appliances in the Mediterranean area;
- the development of more efficient appliances and processes in general.

Most of these factors will continue to have an impact on electricity consumption in the future, though the catch-up effect of increased electrical appliance utilisation in southern Europe, coupled with some fuel switching to electricity in the industrial sector, should ensure that electricity intensity remains stable over the next few years. However, saturation effects will progressively become more widespread, with the result that the electricity intensity of GDP may start to decline over the second half of the 1990s.

Electricity has increased its penetration of total energy consumption, rising from 14.7% in 1980 to 17.9% in 1991. The share of electricity in final energy consumption varies substantially across countries, reflecting the structure of industry, the level of automation in industry, the use of electricity for space heating and the level of appliance ownership in the domestic sector.

Within the EC, France, Portugal, Spain, and Denmark have the highest level of electricity penetration, while Luxembourg, the Netherlands and Ireland have the lowest. In France, electricity consumption in the residential sector has grown with the increased use of space heating, while in Luxembourg, the low share of electricity reflects the dominance of coal use in the important iron and steel sector.

Foreign trade

The flow of electricity between Member States has noticeably increased over the past fifteen years. In 1992, the trade in electricity between the Member States increased to 231.4 TWh, compared to 200.5 TWh in 1989 and 58 TWh in 1973. The amount of electricity traded has risen faster than consumption, such that in 1990 it accounted for 12% of gross inland consumption, up 2% from 1987.

Trade with countries outside the EC is still very limited due to the lack of interconnections between countries. Currently only Austria, Switzerland and Norway exchange significant amounts with the EC. However this is expected to change in the near future as new connections to Central Europe are added and those to Scandinavia strengthened.

France is the major net exporter of electricity within the EC; Spain and Germany also recorded small net exports in 1992.

Net exports from France amounted to about 12.7% of the country's production, a situation that resulted from the development of nuclear power capacity in France at a rate faster than domestic demand growth. The major export markets for France are the United Kingdom, Italy, Germany and Switzerland.

MARKET FORCES

Supply and competition

The mix of generation in each country varies considerably, and reflects access to the various primary energy sources. However, it is possible to determine some key trends that will shape the future supply picture for the Community as a whole.

Hydro-electric power, having maintained a relatively stable share of the total energy input over the 1970s and first half of the 1980s, has seen its share edge lower as growth has returned in electricity consumption. Should electricity production increase further over the next decade, it is expected that hydro-electric's share of the total will fall further. The scope for additional hydro-electric development is limited for a variety of political, economic, and environmental reasons, with the result that the remaining exploitable hydro resources will see limited development throughout most of the EC. Significant developments are only expected to occur in the Mediterranean area.

Electricity production from renewable sources remains limited, despite efforts at the EC and national government level to promote and subsidise their development. Excluding hydro-electricity, only geothermal and wind power have made real inroads into the public supply sector, although across the EC there are wide variations in the use of renewable sources. Of these two energy forms, Denmark has the highest share of wind power, 1% of total generation, while Italy has the highest EC level of geothermal power, 1.5% of total generation. The principal limitations to the development of renewable sources are high investment costs, and concern over siting in a number of countries. However, more recently, considerable interest has been shown in the use of biomass and waste as a source of fuel for electric power plants. It is anticipated that these sources will become more important and widespread in the future.

With the exception of France, no new orders for construction of nuclear power plants (which have not subsequently been cancelled or indefinitely postponed) have been placed in Europe since the early 1980s. The completion of capacity currently under construction, and firmly committed capacity, will lead to a peak in nuclear generation capacity and production in Western Europe in the late 1990s. Unless further nuclear plant is ordered within the 1990s the share of nuclear power will begin to decline in the early 21st century, due to increasing demand and plant retirement. New construction in France and the United Kingdom after the year 2000 will not be sufficient to offset the steady decline in generation capacity (though life-extension programmes are expected to draw out operating spans to as much as 40 years for most reactors).

The slowly declining shares of nuclear and hydro/geothermal power over the next decade will be offset by expansion of the share of conventional thermal power. Consequently, the major capacity development questions facing the Western European electricity supply industry surround the refurbishing, replacement, and expansion of conventional thermal power generation capacity.

In 1992, conventional thermal generation accounted for 56% of supply, down slightly from the previous year. Indeed, the share has declined substantially over the past two decades, down from 83% in 1973, largely due to the increase in nuclear power generation. The share of nuclear power share has risen from 5.4% in 1973 to 34.4% for the EC as a whole in 1991. However, fossil fuel use in conventional thermal power plants continues to dominate the energy input mix within the power generating sector.

Environmental arguments against the continued development of solid fuel-fired generation capacity have, to some extent, been accommodated by the implementation of the Large Combustion Plant Directive (LCPD). In addition, since the removal of the directive restricting gas use in power generation many utilities plan to build efficient and clean gas-fired combined cycle gas turbine (CCGT) plants. However, despite the cost of emission abatement equipment, coal will remain an important source of fuel reflecting the importance the power generating utilities place on flexibility, and the expectation that coal will retain a relatively low and stable price profile. In the longer term, the prospects for coal will be improved with the development of high efficiency Integrated Gasification Combined Cycle (IGCC) generation.

The use of natural gas in combined cycle generation offers higher thermal efficiency than "conventional" generation. There are four main reasons why a shift towards natural gas can be expected in the power generation fuel mix:

- Environmental advantages: growing concern about the environmental impact of energy consumption helps to sustain interest in natural gas, which is less polluting than most of the other fossil fuels.
- Price: although fuel costs are higher than those of coal, the total cost, including capital and operating costs, per MWh of output are less.
- Co-generation: growth in the use of combined heat and power is creating many new market openings for natural gas consumption in industry. The countries showing the largest growth potential for gas-fired co-generation are Denmark, Italy and the United Kingdom.
- Changes in industry structure: the European electricity generation industry is undergoing some degree of change. There is a trend, most noticeable in the United Kingdom, to encourage the generation of electricity from many different sources and new entrants are being allowed into the public supply industry. It can be seen that commercial developers tend to choose CCGT plants due to their lower specific capital costs, and lower level of environmental risk due to the higher efficiency and low levels of polluting emissions.

Production process

In general, the use of a power station will be determined by its marginal cost, and plant will be scheduled in order to minimise costs. However, the nature of electricity requires that any increase in demand must be met with an instantaneous increase in production from within the confines of the transmission system. This imposes technical requirements for the operational management of the system and the scheduling of power stations. Other factors, such as power losses, will also provide a second order input into the economic scheduling of power plant. One way to reduce the call on expensive plant, and to increase system security, is to increase the size of the system. Electrical interconnections across national frontiers have developed over many years as a logical extension of local, regional and national interconnections, and have been driven by the economic and technical advantages that a more profitable use of generating facilities provides.

In the EC, this trend has resulted in one of the most closely integrated high-voltage international networks in the world, although Ireland and Greece are still not directly interconnected with any other Member State. In the case of Greece, who has been disconnected by the UCPTE grid because of the war in the former Yugoslavia, the EC has recently approved funding of the interconnection to Italy as a means of providing Greece with greater security of supply. Plans are also being considered to link Ireland with the UK mainland, but as yet no funding has been agreed.

International exchanges are managed, without executive powers, by two co-operative organisations of the electricity authorities. These are UCPTE (Austria, Belgium, France, Germany, Italy, Luxembourg, Netherlands, Switzerland, Greece, Portugal, Spain and former Yugoslavia), and NORDEL (Denmark, Norway, Sweden, Finland and Iceland). UCPTE announced in March 1990 the development of a computerised exchange system, called the Electricity Stock Exchange. This system enables the daily management of exchanges instead of the previous weekly sessions. However the final implementation

of the system is awaiting clearance from the EC competition authorities.

The electric utilities enter into a range of commercial arrangements for the exchange of electrical energy; these fall into three main categories: hour-by-hour exchanges on a cost basis, including back-up in the event of grid difficulties; contracts (usually short-term) for net transfers; permanent arrangements for the transfer of energy from joint-owned production plants in a neighbouring country. Furthermore, it should be noted that all the elements of the international interconnection system are owned by the companies and transfer arrangements are made on a co-operative and not a mandatory basis.

INDUSTRY STRUCTURE

Companies

The structure of the electricity supply industries in the EC countries varies considerably, and reflects a number of factors including the historical development of the industry, and government policy in such areas as security of supply and competition. Some countries of the EC have industries dominated by a single, often state-owned, vertically integrated utility, others have far more decentralised industries with a separation between generation and distribution, and others have a mixture of small municipal distribution companies and much larger vertically integrated companies. France and Italy have highly vertically and horizontally integrated utilities, while at the other extreme UK and Netherlands have decentralised structures.

However there is a movement throughout Europe towards a greater involvement of independent power producers. It is anticipated that this will continue irrespective of the outcome of the debate over the future structure and regulatory systems that is currently taking place. The reason for this are two-fold; firstly, in countries that are dominated by state control, the need to curb public sector borrowing may cause the government to consider privatisation, which may involve the introduction of competition into the generation business; secondly, technological development is providing end-users with greater flexibility in the way that they can meet their energy needs (through both demand-side and small scale supply-side measures).

In Belgium, the three private generators (Ebes, Intercom, Unerg) were grouped together in July 1990 to create a new entity, Electrabel. This grouping is the result of a sectoral rationalisation process under way since the 1950s and will enable them to better confront foreign competition. The municipalities are responsible for the distribution of electricity destined for lighting and domestic use, as well as to industrial users who consume less than 1 000 kW.

In Denmark, the electricity generation is in the hands of twelve companies, most of which are directly or indirectly owned by municipalities. The public electricity generation companies are grouped into two associations, Elsam and Elkraft, which are responsible for co-ordination and planning of generation and transmission capacities, as well as the daily operational co-ordination of fuel purchases for power stations. Electricity distribution is provided by 111 companies, five of which are generating companies, 54 are municipal companies and 52 are co-operatives or foundations.

In France, the monopoly for electricity generation, transport and distribution was given to Electricité de France (EdF) in 1946. EdF operates 88% of installed capacity and 96% of electricity distribution. The remainder being accounted for by auto-producers and some municipal distributors.

In Germany, the electricity supply industry is highly decentralised, with some 960 individual public electricity companies. However, the sector is tightly controlled by several federal and regional organisations which are responsible for co-ordination and regulation. Nine large public companies (two of which are nationalised) own and operate the majority of generation capacity, including all the nuclear power stations and almost the entire national high-voltage grid.

The former East Germany will soon be connected with the UCPTE network. Prior to unification, East Germany was connected to the IPS grid, which primarily received power from the Soviet Union for base load supply rather than peak exchange as in the case of the UCPTE grid.

In Greece, the Public Power Corporation holds the monopoly for generation, transmission and distribution.

The Irish electricity industry has been substantially reorganised in order to give it greater flexibility and cost transparency, and to accommodate potential developments in regulation at the European level. The Electricity Supply Board (ESB) now has a horizontal structure, with the main activities of generation, transmission and supply, separated into different divisions. The new structure specifically allows for the development of independent power generation. The company is still state owned.

In Italy, the electricity industry largely consists of a single state owned company responsible for electricity generation, imports, exports, transmission and distribution throughout the country. The only exceptions to this are: municipal companies in existence before 1962; generating organisations which con-

sume more than 70% of their own production; production by combined heat and power plants of less than 15 MW; generation from renewable resources. In July 1992, ENEL was incorporated as a joint company following a decision by the Italian government to privatise its industrial and commercial activities. The timing of the privatisation of ENEL S.p.A. will depend on the its ability to reduce its debt to a level more acceptable to the private sector. It is unlikely that this will happen before 1994.

In the Netherlands, electricity generation transmission and distribution is in the hands of municipal and provincial companies. After the sector re-organisation in 1987, there are now seven provincial companies and one municipal company responsible for electricity generation and transmission. They are grouped within the electricity generators co-operative (SEP), which is responsible for capacity planning and inter-provincial and international electricity exchange co-ordination. Sixty seven municipal companies distribute electricity and are grouped within VEEN.

In Portugal, Electricidade de Portugal (EdP) has the quasi-monopoly for generation and transmission. Independent generation and transmission is permissible in those areas not covered by the EdP distribution grid. A recent electricity law in Portugal provides for a new structure (removing generation monopoly) for EdP.

In Spain, the electricity industry has seen a number of mergers and asset swaps as companies respond to the new electricity legislation passed in April 1993 and prepare themselves for a more open European market. This new legislation allows for independent electricity traders and requires the separation of generation and distribution business accounts. The industry currently consists of a number of companies, some privately owned and some public, 17 of which are grouped under Unidad Electrica (UNESA), which is responsible for co-ordinating generation and transmission planning. The electricity grid was nationalised in 1984 and is operated by Red Electrica de Espana S.A..

The United Kingdom undertook a privatisation programme in 1990 and 1991, with the sale of the twelve Area Boards, the CEGB and the Northern Irish and Scottish generating and distribution companies. In England and Wales the 12 distribution boards where sold as separate companies and became the Public Electricity Suppliers (PES) with the responsibility of ensuring security of supply. The CEGB was broken into four parts; three generating companies, National Power, PowerGen and Nuclear Electric; and the National Grid Company (NGC), which is now jointly owned by the 12 PESs, and is responsible for scheduling plant. In Scotland the two vertically integrated utilities were sold largely intact, except for the removal of the nuclear generating business into Scottish Nuclear. In Northern Ireland the privatisation involved restructuring the industry into two distinct companies, one generating company, and one transmission and distribution company. In addition to the privatisation a new trading system has been implemented in England and Wales to orchestrate the trade of electricity between the various companies. This organisation is known as The Pool, and membership of which is enforced by the licensing system. The privatisation legislation also involved a support scheme for promoting non-fossil electricity generation.

ENVIRONMENT

The EC directive (no. 88/609) on emissions control from large combustion plants (those with a rated thermal input equal to or greater than 50 MW) was adopted by the European Council in November 1988, after four years of lively debate. The directive comprises two parts and is based on the use of best available technology at a reasonable cost. Applying this technical constraint helps to ensure the evolution of new and better technologies aimed at pollution abatement.

The first part of the directive applies to new combustion plants, built after 1st January 1990 and whose rated thermal input is greater than 100 MW (coal) or 50 MW (oil and natural gas). Under the directive, all new large combustion plants are subject to a licensing procedure to ensure that the plant meets specified emission standards for SO_2, NOx and particulates. The second part applies to existing stationary combustion sources (those for which authorisation was given prior to 1st July 1987), and specifies target values for reduction of emissions based on the 1980 level. Reductions in emissions are targeted at different levels by country: compared to 1980, overall EC SO_2 emissions must be reduced by 60% by the year 2003, and NOx emissions by 30% by 1998, the former in three stages, the latter in two phases. Plants authorised prior to 1987 and built before 1990 must either conform to the new plant standards or be taken into account in the global ceiling value.

Although new plant emissions standards have been uniformly established, global targets still vary from country to country. In addition, exceptions have been included at the request of specific countries, as well as a number of caveats that allow for the relaxation of targets and or target dates, e.g. "If a substantial and unexpected change in energy demand or in the availability of certain generating installations creates serious technical difficulties for the implementation by a Member State of its programme [of SO_2 and NO_x abatement]."

The emission limits for large combustion plants favour the penetration of natural gas in the power generating sector. The limits imposed on NO_x emissions in new plants can be met without the need for expensive NO_x emission abatement equip-

ment, though the SO_2 emission limits are relatively restrictive as regards the use of coal.

More recently the EC has proposed a carbon/energy tax as a way to give an incentive to consumers to achieve the $C0_2$ and limit other environmental degradation caused by energy consumption. The proposals have yet to gain support from all members of the Community due to concerns that it may affect industrial competitiveness. The carbon/energy tax was proposed as part of a package of measures which included initiatives on energy conservation (SAVE) and the development of renewables (Altener).

REGULATIONS

The development of electricity trade within the EC has received considerable attention from the European Commission, with the Council adopting a number of directives which constitute a first step towards the completion of the internal market in electricity.

The transit directive (no. 90/313/30), approved by the Council on 30th October 1990, provides that "each high voltage transmission utility shall facilitate power exchanges between other utilities through its grid, provided that transmission reliability is not affected." Meanwhile, the price transparency directive (no. 90/185/16), approved by the Council in June 1990, provides that "electricity and gas utilities shall supply to the Statistical Office the rates they charge to all categories of customers on the understanding that published aggregate figures will respect confidentiality."

The Commission has also presented plans for the further development of an internal energy market within the EC, involving two stages in addition to the two directives cited above. The second stage is based on three elements:

The creation of a transparent and non-discriminatory system for granting licences for the production of electricity and the building of electricity lines. The aim of this proposal is to "open up investment in production and transport to independent operators, and in particular to large industrial users."

- The creation of transparency of operations by the separation of the management and accounting of production, transmission and distribution operations in vertically integrated undertakings (commonly called "unbundling").
- The introduction, on a limited basis, of third party access (TPA). The transmission and distribution companies will be obliged to "offer access to their network to certain eligible entities at reasonable rates, within the limits of available transmission and distribution capacity." Those eligible will include large industrial users and distribution companies.

The Commission also wishes to see subsidiarity play a substantial role during the second phase. This involves Member States retaining their regulatory powers for all end-users not eligible for TPA, as well as determining the extent and nature of distribution companies' rights and their public service obligations. Member States will also be free to establish the criteria used for granting licences to build power stations and transmission and distribution lines. The Commission initially wanted to see the second stage enter into force on 1 January 1993. However this did not happen, discussions are still continuing and no firm timetable has yet been announced. The third stage will be defined in detail in the light of the experience acquired during the second stage and is planned to come into force on 1st January 1996.

To achieve a more open market in the field of electricity, the Commission has identified a number of potential obstacles which must be eliminated. The opening up of tenders for the supply of equipment ordered by the public electricity companies, and establishing the 20% guideline for support of indigenous energy supplies, mark important milestones in removing the barriers to a free market for electricity.

OUTLOOK

The principal concerns in the outlook for power generation surround the evolution of the fuel mix for conventional thermal power generation. Development of hydro power, renewable sources, and nuclear power is expected to be limited over the next decade. As a result, increases in demand will have to be met by increases in conventional thermal capacity or explicit demand-side programmes operated by public utilities.

Within this context, there is considerable scope for natural gas use for power generation in Europe. It is, however, only in few EC countries where the use of gas in power generation will increase substantially. Italy, Belgium, Denmark and the United Kingdom are all in the process of changing the fuel mix in favour of gas. Such a move is also planned in Greece and Portugal, but in these countries the future of gas depends upon the spread and extent of supply and distribution infrastructure installation. Natural gas fired power generation could almost double its share of the power generation fuel mix in the EC by the year 2010, from its 1990 level, almost tripling the volume of gas consumed in this use.

By the year 2000, the demand for natural gas fired power generation will increase to the detriment of oil-fired power. Nevertheless, solid fuels will continue to play an important role in the conventional thermal power generation fuel mix.

However in the longer term, after the year 2000, it is unlikely that emissions of CO_2 can be stabilised without recourse to greater use of non-fossil generating capacity. This may lead to new orders for nuclear power stations early in the next century.

Transmission and distribution of natural gas

NACE 162

In 1992, EC natural gas production remained relatively constant compared with the previous year and accounted for 62.5% of gross consumption. The Netherlands and the United Kingdom accounted for 73.9% of the EC total natural gas production. The former Soviet Union was the major external supplier of natural gas to the EC, followed by Algeria and Norway.
Growing concern about the environmental impact of energy consumption has helped to sustain interest in natural gas. It contains virtually no sulphur and by-and-large emits less NO_x per unit of energy than other fossil fuels, it also produces less CO_2 per unit of energy burnt than any other fossil fuel. As a result, natural gas is expected to become increasingly important within the energy mix.

INDUSTRY PROFILE

Description of the sector

Natural gas is used in a variety of ways to meet a number of energy needs across all economic sectors. It is burned as a fuel for space heating and hot water production; used in power stations to generate electricity; provides a feedstock in the chemical industry; and is used in industry for steam raising, firing furnaces, and in drying processes. The natural gas industry embraces a range of activities, of which the three principal ones are exploration/production, transmission and distribution. Some companies carry out all three activities. The industry applies the term transmission to: the purchase of gas from producers or from other transmission companies; the transportation and storage of natural gas; and the sale of gas to other transmission companies, to industrial consumers and power stations and to local distribution companies.

The distribution activity is concerned with the supply of natural gas via a local network to final consumers.

Recent trends

In 1992, EC natural gas production remained relatively constant compared to the previous year, at 6 722.5 terajoules (TJ). A small decrease in Netherlands was offset a small rise in the United Kingdom (the two main producers in the EC). The decline in the proportion of gross consumption supplied from sources within the EC appears to have stabilised at around 62.5%.

In 1992, two countries accounted for 73.9% of the EC total natural gas production, 42.6% for the Netherlands and 31.3% for the United Kingdom. Of the other EC countries, Italy, Germany, Denmark, France and Ireland accounted for a further 25.2%. Greece and Spain each produce less than 1% of the EC total production; Portugal and Luxembourg have no natural gas production.

Gross consumption in 1992 also remained flat for the EC as a whole. However, some countries continued to see large rises in demand, while the more mature markets saw falls. The largest consumers were Germany and the United Kingdom, accounting for 25% and 21% of total EC consumption, respectively. These are followed by Italy (19%), the Netherlands (14%)and France (12%).

The average rate of increase in consumption was 3.2% per annum over the last five years. The most remarkable change in short term trends was in the power generation sector which is now growing at a rate of 5% per annum, and can be expected to increase further.

Foreign trade

Imports from outside of the EC rose slightly by 0.6% in 1992 to 4 175.0 TJ, representing nearly 38.4% of gross EC consumption. The three main sources were the former Soviet Union (43%), Norway (24%) and Algeria (31%). Imports of natural gas into the EC in 1992 were divided between Germany (29%), Italy (26%), France (25%), Belgium (6%), Spain (5%) and the United Kingdom (5%).

Imports from the former Soviet Union decreased 3.7% compared with 1991 and were divided between Germany (46%), Italy (30%), and France (24%). It is possible that exports from this region could rise substantially over the next decade. However, the reliability of the infrastructure and the political and economic conditions seem certain to ensure that the full export potential of the region will not be achieved in the short term.

Norwegian natural gas deliveries into the EC were split between Germany (38%), France (23%), the United Kingdom (21%), the Netherlands (10%) and Belgium(7%). They are set to grow significantly when the development of the Troll-Sleipner project and the corresponding infrastructure are completed in the mid-1990s. A Norway-Western Europe pipeline project, Zeepipe, will have Phase 1 completed in October 1993 and permit the transport of Norwegian gas from Sleipner to Zeebrugge, Belgium. The Norwegian authorities have also agreed on the construction of a new pipeline linking the Norwegian North Sea to Emden in Germany, which is due to come on line in October 1995 and will supply Germany, Austria and the Netherlands (Europipe project). By the year 2000, Norwegian natural gas exports are likely to be approximately 50 million tonnes of oil equivalent (toe), most of it heading into the current EC countries.

Algerian natural gas imports into the EC in 1990 were divided between Italy (44%), France (29%), Belgium (14%) and Spain (12%). Algerian gas is either transported by pipeline via Tunisia and into the Italian grid or is exported as liquefied natural gas (LNG) via Arzew and Skikda to terminals in Belgium, France and Spain. Within a few years Greece will also receive Algerian natural gas in this manner. An extension of the Trans-Med pipeline, expected to be commissioned in 1995, will carry Algerian gas directly to Italy through a 2000 km long pipe. A second Algerian supplied pipeline, the Maghreb-Europe project, is expected to come on line in 1995 and will carry natural gas to Morocco and on to Spain.

MARKET FORCES

Demand

The combined effects of liberalising electricity markets and tougher environmental constraints are expected to expand the market for gas by making co-generation or combined heat and power (CHP) a more attractive option. This market accounts for about 10% of Western European power generation. Countries showing the largest growth potential for gas-fired co-generation are Denmark, Italy and the United Kingdom.

In Denmark, the government has made a commitment to expand gas-fired CHP applications. In Italy, the lack of power generation capacity and the constraining site approval regulations for public power plants have made new industrial co-generation more attractive as it is the easiest capacity to expand.

The recent privatisation of the electricity industry in the United Kingdom has led to higher costs for transmission and distribution of electricity making local generation more attractive. In addition, the public suppliers now face higher costs of

capital, similar to any other private sector company planning to build generation plants. This has also changed the balance of economics in favour of self-generation. Other factors, such as reform of the local tax and regulatory requirements on public electricity suppliers to purchase at least cost, have further levelled the playing field between bulk and local generation.

Gas consumption has stagnated in recent years and it is expected that there will be a decrease in consumption during the 1993/1994 time period.

Supply and competition

In many countries, the price of gas to final consumers is linked to that of competing oil products or other energy sources. Price increases will depend on the economic sector concerned but generally reflect the increase in costs suffered by the distributor, a cost of living index for the domestic sector and any changes in the cost of competing fuels. In some specific cases, e.g., electricity generation, the price may be escalated to the value of the product produced.

Contracts between gas transmission companies and producers have a variety of indices, ranging from the cost of living index or industrial production, to the price of oil (heavy fuel oil and gasoil) or coal. It is usual for a contract to contain some combination of these factors.

Third party access could result in both natural gas falling prices (as increased competition leads to a reduced ability to extract monopoly rent), and real incentives for gas companies to cut costs. However, the increased risks associated with the loss of monopoly power will lead to higher costs of capital, and a requirement for the gas companies to earn higher returns to cover the increased risk. The resulting effect on prices depends upon the relative effects of encouraging new entrants into the national markets and what impact that will have on actual levels of competition against the risk adversity of gas companies. The effects may not be uniform across all countries and will depend on specific structural and regulatory factors.

New pipeline projects linking North Sea fields with Western Europe and new storage capacities will undoubtedly enhance the quantity and security of the EC natural gas supply.

Production process

The physical infrastructure of the gas industry consists of pipelines and of other equipment needed to regulate the passage of gas through the pipelines (notably compressors) as well as for storage and gas treatment. Investment in 1988 was ECU 4.77 billion, an increase of 6% from 1987, and involved an increase in both transmission (+9.67%) and distribution (+5.6%). From 1982 to 1988, transmission investment declined by about 22%, but investment in distribution activities increased by 56% and resulted in an overall increase of 24%. This pattern reflects the maturity of the transmission grid in the majority of Member States, and the continuing expansion of the distribution lines to supply new end-users.

There are plans for a sub-sea pipeline, which will link the republic of Ireland to the United Kingdom. Portugal has no natural gas supply, but planning continues for a proposed LNG terminal to be built south of Lisbon. From there, pipelines will be run north to Lisbon and other principal cities. The gas infrastructure needs of Eastern Europe are expected to result in more integration with the West.

The Czech and Slovak sections of the Transgas east-west pipeline will be renovated to boost capacity by 5 x 10^9 m^3/yr from 75 x 10^9 m^3/yr to 80 x 10^9 m^3/yr. New pipe is being laid in Russia to connect it with Germany Frankfurt/Oder), via Belarus, avoiding the Ukrainian network. This project includes plans to provide a connection to the Baltic States.

Two other projects in the advanced design stage concern Iranian gas and Turkmen and Kazakh gas. The Iranian project is examining the possibility of building a pipeline via Turkey and Greece to Italy or Yugoslavia, or via Turkey to Central Europe (Bulgaria). Turkmenistan is examining the possibility of building a pipeline to Europe via the other Central Asian republics and Turkey. The route seen as the most advantageous includes a passage through Azerbaijan and Armenia, joining Turkey via Nakhichevan.

INDUSTRY STRUCTURE

Companies

The organisation and structure of the gas industry varies from country to country. In some Member States one company covers the whole gas chain, while in others there may be a number of companies involved in the production, transmission and distribution of natural gas. Additionally, some companies are state owned, while ownership is mainly in the private sector for others.

France and Ireland have vertically integrated gas industries, a structure that Greece is also planning to develop. The French (GdF), Irish (BGÉ) and Greek (DEPA) companies are 100% owned by the state.

In Belgium, Luxembourg, Denmark, Italy, the Netherlands and Spain, a two-tiered structure has developed. There is a national transmission company and local governments tend to own the companies that distribute gas. In Italy and Spain, the transmission company is state owned, with their respective transmission companies, SNAM and ENAGAS, are subsidiaries of government controlled companies. Other companies, such as DISTRIGAZ of Belgium, SOTEG of Luxembourg and Gasunie of the Netherlands are 50% state owned and 50% privately owned.

Two companies, GdF and SNAM, have exclusive national concessions for the purchase and/or transport and storage of gas. In Italy, this is limited geographically with SNAM having the exclusive rights in major parts of the country.

There are exceptions to this model within the two-tier structure, the most notable of which is in Germany where there are six companies importing gas, 18 transmitting it over long distances and over 500 regional transmission companies operating local concessions.

In the United Kingdom, British Gas, formerly a vertically integrated state-owned monopoly, was privatised in 1986. This had little immediate effect on the market, but during the early 1990s a process designed to change the structure of the industry was introduced. The franchise limit above which consumers can purchase freely was lowered and British Gas was forced to give up some of its gas purchasers to encourage competitors in the market. There are now several companies competing in the non-franchise market, many of which are joint ventures between, or subsidiaries, of oil companies and the United Kingdom electricity companies. At the same time, British Gas is to create a separate subsidiary to run its pipeline and storage systems. This subsidiary will also serve its competitors on an equal basis. Overall, it can be seen that a number of different structures exist for the supply of natural gas, each with its own implications for consumers and producers.

ENVIRONMENT

Natural gas contains virtually no sulphur and it emits less NO_x per unit of energy than other fossil fuels. It can also make a contribution towards reducing the risk of adverse effects of global warming, as natural gas combustion produces less CO_2 per unit of energy burnt than for the other fossil fuels.

Growing concern about the environmental impact of energy consumption has helped to sustain interest in natural gas. In late 1988, the EC directive concerning emissions from large

combustion installations was adopted which imposes environmental abatement measures on new power plants. Increasingly stringent emission limits for SO_2 and NO_x favour the use of natural gas since in most cases, it does not require the heavy investments in emission abatement equipment that are associated with use of solid fuels and "normal" (i.e. high sulphur) heavy fuel oil.

The years 1989 and 1990 were noted by increasing worldwide concerns about the environment in general, and the greenhouse effect in particular. As a consequence, several countries (i.e. the Netherlands, Denmark, Italy and Belgium) have adjusted their generation capacity plans in order to incorporate an increased share of combined-cycle, gas-fired base and mid load power.

Methane, which contributes to the greenhouse effect if it is leaked or vented, contributed around 15% to the "radiative forcing" added to the atmosphere in the 1980s, based on the estimate that one molecule of methane has about 3.7 times the global "climate forcing" effect of one molecule of CO_2. However, emissions of methane from the natural gas chain currently contribute not more than 1 to 2% of the overall effect.

REGULATIONS

With the creation of the single market scheduled for the end of 1992, the EC has turned its attention to the ways in which a single energy market can be created. There are a number of elements in the Commission's approach to the gas sector that can be seen as an evolution towards third party access (TPA) legislation. First, in some countries the electricity or gas carrier is defined by statute. The Commission took action to remove the discriminatory aspects of these statutory monopolies in 1991 under article 37 of the Treaty of Rome, which requires that state monopolies should create no commercial discrimination. Second, the Commission is taking further action in the form of draft directives concerning two aspects. Two directives are aimed at providing TPA in gas and electricity markets, which find their legal basis in Article 90 of the Treaty of Rome. Two other directives seek to create a level playing field for both the gas and electricity industries, based upon Article 100A of the Treaty of Rome.

The directives based upon Article 100A have severe ramifications for some Member States. They seek to remove the influence of national governments in setting and approving tariffs other than for certain social welfare and rural supply protection cases. The directives also seek to separate the transmission and distribution functions of utilities and require them to produce transparent accounts.

Broad draft proposals were put forward by the Commission under Article 90 concerning opening the internal EC energy markets to more competition. These proposals for directives gave rise to a great debate within the EC institutions, across the industry and among the public. Agreement has been reached as to the objectives of the liberalisation of the market, but consensus is far from being reached as to how to achieve these objectives.

In essence, the original proposals made by the Commission were for the natural gas (and electricity) sectors to: abolish monopolies and exclusive rights for the building of high pressure gas transport lines and high voltage electricity distribution lines; create separate accounts and management responsibilities for the different types of activities in vertically integrated companies (production, transport and distribution); and authorise step by step third party access (TPA) to networks for large consumers or large distribution companies. Other specifics were also part of the debate, however, the TPA aspects of the proposals were the most difficult element. The industry is strongly opposed to TPA, claiming it will undermine the long-term security of gas supply and the higher costs of capital will act as a disincentive to exploration and production, which, in turn, would lead to increased costs of supply. The Commission remains convinced that access to the gas distribution system of some king or other is an essential element for a truly open gas (and electricity) market.

The Commission had pursued the concept of regulated access to the network. In a recent statement, the Commission expressed that it could be possible to progress towards an open market by means of case-by-case negotiations conducted at the commercial level. They felt that arbitration by Member States, who would be given supervisory powers to ensure that access could only be refused for legitimate reasons and that negotiations would be timely, would be essential and could be done by a regulator, by the application of national competition law, by an arbitrating authority or by any other appropriate procedure. The European Commission stated that it would wish to leave as much room as possible for subsidiarity (meaning that, where possible and more efficient, implementation of a policy is left to the Member States themselves).

OUTLOOK

The share of natural gas in Western Europe's energy mix is expected to increase steadily throughout the next two decades. Natural gas for industrial and residential use will make sig-

nificant inroads in some undeveloped markets such as Portugal, Spain, Greece and Ireland. The principal area of demand growth is expected to be in power generation.

There are various other factors which are anticipated to continue to influence the use of natural gas, including: environmental concerns and their consequences for the pattern of fossil fuel use; security of supply; developments in other fuel markets, notably the trends in oil availability and prices, as well as the role of nuclear electricity generation within the EC; the exploitation of new sources (e.g., Nigeria, Northern Norway, etc.); the competitive position of natural gas in the different end-markets; and the impact on the gas sector of the Commission's moves towards an integrated energy market and their long-term effects on the supply and demand patterns of natural gas (given the anticipated growth in European demand underpinned by the need for cleaner forms of energy.)

The industry is represented at the EC level by: European Union of the Natural Gas Industry (Eurogas). Address: Ave. Palmerston 4, B-1040 Brussels; tel: (32 2) 237 1111; fax: (32 2) 230 6291.

Renewable energy

In 1991, renewable energy contributed around 4% to gross inland energy consumption in the EC. Of this percentage, the majority of the share come from large scale hydro-electricity production (31%) and from the combustion of biomass in one form or another (60%). The remaining 9% was a variety of renewable technologies in varying stages of development, bordering on commercial viability. Through national and EC funded research, development and demonstration (R,D&D) and other programmes and actions, this share is expected to increase to 8% of total primary energy demand by the year 2005.

Funding for renewable energy, though low compared to other energy research programmes, has increased substantially in past years. All the signs suggest that this trend will accelerate, driven predominantly by environmental considerations. At the EC level, the major programmes promoting renewable energy are Altener, Joule, Thermie (and Valoren).

INDUSTRY PROFILE

Description of the sector

Energy from renewable sources, that is those that are not depleted due to their exploitation, may be in the form of electricity or in gaseous, liquid or solid forms. Some renewable energy sources are predominantly limited to one form of energy production. e.g. hydro-electric power generation to produce electricity. Others are more flexible; biomass may be converted to liquid fuels, burnt as a low calorific solid fuel or gasified and be used for electricity generation.

The major renewable energy technologies are listed below by the form of energy they most commonly produce.

Electricity

Tidal power extracts energy from the tides using the same principles as hydropower facilities but captures the tidal ebbs and flows rather than the flow of a river to generate electricity.

Small hydro-electricity generation uses the same principles as large scale hydro-electricity, but it generally uses different types and sizes of turbines.

Wind power generation uses the wind turbine to generate electricity by the same principles as the old fashioned windmill but using a higher level of technology.

Photovoltaic systems, use semiconductor materials to convert solar radiation into DC (direct current) electricity without moving parts or thermal energy sources.

Heat and/or Electricity

Geothermal energy use takes heat from the earth directly for heating purposes, or uses it for electricity generation. The temperature determines the application.

Biomass is considered all matter that can be derived directly or indirectly from plant photosynthesis. "Indirectly" refers to the products available via animal husbandry and the food industry. Feedstocks for the technologies include wood resources, agricultural wastes, residues and surpluses and energy crops.

Heat

Active solar generation produces heat by capturing solar radiation. It usually consist of one or more collectors, an energy transport system to move the heat to the point of use, an electronic control system and an energy storage system.

The 'Renewable Energy Industry' is very broad in definition and is not classified as a single industry under NACE. Given the current relevance of the industry in the context of its environmental benefits, compared to other methods of energy production, the different forms of renewable energy are discussed under one heading. In addition, associated industries exist which fall into two types.

- Industries that provide feedstock: e.g., the Agricultural products industries (NACE 011, 014, 020) who provide feedstocks such as straw, slurry and wood residues for biomass derived renewable energies; the pulp and paper and wood processing industries (NACE 471/2, 461/2) who produce waste products and residues which can be used as feedstocks; and the waste and recycling industries (NACE 62, part of 921) who provide low cost feedstock.
- Manufacturing industries that provide components for use by renewable energy technologies: e.g., the mechanical engineering industry (NACE 32) that is involved in the manufacture of renewable energy equipment, the most important being turbines (water turbines for hydroelectric plants, aeroturbines for wind farms and steam turbines for geothermal power stations); agricultural equipment used for biomass collection and processing; and the electrical engineering industry (NACE 34) who, in addition to manufacturing electrical components for control equipment, manufactures semiconductor material for photovoltaic cells.

Recent trends

Mature renewable energy technologies such as biomass combustion and hydroelectric power have been a significant part of EC energy supply for some time. Over the last two decades, the energy supplied by these sources has seen significant growth. Since around the 1970's, energy supplied from other renewable sources has grown very quickly, though it is still a very small fraction of total energy supply.

The situation by Member State for the supply of electricity and heat from each of the renewable energy technologies is shown in Tables 1 and 2. Around 10% of electricity demand is met by renewable energy sources. Hydro-electric power generation accounts for 86% of the renewable electricity supply. Biomass and hydro, together, make up nearly 98%. Biomass sources provide almost all of the renewable heat supply and 3% of total EC heat demand

Greece has the largest installed capacity of solar collectors. In France and Portugal, where the climate is particularly fa-

vourable, active solar technology also makes a contribution. The Danish have by far the largest amount of wind power installed: it accounts for roughly 77% of electricity generated from wind power in the EC. Italy, France and Spain generate the majority of small hydro generated electricity in the EC. Italy has the largest geothermal energy industry, a large proportion of which (520 megawatts, MW) is used for electricity generation. France, Germany and Italy have the largest biomass consumption due to a large amount of direct wood combustion. Denmark, however, uses a high proportion of agricultural waste, mainly crop residues like straw, in biomass consumption. Spain generates the most electricity from biomass in the EC.

MARKET FORCES

Geothermal energy

From a world perspective, the production of electricity from geothermal sources has accelerated over the past decade. Between 1980 and 1990, production increased by 50% from 3 900 MWh (megawatt/hour) to 5 850 MWh. In the EC, the greatest amount of geothermal electricity generating capacity by far lies in Italy (545 MW in 1991) where over 50 geothermal units are in operation. Other countries include France (4.2 MW in Guadeloupe), Portugal (3 MW in the Azores) and Greece (2 MW on Milos). Germany has a 10 MW plant at Neubrandenburg. The capacity of this plant is to be doubled in the near future and a second 50 MW plant is being considered at Schwerin. Further developments are centred in Italy where the largest geothermal power plant in the world, a 60 MW plant, opened in Tuscany in 1991. Plans for three more plants of this size are being considered in line with governments policy to increase the share of geothermal derived electricity to 3% of total national energy production.

In addition to geothermal energy for electricity production, hot ground water may be used for space heating on a smaller scale. Worldwide, the consumption of geothermal energy for heating was around 2 million toe (tonnes of oil equivalent), the majority being used in Japan, China, Iceland and Hungary. In the EC, it is estimated that in terms of primary energy, it represented 370 000 toe in 1990. The regional distribution is the same as that for geothermal electricity production, yet it differs in that it is used extensively in urban areas. In 1990, the equivalent energy saving from using this source of energy was 170 000 toe in France and 200 000 toe in Italy. Other countries with geothermal potential for heating include Spain, Portugal, Greece and Germany. In former East Germany, much use was made of geothermal energy for district heating, a 12

MW plant will come on-line in 1994 in Mecklenburg-Vorpommern. In the west, a 20 MW project in Bavaria will be Germany's largest geothermal plant, and is due for completion in 1994.

Tidal power

The largest tidal power station in the world is at La Rance, in France. Conceived as a prototype for other, possibly larger, tidal plants along the Brittany coast, it has been operating since 1968, with an installed capacity of 240 MW_e (megawatt of electricity). Predominantly due to concern over the environmental impact of tidal barrages, no further sites have been developed despite their considerable potential. The best sites are to be found along the west coast of Portugal, France, Ireland and the United Kingdom. In the United Kingdom, where the tidal potential is approximately 54 TWh/year (terawatt/hours per year) - over half of the total European tidal resource - the government has been heavily investing on tidal energy research and feasibility studies since 1979. A barrage across the Severn Estuary could generate around 17 TWh_e (terawatt/hours of electricity), equivalent to about 2.5 large (1 000 MW) power stations. Another project is on the Mersey which could generate 0.5 TWh_e.

Small hydro-electricity generation

In the EC, the total installed hydroelectric capacity is about 80 GW (gigawatt). Small hydroelectric plants (less than 10 MW) contributed 5 GW to this or just over 6%. There is a marked trend towards small scale applications of hydropower which have a smaller impact on the environment than their larger counterparts. The reason for this shift is mainly due to the limited availability of new large scale sites. The percentage of sites economically exploitable and already in use is 95% for large hydro but only 20% for small hydro-electricity. France, Italy and Spain have by far the largest small hydro potential. The total EC exploitable potential for small hydro-electricity is around 4-5 GW.

Biomass

The theoretical potential for biomass in the EC is very large at around 100-120 million toe. Within the EC, wood, straw and municipal solid waste are the most commonly used biomass fuels. The primary energy derived from these sources amounted to almost 22 million toe in 1989.

The great proportion of this total is given by wood. The EC currently consumes around 20 million toe of wood energy. France is by far the largest consumer of wood taking 45% of the EC total due to the large proportion of wood burning stoves used in rural areas.

The biggest consumer of straw for energy is Denmark, where there are over 12 000 straw-burning stoves on farms and over 30 district heating schemes using straw. Its importance is obvious when one considers that it provides 1.5% of Denmark's primary energy needs. Biomass provides 5.8% of Denmark's total primary energy requirements and the government intends to increase this to 9% by the year 2000.

The most widely used method of recovering energy from municipal solid waste (MSW) is by incineration; the other rapidly expanding major source is landfill gas. In the EC, around 550 schemes were operating in 1988, including 174 with heat recovery of which more than 80% are in France, Germany and Denmark. Disposal of MSW in landfill is widely practised in many Member States. The United Kingdom is notable in that 90% of MSW is disposed of in landfills. Typical schemes generate between 1 to 5 MW and may be used to generate electricity or used directly as fuel in industry.

Biogas consists mostly of methane, produced from the anaerobic digestion of organic residues. Agricultural waste, sewage and a variety of liquid industrial effluents can be treated anaerobically. The technology is widespread at sewage works and it is expected to be used increasingly in treating food industry waste and slurry from intensive livestock farming. Member States currently using biogas to any extent are Italy, United Kingdom, Denmark and the Netherlands, due to their livestock farming industries. The world's first biogas plant was finished in July 1991 in Denmark and is planned to generate 3 million m3 per year of methane.

The development of energy crops is closely tied to the Common Agricultural Policy (CAP). Set-aside land, which farmers must put to a use other than food production, will total around 15% of EC agricultural land. Energy crops are an attractive option to farmers. Wood could be sustainably harvested or coppiced (where the outer branches of a tree are stripped away without causing it any terminal damage). If 15 million hectares of farmland is in surplus by the end of the century, and if it was all turned over to fuel wood crops then it is estimated that 120-150 million tonnes of wood with an energy content of 55 to 65 million toe might be produced per year

Biofuels may also be produced from energy crops. The Netherlands is investigating using feedstocks such as elephant grass, poplar wood or straw for gasification to a fuel for use in electricity generation plants. The Italian chemical manufacturer, Novamont, is operating refineries in Italy and France with a total capacity of 160 000 tonnes/year to produce biodiesel from feedstocks of rapeseed and soya. A second Italian

refinery, run by Distilleria F. Palma with a capacity of 70 000 tonnes/year, has also started up in Naples.

Wind power

Denmark is the largest generator of electricity from wind energy in the EC. The industry has expanded considerably so that in 1991, the total installed capacity in the EC was 509 MW of which Denmark accounted for 70%, the Netherlands and Germany both for 11%. The USA has an installed capacity of 1 500 MW, consisting of around 15 000 turbines. Denmark has one of the smallest wind power potentials, and yet has by far the largest installed capacity. Sizeable subsidies were given by the Danish government during the late 1970s and early 1980s which boosted the industry and enabled it to enter the large Californian, USA export market ahead of competitors. The United Kingdom, in contrast, has the largest potential but relatively few turbines installed.

In Spain, a 30 MW plant has been commissioned, built largely by Endesa, the state electricity company, and Ecotecnica, a Spanish turbine manufacturer. In Greece, a series of wind projects have been approved for use on the Aegean islands. Technical difficulties have meant that off shore farms are less commercially developed. In Denmark, however, the electric utility Elkraft brought on-line the world's first off-shore wind farm consisting of eleven 450 kW (kilowatt) turbines. A second 5 MW farm is planned by the other electric utility, Elsam consisting of ten 500 kW turbines.

Active solar collectors

By far the largest user of active solar collectors is Greece. In 1989, the total installed solar collector surface area was around 1.3 million m2 that contributed around 67 thousand toe to primary energy production. In Greece, hot water from active solar collectors contributes 4.5% to the total hot water needs. In the other Member States, this fraction is considerably less due to less favourable climatic conditions and a smaller area of collectors installed.

Today, solar collector sales in Greece represent over half the total sales in the EC. Solar collector production in Greece, however is solely for the home market, which is very large. At EC level, imports from outside Europe are decreasing: they amount to about 2 500 solar water heaters and about 1 000 additional collectors each year.

Photovoltaic systems

The decrease in cost accompanied by the increase in efficiency of photovoltaic (PV) cells has enabled a rapid growth in the world photovoltaic market. Since 1978, when a mere 1 MW was installed world-wide, it has increased to reach around 56 MW in 1991, primarily for remote sites. However, it is now becoming feasible to use PV for power generation in a centralised manner. In 1992, in Switzerland, a 500 kW PV power station came on-line. In Greece, a 600 kW plant has been completed. In Spain, Germany's RWE and Union Electric Fenosa are to build a 1 MW PV power station, to be completed in 1993. In Italy, a PV power station over three times this size is under construction. Currently, the demand in Europe exceeds the production capacity. In 1991, the two largest PV manufacturers in Europe were BP Solar (E) and TST with a market share of around 15% apiece. Other large PV manufacturers are Helios (GR), Italsolar (I) and Photowatt. Together this group of companies accounts for about two-thirds of the PV market.

Production process

Geothermal energy

Electricity generation is the most attractive use for geothermal energy due to the low distribution costs. At temperatures below 150° C the most common application is for direct heat. This has advantages in terms of its simplicity, efficiency and adaptability and is relatively cheap. The hot water cannot economically be transported a distance greater than about 1 km so the site location is limited by the cnd use location. Other methods such as magma, geopressured and hot dry rock technologies have been investigated though none are near to commercial viability.

Tidal power

The simplest systems generate power by capturing water at high tide and running the head of water through turbines. More complicated systems impede the flow of water in both directions. The turbine best suited for the low head characteristics is the bulb-type turbine and units are manufactured with runner diameters of 7.5 metres and capacities of 60 MWe.

Small hydro-electricity generation

Countries and institutions define what is small differently. An upper limit for small hydro is 10 MW, while capacities may be as low as a few hundred kW. The technology differs compared to large scale hydro-electricity generation in that turbines are specifically designed for low head conditions and the control equipment differs in its complexity.

Biomass

The resource base is huge and is said to be in the order of 100-120 million toe. On a global scale, the majority of the population relies on biomass as its primary source of fuel. In the industrialised world, where energy production is more centralised, biomass energy conversion is perhaps the most technically, economically and socially complex renewable energy option. Old, well developed technologies co-exist with completely new, advanced techniques for converting biomass to useful energy.

Liquid fuels may be produced by various methods, three are mentioned here. First, biodiesel consisting of complex natural esters from the esterification of oils extracted from plants such as rapeseed, linseed and the sunflower. Second, the hydrolysis and subsequent fermentation of plants with a high energy value can produce methanol or ethanol which can be used as fuels in vehicles with engine modifications. Lastly, liquefaction is a variant of the pyrolysis technique where a diesel or gasoline fuel may be produced by one of two methods. An indirect method gasifies the biomass and is followed by the catalytic conversion of the product to a liquid fuel. Direct liquefaction skips the gasification step using lower temperatures to produce partially deoxygenated, complex oils which are then upgraded.

Electricity generation and heating requirements can be met by direct combustion or gasification of wood, straw or other dry biomass. Household waste may be incinerated or the landfill gas used to provide heat and/or electricity. Agricultural waste such as slurries from animal husbandry may be used in the anaerobic digestion process to produce biogas: a high grade gas consisting mostly of methane. In addition, any organic material may be gasified (or liquefied) by thermal decomposition, in the absence of oxygen, by pyrolysis.

Wind power

Wind power in Europe, in its present form, can be said to have begun in the mid 1970s in the wake of the oil crisis. Over this time there has been considerable improvement in the design of turbines so that the efficiency, measured in energy generated per swept area per year, doubled between the beginning and the end of the 1980s. Modern wind turbines operate on either a horizontal or a vertical axis, though horizontal axis machines are the most common units manufactured. The average size of wind turbines installed in the EC has increased steadily and the trend is still continuing. There is no consensus as to the optimum size for machines, though R,D&D work is currently centring on 300 kW machines with rotor diameters of 25 metres. Along with improved technology comes increased reliability and lower costs. A study of the top performing wind farms in California showed an increase in the availability of electricity generated from 60% to around 95% over the 1980's. Based on Danish experience, turbines in the range 100-300 kW have an average total cost per swept area of 280 ECU/m2. The costs vary from country to country and from site to site, depending on the terrain and other factors.

In addition to onshore wind sites, a great potential exists for turbines situated off-shore. There are particular problems associated with this, however, such as difficulties of operation in a saline environment, achieving designs rigorous enough to stand up to storms and the difficulties of access for maintenance. Off-shore sited turbines tend to be larger than their land based counterparts and environmental constraints hindering turbines on land are more relaxed for off-shore sites.

Active solar collectors

In addition to temperature ranges that satisfy building energy needs, active solar technology can supply heat for industrial processes at moderate temperatures. The essential component is the collector and designs include flat plate collectors (glazed or unglazed), evacuated tube collectors and air collectors.

Unglazed solar water heaters are used in outdoor applications, predominantly for heating swimming pools. Glazed solar water heaters form the bulk of the market, representing approximately 90% of total installed collector surface area. Evacuated tube collectors form a small but growing part of the market, particularly in northern Europe. In value terms, they account for approximately 10% of total EC sales. Air collectors are generally built into the building structure to produce warm air directly or in connection with a heat pump for space heating. The most important and widely used application is for drying hay, particularly used in Sweden, where an estimated 200 000 m2 have been installed.

Photovoltaic systems

The basic element is the PV or solar cell. This is comprised of semiconductor materials which have both negative and positive charge carriers. When photons fall on the cell, electrons in the semiconductor are freed, and an electric current is generated. Cells are built into modules of around 1 m2 in size and may generate in the region of 100 W_p (peak watts). Efficiency has been increased by around 50% over the past decade.

Three methods of production exist. First, single crystal silicon is a well established technology, with cells that tend to be stable and relatively efficient. The cost of manufacturing, though decreasing, is still relatively high. Second, polycrystalline silicon ingots with grain sizes of several millimetres can be produced by a casting process less expensive than single crystalline process. Larger areas are needed for the same power and module efficiency is slightly lower. Polycrystalline silicon ribbons may be manufactured using edge defined film-fed growth and dendritic web processes. The manufacturing process is complex though it has high potential for high speed production. Third, thin film technology is an area of intense research effort. Films are deposited directly onto substrates by technologies such as glow discharge, chemical vapour and electro-chemical deposition. Semiconductor materials being investigated include amorphous silicon, copper indium diselenide, gallium arsenide and cadmium telluride.

INDUSTRY STRUCTURE

The renewable energy industry is a heterogeneous mixture of small and large companies. Small companies, which are financially viable through support from EC and national programmes, generally concentrate in niche markets where their core expertise lies. Large multinational companies have historically tended to view renewable energy investments as part of a long term strategy of diversification. Research into renewable energy technologies is conducted predominantly in universities and government research institutes. However the research budget for renewable energy in large companies has been on the increase. Government incentives have made renewable energy technologies more attractive and companies involved in the market have stepped up investment in order to retain a competitive edge in the field.

REGIONAL DISTRIBUTION

The factors currently governing the regional distribution of renewable energy technologies are, in order of decreasing importance, the relative size of national financial incentives promoting renewable energy, the technical and commercial maturity of the technology and the size of the resource base. For more mature technologies, such as biomass combustion and hydro-electricity generation, the size of the resource is the most important. A good example is the wind energy industry in Denmark. The wind resource in the region around Denmark is relatively small, however a government commitment to wind energy has produced the largest wind energy industry in Europe. In the United Kingdom, which has the biggest wind energy resource in Europe, the wind energy industry is less well established.

In the long term, as renewable energy technologies mature, the size of the resource base should become the main factor controlling the size of the industry. PV, active solar energy and biomass all rely on sunlight, hence the southern regions have the most potential. The mountainous regions of the Community have the largest potential for small hydro power. The largest tidal potential exists along the western coasts of the United Kingdom and France. Wind energy has the largest potential in the north west region of Europe. Geothermal power will remain confined to Italy.

ENVIRONMENT

In the mid 1970s, interest in renewable energy was born as a result of high crude oil prices. Current interest is centred more on the environmental benefits that renewables offer, particularly with respect to their contribution to reducing carbon dioxide emissions.

With the exception of biomass, renewable energies are almost free of pollution. This clearly differentiates them from conventional methods of energy production where increasing concerns over pollution from the energy sector is forcing very large investments in emission control equipment. This is not to say that renewable energy has a negligible environmental impact. Ironically, the growth of the renewable energy industry is driven on the one hand by world scale environmental factors such as the threat of global warming, while on the other hand, being constrained by environmental factors on a local or regional level such as the visual impact of wind turbines and the environmental impacts of tidal and hydro-electric schemes.

There are two main environmental factors promoting the industry. The first is that a renewable energy technologies produce zero or negative net CO_2 emissions. Biomass releases carbon dioxide when burnt to produce energy. However, during biomass growth, carbon dioxide is sequestered from the atmosphere. If biomass use is accompanied by afforestation then the net carbon dioxide emissions for biomass could theoretically be zero or even negative in the long run. The second factor is that, with the exception of biomass, energy produced from renewable sources does not produce sulphur dioxide, sulphur trioxide or nitrous oxide, the principal components of acid rain.

The environmental impacts of renewable energy technologies, though less than that of conventional energy sources, are significant since they determine the feasibility of implementation. For example, tidal power systems have a very large impact on the environment. Environmental impacts arise mainly from: changes in water levels, flow patterns and velocities; sediment movement; and the physical presence of the barrage. The most serious effects are felt in navigation and for port facilities, water quality will be affected and the impact on wildlife, particularly birds and fish, is particularly acute.

The environmental impact of wind power is essentially on the human rather than the natural environment. There is significant visual intrusion, especially since the best sites are often the most beautiful and with the least signs of human interference. Noise levels are another factor. Telecommunications may be affected, though this is a localised problem. The impact of large scale implementation of wind turbines on bird life and bird migration is relatively unresearched.

Active solar collectors and photovoltaics have a visual impact since their use is predominantly in a widely dispersed fashion and because they must, for maximum efficiency, be placed in prominent positions.

EC AND MEMBER STATE SUPPORT

At the EC level, several initiatives are underway to promote renewable energy. Over the last decade, many Member States have successfully encouraged the development of domestic renewable energy industries through policies discussed below.

In Denmark, subsidies for installing wind turbines were phased out in 1989 and replaced by tax credits. Shareholders obtain income from the electricity sold tax-free below a set limit. State aid also encourages the use of straw as fuel, biogas plants and certain solar projects.

In France, special grants have been used to cover the exploration risks of geothermal development. In the area of biofuels the French government gives grants derived from a tax on petroleum products and a newly created biofuels agency coordinates R,D&D. Biofuels are exempt from excise taxes.

In Germany, a law (Einspeiseverguetungsgesetz, 1991) has helped wind and photovoltaic energy by forcing the electricity utilities to pay for electricity generated by these methods at a premium rate of 90% of the price paid by end consumers. Subsidies encouraging the installation of wind power are also available. For electricity produced by small hydro-electric generation, biogas and agricultural and forest waste, the rate they are paid is fixed between 65-75% of the electricity sale price.

In Greece, the government has made particular commitments to the promotion of wind and geothermal installations. Financial incentives take the form of subsidies in the region of 40-55% of the total investment. Tax breaks and low interest loans are also available.

In Spain, the national energy plan gives a clear objective for the contribution of renewable energy in the year 2000 and provides for government support.

In Portugal, the EC Valoren project and a national programme to promote renewable energy (SIURE) have benefited around 100 projects such as small hydro-electric generation, active solar collectors, photovoltaics, geothermal energy, wind power, the use of wood residues and the production of biogas. The relaxation of the authorisation procedure for the production of electricity from small installations has particularly benefited small hydro, biomass and biogas. In addition to EC funding,

10 million ECU have been invested in projects in the areas of active solar collectors, photovoltaics, biomass and biogas

In Italy, funding is available covering 30% of the capital costs for renewable energy projects. For demonstration projects, 50% funding is available and 80% subsidies are available for the installation of photovoltaic equipment in buildings. Efforts to remove barriers to the incorporation of electricity from small generators has resulted in very favourable tariffs for wind, photovoltaics, geothermal and biomass energy in particular. Biofuels are exempt from excise taxes.

In the Netherlands, wind power installation is subsidised on the basis of the swept area and in the area of R,D&D, funding for 50% of the costs are made available. General subsidies go to solar, biomass and geothermal projects of up to 40% of costs.

In the United Kingdom's privatised electricity sector, regional electricity companies (REC's) are obliged to purchase a portion of their electricity from non-fossil sources under the Non-fossil Fuel Obligation (NFFO). This obligation also forces the REC's to purchase the electricity at premium prices organised in bands. Different renewable technologies are associated to different price bands according to their commercial status. Other than energy from waste, wind and small hydro-electric generation projects are currently being supported under the scheme.

The European Commission has several programmes running which support renewable energy.

The Altener programme was launched by the Commission (13 September 1993) to promote greater penetration of renewable energy. It will run until 1997 on a current budget of 40 million ECU. The plan contains the political EC objectives which are to increase the penetration of renewable energy's contribution to total primary demand from the current 4% to 8% by 2005, to triple the production of electricity from renewable energy sources (excluding larger hydro-electricity power stations) and to secure for bio-fuels a market share of 5% of total fuel consumption by motor vehicles..

The Joule programme is continuing to run under the Community's Framework Programme on research and technological development. The renewable energy technologies covered are wind energy, photovoltaics, biomass and geothermal energy.

Thermie is the Community's technological programme designed to promote, among other objectives, the greater use of renewable energy sources. Renewable energy takes its share of the funds along with R,D&D into the rational use of energy, hydrocarbons and solid fuels. The programme is designed to run from 1990-1994 with an estimated 700 million ECU of funds.

Valoren was a Community regional funding programme relating to the development of certain, less favoured regions of the EC by the encouragement of their indigenous energy potential.

OUTLOOK

Strong growth in the renewable energy industry is predicted into the next century. Some technologies will see faster growth than others and this will depend more on the type and effectiveness of policies promoting market penetration than technological development, though this will also take place. Photovoltaics are less commercially viable than the other renewable energies discussed and a decrease in the module cost per kW is a prerequisite before photovoltaic technology can compete seriously in the electricity supply industry.

Strongest growth could occur in the area of biomass and other renewable energy technologies, notably wind and geothermal energy. The share of large hydro-electric generation, though remaining large, will see relatively slow growth due to the lack of suitable sites remaining.

For electricity generation, biomass, predominantly wood, agricultural residues like straw, and waste will be increasingly used. Direct combustion will be the main method, though gasification should see larger growth. Electricity generation from wind energy is expected to grow rapidly though it is dependent on political factors to enable its widespread development. In the generation of electricity from geothermal sources, only Italy and Greece have high temperature geothermal resources. Italy is likely to see the largest growth in this area in the short term. Small hydro-electricity generation will experience higher growth than its larger counterpart. Photovoltaics, though a small component, will see growth in applications for remote locations. In the long term, PV will see higher growth through grid connection from either centralised or decentralised generation sites.

For heating applications, biomass will again play the major part, gasification technology showing the largest growth. The future for biofuels, formed from energy crops such as rapeseed or sunflowers, depends very much on future agricultural policy in the EC. Energy crops could supply farmers with a valuable source of revenue from set-a-side land. Tax breaks, as seen in Italy and France and continued Member States support will ensure that the use of biofuels increases.

Geothermal energy for heating will experience growth in all Member States where resources are available. The future prospects for the active solar collectors market depends to a large extent on the effectiveness of national and EC energy plans. Denmark and the Netherlands will see large growth due to government commitments to reducing carbon dioxide emissions; similar conditions should favour the industry in Germany. Italy has recently included the development of active solar energy into its national energy plan, ambitious targets have been made and these should promote strong growth. Spain has considerable potential, a government commitment combined with public education campaigns could result in active solar being widely implemented. In Greece, the market, though large, is not near to saturation and is likely to continue increasing steadily.

Written by: DRI Europe

Overview

Mining and quarrying operations in the EC vary widely in size and operation. The EC is a major world producer in construction raw materials and physical industrial chemicals. Currently the industry suffers from high stockpiles and low demand in the case of metals and oversupply and low minerals prices in the case of industrial minerals.

INDUSTRY PROFILE

Description of the sector

The non-energy mining and quarrying sector is broadly divided into two main sections, metals and industrial minerals. The metals section is subdivided into iron ore (chapter 2) and non-ferrous metal ores (chapter 2), which form the raw material for iron and steel making (chapter 3) and non-ferrous metals manufacture (chapter 4) respectively. Industrial minerals are categorised by their applications into construction raw materials and stone (chapter 2), chemical industrial minerals (chapter 2), and physical industrial minerals (chapter 2). Over 30 minerals are extracted and beneficiated and the EC is major world producer in some products, notably construction raw materials and some of the physical industrial minerals. Individual commodities for which significant mines and quarries are operated in the EC include: copper, zinc, limestone, dolomite, other stone, sand and gravel, silica sand, kaolin, and bentonite.

The value of production in the sector totals approximately 15 billion ECU, a relatively low figure in comparison with other industries but significant in terms of providing vital raw materials for added value industries such as metal products and construction. Construction raw materials account for nearly 75% of production value.

All EC countries bar one, have significant mining activity, with Germany the biggest producer, responsible for over 25% of all supply. Germany, France and the UK combined produce over 60% of EC mined minerals; Italy and Spain also have outputs of over 10% of the EC total. Portugal, Spain, Ireland, and Greece produce over 90% of non-ferrous metal ores, and only France and Spain extract iron ore.

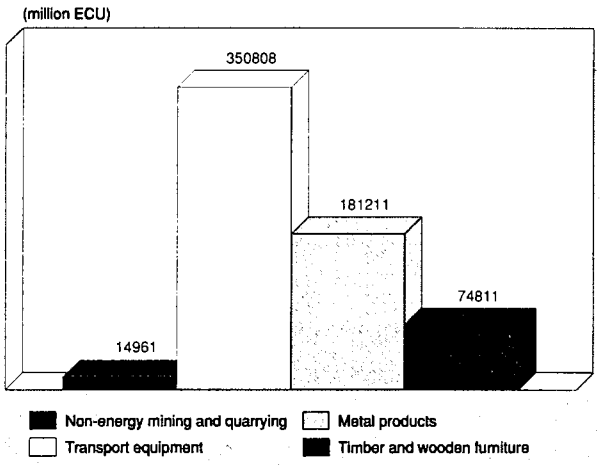
Recent trends

In all categories, production levels which remained on average fairly constant during the second half of the 1980s, have declined since 1989 by over 30% as a result of the worldwide recession. This change is most noticeable in the area of non-ferrous metals where the value of production in constant prices has halved, although 1989 was a particularly good year for that sector. In general terms the reductions have been due to falling commodity prices, which for many minerals, are at an all time low in real terms. Production of physical industrial minerals in 1992 remained close to 1991 levels in constant value terms but reductions were experienced in all other sectors commensurate with declining consumption.

International comparison

The EC remains a negligible producer of iron ore in a world context. In comparison the USA is nearly self-sufficient, although EC consumption is twice as high. Japanese consumption lies between the two with zero production. The EC produces around 20% of its non-ferrous ore needs, compared to over 75% in the USA and just over 10% in Japan. The USA produces 2.5 times more non-ferrous metals than the EC produces.

Figure 1: Non-energy mining and quarrying Production in comparison with other industries, 1992



Source: B.M.Coope & Partners, DEBA

In industrial minerals, the EC is the world leading producer of construction raw materials with output 50% higher than the USA and 300% higher than Japan. The EC remains almost 50% ahead of the USA in the extraction of physical industrial minerals although for the for chemical industrial minerals the USA produces at a level three times greater than EC levels. Japan has experienced only a small reduction of both the latter categories. Overall, EC and USA consumption levels are very similar. The USA is net self-sufficient in minerals, and EC production is 75% of US levels and nearly 4 times higher than production in Japan.

Foreign trade

Trade in metal ores has been heavily affected by high international stocks and reduced demand. The EC's dependency on metal ore imports is very high and major sources of imports are the traditional mining countries, most notably in South and North America and Australia. Exports are insignificant. The net trade deficit for all industrial minerals is only 5%,

representing less than 15% of the overall total. The relatively low unit value of industrial minerals places economic restraints on transport distances and thus EFTA countries are featured more extensively as trading partners.

MARKET FORCES

Demand

Demand for metalliferous ores and concentrates by the consuming sectors, iron and steel making and metal products is dictated by the end use industries, in particular transportation, machinery, and construction, all of which have been adversely affected by the recession. Individual metals are particularly affected by the electrical (copper), construction (steel, zinc, and aluminium), transport (steel, lead, and aluminium), and container (aluminium) sectors. Sign of improvement in these industries has been noted as 1993 progresses.

The poor performance of the construction industry has obviously been reflected in lower demand for construction raw materials. Some minerals in this category are also consumed in the chemicals, metallurgical, glass, and ceramics industries which have been less affected by the recession than the construction industry. The bulk inorganic chemical and fertiliser industries, both of which were oversupplied in 1992, are end-use markets for the bulk of chemical industrial minerals. The physical industrial minerals are used across a whole spectrum of industries ranging from ceramics, refractories, glass, and abrasives to paper, plastics, and paint.

Application diversity of metals and, in particular industrial minerals, continues to provide a hedge against the problems of falling demand in any one sector. Nevertheless, overall demand for virtually all metal ores and industrial minerals was weak in 1992 and the presence of large stockpiles may retard recovery.

Supply and competition

The low production of metalliferous ores is a reflection of the small number of economically treatable orebodies which exist within the EC. This is not the case in many areas of the world where large, high grade deposits exist, often in combination with advantageous labour, energy, and environmental compliance costs. At present the sector is experiencing, high stocks, currently 35 million tonnes in the case of iron ore, over capacity and low demand, so that operating metal mines in the EC is not easy. Where high quality deposits are located, however, such as the Neves Corvo copper mine in Portugal, EC miners have shown that they can compete profitably with overseas operations.

As previously indicated, transport costs militate against imports of at least the low value bulk industrial minerals and encourage local development where possible. The EC is fortunate to have good grade deposits of a range of industrial minerals which are efficiently exploited. The effects of international oversupply are restricted, although the same logic reduces the scope for exports. General exceptions to the above are special circumstances such as where super quarries operate in conjunction with low cost bulk carriers, or where high value materials are required or preferred.

The major world oversupply of chemical industrial minerals, particularly potash, phosphates, and sulphur, have placed pressure on all but the largest and lowest cost producers, although sulphur production in the EC is virtually all involuntary. With lower by-product revenues, greater pressure is placed on the main product

Production process

It is estimated that there are around fifteen thousand mines and quarries of varying sizes operating in the EC, ranging from one million plus tonne per annum super quarries to small concerns employing a small staff. Wherever possible operations are by open pit or quarry which require more material to be removed, but at the same time greatly reduces the cost of extraction and handling. The larger EC operations employ state-of-the-art excavation and transportation equipment comparable to the best foreign mines. Improvements to the efficiency of equipment and processes are largely due to upgrades in materials of construction, computerised control, and scale rather than technical innovation.

Underground mines are confined to a small number of non-ferrous and higher value industrial minerals (such as potash and fluorspar) where the value of the product justifies the increased costs.

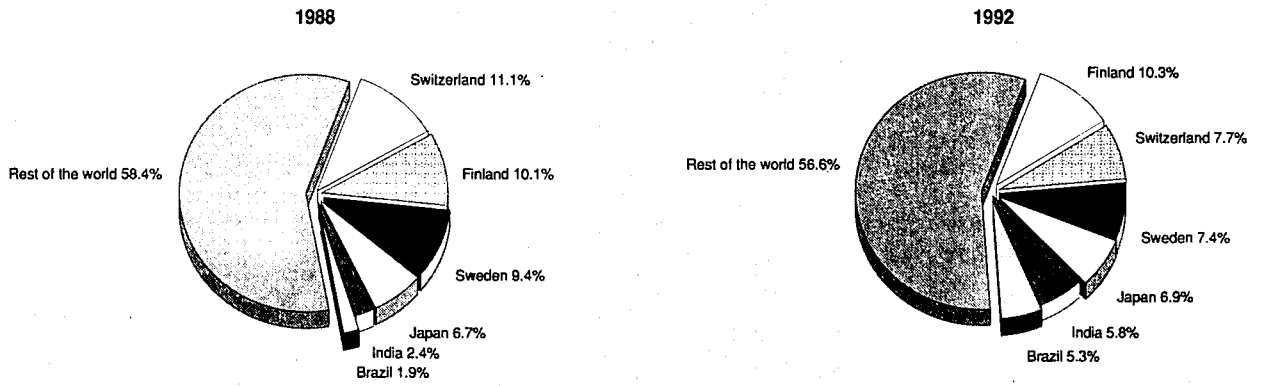
INDUSTRY STRUCTURE

Companies

Approximately 50 metal mining operations exist in the EC employing around 15 000 people. The largest operating company is Somincor, which mines and concentrates copper in Portugal. This mine is the world's tenth largest copper operation. Seven other EC companies employ over 200 staff each. EC companies such as RTZ (UK), Metallgesellschaft (D), and Union Minière (B) are strongly represented among the world's leading non-ferrous metals ores mining companies.

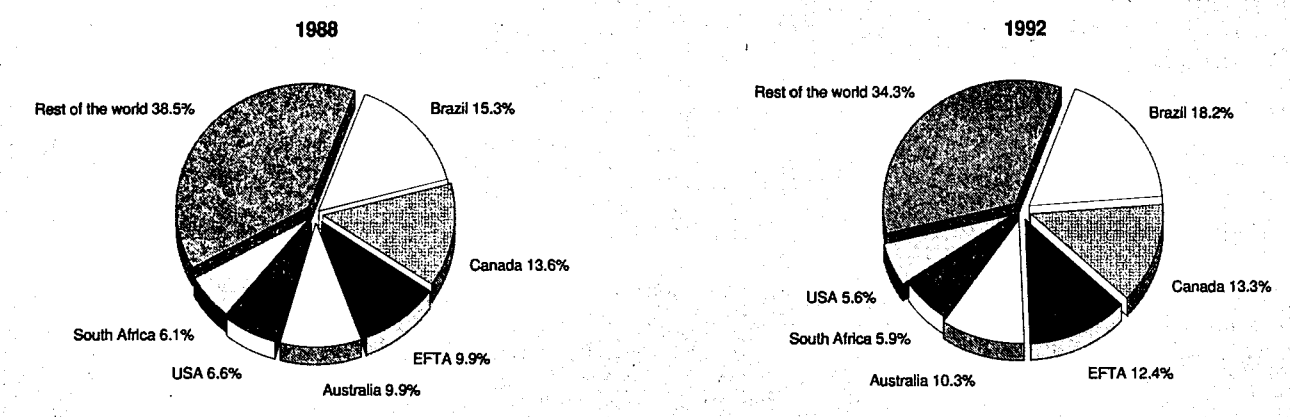
The number of companies, operations, and staff employed in industrial minerals mining and quarrying is difficult to assess, initially because of the lack of official data in virtually all countries. Reliable data is available for some single product companies but for other, larger organisations there is an insufficient breakdown of detail to isolate the industrial minerals data. Nevertheless, it is estimated that there are around 15 000

Figure 6: Non-energy mining and quarrying
Destination of EC exports



Source: Eurostat

Figure 7: Non-energy mining and quarrying
Origin of EC Imports



Source: Eurostat

mines and quarries of varying sizes in the EC involving over 1 000 companies and 200 000 employees.

The largest industrial minerals producing companies in the EC, in many cases among the largest in the world, include, construction groups such as: Tarmac, RMC, Redland, and Blue Circle (UK), Lafarge Coppee and Ciments Français (F), Italcementi (I), CRH (IRL), CBR Cimenteries (B), and Heidelberger Zement and Dyckerhoff (D). These companies are all major producers of crushed stone for aggregate and/or cement manufacture and some are also involved in the production of other products such as lime, gypsum, and clays products. Other major construction raw material producers are the gypsum specialists BPB Industries (UK) and Knauf Bauprodukt (D). In non-construction sectors the major companies include: industrial limestone and dolomite: Lhoist (B) and Carmeuse (B) and Wulfrath (D); industrial sands: Sibelco (B), Hepworth (UK), and Quarzwerke (D); industrial clays: English China Clays (UK) and Sud Chemie (D); potash: Kali und Salz (D); salt: Solvay (B) and AKZO (NL); and sulphur: Elf-Aquitaine (F).

Strategies

Metals mining companies are pleased to operate in the EC if economic deposits are identified. Several companies have active exploration programmes in the EC although the extent of exploration is modest compared with higher priority geological targets in foreign countries, most notably in South America. Most mining companies' strategies are integrated with their metals production interests and an increasing feature has been the establishment of alliances between international groups to provide strength and flexibility in financial and raw material resources. One major European mining company, the Shell group company, Billiton (NL), announced its intention in 1993 to sell its international operations.

Strategic considerations in construction minerals are tied up with downstream activities. There has been a strengthening of the major EC groups by merger and acquisition and the extension of EC ownership of companies overseas, in particular in the USA and increasingly in East Europe. Strategic changes have also occurred with the rationalisation of mines in former East Germany and with companies withdrawing

from sectors, most notably ICI (UK) from salt, limestone, and soda ash production.

REGIONAL DISTRIBUTION

Iberia, Ireland, and Greece are the most important regions for non-ferrous metal ores mining whilst Lorraine and the Pyrenees are the dominant iron ore producing regions. Among industrial minerals the production of construction raw materials is fairly well distributed throughout the EC but the occurrence of many of the more important chemical and physical industrial minerals such as, potash, kaolin, and talc, are more localised.

ENVIRONMENT

Although maximum discharge levels for mining emissions are only fixed in two member countries, most countries now have, or are producing guidelines, or are tightening compliance standards for mines along with other industries. All mining is subject to restrictions on noise and dust emissions and to waste storage and/or dumping and mine site renovation after cessation of operations. The last mentioned is the subject of present discussion. Special problems for individual minerals include acid mine and rock drainage from base metal sulphide ores and salt generation during potash extraction. Mining and quarrying by their nature have an unavoidable environmental impact, albeit a temporary one. Responsible EC operators' standards compare well with international industry parameters and with other industries.

REGULATIONS

General regulations applying to mining activities are well established and followed. As mentioned, environmental legislation is the subject of continuous change on the basis of applying the best available technology without incurring excessive cost.

OUTLOOK

The EC will continue to be a major area of activity in the production, trade, and consumption of industrial minerals. Overall production and consumption will grow only moderately in the medium term but the longer term prospects are good, particularly for construction raw materials and physical industrial minerals. The future for some of the chemical industrial minerals appears less bright because of the uncertainties about future fertiliser usage and because of structural changes in the chloralkalis industry.

In the metals sector the EC is expected to remain a significant producer of non-ferrous metal ores and concentrates and new production can be expected in the medium term, most notably in zinc ore production. Prices and markets are predicted to improve moderately as part of the general upturn in EC economic activity. EC mining companies will also continue to be major players in non-ferrous mining developments in foreign countries. Meanwhile the EC's low level of iron ore mining may not be economically sustainable in the long term due to the low quality of indigenous deposits. EC and world consumption of iron ore is expected to grow strongly in the

post-recession period but, a combination of large existing stocks and adequate low cost international mining capacity should prevent any potential shortages.

Written by: B M Coope & Partners
The industry is represented at the EC level by: International Association of Mining Industries (EUROMINES). Address: Avenue de Broqueville 12, B-1150 Brussels; tel: (32 2) 755 6311; fax: (32 2) 779 0523.

Iron ore
NACE 211

The EC remains a minor and declining producer of iron ore, providing only a small proportion, 6% by volume and 3% by value, of the Community's requirements from operations in two countries. Almost all of the mined ore, which is of low grade, is consumed within the EC iron and steel making industry in which product demand in 1992 fell by 7%. EC output will shrink further due to changing raw material demand patterns from ore to scrap, the poor quality of the EC iron ores and competition from larger and cheaper overseas producers.

INDUSTRY PROFILE

Description of the sector

NACE 211 covers the extraction and physical processing of iron ore, the primary feedstock for iron and steel making. The iron ore may be oxide or less frequently sulphide (pyrite) and open pit methods of extraction are usually employed, however, in France, ore mining is exclusively an underground operation. Mineral processing techniques are used to concentrate the ores which may also be agglomerated and sintered. The products are used as raw material for iron and steel making (NACE 301) and in 1992 they had a total value of 106 million ECU.

Recent trends

Production tonnage within the EC declined 20% in 1992 and is currently less than 35% of 1983 levels. The rate of output reduction, which has dropped for ten successive years, increased in 1992 well above consumption trends, yet commercial factors make it likely that the decline will continue, possibly to the cessation of significant EC output by the end of the decade. Production in both France and Spain has reduced in parallel; the French product is of a particularly low grade and the outputs from both countries consist only of non-agglomerated ore. Consumption within the EC reduced by around 7% in 1992 due to recessionary trends but its predicted to stabilise and increase moderately in the short term at levels in excess of 150 million tonnes (at 60% iron content equals 90 million tonnes of iron), compared to current EC production of less than 90 million tonnes (at 30% iron content equals 2.7 million tonnes of iron). Exports of iron ore from the EC are negligible.

International comparison

The pattern of trade in iron ore in the EC and Japan is similar, although all production in Japan has ceased during the past 5 years and consumption was harder hit by the worldwide recession in 1992, falling down to 11%. The USA, by virtue of recovering from the recession in advance of Europe and Japan, has shown a growth in the value of both production and consumption. Current US consumption is around 50% of EC levels and its domestic production accounts for 83% of its requirements. Japanese consumption remains midway between that of the EC and the USA. In total world terms, EC production is less than 1% and consumption around 16% of overall figures.

Foreign trade

The negative trade balance continues to remain consistent at current prices with the same value for 1983 and 1992. Imports originate most significantly from South America and Brazil now provides about one-third of EC requirements. Australia and Canada are also major suppliers and together they account for a further 25% of total requirements. Exports, mainly to Eastern Europe, are insignificant. Production by low cost operations in countries such as Brazil, Australia, India, Mauritania, and South Africa is set to increase further during the 1990s.

Figure 1: Iron ore
Value added in comparison with other industries, 1992

MARKET FORCES

Demand

Iron ore both produced in the EC and imported from non-EC countries is consumed by EC steelmakers. The decline in demand for steel, particularly by the automobile, construction, and machine manufacturing sectors, has resulted in an overall reduction in iron ore consumption in the EC of 7%, which approximately equals the Western World average. Although certain EC countries are reporting industrial growth in 1993, no significant increase in demand is predicted for the EC as a whole. International production of iron ore is unlikely to be stimulated by moderate increase in demand due to the large surplus of iron ore stocks, reported to vary as between 17 and 35 million tonnes.

Supply and competition

Despite such favourable factors as stable labour costs, high and improving productivity levels and the sheer scale of local

demand, there appears to be little prospect for EC producers to raise production from current levels, which are already below nominal capacity levels. The EC industry, which is based on low grade ores (low iron content and impurities), high transport costs and problems with deposition of waste slags, is poorly equipped to compete with large scale, low cost foreign producers whose existing capacity appears capable of supplying any growth in world demand for the foreseeable future.

Production process

In recent years little modernisation has been introduced into EC operations compared to the large investments major overseas plants have made in modern excavating, haulage, and process plants. These operations have been able to enjoy both technical advantages and massive economies of scale. Despite strong efforts to increase productivity, profitability of EC ore mines decreased to the point that some had to be closed.

The consumption of EC iron ore could also be negatively affected by the trend towards smaller steelworks, including some of those currently accepting EC iron ore, who are converting to modern electric arc furnace technology which favours the use of steel scrap feed material rather than ore.

INDUSTRY STRUCTURE

Companies

The iron ore industry in the EC consists of less than 10 operating units. The major operators are: Lormines (F), who recently stopped operations in the Lorraine district of France; ARBED (L), whose operations in Lorraine near the border with Luxembourg still continue; and Compañia Andalusa de Minas (CAM) (E) in Andalusia, Spain. The companies are small to medium sized private enterprises and are of small significance in world terms when compared with industry giants such as CVRD of Brazil, which exports over 75 million tonnes per annum and has invested over 500 million ECU in recent years on an expansion and modernisation programme. For the reasons already described it is difficult to perceive of circumstances that will halt the decline of the EC iron ore mining industry.

REGIONAL DISTRIBUTION

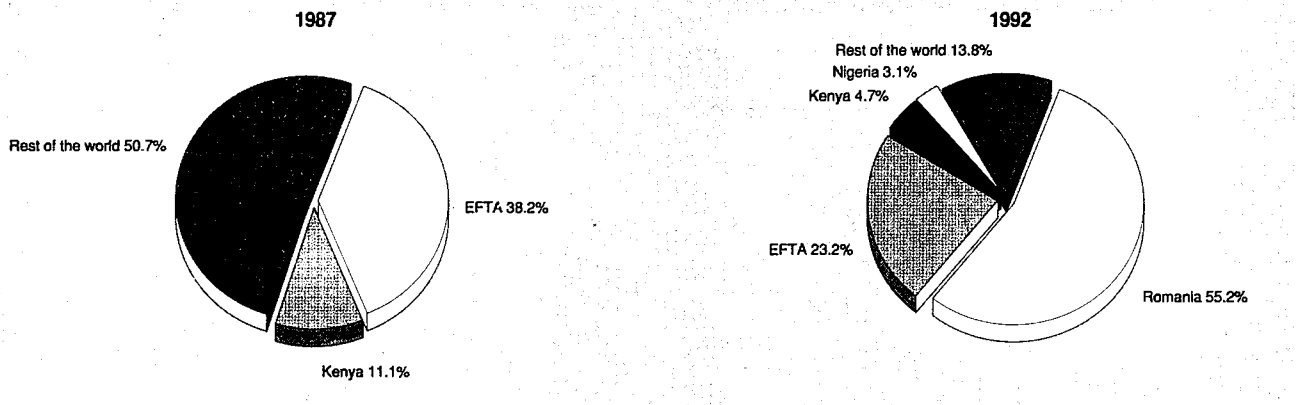
As indicated, operations are concentrated in the regions of Lorraine, France, and Andalusia, Spain, where the only deposits of ore currently deemed commercial exist. Future exploitation of the very limited reserves known to exist in other areas and countries within the EC seems highly improbable.

ENVIRONMENT

Environmental concerns in iron ore mining in the EC are low compared to non-ferrous metal ores. Virtually all ores mined are of the oxide type with the consequent absence of the problems encountered in sulphide ore operations i.e. acidic mine drainage and sulphur dioxide emissions. The major compliance requirements are associated with dust suppression and the avoidance of particulate solids entering water courses. Satisfactory operations are maintained by the use of best available techniques for processes as required by national and EC legislation.

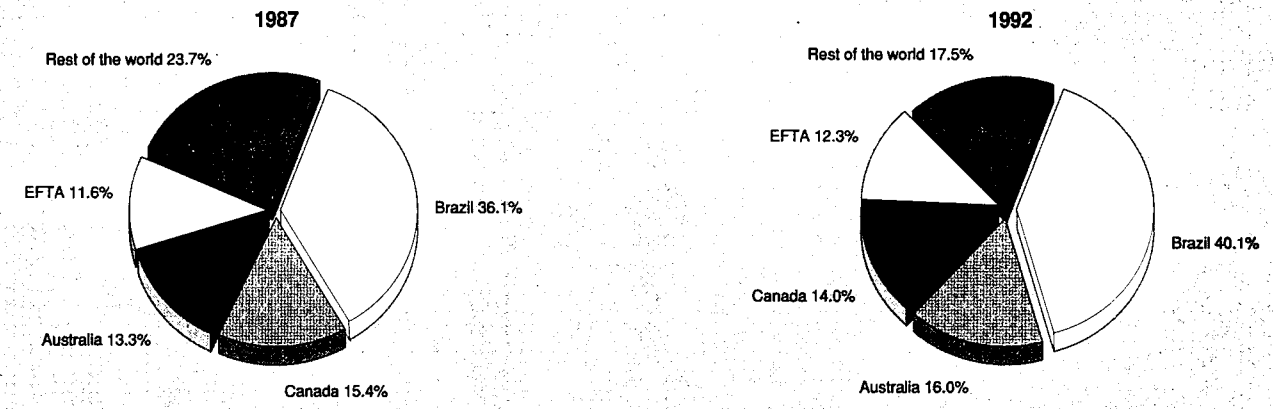
Since EC iron ore has an iron content of approximately 30%, the amount of energy consumed and the amount of CO_2 released per unit of enriched ore is much higher than for ore with higher iron content (such as imports with 60% iron content).

Figure 6: Iron ore
Destination of EC exports



Source: Eurostat

Figure 7: Iron ore
Origin of EC Imports



Source: Eurostat

REGULATIONS

The small number and scale of EC iron ore mining operations is a function of a lack of commercial grade natural resources. Whereas mining regulations in some foreign countries producing iron ore are less stringent than those in the EC, the standards are rapidly converging to EC levels. EC regulations allow responsible development of mining operations and this is reflected in the number and variety of mining operations exploiting other minerals throughout the EC.

OUTLOOK

For the reasons discussed above, the long term prospects for EC iron ore production are unfavourable. Although EC demand far exceeds EC production and will continue to do so under any foreseeable circumstances, resources in the EC are limited and inherently disadvantaged in their economic exploitation in comparison to foreign operations. At best the EC will continue to produce at levels below 10 million tonnes per annum (3 million tonnes in iron content), representing less than 6% of tonnage demand and around 3% in terms of value. At worst, significant production will cease as in Japan, leaving the EC with a complete reliance on imports from abundant and cheap foreign sources.

Non-ferrous metal ores
NACE 212

The EC has a small but significant non-ferrous metals mining industry which provides nearly 20% of the EC's primary raw material requirements for production of all metals. Copper and zinc concentrate production from three major operations account for approximately 80% of revenues from the industry. Non-ferrous metals mining in the EC is a mature industry subject to strong international competition. Little change to the established pattern is expected in the medium term.

INDUSTRY PROFILE

Description of the sector

NACE 212 covers the extraction and physical processing of all non-ferrous metal ores, of which seven are actively mined in the EC and a further eight major ores are sourced solely from imports. Production of two others, mercury and chromium ores, was suspended in 1992. Some gold and silver are present in EC base metal concentrates but separation occurs at the smelter stage rather than as part of the mining and processing operation. Mines in the EC produce around 7% of the world's zinc, 3% of the world's lead, and 2% of the world's copper and bauxite. There is minor production of tin, tungsten, and nickel ores and concentrates. Magnesium metal is also produced from dolomite by the silicothermic process. Products from the sector are used as raw materials for metals production (NACE 224) and in 1992 totalled over 500 million ECU in value. Portugal remains the largest EC mining country in terms of revenue by virtue of the major copper mine at Neves Corvo. Other significant producing countries are Spain and Ireland for their lead/zinc operations and Greece for its bauxite operations. The four countries account for over 90% of EC production.

Recent trends

Overall production levels declined slightly in 1992 as a result of mine closures in Spain, Germany, and Greece and the reduction of bauxite output from Greece. 1992 concentrate prices continued in a trough and were 2-3% lower than in 1991, with the single exception of zinc whose price rose by 11%. Little change in output is expected for 1993, although metals prices should experience some improvement.

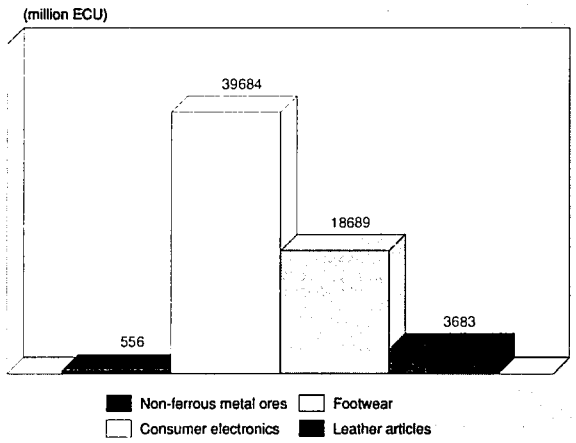
International comparison

Mining trends are more positive in the EC than they are in Japan, but EC output is less than 10% of that achieved in the USA. Mining is a function of geological potential combined with national stability and cost structure. The country particularly favoured at present for new non-ferrous ore developments is Chile. Also prominent for non-ferrous ore mining are Mexico, Ghana, and Indonesia.

Foreign trade

The EC remains heavily and increasingly dependent upon imports from the world's major mining countries; the Americas alone provide over half of the EC's total requirements. Most EC non-ferrous ores are exported out of the EC to other countries. Although EC imports from the former Soviet Union and China have been minor for concentrate ores, they have been enormous for metal, a factor together with persisting recessionary influences, has been responsible for several metal prices being at record low levels.

Figure 1: Non-ferrous metal ores
Production in comparison with other industries, 1992



Source: B.M.Coope & Partners, Mining Annual Review, DEBA

MARKET FORCES

Demand

None of the concentrates produced from mining are products in their own right and all proceed as raw materials for metal production or abrasives, cement, or chemical production in the case non-metallurgical grades of Greek bauxite. The EC is a major participant in world metal production. These metals serve some of the world's largest industries, such as construction, machinery, and transportation, all of which have been affected by the current industrial recession. Substantial stocks of most major metals now exist, reflecting the poor demand in 1992/93.

Supply and competition

By virtue of the grade and reserves of ore in Portugal, Ireland, and Spain in particular, the EC is able to mine competitively at its existing operations. At least one major new zinc mine, Lisheen in Ireland, is scheduled to come on stream in the near future. These operations will continue to be the mainstay of EC domestic supply for the foreseeable future.

Further large deposits of base metals are known to occur in the EC, for instance, the Parys Mountain lead/zinc polymetallic

deposits at Anglesey in the United Kingdom, but potential operational costs are likely to compare unfavourably with the high grades and low costs experienced in other regions such as South America. Similarly some large but relatively low grade deposits of tin, tungsten, and nickel ores exist in the EC but are only likely to become profitable operations should economic or technical circumstances change. Meanwhile production of gold and arsenic is likely to recommence from Salsigne in France shortly and possibly mercury from the Almaden mine in Spain. Further production of chromite from Greece is uncertain.

Production process

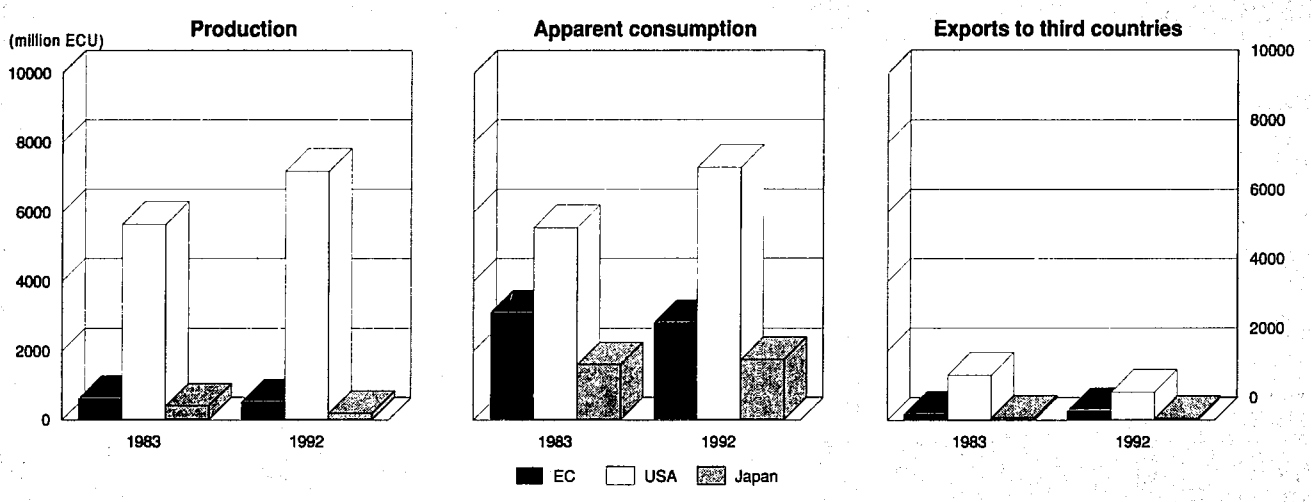
No radical changes in mining and beneficiation methods have been introduced in 1992, although the trend towards larger sized equipment and the treatment of fine material has continued, together with efforts at energy saving and improved environmental compliance.

INDUSTRY STRUCTURE

Companies

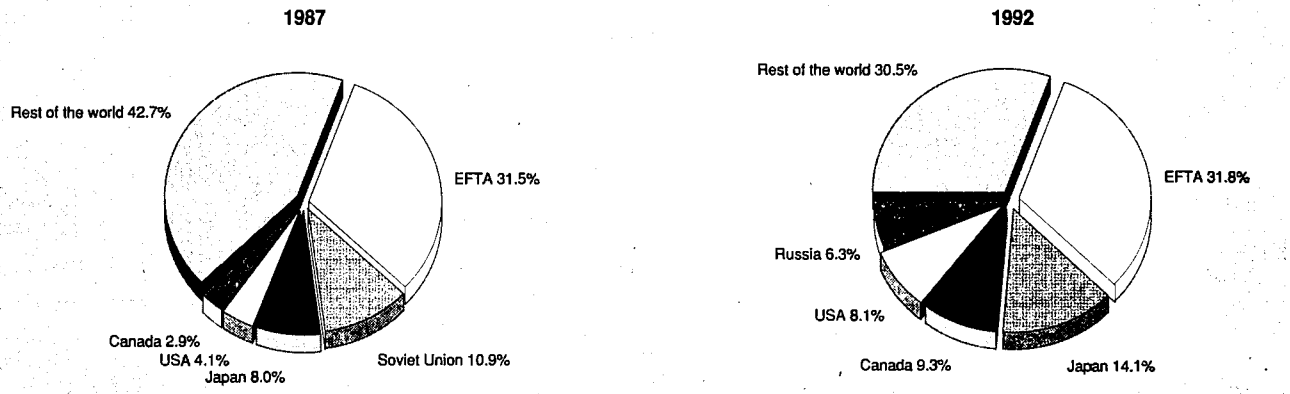
Half of the companies, 22 firms, have over 100 employees and account for 89% of the industry turnover. As indicated above, the largest mines are located in Portugal, Ireland, Spain, and Greece. These operations are owned by European private or public interests. The major companies are Somincor (P), Tara Mines (IRL), Asturiana de Zinc (E), Exminesa (E), and Bauxites Parnasse (GR). There are also a number of EC-based mining companies which operate on a significant international basis, including RTZ (UK), Union Miniere (B), Minorco (L), Metallgesellschaft (D), Pechiney (F), Nuova Samim (I), and Billiton (NL). Together these and other leading companies are responsible for over 10% of worldwide non-ferrous ore mine production.

Figure 4: Non-ferrous metal ores
International comparison of main indicators in current prices



Source: B.M.Coope & Partners, Mining Journal, DEBA

Figure 5: Non-ferrous metal ores
Destination of EC exports



Source: Eurostat

Strategies

Appropriate geological conditions can be found for mining companies and their operations in EC countries. There is also a reasonable exploration aimed mainly at Iberia, Greece, Ireland, and Scotland, although this represents a small fraction of exploration investment in other parts of the world. While EC mining interests have been most active in South America they are cautious with regard to developments in Eastern Europe. There is a significant degree of integration between non-ferrous metals mining and metal production, in fact most companies have dual interests in which metals manufacture provides the major share of EC-based activity. A feature of recent mining and metals company strategies has been establishing international alliances by share ownership to ensure financial strength and availability and flexibility of resources. The trend for oil companies to divest of other mineral interests is on the verge of completion with the announced sell of Shell's mining and metals interests, largely located in Gencor, South Africa.

REGIONAL DISTRIBUTION

As indicated, the majority of non-ferrous mining operations are located in, Portugal with 168 million ECU worth of production, Spain with 122 million ECU, Ireland with 114 million ECU, and Greece with 100 million ECU. There is minor production in Italy, 33 million ECU worth, but other EC countries have insignificant or no operations.

ENVIRONMENT

Stricter standards of environmental compliance are being imposed throughout the EC and the world which force the mining industry to meet waste discharge limits. The most significant emission problem concerns water, and specifically water associated with sulphide operations where acidity levels may be high. There have been no reports of serious environmental non-compliance from EC mines although future compliance standards are a major issue with existing and planned operations, particularly in Ireland.

REGULATIONS

Exploration, mining, and associated environmental legislation is well understood, applied, and observed within the EC mining industry and is not an overriding factor in the development of the industry. The mining industry is not greatly affected by single market regulations.

Table 7: Non-ferrous metal ores
Expected real annual growth rates

(%)	1993-94	1993-97
Apparent consumption	2.0	2.5
Production	0.5	0.5
Extra-EC exports	0.0	0.0

OUTLOOK

The EC is expected to continue to rely primarily on imported sources of ores and concentrates to serve its metals industries. Nevertheless a small number of competitive operations within EC borders will continue to make a significant contribution to its requirements. One or two major new mines will be opened before the end of the decade, the first of which involving lead/zinc deposits in Ireland. Exploration should at least maintain if not increase the overall level of output. Profits for mine operators will be restricted by international oversupply, weak demand, and low prices in the immediate future.

The industry is represented at the EC level by: International Association of European Mining Industries (EUROMINES). Address: Avenue Broqueville 12, B-1150 Brussels; tel: (32 2) 775 6311; fax: (32 2) 779 0523.

Stone
NACE 245

The European stone industry is the oldest and still the most important stone industry in the world. Europe produces, transforms, trades and consumes all kinds of stone materials including marble, granite, travertine and other similar stone. These products are destined for various uses although the largest consumer is the building industry; particularly the upper end of the industry, where there is competition from ceramics and glass whose investment potential from the view point of marketing as well as research and development is greater.

INDUSTRY PROFILE

Description of the sector

The ornamental stone industry is divided into two main parts:

- the excavation of raw materials;
- transformation of raw materials into the various finished products.

The processed materials are mainly calcareous (marble, travertine, etc.) or siliceous (granite, serizzo, beola, etc.). The latter are of greater resistance and are employed mainly for exteriors while the formers are mainly used for interiors.

Recent trends

In the 80s the industry experienced a real boom. From 1981 to 1991, world quarry production rates rose from around 20 to over 30 million metric tonnes and this was accompanied by an equally significant increase in the number of producer countries. At present only 9 countries exceed an annual production of one million metric tonnes and 6 of these belong to the EC. Up until 1992 the EC ornamental stone industry accounted for over 50% of world production and around the same percentage of global international trade in terms of volume. Intra and extra-EC trade involves rough blocks and a wide variety of finished articles.

Production averages around 30 million metric tonnes per annum with a recent, constant upward trend mainly due to the emergence of new producer countries on the world market. Since the early 80s at least ten new significant producers have emerged and become self-sufficient, thereby increasing the production of quarrying, sawing and processing machinery. The machinery sector has in fact experienced a period of rapid growth over recent years and is mainly based in EC Member States.

Source: Various sources

The EC countries in the Mediterranean basin form the heart of the sector at both a European and a world level despite intense development in other areas of the world. In 1992 the greatest producer country of blocks for ornamental use was Italy which has always held the leading position in the market, followed by Spain, Greece, Portugal and France.

International comparison

With the exception of EC countries, all the other significant stone consumers are far from being self-sufficient, even within their own home markets. Since '85 Japan has been a very important importer of granite primarily destined for funeral art. It prefers to procure lower quality semi-processed or finished articles from Taiwan and South Korea, but obtain stone for more complex work which requires the expert use of sophisticated production techniques and a wide range of different products from EC countries. The same applies to the USA despite its strong domestic production. Since 1988, however, the demand for finished products (especially granite) in the USA has gradually decreased due to the slump in the high-rise non-residential buildings. The great decline in this sector, which has been compensated to some extent by the increase in housing in many areas of the USA, has influenced international trade in terms of sales and volumes. The US market, however, like the Far East market, generally remains an advantageous market thanks to the average unit value of the product it absorbs.

In South East Asia there is a tendency towards self-sufficiency which is likely to continue over the next few years. The great buying power of the Japanese market, the extensive building activities in some of the newly industrialised countries, the availability of low-cost labour, the proximity of areas with high raw material production rates such as India, South Africa and more recently, China, all create a shorter distribution chain for products which only excludes a few very privileged niches in the market. The EC occupies a strong position as far as the latter are concerned.

Foreign trade

World trade in volume mainly involved raw and semi-raw materials. Most important exporters are Italy, Spain, Greece. Outside the EC the main exporting countries include India, Brazil, South Africa, and South Korea which primarily export raw materials. South Korea is the only country to have recently (1988-89) penetrated the market as a producer, transformer and consumer.

EC exports include mainly finished products which are largely destined for the building industry. They are intended for fellow Member States and extra-EC countries, mainly North America and the Far and Middle East. Right up until '82-'83, demand from the Middle East was much stronger. Subsequently, external factors led to an abrupt decline in demand. The effects of the international crisis in the Persian Gulf were mostly responsible for the 1990-91 figures, although already in 1992 some positive signs were seen which have continued to develop in 1993. Nevertheless, the strongest market is still within the EC, Germany and Italy first, followed by Spain, France and Greece.

MARKET FORCES

Demand

The demand for stone materials is as varied as ever. It ranges from the large importers of blocks which amount to only a few dozen companies throughout the world, concentrated in Italy and Germany, to the large North American building companies and developers and the end-users for all the other segments of the market.

The greatest problems facing the sector stem from the extreme fragmentation of the consumer market together with the very limited average size of companies. Moreover, the lack of capital to invest in research, development, promotion and marketing makes it difficult to exploit this dispersed consumer market which is often regional and not even national. Demand is maintained thanks to the intrinsic characteristics of the products themselves, such as their reputation, response to technical problems, aesthetic variety and image.

Quarrying technology is relatively simple and more often than not problems arise from the lack of infrastructures rather than anything else. Countries capable of offering technologically advanced finished articles at competitive prices are however very few.

Supply and competition

The traditional usage, the extensive and intensive production, the capacity to transform raw materials and a building industry very keyed in to maintenance and restoration all favour the use of stone in all its aspects. It is often considered a material which adds value and prestige to buildings where it is used, be they residential or non-residential. The difficulties of the

sector which do not allow it to invest sufficient capital in promotional and marketing activities may affect its development over the next few years. Segments of the market which promise expansion despite the recession which is investing certain countries are still confronted with intense competition from rival industries such as glass and ceramics. Indeed, since 1991 the general increase in the competitiveness of all markets has already adversely affected the prices which have had to decrease in real value to retain a share in the major markets.

Production process

The traded materials are mainly calcareous (marble, travertine, etc.) or siliceous (granite, serizzo, beola, etc.) and are used differently according to their peculiar characteristics. Granites are generally employed for exteriors or wherever greater resistance is required to withstand wear and tear and atmospheric pollution; marbles are mainly destined for interiors or where there is greater protection from external elements. The progress in processing technology has widened the scope for the use of stone, especially in the building and furnishing sectors, and this progress has been accompanied by improvements in stone laying and maintenance techniques. Most important of all is the development of techniques for the production and application of thin light weight units which have enabled stone products to penetrate new markets and the avant-garde markets such as the removable floorings market for electronic processing centres and the light vertical claddings market. Marble and granite can now be used to clad lifts, ships, skyscraper facades in areas subject to typhoons and in other situations which were previously inconceivable for traditional methods. Alongside these avant-garde uses, there are of course the more traditional, well-established areas of usage, such as funeral art, furnishings, monuments and decorative architecture where production processes have also undergone a radical technological transformation. For some of the traditional uses, the processing of stone is part of production in other industrial sectors. This is particularly true in the case of furniture production where marble and granite cutting and polishing workshops (which produce vanity tops, kitchen table tops and bathroom furniture coverings) are an integral part of the production line of finished furniture. However, the most important market as regards the quantity of material sold and the value added absorbed remains the traditional building industry including new buildings, restoration and maintenance work.

INDUSTRY STRUCTURE

Companies

The average size of companies in the sector is generally very limited. There are now around 500 000 employees overall, including at least half employed in the quarries. Average company size is no more than 8.1 employees, although various groups of companies have joined forces to develop effective market strategies and pool resources. Great changes have taken place as regards the production methods, speed and costs in recent times due to the widespread introduction of diamonds in the quarrying and processing of marble at the beginning of the 1980s.

The greatest concentration of productive companies is in Italy, where stone materials are available in nearly all its regions. The number of quarry workers is estimated at over 70 000 and there are also a large number of workers in the industries connected to quarrying, processing and trade. The same situation can be seen in Spain, France, Portugal, Greece and Belgium.

Strategies

A major problem which affects almost all the EC countries is the ageing labour force. The turnover of the generations of workers is very slow indeed and this is a problem which may become very serious in the future for a sector which often requires long periods of professional training. The biggest question mark however, rests on economic and commercial prospects. In view of its close links with the building industry in all countries, the sector is inevitably dependent on the building industry, and especially the top end (residential, non-residential, urban landscape, restoration of old town centres, renovation in general) of the industry. The tendency towards self-sufficiency, even partial, of certain producer and consumer areas (as seen in South East Asia and Japan) could even reduce the overall market of the European stone industry and limit it more and more to the market within the EC itself. As far as stone companies are concerned, this could lead to even more problems for smaller companies forced to specialise

still further or opt for subcontracting, leaving the larger companies to deal with the more complicated contracts and the more distant markets. The larger companies and groups already work on this basis on the international market. They are directly present on distant markets, often with local associates, and among other things co-ordinate complex projects. In other words, they have already partly reorganised their presence on the market.

ENVIRONMENT

Important environmental issues affect the stone industry in both its productive areas, that is quarries and workshops. There are serious problems as regards the respect for and restoration of the structure of the mountains where quarrying activities are carried out. Various countries and regions do actually stipulate that exploitation plans should include programmes for the temporary management of quarry dumps and at least partial reconstruction of the natural habitat. This, however, is not always feasible and sometimes leads to the interruption of activities as it is impossible to comply with current regulations. The ecological issue goes hand in hand with the ever complex problems regarding safety in the quarries. Every year, in spite of the increased awareness of workers and employers on the subject of safety measures, accidents continue to occur and are sometimes fatal.

Respect for the environment must continue after the quarrying process and this requires compliance with current regulations regarding interior working environments (microclimates inside the workshops, noise levels, dust, mud, complete safety) and respect for workers and inhabitants in the vicinity of working environments. Thus, refluent slurry, noise, water pollution and overloaded roads are all problems which concern technical researchers, machine manufacturers and environmentalists alike. Technical researchers are trying out new solutions (for example, the reutilisation of marble rubble) while manufacturers are designing machines with lower noise levels and less dust production (sound-proof machines, purified plants at the design stage, etc.) and environmentalists are trying to impose respect for the environment and the observance of current regulations.

REGULATIONS

The stone industry in EC countries is subject to the regulations which in general apply to building material products. It now has to face restraints in two areas regarding:

- production, environmental and workers' safety regulations both inside and outside the quarry and the workshops;
- usage, special safety regulations regarding anchorage systems for vertical cladding and the development of unified EC regulations for certain production methods.

Various technical committees have been set up within the EC. Among these, there is:

- TC 125 which regulates masonry works and plans to set up a sub-commission for natural stone;
- TC 128 which deals with building coverings etc. and has a work group for slates;
- TC 178 which concerns roads and curbs and has a subcommittee for natural stone;
- TC 246 which regulates floorings in general in natural stone, interiors, stairs, terraces, balconies, etc. and exterior facings.

Throughout 1993 as in previous years, the EC has striven to make it possible for stone materials to circulate freely within the EC and withstand competition from similar rival materials.

OUTLOOK

The present economic recession felt on some of the major markets or at least on the more profitable markets for processed stone troubles producers in the sector. In some countries where there is an important stone industry overall excavation is expected to decrease between 5 and 10% by the end of 1993. Although globally the sector seems to be in constant but modest overall expansion, the future of the industry in Europe, in the medium-term, is very closely linked to the European building industry (including new buildings and restoration works, the public and private sectors). The unification of the markets will not affect companies already operating outside their own region. At worst, these companies will have to conform to the new standards and the consequent quality certification requirements. Trade relations with more distant markets will be more difficult as the latter are tending to form autonomous systems to face European competition. It has already become more complicated for individual companies, especially smaller ones, to get a share of such markets without having privileged partnerships with local companies and the necessary support in the form of assistance, services and credit facilities. On the other hand, new quarrying activities in third world countries and increased familiarity with using natural stone since the late '80s are gradually creating much better prospects for new markets.

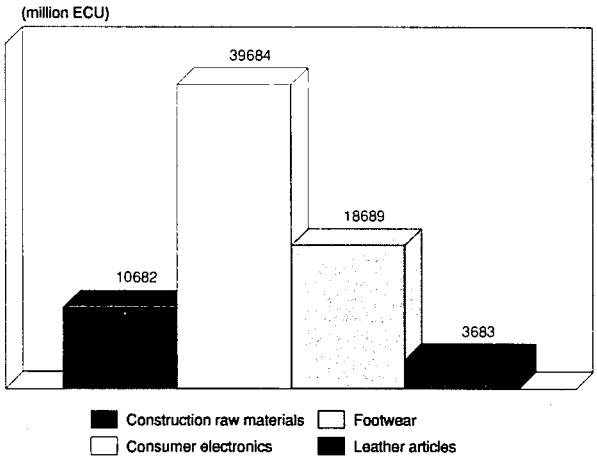
The industry is represented at the EC level by : European International Federation of Natural Stone Industries (EURO-ROC). Address: Avenue Henry Dunant 2, Bte 15, B-1140 Brussels; tel: (32 2) 736 0245; fax: (32 2) 736 0245.

Construction raw materials

NACE 231

The EC is one of the major producing and consuming regions for construction raw materials. In the construction raw materials sector the EC is theoretically self-sufficient. Virtually all mainstream products and external trade tends to be in material chosen on aesthetic grounds. The economic performance of this industry is tied directly to the level of building and construction activity in the EC, which has been low in recent years. Some of these predominantly construction minerals notably limestone, dolomite and silica sand, are also widely used by industries such as, glass and ceramics, metallurgy, paper, paints, plastics, etc. The proportion of construction raw materials ending up in these industries and not in construction is generally less than 10%.

Figure 1: Construction raw materials Production in comparison with other industries, 1992



Source: B.M.Coope & Partners, DEBA

INDUSTRY PROFILE

Description of the sector

Most of the mainstream products fall under NACE 231 category. The following is list of some mainstream products and their end-use markets: crushed stone for construction and road aggregate; sand and gravel for construction and road aggregate; limestone and chalk for cement and lime; gypsum for plaster and cement; and dimension stone including marble and granite. Clays are not included in this category. For more information about dimension stone, please refer to the previous chapter on stone.

Construction aggregates and cement are the bulk raw materials used in the construction of roads, railways and buildings. Value added data are in line with overall economic activity. Thus, Germany displays the largest value added followed by France, the UK, Italy, and Spain.

Many larger operations are owned by large construction and civil engineering groups. However, the abundance of deposits and the localised nature of their markets, which typically fall within a 50 kilometre radius, also allow the existence of a very large number of small enterprises. Limestone and chalk are the main raw materials used in both cement and lime manufacturing and, consequently, quarries for these end-uses are invariably captively owned by the large cement or lime manufacturing groups featured in Chapter 5.

Recent trends

Production and consumption levels increased gradually throughout the 1980s but fell during 1990-93. This reflects not only the strong performance of the construction industry in the late 1980s, but also the more recent downturn in construction activity. Nevertheless, the long term trend is upward and both production and consumption are expected to show renewed growth in 1994.

International comparison

The EC is the world's leading producer of construction raw materials with a 1992 output 50% higher than the USA and 3 times the size of Japan's output. Both the USA and Japan display a similar pattern of production and consumption over the past ten years with growth in 1983-89 period followed by decreases in the 1989-1993 period.

Foreign trade

Foreign trade represents only a small part of the total commercial activity in construction minerals, with imports accounting for about 6% of total consumption and exports are 3% of total production. Nevertheless, the sheer size of the sector means that significant tonnages are involved and the total value of imports has regularly exceeded 500 million ECU in the past 4 years.

Thus, the EC is active in both the importing and exporting of these materials but in recent years has become a net importer. This is primarily due to a surge in the imports of dimension stone granite from countries such as Norway, South Africa, Brazil, and India. Frequently these imports arrive in the EC for further processing increasing activity for EC's domestic stone processing industry, particularly in Italy.

Exports are dominated by shipments to EFTA countries. Construction aggregates have enjoyed large demand in Switzerland. Highlights in export trade to non-EFTA countries are the shipments of dimension stone marble and granite to Japan, the USA, and the Middle East. So far as sources of 1992 imports are concerned, the EFTA countries accounted for about two-thirds of total imports. Products most commonly imported were dimension stone granite and crushed stone aggregate from Norway, Sweden, and Finland.

Intra-EC trade is dominated by cross border movement of aggregates and industrial limestone/dolomite products between Germany, the Netherlands, Belgium, and France and by trade in dimension stone products in which Italy, Spain, Portugal, and Greece are prominent.

MARKET FORCES

Demand

The construction industry is clearly the dominant market for this group of raw materials. As fundamental ingredients in the construction of roads and buildings, demand for the major product lines is directly dependent on overall construction activity. However, it should not be forgotten that the industrial grades of limestone, dolomite, and sand are consumed primarily in the chemical, metallurgical, glass and ceramics industries. These industries are also affected by recession although they are typically more resilient than the construction industry.

No major technological changes have taken place recently in construction materials although on aesthetic grounds the increasing use of natural stone, e.g. dimension stone granite and marble, for the exterior and interior surfaces of buildings has been a noticeable growth area for the sector.

Supply and competition

The EC is a major world producer and is theoretically self-sufficient for virtually all the minerals and rocks in this group. Prices tend to be an intra-EC affair based on contracts negotiated between producer and consumer. Indeed, with the high degree of captive ownership in the construction minerals area, many prices tend to be an intra-company affair. Prices for most of the bulk construction raw materials are usually constant in real terms and thus value growth for both production and consumption reflects increases in volume. Likewise the higher levels of extra-EC exports in recent years reflect higher volume sales of products such as gypsum, dimension stone granite, and carbonate fillers.

Transporting the product between seller and buyer is a major consideration in bulk raw material markets. Producers often operate their own trucks and sell on a delivered basis, and in many cases sell semi-finished or finished products such as ready-mixed concrete, coated road stone, and plasterboard. Sales of these value added products, plus the strong element of service offered to the customer, often combine to give attractive operative margins for companies operating in this sector.

Transportation costs can rule out foreign competition in bulk construction raw materials. The exceptions to this rule cover situations where non-EC countries are neighbours as in the case of Norwegian and Swedish stone shipped to Denmark and Germany, or in the case where "super quarries" have been set up to export stone in low cost bulk carriers e.g. Glen Sanda in Scotland, Wimpey in Ireland, or also in the case where high value items are preferred on aesthetic grounds e.g. dimension stone granite from South Africa, Brazil, and India. In the latter case it should be noted that the EC stone processing industry adds significant value to the material before sale, and is actively engaged in extra-EC exports of the cut and polished versions of the products.

Production process

Construction raw materials extraction is often in the hands of large construction groups whose activities may range from cement and plaster products manufacture to civil engineering. The quarrying divisions of such groups tend to be large scale, highly mechanised operations with quality control well in evidence to cover what is in essence a crushing and grading exercise. Much attention has been focused on improving the efficiency of the crushing process and new or improved technologies are being used to cut costs and maximise the output of high grade products.

INDUSTRY STRUCTURE

Companies

The largest enterprises operating in the construction raw materials sector are the major cement and aggregates groups such as Lafarge Coppee and Ciments Français of France; RMC, Redland/Steetley, Tarmac, Tilcon (BTR), Blue Circle, Hanson, and Evered Bardon of the UK; Heidelberger Zement, Dyckerhoff, and Basalt AG of Germany; Holderbank of Switzerland; Italcementi of Italy; CBR of Belgium; and CRH of Ireland each of whom have thousands or tens of thousands employees.

Other major enterprises extracting limestone include the lime specialists such as Lhoist (B), Carmeuse (B), Rheinische Kalkstein-Werke (D) owned by Wulfrath (D), and Buxton Lime (UK) owned by Minorco (L) and the carbonates producing Omya group (F) fully owned by Pluess-Staufer (CH). In the gypsum and plaster sector the major enterprises are BPB Industries (UK), Lafarge Coppee (F) and Gebr. Knauf (D). Major players in the industrial sands industry are Sibelco (B), Quarzwerke (D), and Hepworth (UK).

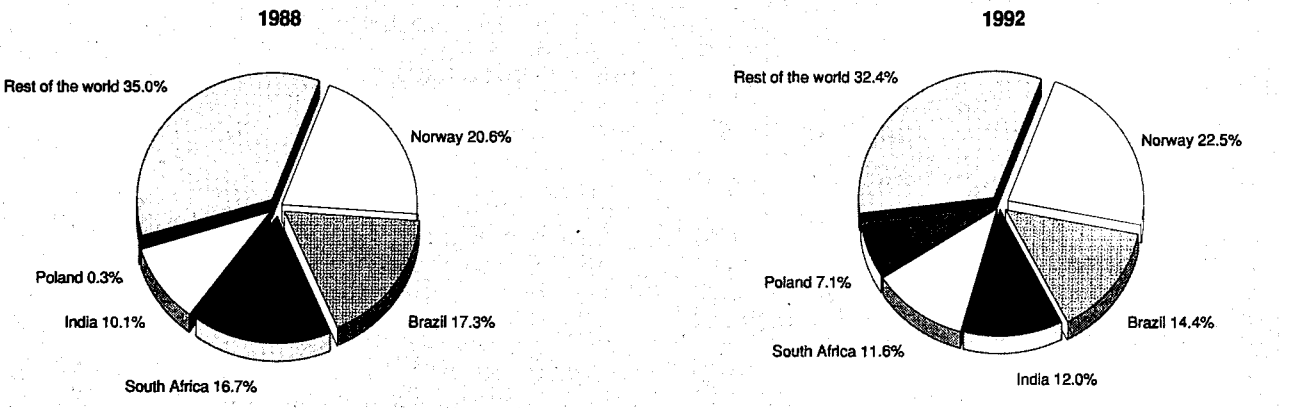
In each of their subsectors the above named enterprises represent over 60% of total EC turnover. All these companies are either European or international in character.

Strategies

In the construction raw materials sector, market strategies for the larger enterprises are tied to their downstream activities. There has been a marked consolidation of the industry within the EC as major groups continue to increase reserves of raw material and influence downstream products by acquisition.

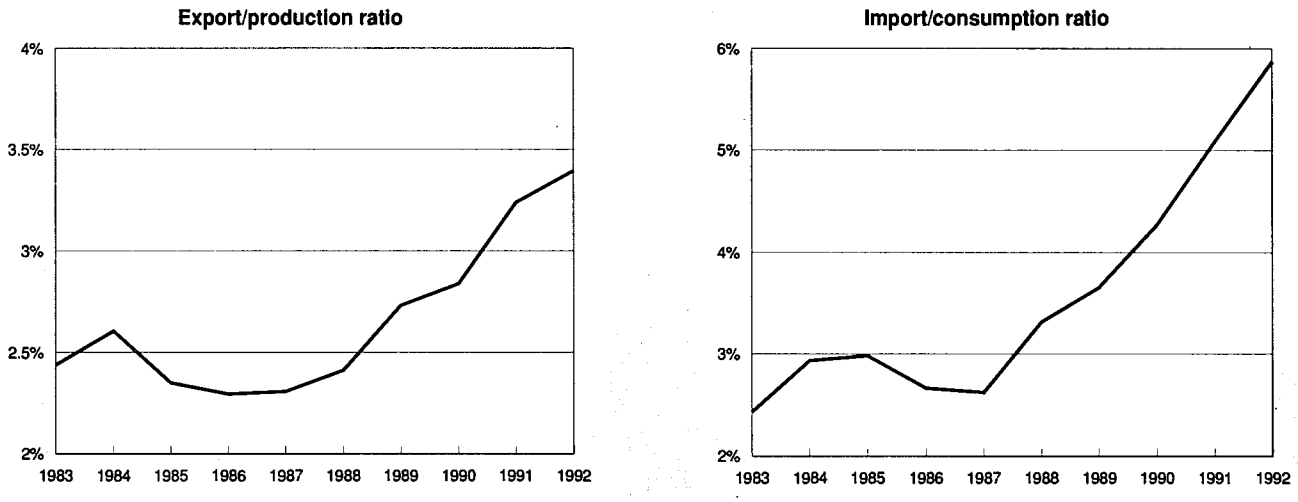
During the 1980s the EC and North America were main areas of focus for acquisitions in the cement and aggregates subsectors. Today the focus has shifted towards Eastern Europe.

Figure 6: Construction raw materials
Origin of EC imports



Source: Eurostat

Figure 7: Construction raw materials
Trade Intensities



Source: B.M.Coope & Partners, Eurostat

In the aggregates subsector, quarries or sand gravel pits are prime targets for acquisition as they are the best way to increase aggregate reserves with planning permission and to maximise involvement in major construction activity. The best approach is to acquire existing operations and invest in expanding or modernising as required.

For the cement subsector, the prime objective is to acquire a cement producing unit, while acquiring a limestone reserves is a secondary consideration. The European cement industry has suffered from overcapacity in the past and thus many mergers and acquisitions were part of the rationalisation process. Recent acquisitions by the big international groups have been aimed both inside and outside the EC. During the 1980s the European cement producers focused their merger and acquisition efforts on North America but since 1990 the closer regions of Eastern Europe have been favoured for EC investment. Nevertheless, intra-EC acquisition and merger activity continues with the drawn out take-over of Greek cement producers, Heracles and Halkis Cement, by the Italian company, Calcestruzzi, another example is Italy's other main producer, Italcementi, taking a major interest in Ciments Français.

REGIONAL DISTRIBUTION

Aggregates and cement are produced throughout the EC with all 12 countries recording production. With regard to aggregates, sand and gravel is more prevalent in low-lying regions and crushed stone more common in highland areas. Dimension stone workings tend to be highly concentrated, for instance in the Carrara marble district of Italy and the Pontevedra/Badajoz granite district of Spain. Gypsum is not as widespread as limestone but large deposits exist in Germany, France, Spain, and the UK and mining, both open cast and underground and processing, including plaster and plasterboard, tend to be carried out at single sites. Sand deposits are fairly widespread although the better quality industrial grades are obtained from

deposits located in Belgium and in the north of Germany and France.

ENVIRONMENT

Most of the minerals and rocks in this group are mined by open cast methods so operations consist of a quarry or sand and gravel pit with associated processing plant. Many such operations are highly visible and subject to the NIMBY (Not In My Back Yard) factor.

The modern quarrying industry has an excellent record for dealing with potential problems such as dust emissions and noise pollution during the life of an operation and for restoration of the land once the extraction process has finished. Nevertheless, the restrictions imposed on new workings in some Member States will lead to some areas of the Community importing materials at higher cost. Although the use of waste materials as aggregates is growing, it will remain small because of the stringent performance requirements which specify only high grade aggregate. Meanwhile, the coastal super quarry will play an increasingly important role in supplying deficient areas.

This sector also supplies products for use in environmental processes, most notably limestone and lime in water and air treatment and silica sands for water filtration. Paradoxically many limestone and lime-based processes to remove sulphur from gases or waste streams yield chemical gypsum as by-product. The use of this by-product gypsum will reduce demand for natural gypsum.

REGULATIONS

Producers of construction minerals are actively engaged in the broad initiative to increase harmonisation of building codes and standards in Europe through the EURONORMS programme of CEN (European Standards Organisation). The scheme involves not only the EC countries but those of EFTA and the former Comecon members of Eastern Europe.

OUTLOOK

The EC will continue to be a major centre for the production of construction raw materials and EC enterprises operating in this sector will continue to be major players on the world scene. Future development of EC production and consumption will be closely tied to the overall level of building activity.

Written by: B M Coope & Partners
This industry is represented at the EC level by: European Aggregate Association/ Union Européenne des Produits Granulats (UEPG). Address: c/o BACMI, 156 Buckingham Palace Road, London SW1 W9TR; tel: (44 71) 730 8194; fax: (44 71) 730 4355.

Chemical industrial minerals

NACE 232, 233, 239

The EC is a major producer of salt, and potash, coming mainly from secondary sources and is a significant producer of sulphur, fluorspar and barite. However, it appears to be almost totally deficient in phosphate rock and borate resources, the EC is a major importer of these minerals and their derivatives. The markets for several of these items are severely depressed at present, particularly those such as sulphur, phosphates, and potash which are heavily influenced by fertilizer demand.

INDUSTRY PROFILE

Description of the sector

Chemical industrial minerals are major raw materials for the chemical and fertilizer manufacturing industries covered in Chapter 6. The products are covered under the new NACE Rev 1 codes 1430 and 1440, but under current system, they are listed as NACE 232 and 233 plus some products of NACE 239. The principal bulk items are salt, potash, phosphates, and sulphur. Other significant products include fluorspar, barite, and borates.

The EC is a leading world producer of salt and potash and is a significant player in world markets for sulphur, fluorspar, and barite. However, it is has no phosphate or borate mineral production of its own. Germany, France, the UK, Italy, and Spain are the principal EC producers of chemical industrial minerals and are all active to some degree in potash, salt, sulphur, fluorspar, and barite production. The Netherlands is also notable for its major contribution to EC salt production.

Recent trends

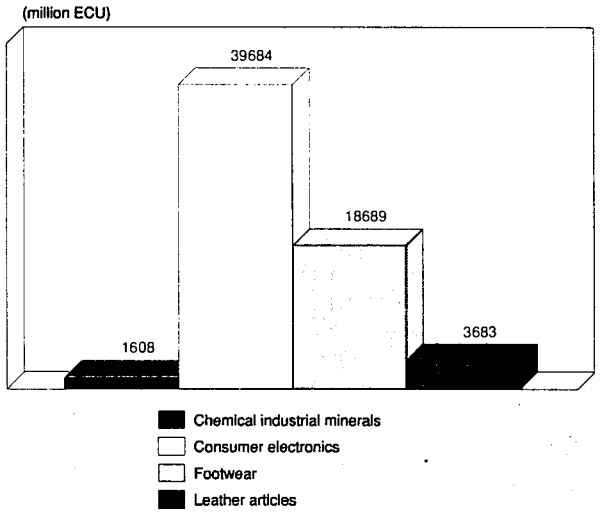
The production and consumption levels for this group of minerals have shown a major decline since 1985. In the case of production this is partly due to falling tonnage output for all the major minerals. Salt is an exception: in 1992 output was 42 million tonnes, slightly above the average for the past decade. However, the decline in production value is exaggerated by falling prices for all the minerals concerned but in particular for sulphur, whose 1992 price was less than one third of the prevailing 1985 price.

The fall in consumption has been more marked in the fertilizer sector rather than the industrial chemicals sector. The decline in fertilizer consumption in the EC has reduced the demand for all fertilizer minerals but especially for phosphate rock. It should further be noted that much of EC phosphate imports now consist of phosphoric acid rather than phosphate rock and this has been one major factor in reducing the trade deficit apparent in the figures presented in Table 2. A sharp reduction in sulphur imports has been another major factor.

International comparison

The USA is the world's leading producer of salt, sulphur, phosphate rock, and boron minerals and is an important producer of potash and barite. Thus, its production of chemical industrial minerals exceeds that of the EC by a factor of three. Declines in some commodities such as sulphur and barite have been balanced by increases in the production of potash, soda ash, bromine, etc. so that production levels have been maintained. Meanwhile, Japan's only significant contribution as a producer is sulphur and the small volume, high value product iodine. Japan is a major importer of all the other commodities, including salt.

Figure 1: Chemical industrial minerals Production in comparison with other industries, 1992



Source: B.M.Coope & Partners, DEBA

Consumption trends in Japan have been similar to the EC as reflected in overall value decline and falling tonnage in the fertilizer sector. This is seen most strongly in reduced phosphate consumption. In the USA demand for fertilizer minerals has held up better and thus overall consumption shows a somewhat smaller decline in value terms.

Foreign trade

The EC is active in both import and export trade of the chemical industrial minerals. Major export items are potash, salt, and sulphur. Major import items are phosphate rock, potash, borates, and sulphur. Although the EC continued to show a negative trade balance in 1992 the deficit is now quite small compared to those of the mid-1980s. This is due to both reduced imports, particularly of phosphate rock and sulphur, and increased exports, particularly of potash and salt.

The most important supplier countries to the EC are Morocco (phosphates), the USA (phosphates), Israel (phosphates and potash), the former Soviet Union (potash), Turkey (borates), South Africa (phosphates), and Canada (potash).

MARKET FORCES

Demand

The main consuming industries for these minerals are the bulk inorganic chemical and the fertilizer industries. Salt is the main raw material of the chloralkali chemical sector whose products include chlorine, caustic soda, and soda ash. Such products and their derivatives are used not only within the inorganic chemicals sector but also in plastics (PVC), soaps and detergents, glass, paper manufacturing, and in a wide range of general industrial processing.

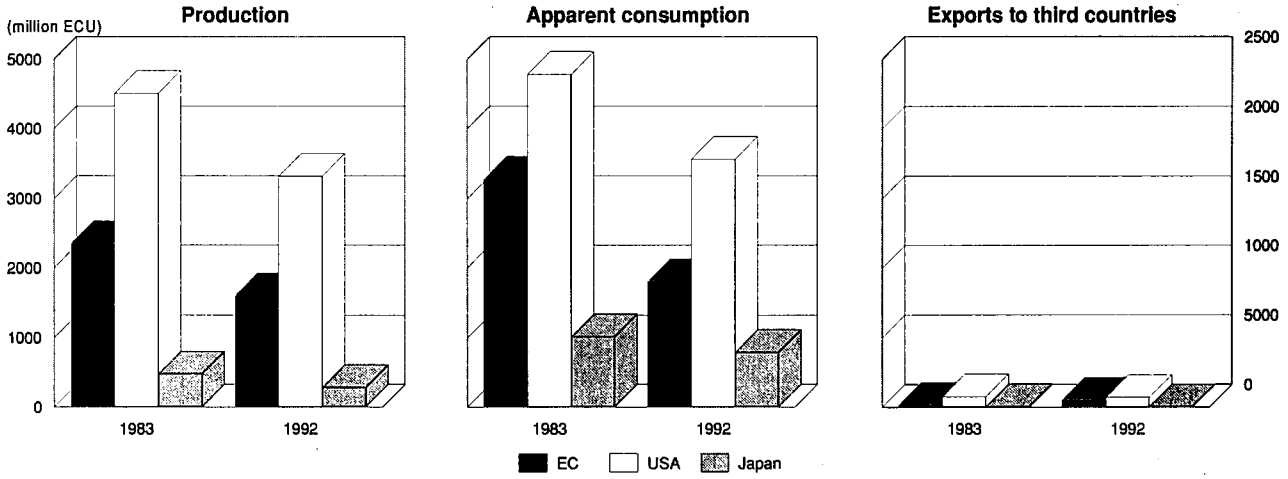
Sulphur is the source of sulphuric acid, probably the most versatile chemical used in chemical and other industrial processes. Nevertheless, it should be pointed out that about 60% of sulphuric acid is consumed by the fertilizer industry. Thus, fertilizer manufacturing, which in turn is highly dependent on demand from EC agriculture, is a major influence on the EC markets for sulphur, phosphates, and potash. It follows that these three minerals have all been adversely affected by EC agricultural reforms and environmental legislation concerning fertilizer usage.

Supply and competition

There is a major world oversupply in all the major products of this grouping although this is less true for salt than for potash, phosphate rock, and sulphur. The downward pressure on prices that this situation has created is certainly hurting some of the more vulnerable, the smaller, higher cost producers of these minerals.

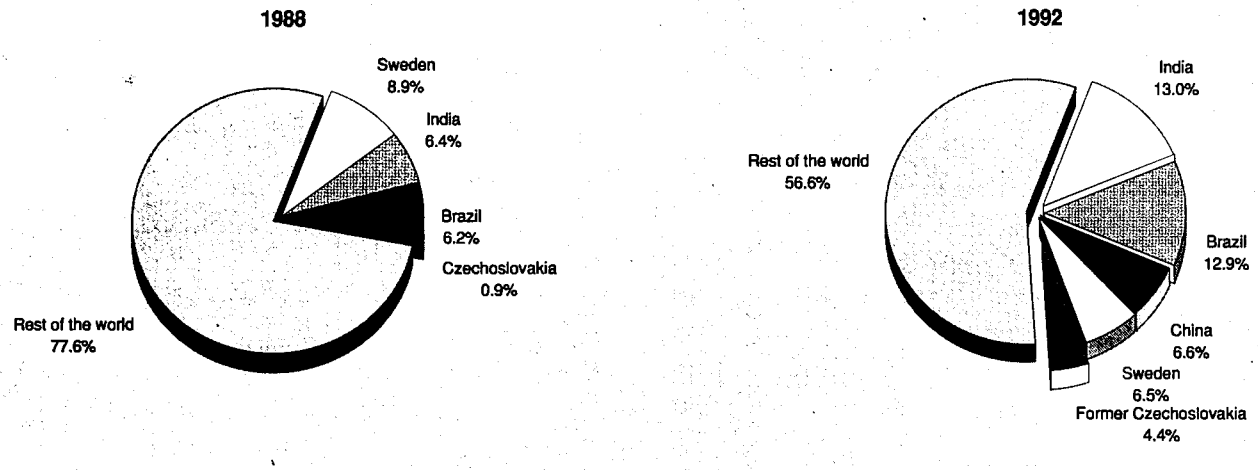
The sulphur supply situation is further complicated by the high proportion of co-product and by-product output in world production. Apart from Spanish pyrites, all EC sulphur production is from secondary sources ranging from elemental sulphur recovered from sour natural gas and oil (particularly

Figure 4: Chemical industrial minerals
International comparison of main indicators in current prices



Source: B.M.Coope & Partners, Eurostat

Figure 5: Chemical industrial minerals
Destination of EC exports



Source: Eurostat

in Germany and France) to sulphur recovered as sulphuric acid from metal smelters. Major cutbacks have been made in Spanish pyrite production, but output has been maintained at other operations in line with the output of primary products. It should be noted that the profitability of some operations has been curtailed by loss of these sulphur by-product revenues.

The EC potash industry has been facing a number of problems and challenges in recent years including the increased competition from low priced material from the former Soviet Union and the integration of the former East German potash industry into unified Germany. The EC imposed anti-dumping duties on potash from the former Soviet Union during 1992. The industry also has to compete with low cost producers in Canada, who benefits from economies of scale, and Israel, who has low cost brine operations.

As a high volume, low value commodity, salt tends to be less vulnerable to foreign competition and most bulk grades of salt, i.e., for chemicals and road de-icing, are consumed close to the point of production. Much of this production is captive or subject to long term contract agreements.

The EC's domestic fluorspar industry has been cut back drastically in recent years as result of exposure to low priced competition from foreign countries. In fact, the main source of these imports, China, has been the focus of anti-dumping action by the EC in 1993.

Production process

No major new technological developments have taken place in the processing of chemical industrial minerals although the trend towards larger sized equipment and the treatment of finer material has continued together with efforts at energy saving and improved environmental compliance.

INDUSTRY STRUCTURE

Companies

EC production of chemical industrial minerals is highly concentrated in the hands of few large organisations. The salt industry involves major chemical groups such as AKZO (NL), Solvay (B), BASF (D), and SKW Trostberg (D), as well as salt specialists such as, CSME-Salins du Midi (F), Salt Union (UK), British Salt (UK), and Union Salinera (E). The EC potash industry consists of six operating companies: the BASF

subsidiary, Kali und Salz (D); the Entreprise Minière et Chimiques subsidiary, MDPA (F); the two INI subsidiaries, Suria K and Potasas de Subiza (E); the Anglo-American subsidiary, Cleveland Potash (UK); and the IRI subsidiary, Italkali (I). Most potash producers are also significant producers of by-product salt and Kali und Salz produces another important by-product, the magnesium sulphate mineral kieserite. Meanwhile, sulphur is recovered from sour gas by the two energy companies, Elf-Aquitaine (F) and BEB (D).

Major EC fluorspar producers include Sogerem of the Pechiney group (F); Laporte (UK); Mineraria Silius (I); Minersa (E); and Sachtleben of the Metallgesellschaft group (D). The most important barite producers are M-I (UK and IRL), Barytine de Chaillac (F), and Sachtleben (D).

Strategies

A strategic decision of note made in the salt industry in recent years was the decision of the major UK chemical concern, ICI, to remove itself from both salt and soda ash production. It sold its soda ash interests to Penrice of Australia in 1991, which are now run under the name of Brunner Mond Ltd., and in the following year sold its salt operations mines to D George Harris Associates of USA, which are now run under the name Salt Union Ltd. ICI now buys salt for its chlorine

Figure 7: Chemical industrial minerals
Trade intensities

chemical production under long term contractual arrangements.

REGIONAL DISTRIBUTION

The underground potash and salt operations are associated with the Zechstein geological formation in northern Europe. Salt operations based on the solar evaporation of sea water are located in the more arid climes of the EC Mediterranean coast countries.

ENVIRONMENT

In the recent past the principal environmental issue facing the EC potash industry has concerned the disposal of waste salt from processing operations -- particularly into water courses or rivers such as the Rhine and the Werra. Legislation has forced producers to adopt alternative means of disposal, to increase production of saleable salt, or to close down offending operations. The introduction of phosphates to water courses through their incorporation in fertilizer and detergent products also became a major issue in the 1980s and has been a contributing factor towards the reduced levels of fertilizer application in recent years.

The by-product nature of most of EC sulphur production has already been commented on and it is worth noting that sulphur recovery units are required by legislation to prevent emissions. Some sulphur control processes yield gypsum rather than sulphuric acid as by-product.

Environmental constraints have made a major impact on the EC fluorspar industry through drastic cuts in the production of chlorofluorocarbons (CFCs) in response to the requirements of the Montreal Protocol. The ozone depleting CFCs were once the major market for fluorspar. Although certain hydrofluorocarbons (HFCs) may provide ozone friendly replacements in some applications, they are unlikely to provide the same scale of sales for fluorspar producers.

OUTLOOK

The outlook for the chemical industrial minerals does not look very bright in the short term. The existing lack of demand caused by industrial recession combined with major oversupply for the major internationally trade products is expected to prolong this period of low prices and trade disputes for some time to come. Thus further mergers, rationalisation, and closures may be necessary before any major recovery occurs. Recovery is hoped for the late 1990s in response to renewed demand in the former Eastern Bloc and the agriculturally less mature areas of world.

The industry is represented at the EC level by: International Association of European Mining Industries (EUROMINES). Address: Avenue de Broqueville 12, B-1150 Brussels; tel: (32 2) 775 6311; fax: (32 2) 779 0523.

Crystallised salt
NACE 233

EC production of crystallised salt amounted to 18.3 million tonnes in 1992. Sales declined to 16.4 million tonnes, a 16% decrease from 1991. Sales of road salt were soft across the area in 1992 due to the mild winter conditions. The chloralkali sector was under significant pressure, mainly for environmental reasons and, as a result, sales of crystallised salt continued to slow down. As both sectors represent nearly 70% of the total sales of this type of salt, the situation looks rather bleak, overcapacity being thus emphasised.

INDUSTRY PROFILE

Description of the sector

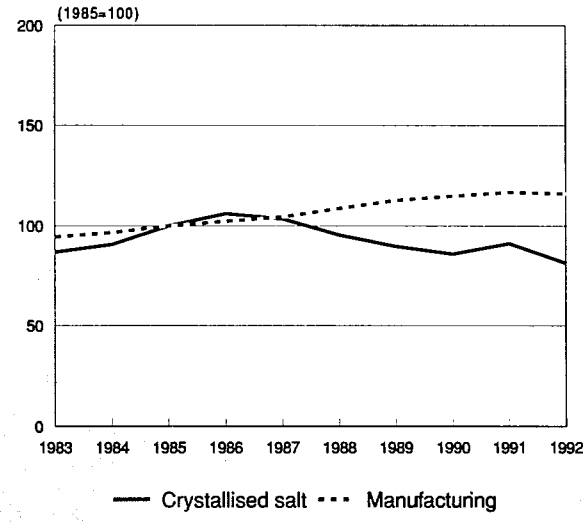
Salt production basically involves solar evaporation (sea salt), dry mining (rock salt) and solution mining (vacuum salt, salt in brine). In the monograph, salt in brine will be excluded unless otherwise specified. The differences in technology do not prevent the identification of this substance in "common salt" or "salt". Salt is mainly sodium chloride (NaCl), and is generally considered not to be a chemical substance.

Recent trends

Output of crystallised salt contracted in the past decade from a 1980-82 average of 24.5 million tonnes to a 1990-92 average of 19.3 million tonnes. Weather climate explains both market and output ups and downs for sea salt and rock salt, but a shrinking demand over years leads to the conclusion that this negative trend will continue. Salt consumption within the EC declined to 16.4 million tonnes in 1992.

The breakdown of production by the main technology line shows that in 1992 rock salt accounted for 39% of the total crystallised salt production, sea salt for 17% and vacuum salt for 44%. Successive mild winters in Western Europe have had a negative effect on the demand for road salt, which is reflected in rock salt production. Adverse weather conditions have detrimentally affected the solar salt harvest in several EC regions.

Figure 1: Crystallised salt
Production in volume compared to EC manufacturing



Source: European Committee for the Study of Salt, Eurostat

International comparison

Salt consumption is higher in the USA than in the EC. In 1992, US salt sales stood at 22.2 million tonnes showing a 7% decline compared to 23.8 million tonnes in 1991. By chance, salt requirements for servicing the highways amounted to 10.5 million tonnes an increase of 7.5%. In 1992, Japanese salt sales amounted to 8.4 million tonnes. Since Japan has very few salt facilities, this country depends on imports for 84% of its requirements.

The US, Canadian and Mexican production totalled approximately 55 million tonnes (salt in brine included) in 1992 compared to 35 million tonnes (salt in brine included) for the EC. The scheduled enlargement of the EC is not of a nature to alter this ratio, Austria, for example, represents only 0.7 million tonnes, salt in brine included.

Foreign trade

In 1991, extra-EC imports amounted to 0.35 million tonnes and extra-EC exports reached 1.96 million tonnes. Intra-EC trade represented 3.44 million tonnes. Apart from specialities,

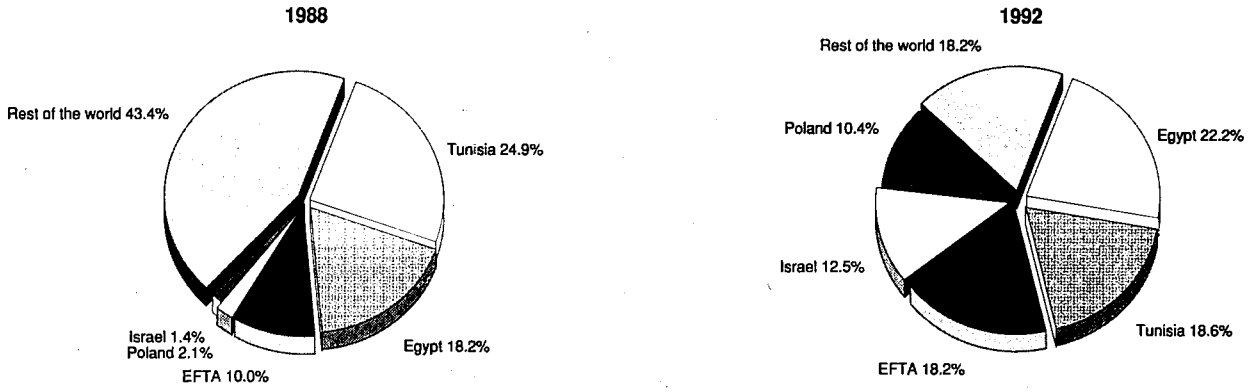
Figure 3: Crystallised salt
Origin of EC imports



Source: Eurostat

salt is a widespread, low value bulk commodity. Transportation costs which represent a significant proportion of the total price prevent any trade expansion as does the abundance of sources. The major market for EC salt producers is non-EC Scandinavia which has no production. Most of the salt imported by Norway, Sweden and Finland is used in the chemical industry. Virtually all of the rest of the salt trade in Western Europe is carried on between neighbouring countries. Surprisingly, the current recession is not slowing down intra-EC trade activities.

MARKET FORCES

Demand

Some 60% of world salt consumption is used as raw material for the chemical industry, followed by food grade salt with 20%, road salt with 10%, special salts for water treatment, salt used in animal feeding etc. The consumption pattern differs in Western Europe. Deliveries of crystallised salt have been broken down are in Figure 5.

Chlorine, a major market for salt, is subjected to environmental pressure. The most buoyant sector in the chlorine industry is the production of PVC, but even this use is now being questioned. The latest scientific studies show that modern PVC plants, equipped with efficient treatment installations can operate without releasing hazardous waste in the environment. The use of recycled glass which has doubled in Europe since 1985, is pushing down demand for soda ash. Salt remains the basic de-icing agent used for winter service. Research on alternative products has focused on abrasive mixes, glycol, urea, calcium magnesium acetate (CMA). Studies have also been conducted on automatic spreading, roadway heating combined with weather forecasting. Salt is still acknowledged as the least expensive and the most efficient de-icer. This was pinpointed by the OECD in a comprehensive survey (1989).

Other sectors where salt is used include diet and food processing, agriculture and water softening. Salt consumption in the EC for water softeners is estimated at 1 million tonnes. But the ion exchange process where salt is used as a regenerant for the resins is challenged by other processes like the reverse osmosis or electro-magnetic devices. Several studies performed by scientific institutes and consumer associations have made evident that the physical treatment of water remains disputable. Traditionally the dyestuffs and soap manufacturing industries use salt. Leather tanning implies special grain size of salt for the preparation of skins. High purity salt is required in the production of pharmaceuticals.

Supply and competition

The difficulty of allocating certain quantities under the right heading remains unsolved. Food grade salt covers, to a large extent in certain Member States, salt which is marketed for non-food uses. In 1992, sales of food grade salt amounted to some 2.3 million tonnes. Some attention has already been paid to the absence of the equivalence between "food grade salt" and "table salt" or between "salt consumption" and "dietary salt intake". For miscellaneous industries, which include in particular the manufacture of feeding stuffs and water softening, salt deliveries amounted to 3.1 million tonnes. In both the manufacture of feeding stuffs and water softening markets, the situation remains contrasted and varies from one Member State to another.

Road salt sales were less than 2.3 million tonnes in 1992 compared to 5.9 million tonnes in 1991. The requirements for this type of salt depend on the severity of winter. Winter maintenance with curtailed salt spreading increases the risk of accidents. The release of Marquette University's study which quantifies the lifesaving benefits of de-icing was presented to the ECSS plenary session in September 1992. In the past, the use of salt was only decided on cost criterion, now this study provides reliable data that quantify the benefits of de-icing.

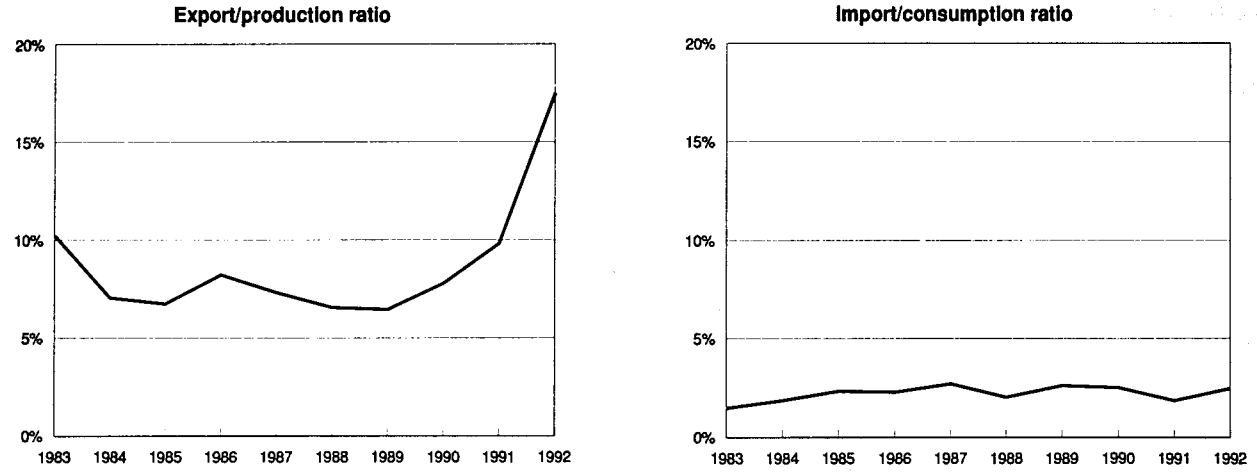
Sales of crystallised salt to the chemical industry decreased by 5% to 8.6 million tonnes. The recession and the sluggishness of demand explain the negative trend affecting chlorine production at the beginning of the 90's, most notably in the pulp & paper and aluminium industries. The following indexes illustrate this trend: 1990: 100; 1991: 95; 1992: 93. There is a strong correlation between chlorine and caustic soda. But they each have different markets.

The introduction of membrane cell technology has been a very slow process in the EC. Japan, however has now equipped more than 80% of electrolysis with membrane cells. As mentioned before, the PVC industry is committed to combating PVC's tarnished environmental image, particularly in the packaging sector.

Production process

Sodium chloride is a common substance in nature. Its main source are the oceans but it is also available in large quantities as rock salt or as subterranean brine. There are three methods of producing salt. One of these involves direct mining of rock salt. The other two are based on the evaporation of brine by heating (vacuum salt) or using sun and wind to mediate crystallisation (sea salt or solar salt). Large amounts of brine

Figure 4: Crystallised salt Trade Intensities



Source: European Committee for the Study of Salt, Eurostat

are used as raw material in the chemical industry without the formation of crystalline salt as an intermediate.

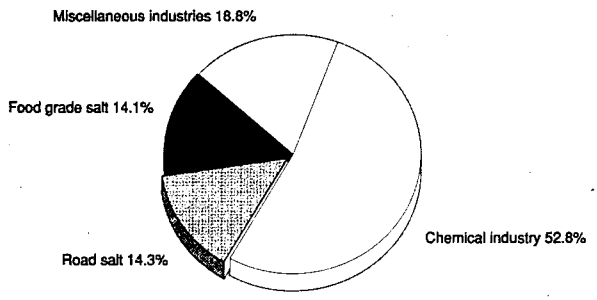
There are three methods used currently to manufacture chloral-kalis by electrolysis. The diaphragm cell process is based on salt in brine. The mercury cell and the membrane cell technologies require crystallised salt. All types of electrolysis work on the same principle: electric power passing through a saline solution between immersed electrodes. While positive ions migrate towards the cathode and lose their electric charges to form neutral molecular products, the neutralisation of negative ions occurs at the anode. The distribution of technology use in 1992 is estimated: mercury cell: 62%; diaphragm cell: 23%; membrane cell: 15%.

INDUSTRY STRUCTURE

Companies

The structure of the EC salt industry has already been described in the Panorama. Producing companies can be split into three categories: the large multinational chemical companies, the medium sized producers specialising in salt, and other companies like potash producers who are also producing salt.

Figure 5: Crystallised salt Consumption by sector, 1992



Source: European Committee for the Study of Salt

Strategies

The multinational companies like Akzo (NL) and Solvay (B) have subsidiaries in various Member States. On January 1st, 1993, Akzo Salt and Basic Chemicals became Akzo Chemicals BV. It was decided to spend 38 million Dutch florins on renovations at its Delfzijl salt facility. In 1991, the company upgraded its salt processing facility at Stade and in 1989 spent approximately 100 million Dutch florins to modernise its Hengelo facility. In Spring 1993, Dansk Salt (DK) became fully owned by Akzo. Akzo is the world's largest salt producer with an annual production capacity of over 15 million tonnes per annum (tpa), of which roughly 10 million tpa in the USA. Solvay is the largest producer of salt in Europe with a total output of about 7 million tpa of crystallised salt and a large but variable amount of salt in brine. Solvay is principally involved in the production of chemicals derived from salt, such as the manufacture of soda ash and the processing of chlorine derivatives such as PVC.

The companies Kali und Salz (D) and Mitteldeutsche Kali (D) decided in 1992 that it would be beneficial to merge their assets in a joint venture. Their objectives over the next five years include a gradual elimination of uneconomical potash and rock salt capacities to 3.1 million tpa of K2O and 2.1 million tpa of NaCl, relocating production to the most suitable sites, and reducing distribution and administration costs. The merger was brought to the attention of the EC Commission in July 1993 to be examined under the European merger control rules. The Commission is also currently examining, in parallel proceedings, the State aids relating to the merger: DM 1 billion granted by the Treuhandanstalt.

ICI (UK) recently announced the closure in 1993 of its chlorine plants at Hillhouse, Lancashire. ICI's UK chlorine capacity will total 0.8 million tpa. As ICI sources all its own brine operations in Northwich, Cheshire, the above mention closure should not affect salt business directly. ICI's soda ash plants in the UK along with a subsidiary in Kenya was sold in 1991 to Penrice Soda management in a buy-out from ICI Australia. In the UK, a significant investment is being made to improve plant reliability and efficiency. The Penrice Group, with a current capacity of 1.7 million tpa, is aiming at growing in the international soda ash market.

The privatisation process of Hellenic Saltworks (GR) continues, their production at Messolonghi represents more than 50% of the national requirements for salt in Greece which are estimated to about 200 000 tons p.a.

A consortium plans to develop a new salt works with a capacity: 1.2 million tpa in the north of the Netherlands with the financial support of the government and of a government-controlled regional agency. The Dead Sea Works Ltd (Baer Sheva) who markets 560 000 tons of salt for chemicals, water treatment, fisheries etc. has announced the construction of a new facility to be built at Sodom for export (700 000 tons).

ENVIRONMENT

The International Conference on Nutrition which took place in Rome in December 1992 emphasised measures to prevent and alleviate health problems thanks to nutritional solutions. Salt supplementation is one of the solutions. Salt iodisation, for example, was called "the most effective long-range measure for preventing and correcting iodine deficiency disorders (IDD)." The introduction of fluoridated salt in the German market during the period under review constituted a major response to the prevention of dental decay in this Member State. Salt is a very appropriate carrier for both iodine and fluoride but there are still pending problems due to the progressive reduction of dietary salt intake (discretionary salt contributes less intake than commonly believed) and the variety of legal provisions in force in the Member States. Common salt used for highway de-icing is by far the most popular product because it is quickly available, easy to handle, store and apply and inexpensive to purchase. The side effects, motor vehicle and infrastructure corrosion, degradation of the roadside vegetation, and migration through the soil into ground water, are sometimes evoked. In terms of corrosion, acid rain has greatly increased the corrosivity of the highway environment and manufacturers have already developed corrosion-resistant vehicles by improving materials and manufacturing processes. Currently most of the bridge decks are equipped with protective systems. Given the complexity of the matter and the site specific conditions prevailing in the natural environment, it is very difficult to quantify these alleged effects. The sensitivity of ground water to salt depends on many factors (soil, climate, water volume etc.). Other sources of salt or sodium including natural brines and salt deposits are generally more susceptible to alter sodium concentration in drinking water. Some controversy exists about the use of disinfectants spreading waterborne diseases. It is important to make the right distinction between risk and danger.

Campaigns against chlorine and especially PVC have developed in recent months calling for a phase out. Environmental considerations were said to have forced reductions in chloride bleaching. Many of chlorine components are essential to medical and agricultural activities and to construction, packaging and other industries. Ill-considered restrictions of their use would have serious consequences on health and quality of life.

In the case of the use of land for solar salt evaporation, a natural resource is exploited in the least harmful way for the environment. Salt works constitute a natural park. A recent book published as part of the EC project on the upgrading of the Messolonghi salt works expresses from the ecological point of view that salt production is a positive combination of economic development and ecological protection (birdlife, halophytic vegetation etc.). This is valid for many other sites as well.

REGULATIONS

The Council Regulation no. 793/93 of March 1993 on the evaluation and control of the risks of existing substances, is a matter of concern for the manufacturers because of the very nature of salt which is, essentially a foodstuff. Most of the requested data are already available. A literature search on the various aspects of its constitutive ions represents a considerable amount of work from individual companies. The monograph on "Sodium chloride (the production and properties of salt and brine)" edited by Dale W. Kaufmann should have been considered as a suitable response.

Several directives and regulations are enabling food law in Europe to be harmonised. The profession has developed a preliminary draft directive on iodised salt which corresponds to the concerns of the EC Commission and of the endocrinologists. Salt iodisation was also discussed in September 1992 within the framework of the Codex Committee on Nutrition and Foods for Special Dietary Uses. A similar document has been produced on fluoridated salt.

OUTLOOK

It is very difficult to forecast the future of the salt industry. The sales of salt are highly dependent on developments occurring in the chemical industry (technology, regulations, outlets). The second largest use of crystallised salt relates to winter service which is widely varying according to weather conditions from year to year.

Although overcapacity is emphasised by the economic recession, projects relating to new facilities have been disclosed recently. According to various sources, it can be assumed that the European salt market is sluggish; salt demand is expected to fall by a further 3 to 4 million tonnes by the end of the century.

Written by: ESPA
This industry is represented at the EC level by: European Salt Producers' Association (ESPA). Address: Rue Daru 17, F-75008 Paris; tel: (33 1) 47 66 52 90; fax: (33 1) 47 66 52 66.

Physical industrial minerals

NACE 231, 239

The EC is the world's major consuming region for physical industrial minerals and currently produces around 85% of its own requirements. The products included in this sector are minerals for non-chemical industrial application. Foreign competition is stiff in some areas and there is a high volume of intra-EC trade. Overall, major EC producers of these minerals are recognised as world leaders in their fields and are actively involved in operating in other countries. This leadership has been gained through technical expertise and a close understanding of its consuming industries' requirements.

INDUSTRY PROFILE

Description of the sector

The physical industrial minerals are defined as those industrial minerals used predominantly for their physical characteristics rather than for their chemistry. They correspond with the minerals covered by the existing NACE codes 231.7 and non-chemical items in NACE 239 and are listed under the new NACE Rev 1 codes as 1422 and 1450.

Thus, these minerals are used in such fields as ceramics, refractories, and abrasives; as filler/ extender pigments for incorporation into paper, paints, and plastics; and as filters, absorbents, and insulating materials. The range of products includes clays such as kaolin, kaolinitic clays, bentonite, and sepiolite as well as a variety of minerals such as diatomite, feldspar, magnesite and magnesia, asbestos, perlite, pozzolana, pumice, and talc. The EC is a leading producer and exporter of these products.

Recent trends

EC production and consumption of the physical industrial minerals displayed excellent growth during the 1980s followed by a fall in 1990 and 1991. The declined seemed to stabilise in 1992 and the signs are that there may be a modest return to growth in 1993. Extra-EC exports have increased during the period under review although the trade balance has remained consistently negative during this time.

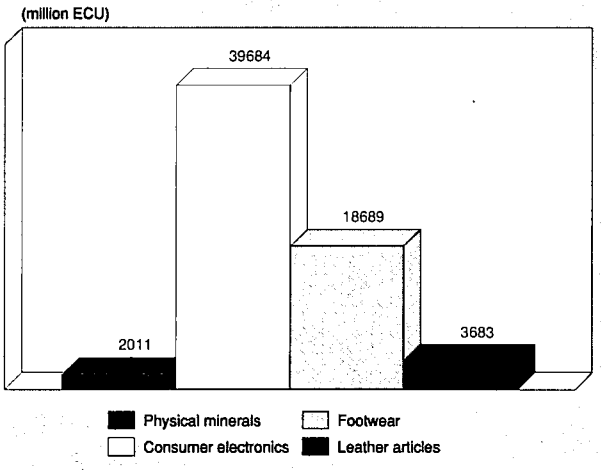
International comparison

In 1992, EC production of physical industrial minerals was 40% higher than the USA, and EC consumption was over 2.5 times USA's consumption. As these figures suggest, the USA exports more of these minerals than the EC. Japan is a minor producer of physical minerals and in 1992, its consumption less than 30% of EC consumption, is heavily based on imported raw materials. The EC displayed stronger growth in consumption than either the USA or Japan over the last ten year period. Indeed, the USA appeared to show a clear value decline between 1983 and 1992 although this has more to do with exchange rate movements than any decline in volume terms.

Foreign trade

The EC is net importer of physical industrial minerals. Nevertheless, during the 1983-92 period exports grew by nearly 90% while imports grew 35%. Major EC export items are the industrial clays, kaolin, ball clay, bentonite, etc. are responsible for over 60% of total exports in 1992. Ironically, industrial clays are a major imported item in this group, and indeed the value of imports almost exactly balances exports in most years. It should be noted, however, that for a number of other important EC export items such as magnesia and talc, imports actually exceed exports by a considerable margin.

Figure 1: Physical minerals Production In comparison with other Industries, 1992



Source: B.M.Coope & Partners, DEBA

Major sources of EC imports of physical industrial minerals are the USA for kaolin, other clays, diatomite, and talc, Brazil for kaolin, China for magnesia and graphite, Canada for asbestos, Austria for magnesia and talc, Finland for talc, and Norway for feldspathic minerals. The major destinations for EC exports were the EFTA countries, an important element of which is the supply of kaolin to the paper industries of these countries.

MARKET FORCES

Demand

The physical industrial minerals are consumed by a wide range of industries. The most significant end markets for physical industrial minerals are: ceramics, refractories, glass, and abrasives; paper, paints, and polymers in terms of plastics, rubber, sealants/adhesives, etc.; and as filters, absorbents, and insulating products. Since the ceramics industry also includes

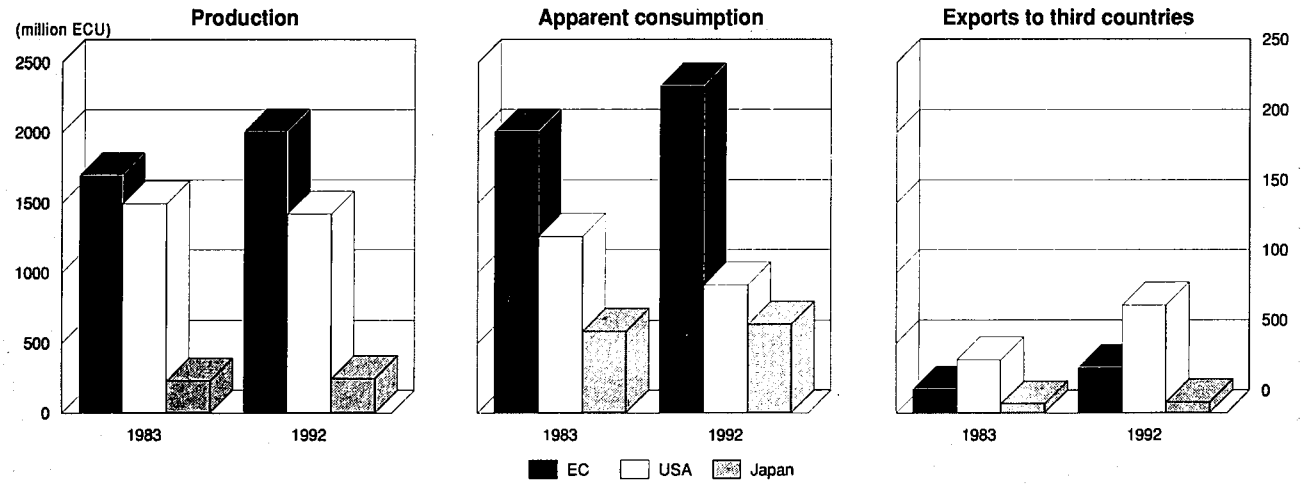
building products such as bricks, tiles and pipes based on common clays, the construction industry is also a large direct and indirect consumer of these other products. The technical requirements of manufacturing many of these products have become more stringent with time, but the raw material producers have tended to upgrade their products accordingly. Many producers of physical industrial minerals maintain close technical relationships with major consuming companies in order to meet future requirements. Thus, many products are "speciality" rather than "commodity" minerals and long term contracts between major producer and major consumer are common.

Supply and competition

The degree of intra-EC trade is due partly to the multiplicity of grades available and the suitability of certain grades for specific end-uses. EC producers usually compare well against foreign competition as result of either the quality of deposits or the processing expertise or a combination of both. The high technical input into many products is undoubtedly reflected in the USA, Canada, and the EFTA suppliers. It should also be noted that certain products such as graphite, mica, and clays are bought in raw form for further processing in the EC before reaching the eventual consumer. Nevertheless, the EC is clearly deficient in certain minerals such as asbestos, vermiculite, and graphite and must import the bulk of its requirements. Asbestos is no longer as vital as it used to be and a range of replacements has been developed, many of them based on indigenous EC raw materials, to overcome the health hazards associated with this mineral.

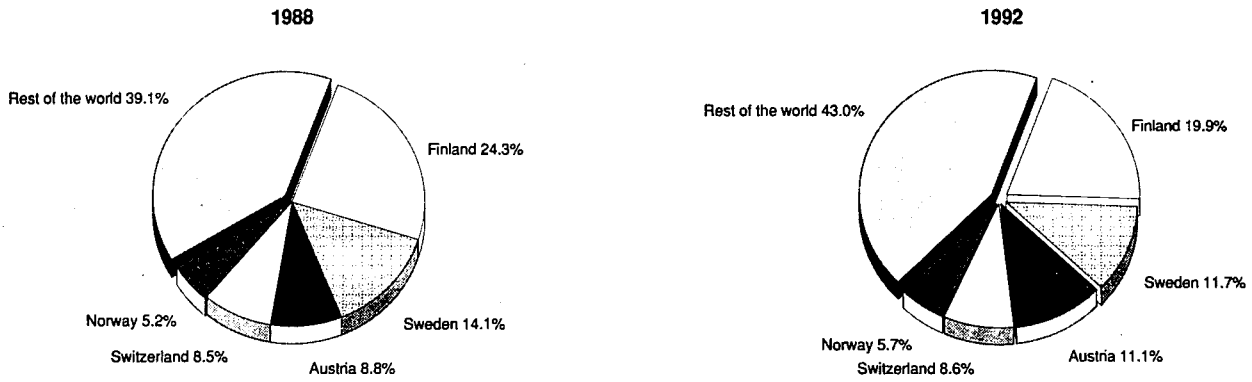
Magnesite and magnesia is one area where EC industry is suffering from foreign competition. The EC produces a wide range of grades of magnesia from natural magnesite, or from sea water, or brines for applications in refractories, construction, general chemicals, and agriculture. For most of the past

Figure 4: Physical minerals
International comparison of main indicators in current prices



Source: B.M.Coope & Partners, Eurostat

Figure 5: Physical minerals
Destination of EC exports



Source: Eurostat

decade EC magnesia producers have had to meet strong competition in the lower grade sections of the market from low priced products from China. More recently further competition has become evident in the higher grade sectors of the market from new low cost production in Australia and China, who is now able to improve the quality of certain grades. During 1992 anti-dumping action was taken against China and a duty imposed on certain products. Even so the EC magnesia industry is undergoing a process of rationalisation with producers focusing on more specialised grades and value added products.

Production process

Many of the minerals in this group are beneficiated or their properties enhanced by highly sophisticated processing techniques. Kaolin, bentonite, talc, magnesia, and diatomite are all subjected to a wide range of treatments involving such processes as high intensity magnetic separation, acid or alkali treatment, high temperature processing, laser sorting, jet milling, attrition grinding, classification at micron sizes, and surface modification. Such techniques have not only improved product quality in traditional uses but have introduced new grades to new markets and have expanded viable reserves.

INDUSTRY STRUCTURE

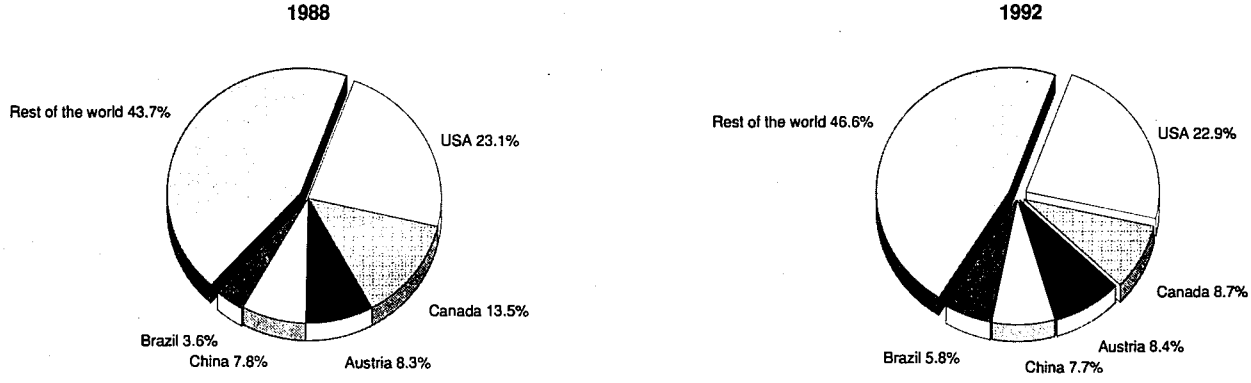
Companies

Most of the companies operating in this sector tend to be industrial minerals specialists although some companies come from other industries like: the construction, e.g. Redland/Steetley (UK) and CRH (IRL), petroleum, e.g., Elf-Aquitaine (F) and Shell (NL), and metals, e.g., RTZ (UK). In the kaolin and ceramic clays sector major enterprises include: English China Clays (UK) and Watts Blake Bearne (UK), Amberger Kaolinwerke (D), and AGS (F) and Imetal (F). Major enterprises in the bentonite and special clays sector are Sud Chemie (D), Laporte (UK) and Redland/Steetley, Tolsa (E), Eliopoulos (GR), and Laviosa (I). Leading companies in other minerals are CECA (F) for diatomite; Grecian Magnesite (GR) for magnesia from natural magnesite; Redland/Steetley, Sardamag (I), Billiton, part of Shell, and Premier Periclase (F), part of CRH (IRL) for magnesia from sea water and brines; and the RTZ subsidiary, Talc de Luzenac (F).

Strategies

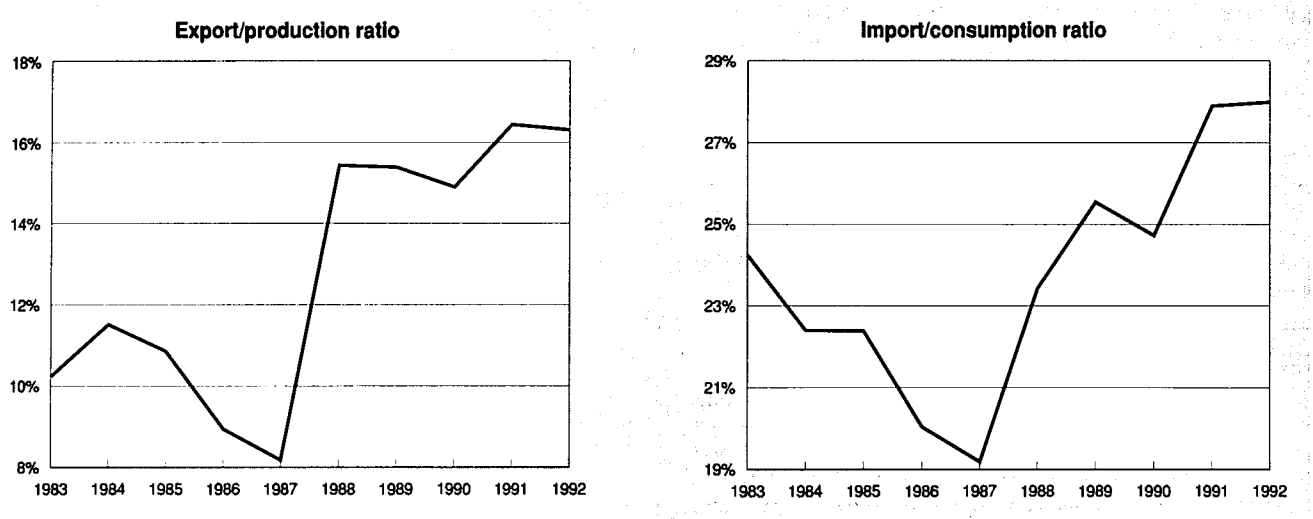
Several of the companies mentioned in the previous section operate on an international level, and are justly recognised as world leaders in their own particular fields. English China

Figure 6: Physical minerals
Origin of EC imports



Source: Eurostat

Figure 7: Physical minerals
Trade intensities



Source: B.M.Coope & Partners, Eurostat

Clays (ECC), Watts Blake Bearne (WBB), RTZ/Luzenac, Laporte, and Sud Chemie all have important operations in North America and are becoming increasingly involved in the Far East. At the same time, WBB is currently subject to a bid from Sibelco (B) who was, until recently, only a minority shareholder. Germany's main kaolin producer, Amberger Kaolinwerke (AKW), has been active on the acquisition trail first buying some of the more important kaolin operations in former East Germany (Kemmlitz and Caminau) and more recently its near neighbour in Bavaria, Eduard Kick GmbH. The world's largest kaolin producer, ECC of the UK, is currently planning to liquidate its Construction Materials Division, an important aggregate producer in the UK and the USA, while simultaneously buying into the Calgon speciality chemicals business in the USA. Recent strategic developments in the bentonite sector have included the move by Laviosa of Italy into processing in Spain through a joint venture with Promasa of Bilbao and the investment made by Navan Resources of Ireland into the Hungarian bentonite industry.

REGIONAL DISTRIBUTION

Clays of a type suitable for the production of bricks and tiles are to be found in many regions of the EC although the more specialised industrial clays are much rarer and more localised. The Cornwall and Devon region of England accounts for about two thirds of total EC kaolin output. Other significant centres include Bavaria in Germany and Brittany in France. The main ball and ceramic clay producing districts in the EC are Wester-

wald in Germany, Charente in France, and Devon in the UK. The main bentonite centres are Bavaria in Germany, Milos island in Greece, Sardinia in Italy, and south-east England whilst the region around Madrid is the sepiolite capital of the world. The volcanic regions of Greece and Italy are well known for their deposits of perlite, pumice, and pozzolana.

ENVIRONMENT

The main environmental issues concerned with quarrying physical industrial minerals are shared with those in construction raw materials discussed earlier in this chapter and indeed most of the EC mining industry. The modern quarrying industry has an excellent record in overcoming potential problems of dust, noise, waste disposal, and land reclamation.

OUTLOOK

The EC will continue to be a major producing and consuming area for the physical industrial minerals and the influence of major EC producers will continue to spread well beyond Europe. Technical expertise and innovation will continue to play a major role in the development of the industry and projects in other countries. Eastern Europe and the Far East will benefit from the involvement of EC-based expertise. Within the EC itself most new developments are likely to be extensions to existing producing areas although some new projects, such as kaolin in Spain and Portugal, and talc in Scotland, may be launched in the near future.

Overview
NACE 221, 222, 223

After an annual increase of 8% in 1988 and 1989, the EC production of ferrous metals has witnessed continuous decline. The 1989 peak was achieved after a period of crisis, dating back to the 1970s. Low growth in the main customer sectors, the emergence of new producing countries and substitute products contributed to the crisis. In the first half of the 1980s, the steel industry underwent a process of rationalisation and capacity reduction. The restructuring made productivity gains possible. However, because of the upswing in 1988 and 1989 the restructuring process was not entirely completed, and identified excess capacity, meant to disappear, remained in production. This, together with the ever increasing competition from newly industrialised and East European countries and the depressed general economic situation in 1992/1993, plunged the sector into a new crisis, urging a new restructuring programme.

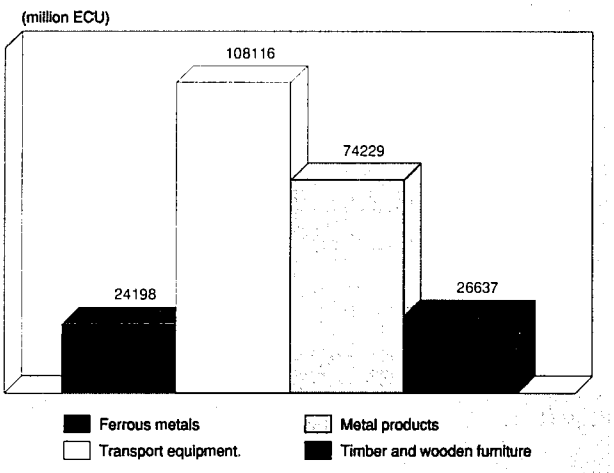
Value added in comparison with other industries, 1992



Source: DEBA

INDUSTRY PROFILE

Description of the sector

This monograph covers the activities of the steel industry as defined by the European Coal and Steel Community (ECSC) Treaty and the other ferrous metal industries. According to the NACE classification, these activities are the following:

- Steel industry (NACE 221);
- Manufacture of steel tubes (NACE 222);
- Other first processing of steel (NACE 223).

This last sector can be further divided into four subsectors: cold drawing of bars (NACE 223.1); cold rolling of steel strip (NACE 223.2); cold forming of steel flat products (NACE 223.3); and cold drawing of steel wire and manufacture of wire products of steel (NACE 223.4).

The manufacture of steel accounts alone for about 70% of total ferrous metal production, while the manufacture of steel tubes accounts for 13% and the other first processing of steel for 17%.

Germany contributes more than one third to the total value added of the ferrous metals sector in the EC. Italy, France and the United Kingdom follow with 17%, 14% and 11% respectively. Hence four Member States allow for three quarters of the total value added of the EC ferrous metals sector.

The development of the ferrous metals industry has clearly deviated from the trend of total manufacturing sector in the EC. Unlike the total manufacturing industry the ferrous metals industry showed a fluctuating development pattern over the past ten years. However, since 1989 its production has continuously declined, which resulted in a 1992 production level that was similar to the 1983/84 level. Conversely the total manufacturing industry's production grew by 29% over the period under consideration, although since 1989 it has remained virtually unchanged.

The employment level of the total manufacturing sector has been rather stable from 1983 to 1992. This with a drop of 3.5% in 1992. The employment level in the ferrous metals industry dropped at a faster rate (4.7%) in 1992. As a result of a rationalisation and restructuring process, which particularly affected the steel industry, employment level in the ferrous metals industry has constantly decreased over the reference period; in 1992 it was 39% lower than in 1983.

The significant decline in the extra-EC exports is worthy of note. This development has a negative impact on the production. At the same time the extra-EC imports grew. Consequently the trade balance has deteriorated increasingly, particularly since 1985.

Recent trends

The production and consumption of ferrous metals in the EC were highest in 1989. Since then, the demand for ferrous metals declined increasingly, resulting in a significant drop in the production level between 1989 and 1992. Production decreased faster than the consumption, which affected the trade balance adversely. The employment in the ferrous metals industry revealed a continuous decline too. However, unlike the production and consumption the employment level has not dropped since 1989, but it decreased throughout the reference period 1983-1992. In 1993 the situation is not expected to improve and the production and consumption of ferrous metals will further decline.

International comparison

International comparison of main indicators in volume

Due to lack of data a comparison of the ferrous metals industries of the EC, the USA and Japan can only be assumed. Taking crude steel as an indicator, it can be seen that the EC is the world's largest producer of ferrous metals, followed by Japan and the USA. At the same time the EC and Japan are the principal exporters of ferrous metals, although in 1992 these exports were lower than in 1983. This applies particularly to Japan, that witnessed a considerable drop in its ferrous metals exports between 1983 and 1992. Unlike in the EC and Japan, USA the consumption of ferrous metals is higher than their production.

All the countries under consideration show a fluctuating development pattern of their production of ferrous metals from 1985 to 1992. After a rather stable level between 1988 and 1991 the EC and Japan show a significant decline in 1992. Conversely the USA's production of ferrous metals increased significantly in 1992, after a decrease in 1992. The 1992 production level was still lower than in 1988-1990.

Foreign trade

Ferrous metals account for about 4% of total EC exports of goods and 2% of its total imports. The extra-EC trade of the sector shows a significant export surplus. Due to increased imports and declining exports, however, the trade surplus decreased considerably over the reference period; in 1992 it was 65% lower than in the top-year 1985.

The major export market for EC ferrous metals are the EFTA countries; the USA ranks second. The share of the EFTA in the total extra-EC exports was higher in 1992 than it was in 1987; conversely, the USA was in 1992 relatively less im-

portant than in 1987. Japan is not relevant to the exports of ferrous metals from the EC.

The EFTA countries play an overwhelming part in the EC imports of ferrous metals, although their share in the total extra-EC imports was in 1992 smaller than in 1987. Japan and the USA are only of marginal importance to the imports of ferrous metals into the EC. Among the countries included in the rest of the world, in particular the East European countries have recently become more important.

The intra-EC trade in ferrous metals increased significantly from 1983 to 1992 (see Table 4), owing to the well established integrated market for these products. Remarkably, although the share of extra-EC imports in the total imports of ferrous metals remained virtually unchanged over the reference period, the penetration rate of foreign competitors increased steadily from 6.9% in 1983 to 9.5% in 1992.

MARKET FORCES

Demand

The ferrous metals industry is a major supplier of intermediate goods. The major clients are the manufacturers of metal products, electrical machinery, transport equipment and the mechanical engineering and construction sectors. As a result of the improvement in the activity level of ferrous metals-using industries the EC consumption of ferrous metals increased strongly in 1988 and 1989. In addition, strong stockpiling on the part of producers, traders and consumers had a positive impact on domestic demand. The recovery in the ferrous metals industry took place after a long period of crisis, entailing an average annual production decline of 1.8% over the period 1982-1987.

Other factors, which contributed to the downturn in the ferrous metals industry were the emergence of substitutes such as plastics and the emergence of new competitors, particularly in the newly industrialised countries with their relatively low production cost. A growing number of these countries succeeded not only in covering their own needs, but they also broke into the EC market and competed successfully on the world market. Together with the reduced demand of traditional export markets in Eastern Europe and China the extra-EC exports of metal products declined sharply and in 1992 the lowest level ever was achieved.

Supply and competition

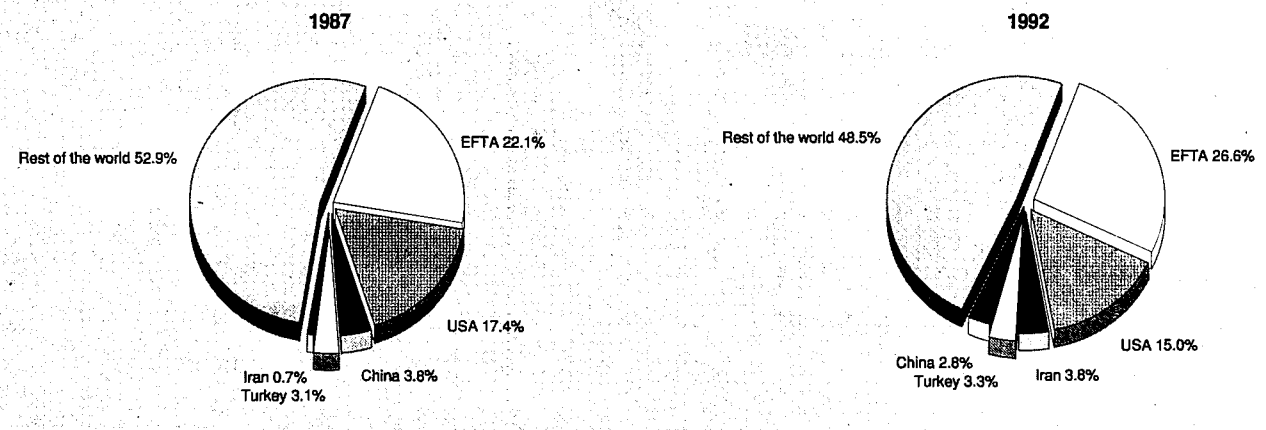
Despite a permanent process of reducing workforce and technical capacity, the EC ferrous metals industry currently suffers from a global overcapacity. Customers, therefore, have ample opportunities to obtain their supplies, enabling them to exercise strong pressure on producers. This has an adverse impact on profit margins, particularly in export markets and for products with a low share of value added.

Competition within the EC is strong, which is revealed in high intra-EC trade. Over the past decade the share of intra-EC consumption increased, in real terms, from about 25% to over 30%.

The use of up to date technology is of utmost significance to the competitiveness of the EC ferrous metals industry. However, with regard to cost, the EC suppliers are in an adverse position. Newly industrialised nations produce at lower cost and enter the EC market with lower prices. The import pressure from East European countries also increased, particularly because their lower selling prices are not truly reflecting their production cost. The share of foreign extra-EC imports in the EC consumption of ferrous products increased from around 7% in 1983 to nearly 10% in 1992.

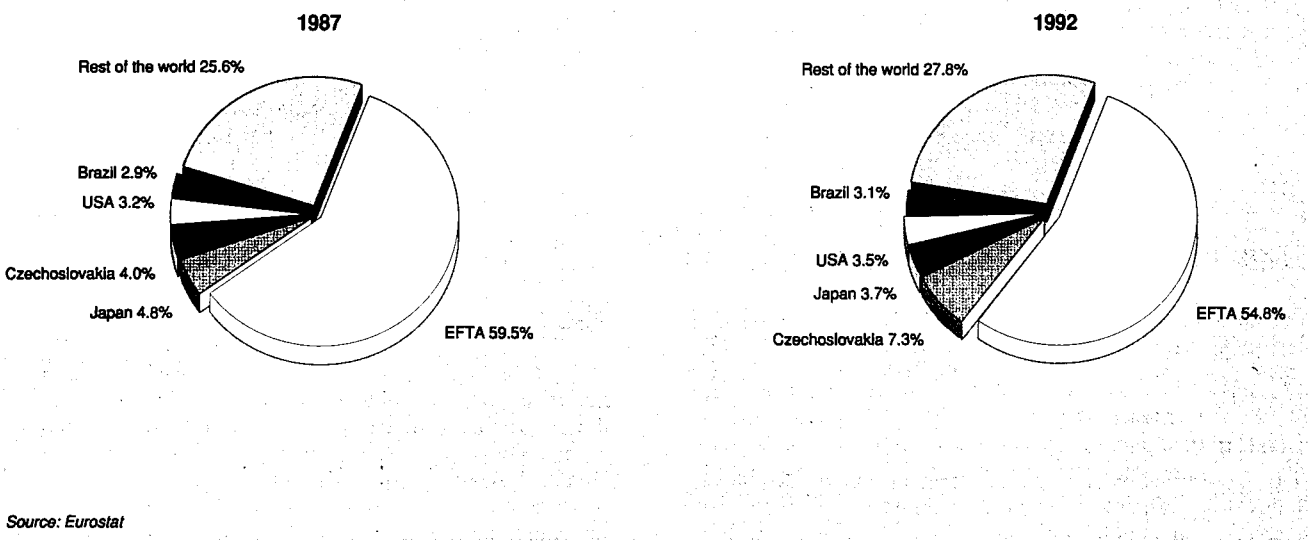
During the restructuring period 1980-1986, the steel industry experienced a considerable reduction in its production capacity

Figure 6: Ferrous metals
Destination of EC exports



Source: Eurostat

Figure 7: Ferrous metals
Origin of EC Imports



Source: Eurostat

and the labour force. Currently a further restructuring of this sector is required. The crude steel and its rolled-steel capacity must be reduced by 30 and 20 million tonnes respectively, whereas the labour force will have to decline by 70,000 workers.

To facilitate the restructuring process and to alleviate the hardship resulting from the redundancies, the Commission has already put forward a proposal for special measures for the ECSC workers. The final restructuring programme will be launched at the end of September 1993.

Production process

In terms of technology the EC ferrous metals industry is one of the most advanced in the world. Research and development constantly assure high quality steel production and rolling processes. Drastic restructuring measures, especially in the steel industry resulted in a significant reduction of the employment level of the EC ferrous metals industry. Over the period 1983-1992 the labour force dropped by 39%, a rate of 3.8% per year.

The necessary modernisation of the EC industry was undertaken fairly late; not beginning until the end of the 1970s. This explains why the return to profitability did not start until the second half of the 1980s.

INDUSTRY STRUCTURE

Companies

The degree of concentration in the EC ferrous metals industry varies from the steel and the steel tube sector on the one hand, and first processing on the other hand. Both the steel and the steel tube sector are characterised by large companies and a large degree of concentration. In contrast, the other first processing of steel sector is formed by a majority of medium size companies and is characterised by a low degree

of concentration. Moreover, steel tubes manufacturers are often linked to steel producers, while a considerable part of the other first processing of steel mills belong to independent companies.

Strategies

The modernisation and restructuring of EC ferrous metals industries, particularly in the steel industry, is reflected by mergers. acquisitions and joint-ventures. Some of these investments look to widen the company's competitiveness by branching out into new related activities whereas others simply look to increase market concentration. Unlike the major companies in the steel, and the steel tube industry, the other first processing of steel sector tend to stress rationalisation and specialisation rather than concentration in order to strengthen its competitiveness.

Further it should be mentioned that companies are diversifying and upgrading their supply. There is a tendency to reduce the supply of ordinary, mass products in favour of more sophisticated products. For example, the development of high-yield point sheet steel and coated sheets, particularly for the car industry enabled the steel industry to increase unit prices and value added. Furthermore, special alloyed and non-alloyed steels are becoming increasingly important. The great efforts the EC ferrous metals sector puts in the rationalisation and modernisation of its facilities in view of the Single market, however, are not visible in the development of the domestic investment due to lack of current data.

REGIONAL DISTRIBUTION

Only three Member States account for nearly two thirds of the EC production of ferrous metals. Germany with over one third of the EC production ranks first, followed by Italy and France. Further the five minor producing countries (Denmark, Greece, Ireland, Luxembourg and Portugal) have a joint share of about 4%. The remaining Member States Belgium, Spain, the Netherlands and the United kingdom hold medium positions.

The development of the production of ferrous metals was similar in most EC countries during the 1980s, which lead to little change of their shares in the total EC production. However, some major exceptions should be mentioned. France, whose market share declined, was overtaken by Italy for the second position while, Belgium and Luxembourg revealed significantly increasing shares. Further in 1992 most of the Member States revealed a drop in their production of ferrous metals; it was only in some minor ferrous metals manufacturing countries (Denmark, Ireland and Portugal) that production grew. The production decline was particularly substantial (over 30% in terms on value added) in the United Kingdom.

ENVIRONMENT

In the ferrous metal producing industry the cost arising from environmental protection are considerable, especially for the steel industry. The costs are largely due to: the treatment of smoke emissions from raw material production units, the re-

heating of the furnaces, the treatment of waste water from the pickling installations and noise control in the production units.

Because of high costs, and the dissimilar requirements and enforcement of environmental protection in the various Member States, environmental legislation should be harmonised within the Community in order to avoid distortion of competition. Within the framework of the Environmental Protection Research Programme (established under Article 55 of the Treaty of Paris), the European steel producers together with the European Commission continue to work on such a harmonisation.

REGULATIONS

With the establishment of the ECSC in 1951, the founding countries committed themselves to subordinate their national steel policies to the decisions of the ECSC institutions. These institutions were particularly active during the steel crisis between 1980 and 1988, when quotas for the EC production and imports into the Common Market from non-ECSC were established. At the same time steel prices were fixed and investments directed.

Government subsidies are strictly forbidden by the ECSC Treaty. Nevertheless, national governments often pursue a policy subsidising their steel industry. This has been tolerated by and large by the European Commission. Moreover, in 1980 the European Commission facilitated the granting of subsidies by stipulating in the Aid Code that the prohibition of subsidising was not applicable to subsidies within the framework of a common steel policy. Subsidies, aimed at achieving the goals of the ECSC Treaty were also allowed. Consequently during the restructuring process of the EC steel industry subsidising was a widely spread activity. The Aid Code was to expire at the end of 1985. However, it has been prolonged several times, although it became increasingly hard for governments of the Member Sates to subsidise their steel industry. Since the beginning of 1986 subsidies may only be geared to the encouragement of research and development, to safeguard the environment and to meet the social costs, incurred by total plant closure.

In summary, future regulations for the steel market and the steel policy of the EC are expected to be increasingly geared to liberalisation. Supporting measures and measures to monitor competition rather than direct interventions will be increasingly pursued.

OUTLOOK

At the end of 1989 the consumption of ferrous metal products weakened; the decline in demand, which still continues on an intensified level. An adverse development in the consumer demand of the ferrous metal industry is the main reason. Additionally, the EC exports to non-EC countries has fallen substantially since 1989. These developments resulted in a reduction of the EC production of ferrous metals of 2.3% and 3.7% in 1991 and 1992 respectively.

Due to both cyclical and structural factors the situation is not expected to improve in the short-term; the economy is anticipated to remain depressed, which will adversely influence the major consumers of the ferrous metals industry. The primary transformation of steel sector witnessed a net decline in new orders. The steel tube industry, is excepting a production loss of about 10% 1992, and new orders decreased by 12% in the first quarter of 1993. In addition, the steel industry is not expected to achieve sustained recovery, until the restructuring is completed. This will be at the earliest in 1996. Under these circumstances in the short term both apparent consumption is expected to decrease by 2.5%, whereas the extra-EC exports are expected to remain stable in 1993 and 1994, due to a envisaged drop in the exports of the steel tube sector.

Looking further ahead to the medium term, the general economic situation is expected to improve and the demand for EC ferrous metal products will increase. However, while the restructuring of the steel industry is not completed, a low growth rate of both production and consumption are anticipated 1%. Extra-EC exports are expected to grow by 0.5%.

Written by: Netherlands Economic Institute

Iron and steel
NACE 221

Between the mid-1970s and 1987, the steel industry in the industrialised countries suffered serious set-backs due to reduced demand from steel-using industries, the emergence of steel substitutes and increased competition from newly industrialised countries. During the 1980-86 period, major restructuring measures were taken, which allowed the achievement of significant productivity gains by reducing capacity and by cutting labour force.
In 1988 and 1989 record levels of steel production and consumption were obtained. However, in the 1990s new problems arose, partly because of the depressed general economic situation, partly because the EC steel sector has to cope again with a structural overcapacity. Both production and consumption have been decreasing since 1990. These developments urged a new three year restructuring programme, whose full content will be known at the beginning of 1994. Before its completion no recovery of the EC steel industry can be expected.

INDUSTRY PROFILE

Description of the sector

Steel and coal were the subject of to the ECSC Treaty in 1952, one of the first European industry agreements. The special provisions governing these two products remained in force after the two administrative bodies of the Community were merged.

The steel industry encompasses steel production from raw material processing to the production of finished rolled steel products and covers the following operations:

- coke manufacture (except if coke is purchased from the coal industry or from independent coking plant);
- ore preparation, especially for the production of sinter and pellets;
- manufacture of pig-iron in blast furnaces;
- manufacture of steel from pig iron in converters and from scrap in electric furnaces;
- continuous casting and/or hot rolling of semi-finished products;
- hot rolling of long products and flat products;
- cold rolling of flat products;
- metallic and organic coatings.

The finished products of the steel industry, including ordinary, special and alloy steels, can be divided into hot-rolled and cold-rolled products.

Hot-rolled

- Flat products: sheet strip obtained directly from the hot mill or by slitting of sheet in coils; heavy or medium wall plate obtained directly from the hot mill or by cutting of sheet;
- Long products: heavy sections, light sections, including concrete reinforcing bars, and wire rods.

Cold-rolled

- Thin wall sheet in coils uncoated or coated with zinc, tin, lead, aluminium, plastic, paint, etc.

Four countries (Germany, France, Italy and the United Kingdom) allow for three quarters of the total production of steel in the EC. With about 40 million tonnes, Germany is the largest steel producing country in the EC, followed by Italy with about 25 million tonnes.

Recent trends

Over the period 1983-1988 both production and consumption of steel grew at an annual rate of 4.6% and 4.8% respectively, entailing record production and consumption levels in 1989. Following the unfavourable economic climate which started in 1990, significant reductions in demand were recorded, which adversely affected the EC steel industry. Although a slight increase in production and consumption of steel was recorded in 1989, this was solely due to the inclusion in the statistics of the new German Bundesländer. In 1992 both production and consumption declined further by around 4% and 1% respectively. A further deterioration of the EC steel market is expected for 1993.

A breakdown of the steel production by the principal product categories is shown in Table 2. The proliferation of new production techniques since the 1970s (such as continuous coating

and electric arc furnaces has greatly improved productivity in certain production processes.

Figure 3 shows the decline of the EC steel industry compared to the manufacturing industry average.

International comparison

The EC is the world's largest steel producer, followed by Japan and the USA. In the EC and in Japan, steel production in 1992 appears to exceed steel consumption, respectively by 7% and 17%. The EC is also the principal exporter of steel, although in 1992 its exports were about 10% lower than in 1983. Japanese exports declined at a much faster pace (40%) than those of the EC. Unlike the EC and Japan, the USA is a net importer of steel.

All the three major producers show a fluctuating development pattern for production during the period 1985-1992. For the EC and Japan these developments resulted in a 1992 steel production which was considerably lower than in 1991. Conversely US steel production increased considerably in 1992, surpassing the 1985 level, but remaining lower than in the period 1988-1990.

Foreign trade

The EC has a significant trade surplus in steel. However, since 1985 declining extra-EC exports (which were in 1992 nearly 20% lower than in 1985) and increasing extra-EC imports (which were in 1992 nearly 45% higher than in 1985) are entailing a slow decrease of the trade surplus. At the same time the export/import ratio declined substantially. Re-

markably, the peak production of steel did not interrupt the downward trend in extra-EC exports as it was primarily needed to meet the exceptionally high demand within the EC.

Three major export markets for EC steel can be observed: Asia (excluding Japan), the EFTA and the USA. The share of the first two markets has increased since 1987, whereas the USA was in 1992 a slightly less important destination than in 1987. Steel exports to Eastern Europe have been halved during the 1987-92 period. Conversely, Africa has become an increasingly important market for EC steel.

The EFTA countries and Eastern Europe play an overwhelming part in EC steel imports steel; their joint share in total EC steel imports totalled nearly 78% in 1992, against 76% in 1983. The increase is due to a clear substitution process which favoured cheaper steel imports from Eastern Europe to the detriment of imports originating from EFTA.

Thanks to the long time integrated EC steel market, intra-EC trade in steel increased by 67% in volume terms from 1983 to 1992.

MARKET FORCES

Demand

Primary processing industries account for over one third of the ECSC steel used in the EC. Most of steel is used for the production of steel tubes (14%), for wire and bright drawing (9%) and for cold rolling and cold forming (6%). In terms of final internal demand the principal consumers are building and civil engineering (15%), transport equipment (11%) and metal products (10%). Other important customers are mechanical engineering (7%) and structural steel work (6%).

Since the mid-1970s steel consumption in the EC (and in the industrialised countries in general) has decreased. Various factors contributed to this development such as: the recent cuts in the production of a number of steel-consuming industries; technological development, entailing a decrease in the quantity of steel needed for the production of a given product; an improvement in the quality i.e. the durability of the steel products themselves; the substitution of steel by other materials (plastics, aluminium etc.).

In addition to these factors, the EC steel industry has been suffering from a reduction in demand because of the emergence of new competitors, particularly in the newly industrialised countries and more recently in Eastern Europe. These countries succeeded not only in covering their own domestic demand, but they also competed successfully on the world market.

Supply and competition

The reduced demand for steel, induced by the structural and cyclical factors dealt with before, gave rise to a massive restructuring programme. Market controls regulated by article 58 of the ECSC Treaty and the State Aid Code, enabling national governments to support their steel industry, were underlying the restructuring process which took place between 1980 and 1986. The market controlling measures expired mid-1988. The restructuring process brought about a reduction in the EC's production capacity for crude steel of 40 million tonnes (19%). Moreover, by the end of 1988 the hot rolling capacity had been reduced by 34 million tonnes (18%).

At the same time, however, the newly industrialised countries increased their production significantly. Low production costs (cheap labour and energy, indigenous raw materials) and technological development in steel production (mini-mills) enabled them to compete successfully with traditional exporters in the world market. This had an adverse impact on extra-EC

Figure 6: Iron and steel
Destination of EC exports (1)

exports. In addition, the newly industrialised countries, and the East European countries broke into the EC steel market by supplying large quantities of low-priced steel. Consequently the non-EC share in apparent consumption grew from 5% in 1975 to nearly 10% in 1992.

Detrimental to the EC steel industry's competitive position is its relatively high cost structure; moreover unit labour cost increased by more than 50% during the 1985-92 period. At the same time, labour productivity the EC steel industry increased substantially, mainly thanks to the massive labour force reduction: in terms of output per worker, the increase totalled 62% between 1983 and 1992.

Despite the considerable reduction in the production capacity and the labour force of the EC steel industry during the period 1980-1986, the restructuring was not completed. Envisaged capacity reductions were not carried out. The sudden improvement of the market in 1988 together with the subsidies enabled the less competitive manufacturers to survive. The same manufacturers are currently facing again huge financial problems, as they are confronted with high production costs and low prices. The Commission identified reductions of 30 and 20 million tonnes in crude steel and rolling capacity respectively. Unlike in the 1980s, the Commission currently wants the steel industry to solve itself problems i.e. the steel producers will have to indicate which enterprises should reduce their capacity and to which extent. The main plank of the EC restructuring is a partly self-financed scheme (Art. 53A of the ECSC Treaty) under which companies remaining in the industry would pay rivals to cut capacity or leave the business. The reduction

must be permanent; capacity may not be restored as soon as the economy recovers. The restructuring process is expected to require three years.

The Commission intends to strictly control state subsidies (Art. 4c of the ECSC Treaty); state subsidies should only be authorised by the EC Commission if they are aimed at achieving substantial reductions in inefficient production capacity.

To facilitate the restructuring process and to alleviate the hardship resulting from the redundancies, estimated at 70 000, the Commission has already put forward a proposal for special measures for the ECSC workers. Under the condition that the EC Member States will pay a similar amount, to cover costs of redundancies up to 5 000 ECU per worker will be made available. Further the Commission will pay up to 4 000 ECU per worker. Finally, the Commission has accepted in principle to pre-finance the funds required for the elimination of excess capacity. These ECSC loans will be entirely repaid by the industry.

Production process

The application of improved production techniques together with the reduction of production capacity enabled the EC steel industry to reduce its cost and to increase its efficiency. An example is the proliferation of continuous-casting plants, (in which one step in the production process is eliminated with a subsequent drop in the crude steel requirements). Nowadays in the EC around 90% of the crude steel is produced by way of the continuous casting method (in 1980 this was only 30%). In some countries all the crude steel is produced with this method.

Besides technological developments the productivity in the EC steel industry has increased through a drastic reduction in its labour force. The labour force reduction is estimated at 45% to 50% over the period 1980-1992. This reduction, together with the technological innovation of the production process, has brought about a significant increase in (labour)productivity since the beginning of the 1980s. From 1983 to 1992 productivity (in value added per person employed) increased at an average rate of nearly 8% per annum, whereas the output by 5.5% per annum.

INDUSTRY STRUCTURE

Companies

Two major categories of producers can be distinguished: the integrated companies and the mini-mills.

The integrated companies account for 70% of steel production in the EC. These companies produce pig iron in their blast furnaces and convert it in oxygen-based steel works, using scrap to maintain the temperature of the molten steel. Companies using this method are usually geared to the production of flat products, including subsequent cold rolling into thin sheet steel (which may be coated), and the production of heavy sections and wire rod. Integrated mills generally have large production capacities, ranging from 2 to 10 million tonnes of finished products. Although these large production units allow economies of scale, they allow little production flexibility.

Mini-mills are relatively small companies with annual capacities ranging from 0.15 to 1.2 million tonnes. They are involved in the production of more specialised products. The mini-mills encompass enterprises whose sole operations are electric steel works, continuous casting plants and rolling mills. Mini-mills play a significant part in the management of industrial waste; they convert scrap into quality steel products. These products include reinforcing bars, reinforcing mesh and small and medium-sized sections for the construction industry. The mini-mills also produce merchant bars and wire rods, particularly for the use in the automobile and construction industry. The mini-mills owe their success to their flexibility and capacity to adapt production to market demand. In certain Member States mini-mills account for a substantial share in total steel production. Good examples are Italy and Spain, where mini-mills account for 55% and 42% respectively of total steel production.

The iron and steel industry is a sector with a high degree of concentration. In 1992 almost half of the EC crude steel production came from only five companies. In descending order of turnover they were: Thyssen Stahl (D), Usinor-Sacilor (F), Ilva (I), British Steel (UK) and Hoesch (D).

A number of mergers and acquisitions have taken place in the course of the modernisation and restructuring of the EC steel industry. Examples are the merger between Usinor and Sacilor in France, the creation of Ilva in Italy and the rationalisation agreement between Krupp and Mannesmann in Germany. The most recent example is the takeover of Hoesch by Krupp. With the exception of Usinor-Sacilor, British Steel, Ilva and Thyssen, most of the European steel producers are only medium-sized firms in comparison to other international steel firms.

Strategies

In 1952, the ECSC Treaty created for coal and steel the necessary conditions for the Single Market, which after 1992 has extended to all other industrial sectors. The Single Market is already a reality for the EC steel industry.

In order to better face the hardships of the present situation, steel companies are starting to protect themselves against future downturns and strong competition from outside. Such measures include: paying more attention to customer service and commercial investment; diversifying into areas other than steel; take-overs and mergers; specialising in high-quality products; and more integrated production techniques.

REGIONAL DISTRIBUTION

There are steel plants all over in the EC, with varying levels of production capacity. Originally the steel plants were built inland, usually near the coal or iron-ore fields from which they used to draw their supplies, or near steel consumers. More recently they are built on the coast, where they have easy access to imported raw materials, without the cost of land transport. They are also better placed to capture international markets.

Whereas Germany is the greater EC producer of steel, the importance of the steel industry in the economy is the largest in Luxembourg, where the share of steel production in total industry exceeds 40%. By contrast, the contribution of steel to total manufacturing production only accounts for about 1% in Denmark, Ireland and Portugal.

With regard to mini-mills, the highest concentrations of such mills can be found in Northern Italy and Spain.

ENVIRONMENT

The steel industry is conscious of its responsibility with regard to environmental protection. Long before the protection of the environment had been placed on the political agenda, the steel industry intensively developed and generated techniques to reduce environmental pollution. These measures include the low-pollution manufacture of steel products, steel recycling and the utilisation of waste material. The restructuring of the industry in the 1980s encouraged the innovation of the production process; older installations were replaced by modern plants, fully equipped with a whole range of pollution-control equipment. The increasing use of electric arc furnaces (EAF) across Europe is a leading example of such new processes.

The steel industry's dust emissions have been lowered considerably. Emissions of carbon dioxide (CO2) have also been strongly reduced by optimisation of process technology and an overall reduction in energy inputs. For example in the mini-mills the average required input of electricity per tonne of steel declined from 510 KWh in 1980 to 380 KWh in 1990.

In recent years the EC steel sector consumed about 60 million tonnes of steel scrap, the bulk of which was collected from discarded steel-containing products. This recycling of scrap, which represents about 45% of total steel production, is one of the highest rates for any industry.

Environmental protection places considerable financial burdens on the iron and steel companies. In the light of the high costs and the fact that the requirements and enforcement of environmental protection is not equally strict in all countries, a harmonisation of environmental protection legislation in Europe is essential for avoiding distortion of competition. European steel producers continue to work with the European Commission in the framework of the Environmental Protection Research Programme established under Article 55 of the ECSC Treaty.

REGULATIONS

For more than forty years, the European steel industry has been regulated by the European Coal and Steel Community (ECSC). The ECSC was originally established in 1952 to regulate pricing, transport, tariffs, etc. for coal, iron ore and scrap iron among the Member States.

As to recent legislation particularly in the field of the environment, it is worth to note the EC Council Directive of 1st February 1993 on the movement of waste (ferrous scrap is on the Green list) within and outside the EC. This Directive follows the conclusions of the Basle Convention as well as other similar conclusions at the OECD level. The industry fears that this Directive will include scrap into the waste list rather than consider it as a raw material. The subsequent cost increase (because of penalties) may be detrimental to the further innovation of the production process and it may jeopardise further reductions of environmental pollution.

An energy tax to stabilise CO2 emissions will also penalise rather than encourage steel producers' efforts to reduce energy consumption. In fact, CO2 emissions have already been reduced by 25% since 1974. A CO2 tax would have no effect on the reduction of CO2 emissions, because the industry is already using the best available technologies.

OUTLOOK

The general economic activity in the EC has considerably declined in 1992 and many countries entered a recession phase. After a two-year decline, steel prices in the Community reached their lowest level at the first quarter of 1993. Since then prices have increased on average by about 10%, because of the following reasons: an adaptation of EC production to reduced consumption; the sharp demand increase from the Far East; and the stabilisation of the US dollar versus European currencies. However, the medium term-prospects for the EC steel sector remain dim. Sustained recovery is heavily dependent on the restructuring of the EC steel industry. In the short-term, the general economic situation in the EC is expected to deteriorate, adversely affecting the demand of the steel-using industries. Most steel-using sectors are reducing their demand in 1993; the automobile industry will account for the greater decline (about 16%), whereas metal manufacture, mechanical construction, building and civil engineering and other means of transport are expected to reduce their

Table 7: Iron and steel

Source: NEI

demand by 1.5% to 3%. Only for electric construction a demand growth is foreseen in 1993 (2%). Allowing for stock variations, the joint impact of these developments will result in a decline of the EC steel consumption in 1993 of around 10%; the decline in production will be slightly less, namely about 9-10%.

Neither in the short-term (1993-1994) nor in the medium-term (1993-1997) drastic improvements of EC steel production and consumption are envisaged; an increase in the demand will be largely met by non-EC imports.

Steel tubes
NACE 222

The steel tube industry has faced a severe volume and financial downturn since the mid-1980s due to worldwide over capacity. Seamless tubes and welded tubes with an outside diameter of over 406.4 millimetre in particular were deeply influenced by import quotas imposed by the USA until March 1992 and later by the harassing threat of trade cases, and by the low international value of the dollar. Furthermore, the collapse of the former Soviet Union and other East European markets and the lack of orders from China are of great concern to EC manufacturers. The EC has maintained its leading position in the world market, ahead of the USA and Japan, due to continuous productivity gains achieved over recent years through industry restructuring. Nevertheless, foreign trade has been steadily deteriorating. Despite its improved competitiveness, the EC steel tube industry is under the strongest pressure from massive volumes of low priced imports from Central and Eastern Europe which forced EC mills to significant reductions of output, capacities and workforce.

INDUSTRY PROFILE

Description of the sector

The activity of NACE 222 encompasses the manufacture of steel tubes as well as of steel tube fittings and compressed gas cylinders. This monograph however covers only the manufacture of steel tubes; the data are based on production figures compiled by surveys conducted by the organisations of the producers located in the EC Member States. Export and import figures are provided by Eurostat sources. Steel tubes cover three product categories which differ considerably in their manufacturing processes, raw materials, and investment requirements. These categories are classified as: seamless steel tubes, welded steel tubes of circular cross-section over 406.4 millimetres in outside diameter, welded steel tubes of circular cross-section up to and including (uti) 406.4 millimetres in outside diameter and welded steel tubes of non-circular cross-section of any perimeter.

The main consumers are the energy markets (e.g. oil, gas, nuclear, steam generating industries), petrochemical, automotive, mechanical engineering, mechanical services, and construction industries. The economic development in each of the product areas of the steel tube sector vary according to their different end markets. Calculated, using a crude steel equivalent, the EC steel tube production consumes 16-19% of ECSC steel output. Steel tubes are manufactured at varying levels in each EC country.

Recent trends

After a peak in 1990 and an expected steep downturn in 1993, the long term trend of consumption can be seen as developing moderately. Since 1992 production has had to be reduced dramatically in some countries as a consequence of lower export possibilities and heavy imports. In 1992 apparent consumption of steel tubes in the EC was practically the same in volume as in 1991 thanks to a recovery of demand for welded tubes over 406.4 mm. Consumption is expected to decrease 8% in 1993. Production diminished by 10% in 1992 and will continue to decrease at an estimated 8% in 1993. Exports fell 27.4% in 1992 with even less opportunities in 1993, while imports increased by 4.6% and are estimated to remain at the same level in 1993.

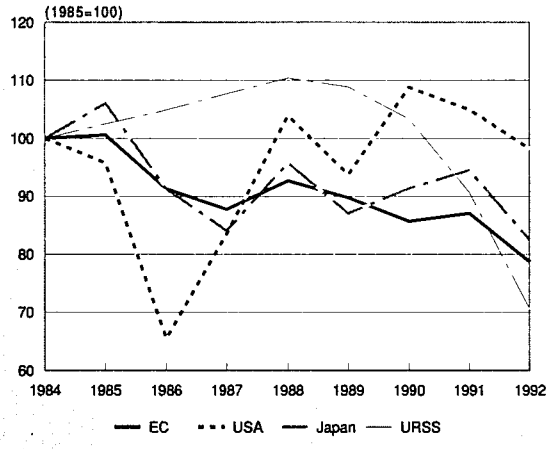
MAIN INDICATORS

Data show marked decreases in production and exports of steel tubes which have resulted in a loss of employment of 38 200 (38%) employees between 1984 and 1992. Although apparent consumption has increased steadily, or at least has remained level, over the past decade, it has mostly been to the advantage of third country competitors. The share of imports from third countries of EC consumption, measured in terms of tonnes, increased strongly from 9.3% in 1984 to 15.2% in 1992. Growth in the steel tube sector has clearly lagged behind developments in general manufacturing as a whole and since 1987 general manufacturing has been characterised by strong growth in production and consumption and a stagnation in extra-EC exports and in employment. In contrast, all indicators for the steel tube sector, with the exception of consumption, show a sharp decline.

International comparison

EC production of steel tubes in 1992 accounted for 19.2% of world production against its 1984 production rate of 20.6%.

Figure 4: Steel tubes
International comparison of production in volume



Source: CdL

In world ranking, the EC is ahead of Japan and the USA. The former Soviet Union has been at the top of the league for the past several years. Particularly in Japan, but also in the EC, steel tube production greatly exceeds consumption which reflects their role as the most important steel tube exporters.

While the EC, the USA and Japan suffered setbacks in their shares of world production since the 1980s, the newly industrialised countries (NICs) and the developing countries (DCs) were the winners. Some of these countries have continued to expand their production capacity, often supported by heavy public subsidies. This group of countries includes Turkey, Mexico, Venezuela, Brazil, Argentina, Taiwan, The Republic of Korea and Thailand.

Foreign trade

The EC's share of estimated world exports of steel tubes in volume amounts to about 43%, if intra-EC trade is included, or to roughly 25%, if intra-EC trade is excluded. Extra-EC exports of steel tubes have decreased continuously since 1984, with an unusual exception in 1991, while extra-EC imports increased steadily in volume, leading to a declining trade balance.

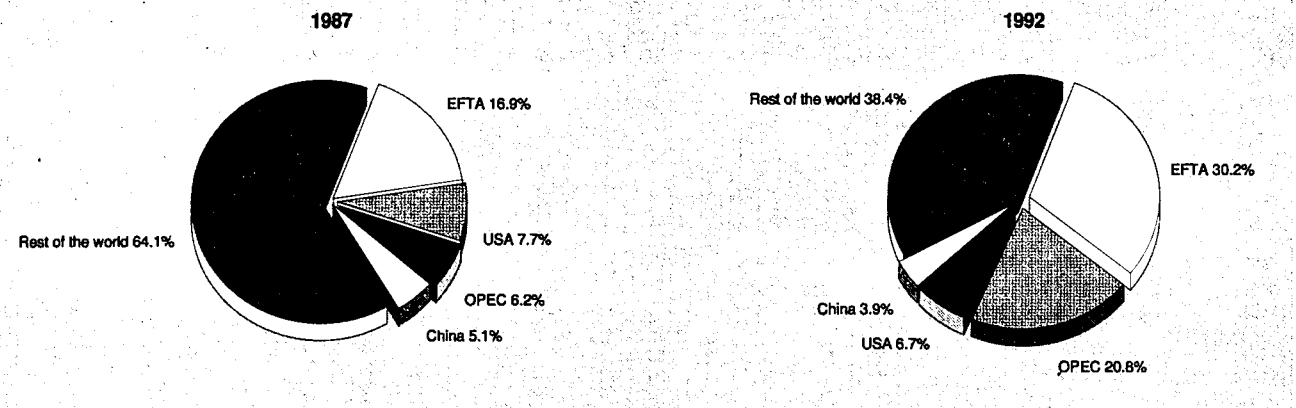
The list of countries receiving EC exports has changed considerably between 1987 and 1992. Exports to EFTA and OPEC countries more than doubled during this period. The former Soviet Union in the past was a major export market, but now the lack of hard currency has reduced its share of EC exports from 42% to almost zero. The EFTA countries are dominant suppliers to the EC steel tube market. However, over the last five years, there has been a decrease in the share of EC imports coming from EFTA countries and also Japan while Central and Eastern Europe countries have almost tripled their exports to the EC. Intra-EC trade is significant and has strengthened in the past decade in absolute value. In value it amounted to roughly 73% of total EC imports in 1992.

MARKET FORCES

Demand

The most important steel tube consuming sectors are: oil and gas exploration and extraction, transport of oil and gas by pipelines, nuclear and other steam generation industries, mechanical engineering, the automotive industry, structural steel

Figure 5: Steel tubes
Destination of EC exports



Source: Eurostat

work, the building industry and other metal processing industries. Due to economic developments in these sectors, apparent consumption of steel tubes in the EC rose by 30% from 1984 to 1990 reaching a volume of 10.6 million tonnes. Since that time however, consumption shrank due to lower investment activity in almost every steel tube consuming sector. At the same time the majority of the export markets for EC mills have decreased. In 1984, 48.3% of EC steel tube production was exported to third countries. The decrease of this share to 26.5% in 1992 shows a serious fall in the sales opportunities of the industry. The main reason for the reduction in extra-EC exports is the dramatic fall in orders from the Commonwealths of Independent States and China, caused by their lack of purchasing power, not by loss of EC market share.

Supply and competition

Regardless of continuous workforce and production cutbacks, the EC steel tube industry still suffers from the worldwide over capacity. The effects on profit margins are considerable, especially in export markets and for commodity steel tubes. Given the range of purchase possibilities worldwide, and rising imports, customers are in a strong position to dictate prices to producers. Internal competition within the EC is high and continues to increase. In 1984, intra-EC trade amounted to 2.5 million tonnes or 30.3% of the consumption of steel tubes, whereas in 1992 imports were 3.8 million tonnes or 38.4% of consumption. Intra-EC imports in 1984 totalled 1 763 million ECU or 31.5% of consumption, by 1992 this figure had increased to 2 833 million ECU or 42.8% of consumption. This development is an indication of the fact that there are today very few trade barriers in the steel tube sector. Further impact of the single market, therefore, is expected to be low.

EC competitiveness with respect to third countries, however, is threatened when imported steel tubes are subsidised in their production and/or are produced under non-market economy conditions. This is the case with most of the imports that have flooded the EC from Central and East European countries, especially since the second half of 1991. Their "costs" are not real and thus are often not reflected in pricing. For example, raw materials are often purchased in exchange for other materials, while electric power, and water supply, are heavily subsidised. Given the situation, these imports oversupplied the EC market with price differences of 30% to 50% below

the EC price level. The consequences are plant closures. Two production lines for seamless tubes in the United Kingdom were closed in 1991 and several modern facilities with very high productivity were closed in 1992, including one well known continuous mill in Germany. In contrast, old and inefficient mills in Central and East European countries have been trying to replace the collapse of their exports to the former Soviet Union by increased exports to the EC. While exports to East European countries virtually melted away to zero, imports from this region were five times higher in 1992 than in 1986 and caused severe injury to the EC steel tube industry.

Production process

Technically speaking, the EC steel tube industry is a very strong performer. Continued investment in research and development assures high quality steel production and rolling processes. On-going rationalisation efforts both in production and labour have kept the costs at a competitive level. In the period from 1984 to 1992, the number of employees in the steel tube industry dropped by 38%. Productivity (measured in terms of tonnes per person employed) increased by 27.4% over the same time period.

It should be noted that in many sectors of seamless and welded tubes different product categories are manufactured in the same mill, i.e. tubes of commercial grade as well as tubes of highly sophisticated quality. This means that the installations need to be filled with a substantial base load of commodity products along with high added value grades to obtain a cost level which is competitive in the world market

INDUSTRY STRUCTURE

Companies

The steel tube industry is a primary steel processing industry with a highly concentrated structure. Five countries Germany, Italy, France, the United Kingdom and Spain, account for roughly 90% of total production. In some countries, a single company can account for 50% or more of national output. In addition to the major steel tube manufacturers who are usually linked to the large steel producers, especially when manufacturing welded tubes, there are a relatively large number of medium-sized and small firms. Some manufacturers, often small in tonnage terms, operating in small, high value-added markets, specialise in the manufacture of special dimensions and grades of tubes according to a customer's particular specifications. At the end of 1991 there were 285 production units in the EC belonging to an estimated 245 enterprises, 67 of which were specialised in cold drawing of seamless or welded tubes.

Strategies

No significant investment has taken place in recent years due to the reductions in capacity imposed by difficulties in the market since 1985. Contrary to the early 1980s where some investment was directed towards expanding capacity, current investments relate to improvements in productivity and quality. In the past, companies and countries tended to either manufacture a full range of products or to specialise in niche markets. To strengthen the competitiveness of the industry, thought is now being given to cross-border cooperation and by capacity reductions.

ENVIRONMENT

Costs arising from environmental protection legislation are considerable. To a large extent, the costs of classical end-of-the-pipe measures such as the treatment of emissions from raw material production units, reheating furnaces, noise control, and the treatment of waste water can amount to as much as 50 ECU per tonne and average at least 1% of the turnover of EC firms. Waste reduction strategy is implemented more often in refurbishments or modifications of current production processes, procedures and feed stock than it is implemented in the input/output balance. Heat usage and water saving measures, treatment of process liquids, recycling of materials and maximising yields are just a few of the measures used that follow the needs of "best available technology" (BAT). Additional costs, which cannot at present be estimated, come from the installation of measures to maintain and boost confidence in an environmentally friendly industry. This prevents site closures for environmental reasons. These measures are in line with the Community Eco-Audit Regulation and of the Regulation of Free Access to Environmental Information requirements. Steel and steel tube manufacturing enjoy the advantage that during the production process no toxic gases develop and the waste material is recycled immediately and

completely. Another environmentally sound characteristic of steel is that the product itself can be entirely recycled without polluting the environment.

REGULATIONS

Trade regulations are a key source of concern for the EC steel tube producers. Trade barriers in several countries of the world hamper the penetration of EC exports. The reduction of non-tariff barriers is an important item in the framework of the Uruguay Round trade negotiations. The harmonisation of EC standards in the sector is well advanced, internal barriers have practically disappeared and do not impede the free circulation of goods among the Member States. The EC steel tube market remains open for imports from third countries under fair trade conditions. Imports continue to face strong competition from domestic suppliers and suppliers in other Member States and third countries. Unfair trade practises will be countered by Antidumping procedures.

OUTLOOK

In 1993, EC consumption of steel tubes is expected to decrease by 8% due to the slowdown of overall economic growth as well as stock reduction by distributors and users. Also production is estimated to decline by 8% after the 1992 downturn of 10%. EC countries which are affected at the same time by heavy imports and lack of export orders suffer most from the production setbacks, which rose to 14% in 1992 and are estimated at 25% in 1993. Recovery of the steel tube industry cannot be expected before mid-1994, brought about by stronger overall economic growth and stabilisation of exports.

In the medium term, the development of the EC steel tube industry will be characterised by a number of risks and opportunities. The main risks are a continued increase of imports from Central and East European countries which could lead to further plant closures in the EC. Continued weak demand in the US market and an increase in the export activities of subsidised producers in third countries will dampen export demand for EC steel tube manufacturers. CIS imports will not improve for some years. However there are promising opportunities for the future. The economic recovery in the CIS and in Central and East Europe will bring larger export markets, as well as an improvement in the world economic situation with a related increase in the demand from the energy industry. Fair trade enforcement under confirmed GATT regulations will also increase the industry's activity.

First processing of steel

NACE 223

After substantial growth in 1988, 1989 and 1990, production of the first processing of steel sector fell to 16.1 million tonnes in 1992 against 17.2 million tonnes in 1990. This was primarily due to the economic downturn experienced by the end-users, particularly in the building sector, the automotive sector and in mechanical engineering.
In the past, developments were marked by decidedly weak growth rates due to slack demand and an ongoing deterioration of foreign trade. Emergent industrial competition from East European countries made incisive inroads into the EC market as extra EC exports receded simultaneously. One consequence of this unfavourable trend and of intensified rationalisation measures was a drop in employment. Production in value in 1992 was by 10.5 % lower than in 1989.

INDUSTRY PROFILE

Description of the sector

Sector 223 of NACE is in fact a part of first processing of steel. It includes the following four subsectors:

- NACE 223.1: Cold drawing of steel bars
- NACE 223.2: Cold rolling of steel strip
- NACE 223.3: Cold forming of steel flat products
- NACE 223.4: Cold drawing of steel wire and manufacture of wire products.

The manufacture of cold drawn wire and wire products is the largest activity of the sector with a share of 54 % of production and 45 % of extra-EC exports in 1992. The manufacture of steel tubes referenced NACE 222 is also a first processing of steel activity but is considered separately in this publication.

Manufacturing process

Transformation of hot rolled raw material by cold working is a common feature of the four subsectors which leads to more accuracy in size and mechanical properties, as well as improvement of the surface condition (except for cold forming) compared to products obtained on the hot mill. The products are or standard or manufactured according to the requirements of each individual customer which is obviously not possible for the primary steel industry.

Cold drawing

"Cold drawing" concerns the manufacture of steel bars or sections by cold drawing, grinding or peeling of hot rolled steel bars, into so-called "Bright steel bars", having the form and characteristics required by the users. The finished product has tight tolerances, accurate mechanical properties and a high quality surface. Improved quality surface conditions and closer tolerances can be achieved by additional grinding and polishing. Cold finishing during drawing operations hardens and increases the tensile strength of the steel, while at the same time reducing the ductility, which may require an annealing treatment of the product after drawing. Bright steel bars are mainly of circular, square rectangular or hexagonal section, but all kinds of sections can be produced according to demand. They are delivered in fixed length.

Cold rolling

Cold rolling of steel strip is a process in which pickled flat hot rolled steel products are rerolled between polished cylinders. The dimensions of the finished product are of less than 600 mm in width and 0.025 mm up to 12.5 mm in wall thickness.

In the wall thickness range of 0.3 mm up to 3 mm, other flat cold rolled steel products can be obtained by slitting coils of large cold rolled sheet manufactured by the primary steel industry. This operation is done either by the primary steel industry itself or by distributors of steel products.

Rerolling gives a high quality product with consistent dimensional and internal characteristics. The equipment used to roll, anneal, slit, edge and heat treat cold rolled steel strip is highly capable of producing a unique product when compared to large cold rolled sheet mills found in all integrated steel plants throughout the world.

The specialised rolling mills and processing equipment used allow to meet all the different requirements of each individual customer: mainly close tolerances, special forming capabilities and special finishes (surface edges, coating, for instance) which are not possible for the primary steel industry.

Cold forming

Cold forming concerns the manufacture of open sections of steel by progressive forming on a roll mill or folding on a press of hot rolled descaled flat products of steel or cold rolled coated flat products of steel. Cold forming is a continuous process which allows the manufacture of big quantities of simple or complex forms. Cold folding is generally used to obtain sections of simple forms in small quantities. Compared to the simple form sections produced on the hot mill, cold formed sections are more accurate in size.

Wire drawing

Wire drawing is an operation consisting to cold stretch hot rolled wire rod, through a die, with an aperture of a form corresponding to the cross-section of the finished product. The mechanical properties of the hot raw material must be appropriate in order to have sufficient ductility to pull it through the die. After this operation, the hardness and tensile strength of the wire becomes higher and may require an annealing after drawing. In some cases a patentage heat treatment is required. The finished products have tight tolerances, ac-

curate mechanical properties and a smooth surface. Their cross-section may be circular, flat with rounded edges, rectangular, hexagonal, triangular, oval, semi-circular etc.

Products manufactured

Cold drawing

The subsector manufactures the following products: non alloy steel bars of free cutting steel and carbon steel bars; stainless steel bars; alloy steel bars of different grades including high speed steel and other tool steel and shapes and sections of different grades of steel. All these products meet the specifications of each individual user.

Cold rolling

The subsector manufactures the following products: steel strip of a carbon content of 0.50 % or under, including as rolled or blue strip for packaging; steel strip coated with zinc, tin, lead, copper, nickel or with paint, varnish or plastic, printed on request; cladded steel strip; quenchable or quenched steel strip; stainless steel strip; and other alloy steel strip.

Cold forming

The subsector covers two production areas: standard sections of simple form such as L,C,U, Omega and Z and products for specific uses of complex form according to the requirements of each individual customer; wide size sections for building purposes in low carbon steel coated with zinc, paint, varnish or plastic, such as sandwich panels, corrugated sheet, profiled sheet and safety barriers. These products are mainly of non alloy steel with a content of carbon up to 0.25 %. There are also manufactured sections of stainless or other alloy steel.

Wire drawing

The subsector covers two fields of activity:

- Wire drawing: mild steel wire with a carbon content up to 0,25 % and hard steel with a carbon content of over 0,25 %. These products are delivered uncoated or coated with zinc, copper, tin, nickel, chrome, plastic, varnish or other materials; stainless steel wire; and other alloy steel wire.
- Wire products: strand and ropes, heavy welded mesh, plaited bands; barbed wire, wire fencing, grill, netting; welded link chains, hooks, springs, nails, etc.

Classification in the Combined Nomenclature (C.N.)

Products covered here are classified in chapters 72 and 73 of the "C.N.". Except for cold rolled strip, external trade statistics can be used for the calculation of apparent consumption. The problem for cold rolled strip is that strip produced by the cold rolling industry cannot be classified apart of the cold rolled strip obtained by slitting of cold rolled sheet manu-

factured by the primary steel industry. Consequently, apparent consumption is not available for sector 223.

Period covered

In order to have homogenous figures for external trade statistics, the table and figures begin in 1988, the year of enforcement of the C.N. based on the Harmonized System, which has replaced the previous Common Custom's Tariff and Nimexe nomenclatures. Accordingly, the period 1988 to 1992 has been selected for all other statistical information.

Recent trends

After several years of weak growth, the sector was able to record healthy growth rates in 1988, 1989 and 1990. With the slowdown of production in consuming industries that began in 1990 and intensified in 1991, consumption of drawn wire and bars and cold formed products decreased by 1.2% in 1991 and 3.2% in 1992 and is doomed to decrease again in 1993. The trade balance has dropped by 14.6% in 1990, 17.7% in 1991 and 6.2% in 1992. As a result of these trends, production in value has decreased steadily since 1989 falling down to 12.5 million ECU in 1992 (-10.5%).

Similarly to the primary steel and steel tube sectors, production in the first processing of steel industries has clearly lagged behind the continuous growth in the manufacturing industry as a whole. Productivity in tons per worker has decreased since 1990 with the slowdown of production. Productivity in value added, in 1992 prices per person employed, has decreased since 1990. Unit labour costs have increased since 1990 while total unit costs have decreased since 1990.

International comparison

International comparisons are difficult due to the lack of data on first processing of steel in the world. EC is probably the world's largest producer followed by Japan, the USA. Sweden, Finland, Switzerland and Austria, among the EFTA countries, and East European countries are also major producers.

Foreign trade

A look at table 7 shows the deterioration in value of extra-EC trade leading to a declining trade balance and a declining exports/imports ratio. The export/production ratio for the sector decreased. Conversely, the import/consumption ratio (excluding cold rolled strip) grew steadily.

Figure 2 shows some changes in the destination of extra-EC exports comparing 1988 and 1992. The share of EFTA countries has increased but the shares of the USA and of the former Soviet Union have decreased. As for extra-EC imports, the share of the EFTA countries has decreased but remains the highest, while the share of East European countries increased.

MARKET FORCES

Demand

A wide variety of sectors are users of the products of the first processing of steel industries which are described in the paragraphs below. At present, most users have to cope with recession which will worsen in 1993 and possibly also in 1994.

Cold drawing

Bright steel bars are used by industries such as manufacture of motor vehicles, machinery, electrical goods and other industries, where a high quality basic material is compulsory. There has been a severe slowdown of demand especially from the automotive industry due to recession in this sector.

Cold rolling

Cold rolled steel strip is used for the manufacturing of automotive parts, hardware, office equipment, fasteners, bearings, chains, tubes and many other products, whenever a high quality basic material is compulsory.

The most important consuming sectors are the manufacture of motor vehicles and other transport equipment including bicycles, which account for more than half of the demand. Due to recession, there is a slowdown of demand from the industrial sectors who use cold rolled steel strip.

Cold forming

Sections are used by sectors such as building, civil engineering and transport equipment, mainly for safety barriers for the highways, sheet piling and manufacture of trucks, railway rolling stock and furniture. Some of these sectors are in recession.

Wire drawing

Drawn wire and wire products are used by the construction of buildings and civil engineering sectors, the manufacture of motor vehicles, of machinery, of fasteners , screw machine products, chains and springs and furniture sectors, agriculture and telecommunications. There has been a slowdown of certain of these sectors in 1992 due to recession.

Supply and competition

The first processing sector has been cutting its work force and improving its productivity. Progress is due to wire cold drawing and cold forming industries. There has been a loss in employment of about 5 400 workers between 1988 and 1992. Capacity is estimated at around 20 million tonnes in 1992 compared to a production of 16 million tonnes. This situation of persistent overcapacity is at the present time shared by most producing countries.

Internal competition within the EC has been active. Intra EC imports which were of 4.3 million tonnes in 1988 climbed progressively up to 4.6 million tonnes 1992, corresponding to 3.6 million ECU and 3.9 million ECU respectively.

Imports from third countries have been constantly increasing since 1988 passing from 1 million tonnes up to 1.3 million tonnes in 1992 corresponding to 0.9 million ECU and 1.1 million ECU respectively. Imports from EFTA countries were in 1992 14.6% higher than in 1988, with 573 980 tonnes against 500 627 tonnes. Imports from East European countries were in 1992 108.7% higher than in 1988, with 420 079 tonnes (37.4 % of total imports) against 201 432 tonnes, at far lower prices than for other foreign competitors. Czechoslovakia is the most important competitor with 277 918 tonnes or +178% over 1988. Low price imports from this group of countries have a disastrous effect on the market. The other main competitors were South Africa with 59 488 tonnes in 1992 against 51 168 tonnes in 1988; China with 25 100 tonnes in 1992 against 16 171 tonnes in 1988, and the USA with 23 361 tonnes in 1992 against 19 089 tonnes in 1988.

Cold drawing

There has been a loss in employment of about 1 000 workers between 1988 and 1992. Production capacity, which was of 4.3 million tonnes in 1988 was around 4.1 million tonnes at the end of 1992.

Intra-EC imports amounted to 643 160 tonnes in 1992 against 639 053 tonnes in 1988. Imports from third countries have decreased after a strong increase in 1989 and 1990, but are still higher by 4% over 1988 with 163 490 tonnes against 157 431 tonnes. Imports from Switzerland were in 1992 24%

higher than in 1988 with 36 545 tonnes against 29 377 tonnes and those from Czechoslovakia 124% higher, with 40 092 tonnes in 1992 against 17 653 tonnes in 1988.

Cold rolling

There has been a loss in employment of about 1 700 workers between 1989 and 1992 and the production capacity of 4,6 million of tonnes in 1988 was reduced to 4,3 million tonnes in 1992.

Internal competition within the EC is high and has strengthened during the last five years. Intra EC-imports amounted to 1 534 032 tonnes in 1988 compared to 1 652 124 tonnes in 1992. With regard to extra-EC imports, in 1992 imports from Austria were 111 543 tonnes against 103 826 tonnes in 1988. Among East European countries, imports from Czechoslovakia reached 56 850 tonnes in 1992 against 25 278 tonnes in 1991.

Cold forming

Productivity has passed from 191.9 tonnes by employee in 1988 to 245.8 tonnes in 1992. Employment was reduced of about 1 000 workers since 1988. Capacity investments have been high in the years previous to 1988. Thus, with the slow-down of demand, the industry suffers of overcapacity as most producing countries in the world.

Internal competition within the EC has been active. Intra EC imports which were of 233 158 tonnes in 1988, were of 332 050 tonnes in 1992. Imports from EFTA countries increased by 56.7% in 1992 with 71 956 tonnes against 46 204 tonnes in 1988. Imports from East European countries increased from 10 850 tonnes in 1988 to 50 404 tonnes in 1992, at very low prices. The countries of origin are mainly Poland and Hungary.

Wire drawing

Employment in the subsector has decreased by about 2 000 workers between 1988 and 1992. Intra-EC imports amounted to 1.99 million tonnes in 1992 against 1.86 million tonnes in 1988. Extra-EC imports in volume increased by 24.3% during the 1988-92 period, mainly because of increased imports from East European countries (+170% during the same period), the EFTA countries (+13%) and South Africa (+62.8%).

Production process

Cold drawing and wire drawing

There has been steady progress in processes used to manufacture bright steel bars, mainly with the introduction of computers in the production lines, in order to meet the demand of users for even higher quality finished products. The methods used keep gauge, mechanical properties and surface condition under much stricter control. The same comments can be applied to the subsector of cold drawing of steel wire and manufacture of wire products.

Cold rolling

In the 1960s, an important technological innovation was brought on by the multicylinder rolling mills and particularly the so-called Sendzimir mill, which allowed rolling of wall thicknesses under 0.20 mm and as low as 0.025 mm. Since then numerous technological innovations have been made, e.g. the introduction of computers in the processing lines which keep gauge, mechanical properties and rolling speed under much stricter control.

Cold forming

One of the main technological innovations has been the automatic machining of forming rolls. The automatic conditioning of products before shipment is also to be mentioned.

INDUSTRY STRUCTURE

Companies

The number of mills declined from 981 in 1988 to 932 in 1992 due to the closing of redundant installations. The situation at the end of 1992 was : 302 mills in Germany, 232 in Italy, 133 in France, 123 in Spain, 90 in the United Kingdom, 29 in Belgium/Luxembourg, 13 in Holland, 7 in Denmark, 3 in Portugal, 2 in Greece. Among the biggest companies, some are integrated to the steel industry, the others are independent and mostly small-size specialised companies.

Cold drawing

The number of mills declined from 162 in 1988 to 143 in 1992. The situation at the end of 1992 was the following: 51 mills in Germany, 25 in France, 25 in Italy, 25 in Spain, 16 in the United Kingdom, 1 in Denmark.

Cold rolling

The number of mills declined from 164 in 1989 to 155 in 1992: the situation at the end of 1992 was of 64 mills in Germany, 32 in Italy, 18 in the UK, 15 in Belgium/Luxembourg, 13 in France, 11 in Spain, 1 in Portugal, 1 in Holland.

Cold forming

The number of mills was of 137 at the end of 1991: 30 in Spain, 26 in the United Kingdom, 25 in Germany, 25 in Italy, 20 in France, 5 in Holland, 4 in Denmark, 2 in Belgium.

Wire drawing

The number of mills declined from 520 in 1988 to 497 in 1992. The situation at the end of 1992 was: Germany 162, Italy 150, France 75, Spain 59, United Kingdom 30, the Netherlands 7, Belgium/Luxembourg 12, Greece 2, Denmark 2, Portugal 2.

Strategies

In contrast to the major firms in the primary steel industry and the steel tube industry, mergers, acquisitions, alliances and cooperation form a less suitable strategy for the medium and small size companies of the first processing of steel sector. The emphasis will continue to be placed on investments in rationalisation to achieve productivity gains. In addition, the trend towards specialisation will intensify. This applies also with regard to the completion of the Single Market. The introduction of the Single Market has had only relatively minor effects on the sector, given that trade among the various Member States is hardly hindered at the present time.

Products exchanged within the EC amounted to 4.6 million tonnes in 1992 which is considerable compared to the total deliveries on the different domestic markets which amounted to about 10 million tonnes. Due to comparable production techniques in all Member States and harmonisation of Standards published by the National Standardization Organizations, the quality of these products is consistent.

Wire drawing

A number of mergers and restructurings have taken place since 1988, especially in and among major steel producing group subsidiaries. Besides these efforts to improve productivity, a tendency to rationalise and specialise production has been spreading among the main European wire-drawing and wire products companies concerned.

REGIONAL DISTRIBUTION

The majority of the mills is concentrated in the highly industrialised regions: Ruhr district, Northern part of Italy, East and North of France, North East of Spain, West and South Midlands in the United Kingdom.

ENVIRONMENT

Costs arising from environmental protection are significant in the first processing of steel sector. They are, to a large extent, due to costs incurred by the treatment of smoke emissions from reheating furnaces, treatment of waste water from the pickling installations where they still exist and noise control in the production units.

Cold drawing

An innovation is this field has been the substitution of pickling by shotblasting in the descaling of raw material. This has eliminated problems of discharging acid pickling tank contents into local waterways. This industry is noiseless, except when charging raw materials in the drawing mill.

Cold rolling of steel strip

Pickling installations have disappeared from the factories in many cases because coils ordered from the steel industry are delivered pickled and protected. In the coating installations, it is necessary to aspirate smokes especially when strip receives a metallic coating. Today, smoke aspiration is also necessary for annealing processes. As for noise problems, cold rolling mills are not noisy except when charging the coil in the rolling mill.

Cold forming

Pickling installations have disappeared from the factories because coils ordered to the steel industry are delivered pickled and protected. Previously used acid waters were rejected from the pickling tanks in the rivers or the lakes. This industry is noiseless, except when charging the coils in the forming mill.

Wire drawing

Pickling installations have disappeared from most factories because the hot rolled wire ordered to the steel industry is delivered pickled and protected. In the coating installation, it is necessary to use fume extractors especially when applying metallic coatings. As for noise problems, cold wire drawing mills are noiseless except when charging the raw material in the drawing mill.

REGULATIONS

Trade regulations are a key concern for the EC producers of steel and articles of steel. Up to the end of March 1992, the Voluntary Restraint Agreements (VRA) provided for quotas by group of products for exports to the USA. Since then, trade barriers have hampered the penetration of EC exports into the USA. These barriers might be subject to revision in the context of the Uruguay round trade negotiations.

Different versions of a draft of "Multilateral Agreement on Steel Liberalization" have been subjected to negotiations between steel producing members of the GATT, particularly the USA, EC Member States and other partners who were under a VRA. Other meetings will be held in Geneva on the subject.

OUTLOOK

As consumption is likely to drop again due to recession, EC production is expected to decrease by around 8 % in 1993. A recovery of the first processing of steel sector can not be expected before the end of 1994 or the beginning of 1995.

In the medium term, the development of this sector will be characterised by a number of risks. The main risk is a further increase of imports from East European countries and continuing diminished opportunities to export to the USA. On the other hand, three main opportunities might be seized: first, in the medium and long term, the economic recovery in the CIS and East European countries; second, an improved access to the USA under GATT conditions; and third, a recovery in the worldwide economic situation.

Overview
NACE 224

The EC non-ferrous metals industry employed just under 300 000 people at some 3 000 industrial units in 1992. Having very few mining resources at its disposal, the EC is responsible for less than 3% of the mining production of the market economy countries for aluminium, copper, zinc and lead. Nevertheless, in refined metal production, the EC is a leader among the market economy countries with refined metal output of the four major non-ferrous metals (Al, Cu, Zn and Pb) representing 21% of the market economy country total. EC consumption of these same metals is even higher, representing 30% of market economy country demand. The EC non-ferrous metals industry is a net importer of raw materials : ores, concentrates and other raw materials for refining, and unwrought metals for processing. It is also highly dependent on secondary materials (scrap and residue), which constitute the only "domestic" resource of major size in the EC. In purchasing the raw materials which are necessary for its supplies, and, to a lesser extent, in selling its products outside the EC borders, the EC non-ferrous metals industry is very much present on the international market and subject to its price fluctuations.

INDUSTRY PROFILE

Description of the sector

The EC non-ferrous metals industry is widely diversified in terms of metals which are produced or processed. These include: the four major non-ferrous metals aluminium (Al), copper (Cu), zinc (Zn) and lead (Pb); the precious metals gold (Au) and silver (Ag); the platinum group metals platinum, palladium and rhodium; and the alloying metals and other minor non-ferrous metals such as molybdenum, vanadium, tungsten, manganese, cobalt, germanium, cadmium, etc. In view of the fact that the EC is relatively poor in mining resources, its industry is largely dependent on primary raw material imports, and also finds a significant proportion of its supplies in secondary materials (scrap and residue). It is consequently geared to primary and secondary smelter and refining metallurgy and to processing.

The most important consumer markets for the EC non-ferrous metals industry are within the EC itself, but outlets have also been found beyond EC borders. The industry is therefore involved in the international non-ferrous metals market, not only as a purchaser of raw materials, but also as a supplier of metals and processed or speciality products. In both these respects, it is extremely sensitive to the world balance of markets and to their often irregular cyclic developments. The EC non-ferrous metals industry operates in a highly competitive field and is supported by long years of technological expertise making it the world leader in various segments of its activities.

MARKET FORCES

Supply and demand

In terms of volume produced, aluminium, copper, zinc and lead are the dominant metals of the EC non-ferrous metals industry.

In the aluminium sector, EC production amounts to about 4 million tonnes of metal per year, which is equivalent to over 65% of EC demand. This represents only 16% of world production, however.

The aluminium industry is facing two serious problems: the recent massive increase in exports of metal from the CIS (Commonwealth of Independent States) and the ongoing tendency to move production units to geographic zones where energy (an important cost component) is both abundant and inexpensive.

The EC zinc industry produces about 1.7 million tonnes of metal per year, 30% of which come from the processing of ores and concentrates extracted in the EC - an unusually high ratio in EC non-ferrous metals. The EC zinc output represents 24% of world production and is approximately equivalent to EC market demand. The industry's major problem is unquestionably how to manage the long cycles which affect its market, with a certain degree of inertia in the adjustment of supply to demand.

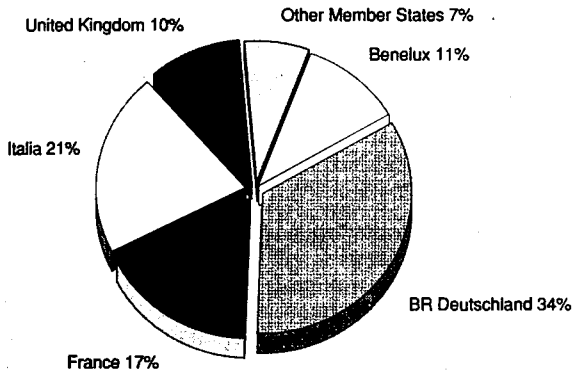
Figure 3: Copper semis
Breakdown of production by Member State, 1992



Source: World Bureau of Metal Statistics

In the copper sector, the EC produces about 1.2 million tonnes of metal each year. As the EC is the largest consumer market in the world, this production volume equals somewhat less than 45% of its requirements. To lessen its dependence on imported copper raw materials, the EC industry has considerably developed recycling technologies, and is therefore able to secure a significant amount of its supplies from scrap and residue within the EC itself.

Producing about 1.4 million tonnes of metal per year (one quarter of world production), the EC lead industry is able, for the most part, to satisfy the requirements of its market. The industry is experiencing problems due to inherent properties of the metal, the use of which, particularly in "diffuse" applications, is tending to decrease due to constraints connected with the environment. With this in view, the car battery sector is the only consumer industry capable of offsetting the losses of consumption in the other sectors, and increased recycling will further boost the share of secondary lead in the industry's supplies (more than 50%).

Figure 4: Refined metal (aluminium, copper, lead, zinc)
Breakdown of production by Member State, 1992

INDUSTRY STRUCTURE

Companies

The EC non-ferrous metals industry comprises about 3 000 companies, most of which are active in the processing sector. The upstream sectors of primary and secondary smelting and refining metallurgy are more concentrated.

Of the four basic non-ferrous metals - aluminium, zinc, copper and lead - the activities of the primary aluminium industry are strongly integrated.

In 1992, Germany accounted for 30% of the total EC refinery output of the four major non-ferrous metals, compared with 16% accounted for by France. Italy, Spain and the United Kingdom followed closely with 12 to 13% each, while Belgium and the Netherlands trailed behind. The breakdown of semis production by country confirm the leading position of Germany with about 34% of the total EC copper and aluminium semis output, followed by France and Italy.

Strategies

Recycling is an important aspect of the EC non-ferrous metals industry. "Secondary" materials, or recyclable scrap and residue, constitute an essential input for many of its metallurgical and processing concerns. Some of the latter's supplies depend entirely on access to secondary materials, although for most of the producers, recourse to secondary materials goes together with primary raw materials supplies for both economic and technical reasons.

As a result of the scarcity of European mining reserves, the EC non-ferrous metals industry has naturally developed much expertise in the processing of secondary materials. Recycling has therefore traditionally enabled the industry to reduce its dependence on raw materials imports by making use of the "surface" resources generated by the consumption of goods (old scrap) and by the industry itself (new scrap and metallurgical residue). Considerable investments are devoted to recycling, in terms of research, equipment and human resources, to such an extent that recycling is at the root of more than 50% of total EC production of the four major non-ferrous metals (aluminium, copper, zinc and lead), and accounts for more than 35% of their consumption in the EC.

ENVIRONMENT

More than ever, environmental concerns are impelling the EC non-ferrous metals industry to keep abreast of innovation in the recycling sector. Upgrading and processing scrap and metallurgical residue contributes to environmental protection, reducing the need for disposal capacities and dependence on non-renewable natural resources, and allowing considerable energy savings in the extraction and processing of metals (from 60% for copper to 90% for aluminium).

EC environmental policy emphasises integrated pollution control. Many of the issues related to the protection of the environment are of direct relevance to the non-ferrous metals industry.

Several legislative proposals currently being drawn up by the EC in the field of industrial pollution are based on the concept of "Best Available Techniques". This approach increases the need to analyse, in an integrated way, the impact of an activity on the whole environment taking into account the whole life-cycle of a product and managing the specific risks accordingly at each individual stage. Legislation on hazardous products is developing in such a way as to take into account the conditions of exposure over and above the intrinsic properties of products, which is a positive trend when it comes to assessing the real impact of heavy metals.

Waste management also raises difficult questions of direct relevance to the non-ferrous metals industry. A clear definition

of waste, as opposed to product or by-product, and legislation on the management and the control of movements of wastes are critical for the non-ferrous metals sector; non-ferrous scrap and residue are used as feed materials by the sector and are traded extensively on the international market. A competitive recycling industry and considerable energy-saving potential could be affected by limits on this trade.

Additional measures are under discussion concerning waste incineration and landfills. This is another area which could entail a large number of adjustments for the industry. Finally, the new directive on packaging waste will also have implications for the non-ferrous metals industry.

OUTLOOK

During the 1990's, the industry will have to face two major problems. The first is the opening-up of the economies of Central and Eastern Europe. The changed macro-economic position of the CIS and former COMECON countries now almost exclusively takes the form of movements of raw materials; consequently, the full weight of these changes is being borne first and foremost by the non-ferrous metals industry. For this reason, it is the EC's non-ferrous metals sector which is exposed to the chaotic exports of these countries.

The sudden, massive development of their exports on the international market and, first and foremost, on the Community market, is throwing the cyclic adjustments between supply and demand structurally off balance and jeopardising the very survival of companies.

In the case of aluminium for instance, the export level of the CIS has dramatically increased by more than 100% in 1991 and by a further 70% in 1992.

The current imbalance of the world aluminium market is the result of this increasing export flow, which appeared just over two years ago, and continues at such a pace that world market prices have dropped to unbearable levels which threaten the viability of the whole industry.

In the case of zinc and lead, the CIS has become a net exporter, whilst it was previously an importer trading more particularly with the COMECON countries.

In the case of non-ferrous metals semis, the countries of Central and Eastern Europe are exporting rapidly increasing tonnage at lower than prevailing market prices, fostering a severe downward pressure on the industry's revenues.

In view of these developments, it is vital to make every effort to ensure that the liberalisation of trade in the international markets develops on a more harmonious basis by placing greater controls on flows, by adapting qualities to international standards, by diversifying outlets and by taking into account the free-market mechanisms in which this trade will henceforth be conducted.

The second major challenge of the non-ferrous metal industry for the 1990's is the mushrooming legislation relating directly or indirectly to environmental protection, the development and effects of which ought to be managed not only with a view to maintaining the access to a whole range of raw materials (secondary materials) but also to maintaining future development of non-ferrous metal uses.

Written by: Eurométaux
The industry is represented at the EC level by: Association Européenne des Métaux (Eurométaux). Address: Avenue de Broqueville 12, B-1150, Brussels; tel: (32 2) 775 6311; fax: (32 2) 779 0523.

Aluminium
NACE 224

The aluminium industry is currently having to adjust to a sudden inrush of exports from the former Soviet Union which is throwing the cyclic adjustments between supply and demand off balance and pushing market prices down. The EC is particularly hit by this phenomenon, being the closest market outlet for CIS producers. However, the industry can count on sound fundamentals to overcome the current difficulties: there is still room for structural growth of demand from the major consumer industries (transportation, packaging and construction), and the producers are continuously improving and rationalising their installations with a view towards higher productivity and environmentally-sound production conditions.

INDUSTRY PROFILE

Description of the sector

The aluminium industry is the largest of the non-ferrous metal industries, and is the youngest as well in that aluminium smelting only began about a century ago. Lightness, longevity, resistance to corrosion, electrical and thermal conductivity and reflectivity make aluminium a popular choice in many sectors of the economy. Its aesthetic qualities, alloy possibilities and easy recyclability all add to this appeal.

The aluminium industry encompasses several activity segments, from bauxite mining and alumina production to primary and secondary smelting and metal processing into semi-finished products (bars, profiles, wires, sheets, foils, tubes, pipes, etc.) or specialty products (powders, special alloys, etc.).

As far as the EC major metal producers are concerned, those activities are integrated to a large extent but a number of EC concerns are focusing their activity on one particular segment only, such as recycling and secondary smelting or semis fabrication.

Recent trends

The EC aluminium industry directly represents a workforce of about 200 000 people and its annual turnover is in the order of 20 billion ECU. Total production of refined metal amounted to 3 642 400 tonnes in 1992, a slight increase over the 1991 figure. About 45% of this output is accounted for by secondary production, i.e., the recycling of scrap which is an activity that is regularly expanding.

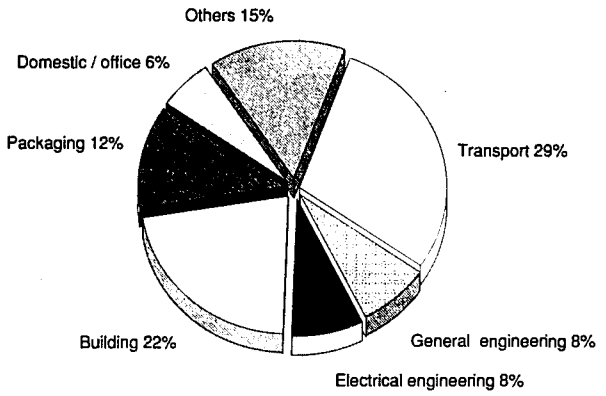
The EC consumer market for aluminium exceeds domestic supply, posting 5 740 000 tonnes in 1992. Demand develops along a rising trend of approximately 2.5% per year in the long term, with ups and downs in relation to business cycle fluctuations.

International comparison

In terms of primary metal production, the EC ranks second to the USA and its output accounted for 15% of the market economy countries' total production in 1992. Its secondary production is the highest, and hovered at more than 1 600 000 tonnes in 1992, about 60% above the US secondary output and 67% above the Japanese figure, representing 40 to 45% of the market economy countries' total.

Regarding the production of semis in 1992, the EC was responsible for approximately one-third of the market economies' output of rolled and drawn products, wires, cables and castings, with 5.5 million tonnes.

Figure 1: Aluminium
Total EC consumption by end use



Source: European Aluminium Association

Feed supply requirements of the EC primary and secondary metal producers are largely met by domestic alumina production and scrap recycling, but the total metal output falls short of the processing industry needs: it meets only 52% of EC demand, which is rising, while there has been hardly any growth of metal production capacity during the past years.

Foreign trade

As a result of the deficit in metal production capacity versus semis production capacity, the EC is a regular importer of unwrought aluminium. The EFTA countries traditionally accounted for about 45 to 50% of these EC imports with Brazil, Africa and Canada making up another 25% at least. Imports from the former Soviet Union, however, have made sharp inroads since 1991, increasing from about 60 000 tonnes per year in the late 1980s to 528 000 tonnes in 1992.

This phenomenon not only affected the import picture regarding the sourcing of the metal, but it also had a major disturbing impact on the overall market balance. The sudden and massive aluminium export flow originating from the CIS created a massive surplus which resulted in soaring inventories on the London Metal Exchange (LME) and unprecedented price collapse.

Regarding trade of semi-finished aluminium products, the EC was a net exporter after having met domestic requirements. This trade, however, is highly contingent on monetary phenomena and during the last years it was adversely affected by the development of the USD/ECU exchange rate.

MARKET FORCES

Demand

Aluminium is the material with the largest range of applications in the transportation, construction and packaging industries, the electricity sector, household appliances and the mechanical and agricultural sectors. Researchers and engineers have been constantly improving the material qualities; they have developed new alloys and production processes to open up new areas of application.

The transport sector is by far the largest client sector, accounting for approximately 29% of total EC aluminium consumption. It is the market segment with the best growth potential, as the strength and stability properties of aluminium

Table 1: Aluminium

alloys, combined with their lightness, make them an attractive material in all transport applications where reduced weight immediately translates into energy consumption savings. In the car industry for instance, 90% of cylinder heads and 25% of engine blocks, gear boxes and wheels are made of aluminium castings. Many other components are made of rolled and extruded aluminium products (radiators, roof racks, ABS components, licence plates, etc.). New casting and body-frame techniques should allow further development of the use of aluminium by the automobile producers, while this metal is already widely used for frame parts in air, road and rail transportation, as well as in commercial and cruise ships.

Construction is the second largest aluminium consumer sector, making up about 22% of EC demand for aluminium. Aluminium products such as profiles, claddings, window and door frames, staircases, roof panels, greenhouse frames, smoke and fire protection systems, etc., find markets not only in new buildings but also in the renovation of old ones. They are selected for a number of qualities such as resistance to corrosion, lightness, easy machinability, easy installation, low maintenance and repair costs and good formability and shaping along modern design requirements.

The third most important client sector for aluminium is packaging, which accounts for an estimated 12% share in EC aluminium demand. Packaging applications are numerous, not only in relation to foodstuffs and household products, but also for pharmaceuticals and cosmetics. Aluminium has the necessary properties to protect and preserve these goods and to ensure their safe transportation and distribution as well as their convenient use. Further progress can be expected in the use of aluminium in this sector as technical developments will further improve thin strip quality, down-gauging, lacquering and coating.

Supply and competition

The world aluminium market has deteriorated considerably since 1991, following three years of a more or less full balance between supply and demand.

The exports from former Soviet Union are playing a determining role under these circumstances. Until 1990, trade between the market economy and socialist countries resulted in net imports from the latter, which hovered around 300 000 tonnes per year. However, from 1991 onwards, the collapse of the Soviet system fundamentally changed the picture: the loss of the COMECON outlets, the sudden drop of domestic demand for military applications and a surge in the need for hard currency have propelled the former Soviet Union aluminium industry out into the international market. The export level of the CIS increased by more than 100% in 1991 and by a further 70% in 1992. The 1993 estimates show another 90% increase, up to a minimum of 1.4 million tonnes. As a result, primary aluminium inventories on the LME jumped from a mere 300 000 tonnes at the end of 1990 to five times as much at the end of 1992 (over 1 500 000 tonnes), and are heading for 2 400 000 tonnes by the end of 1993.

The EC market was the first to be hit, being situated nearest to the former Soviet Union. It is estimated that three-quarters of CIS exports have been directed to the EC; 1992 imports from the CIS were recorded at 528 000 tonnes.

The resulting price collapse on the LME seriously affected the profitability of the aluminium producers in the market economy countries and, in Europe, price levels have dropped by more than 20%. Production cutbacks have been implemented mostly in the EC where 13% of the 1991 production capacity was temporarily frozen in addition to the rationalisation cuts which had been planned several years ago.

INDUSTRY STRUCTURE

Companies

At the beginning of 1992, 22 primary aluminium smelters were operating in the EC, but the number of producer companies is, in fact, much smaller: the major ones being Aluminium Pechiney (F), VAW (D), Inespal (E), Alumix (I), Hoogovens (NL) and British Alcan (UK). Some of these companies operate plants in different EC countries or have subsidiaries or branches in other parts of the world.

The number of companies involved in aluminium processing is much larger, although there is a fairly good integration of the rolling activity into the smelting. The structure of the extrusion industry is, on the contrary, much more diffuse and much less integrated, with about 170 production sites scattered throughout the EC.

ENVIRONMENT

Aluminium has properties which make it increasingly competitive in an ecology-conscious world. As previously mentioned, its light weight is particularly effective in increasing energy savings in transportation applications. The high recyclability of aluminium is an additional important competitive advantage, particularly in packaging, but in other sectors as well. Currently, 45% of total EC aluminium output arises from scrap recovery. The proportion recycled varies widely among Member States, however.

Aluminium projects for packaging will be affected by the planned "EC Directive on Packaging and Packaging Waste" which is aimed at reducing the amount of waste and sets certain targets for recycling used packaging materials. In co-operation with other industries which are affected by this legislation, the aluminium industry is prepared to play a leading role in minimising the impact of packaging on the environment and is working together with the public authorities to reduce the quantity of packaging waste going to landfills. At the same time, the industry would like to emphasise packaging's contribution to product protection and the safe transportation and distribution of goods.

Aluminium, as a mineral, is available in almost unlimited quantities: 7% of the earth's crust is aluminium. In order to produce aluminium, the raw material, bauxite, has to be extracted in the same way as other ores which can have negative effects on ecological systems. Reclamation of mined land is a top priority for the industry; experiments and continuous efforts have yielded positive results in this area.

The reduction process for producing the metal consumes electricity and gives rise to emissions. The worldwide aluminium industry reduced its electricity consumption from 17 kWh (kilowatt hours) per kg produced in 1980 to less than 16 kWh at the beginning of the 1990s. Major emissions were reduced by a factor of four or more during the same period with the EC producers complying with stringent emission constraints.

OUTLOOK

Primary aluminium consumption in the EC is expected to grow at an average annual rate of 2 to 3% during the 1990s. Total aluminium demand, i.e. including secondary aluminium, should grow at a slightly higher pace as a result of the development of secondary uses, especially in the transportation and packaging sectors.

The packaging industry is expected to make considerable progress: the canning sector is far from maturity and will give rise to considerable demand.

In the transportation industry, the growth of aluminium demand is expected to arise chiefly from the private automobile sector, where aluminium can further contribute to weight reduction of cars, not only in castings, but also in wiring and body frames.

Increases in aluminium consumption in the construction industry is more a function of the recovery of that sector as such.

Production growth prospects are being considerably hindered by the recent development of CIS exports which are throwing the cyclic adjustments between supply and demand structurally off balance and jeopardising the survival of EC companies. As a result, at the end of 1993, the world market primary aluminium inventories were more than twice their normal levels and prices had dropped to such low levels as to discourage any new investment. Worldwide production cutbacks are necessary to reduce the huge excess supply hanging over the market; in this respect, any recovery in production growth is unlikely before the mid-1990s at the earliest.

Copper
NACE 224

The EC possesses few copper mine resources, but its copper metallurgical activities are highly significant. Its refining and semi-manufacturing capabilities have developed in line with the requirements of its large consumption, by using imported primary raw materials and domestic as well as imported scrap. EC copper demand follows the slow growth pattern of a mature market. Recycling is brought to a high level as, in many applications, copper can be reprocessed without loss of its intrinsic properties in many of its applications.

INDUSTRY PROFILE

Description of the sector

The core of the EC copper industry is in refining and semi-manufacturing, in comparison with which the EC mining capabilities are negligible. Since the start-up of mining at Neves Corvo in 1989, Portugal has become the only EC country with a sizeable copper mine production (149 000 tonnes of copper in 1992). At present, with about 159 000 tonnes of copper extracted from domestic ores in 1992, the EC accounts for no more than 2% of total Western world (referring to market economy countries) copper mine output.

Annual refined copper production in the EC slightly exceeds 1.2 million tonnes. The largest facilities are located in Germany, Belgium and Spain. Refinery output essentially arises from electrolytic processes, in the form of cathodes, that are often melted and cast on the premises into "refinery shapes", i.e. billets, cakes and wire-rods, principally. About 60% of the feed supplies to the EC copper refineries are purchased on the international market in the form of copper blister, anodes or scrap. The remaining 40% come from the refiners' smelting operations, whose feed consists of domestic and imported copper ore concentrates as well as copper bearing residue or scrap.

Refineries' products are the major feed material for the copper semis manufacturers. The EC copper semis output exceeded 4.4 million tonnes in 1992. Germany, Italy and France accounted for about 72% of EC output in this industry segment, with the Benelux countries, the United Kingdom and Spain making up most of the balance. The range of products supplied by the semis manufacturers is very wide. They consist primarily of rods, profiles, wires, sheets, strips, tubes, etc. which the end-users integrate in the manufacture of their own products, with applications in such varied sectors as the electrical industry, the automobile industry, construction, machinery, shipbuilding, the aviation industry, the precision instrument and optics industry, the watch and clock industry, etc.

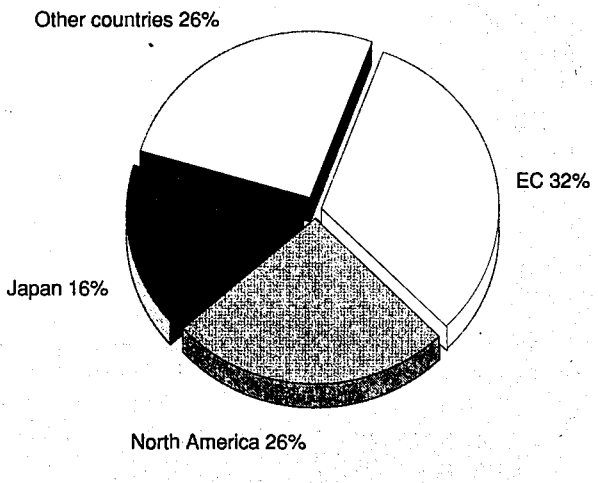
With an output which is three and half times that of EC refinery output, the EC copper semis manufacturers must turn to the international market to secure adequate volumes of feed supplies, together with the required alloying metals (zinc, tin and nickel for the most part).

The EC semis production is in excess of demand, and the EC copper semis manufacturing industry is a net exporter by about half a million tonnes per year.

International comparison

Nearly one third of the Western world's 8.9 million tonnes demand for refined copper, arises from the EC market. The EC consumed 2.9 million tonnes of copper, more than both North America's consumption of 2.4 million tonnes and Japan's consumption of 1.4 million. Germany, France, Italy, Belgium and the United Kingdom are each among the top ten consumers, together with the United States, Japan, South Korea, Taiwan and Canada.

Figure 1: Refined copper Consumption in market economy countries



Source: World Bureau of Metal Statistics, April 1993

In terms of production, the EC refiners account for about 14% of the Western world output. The EC's 1.2 million tonnes produced per year is slightly ahead of Japanese production of around 1 million tonnes, but behind North American production, of 2.7 million tonnes. In the coming years, however, EC production will most probably lose its second place ranking to Chile, whose production exceeded the 1.2 million tonne mark in 1991. For copper semis production, the EC countries hold by far the most dominant position worldwide, accounting for 39% of the market economy countries' 10.8 million tonnes output in 1991, the United States and Japan each contributing 23%.

MARKET FORCES

Demand

Though lacking copper primary resources, the EC has a strong copper industry, being the largest copper consumer market

in the Western world. Demand for copper mainly comes from the electrical and electronic industries, which absorb about 50% of total EC consumption. These industries use copper primarily as a conductor material to carry electricity, in the form of wires, profiles and rods made of unalloyed copper. The construction sector is the second largest consumer, it accounts for approximately 25% of total EC copper demand. A wide variety of semifinished products, of both unalloyed and alloyed copper, is used in plumbing, wiring, roofing, decoration, etc. The remaining 25% of demand arises mostly from industrial machinery and equipment, transportation equipment, consumer and general products.

Copper applications are well developed and the growth pattern of copper consumption closely follows the ups and downs of industrial activity at large. Copper demand on the EC market as a whole is growing slightly, as in most industrialised areas in the world. Trends differ from country to country, however. The economic revival in the former East Germany is expected to induce higher than average copper demand in the years to come.

Supply and competition

EC copper refining activity has been able to grow primarily by securing raw materials on the international market and making use of the domestic "surface mine" consisting of copper scrap and residue generated by consumers and production facilities. Access to feed supplies has become increasingly difficult over the past few years, however, as copper mining countries have developed their own refining facilities near to their mines, thereby reducing raw materials availability on the international market. Furthermore, competition by rapidly industrialising countries for copper raw materials has increased as these countries develop domestic refined output capabilities to satisfy the requirements of their consumer markets.

The EC copper refiners are confronted with heavy international competition for their feed purchases. This market is being negatively affected by competition from refiners in certain markets, mainly in the Far East, which benefit from protective measures. Furthermore, the movement of materials is increasingly being restricted by environmental regulations such as the Basel Convention. Any expansion of the copper refinery capacities in the EC is limited due to the difficulties of access

to feed supplies and the heavy investment requirements and operational costs arising from environmental protection measures, which are far above the average world standard. Hence, no major new projects in this field are due to reach completion in the short or medium term. The structural shortage of EC refined copper output versus the manufacturing industry's needs is therefore expected to continue.

EC copper semis output, on the other hand, is large enough to adequately supply the EC consumer market towards which it is primarily geared. Excess capacity should enable consumption growth to continue, while net export flows are maintained.

Prices

The London Metal Exchange (LME) quotations for copper cathodes generally govern the pricing on copper transactions made by the industry. The evolution of the LME copper price generally reflects the market balance at world level.

INDUSTRY STRUCTURE

Companies

There are ten major refineries in the EC, and it is estimated that the copper refining industry employed around 10 000 people in 1992. Two companies have facilities of over 250 000 tonnes refined copper per year capacity, Union Minière (B) and Norddeutsche Affinerie (D). Two others, Hüttenwerke Kayser (D) and Rio Tinto Minera (E), produce more than 100 000 tonnes per year each. Production capacity at the other facilities, in Spain, Italy, the United Kingdom, France and Belgium, ranges between 35 000 and 100 000 tonnes of copper per annum.

Upstream integration into smelting operations varies from one refinery to another. Some are fully or partially integrated whilst others have no smelting facility at all. One company only has a smelting capacity which significantly exceeds its refining capacity (Metallo-Chimique in Belgium). At EC level, there is a deficit in copper smelting capacity.

There is much less concentration in the copper semis manufacturing industry, where about 100 companies are involved throughout the EC, employing some 75 000 people. Altogether, these enterprises have a production capacity which is not fully used at present. Activity is developed where demand develops, causing widespread presence throughout the EC. The EC copper semis manufacturers turn to the international market not only to fulfil their feed supplies requirements but also to sell their surplus output, as their production is in excess of EC consumption.

ENVIRONMENT

Recycling constitutes an important component of the raw material supplies of the copper refining and manufacturing facilities. Copper can be recovered from many of its applications and returned to the production process without loss of quality in recycling. Having extremely limited access to domestic primary sources of copper, the EC industry has traditionally given much attention to so-called "surface mine", relying to a large extent on scrap feed to reduce the large deficit of its copper raw materials trade balance. Altogether, "secondary raw materials" account for about 40% of EC refined copper use. More than 40% of EC refined copper production arises from copper scrap recycling, and nearly 20% of copper semis output results from the direct use of scrap. In some cases, such as brass rods, for example, semis use 100% recycled copper.

The EC copper industry has developed advanced technologies and made considerable investments so as to be able to process a wide range of copper scrap, including complex, low-grade residues, and to comply at the same time with increasingly stringent environmental constraints.

Written by : Eurométaux
The industry is represented at the EC level by: European Metal Association (Eurométaux). Address: Avenue de Broqueville, 12, B-1150, Brussels; tel: (32 2) 775 63 11; fax· (32 2) 779 05 23.

Zinc
NACE 224

The EC zinc industry holds a top ranking position at world level, not only in terms of production, but also in terms of know-how and consumer market basis. It is currently confronted with the effects of serious market imbalance created by both the lasting slump in demand and the sudden inversion of net trade with the former COMECON countries and the CIS. Prices have dropped to unbearable levels which may lead the industry to fundamental restructuring.

INDUSTRY PROFILE

Description of the sector

Zinc is the third most used non-ferrous metal, behind aluminium and copper. Primary zinc production results from the processing of zinc ores into zinc concentrates of approximately 60% zinc content which are then smelted and refined into zinc metal. Zinc production may also arise from secondary source materials such as metallurgical residue, ash from galvanising, new and old scrap. Zinc production from secondary sources accounts for 6% to 7% of refined zinc output in the market economy countries.

Zinc is supplied to the market in various qualities and shapes: metal ingots of various grades (the highest quality is SGH i.e., Special High Grade which rates 99.995% Zn and the poorest is only about 98% pure); extrusion products such as bars, rods and wires; rolling products such as sheets and strips; casting alloys; powders; and chemical compounds, such as oxides.

End-uses include a wide range of applications, the most important one in terms of volume being steel protection against rust through galvanising for the automobile, appliance and building industries. Brass and other alloys, mostly for die-casting, are respectively the second and third major consumption areas with applications also in the building, appliance and car industries.

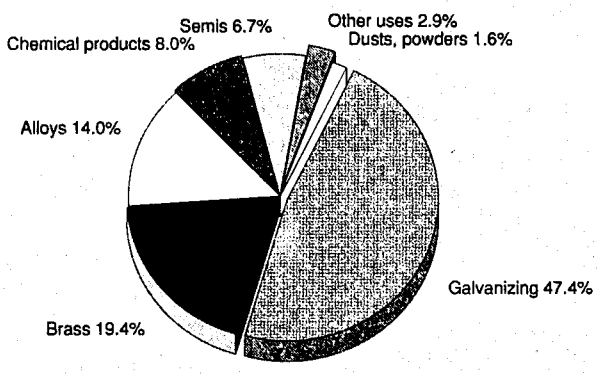
In 1992, the EC mine output dropped to 500 000 tonnes of zinc contained in concentrates as a result of the exhaustion of reserves and lower ore grades at some mining operations. Metal production reached a record level, however, at 1 827 000 tonnes zinc, while consumption of refined zinc stayed above the 1 700 000 tonnes mark which it had overstepped in 1991, accounting for 32% of the demand for zinc in the market economy countries.

International comparison

As shown in Table 1, and although it has been decreasing since the late 1980's, the EC production of zinc concentrates is still significant at international levels, ranking in 5th position behind Canada, Australia, Peru and the USA.

The EC mine output is essentially accounted for by Spain and Ireland. In the other countries, mining is gradually being phased out as mine reserves are exhausting and operations are becoming uneconomic due to the high cost for labour and environmental protection, and the relatively low grade of ores. Considering these factors, combined with the persisting low prices for metal, zinc mining in the EC is most likely bound for further decline in the coming years. While EC concentrates used to meet more than 45% of the EC refinery requirements 10 years ago, they now account for less than one third of EC requirements. The deficit is filled in by increased imports, as mine production is currently increasing in North America, Australia and some South American countries.

Figure 1: Zinc
Breakdown of consumption by end product, 1991



Source: International Lead and Zinc Study Group, January 1993 Bulletin

In terms of refined zinc production, the EC definitely stands as the world leader, way ahead of Japan and Canada which rank on the second and third position respectively. In 1992, the EC output reached a new record level with 1 827 000 tonnes metal, accounting for 34% of the market economy countries total of 5 435 000 tonnes.

The EC is also the major consumer area for zinc among the market economy countries. The 1 718 000 tonnes zinc consumed in 1992 was 67% above the second largest consumer market, the US, and 119% above Japan.

MARKET FORCES

Trade patterns

Zinc metal is a widely traded commodity as shown in Tables 4 and 5. Trade patterns have undergone a major change, however, with the opening of the "Eastern Bloc". In the past, the countries of Eastern Europe and the former Soviet Union were net importers of about 75 000 tonnes of zinc per year from the West. With the dismantling of the COMECON and

the collapse of the State monopolies, the trade flows which traditionally existed between those countries were dismantled. Also the rouble clearing system broke up, this phenomenon being accelerated, in fact, by the rouble devaluation. Simultaneously, major production outlets in defence applications vanished, and as the conversion of the industry from defence to consumer products is a slow process, metal demand has dropped dramatically.

Owing to these developments and the urgent need of these countries for "hard currencies", domestic production has been diverted from home markets and it is estimated that about 250 000 tonnes of refined zinc were exported from Eastern Europe and the CIS during 1992. Since the traditional 75 000 tonnes per year net export flow from the West to these countries dried up in fact at the beginning of the 1990s, it can be estimated that an excess supply of approx. 325 000 tonnes has consequently developed on the "Western" market.

The EC zinc industry used to export significant tonnage of zinc to the former Soviet Union and, to a lesser extent, Czechoslovakia on a regular basis, while imports from the COMECON remained negligible.

By the beginning of the 1990s however, a drastic change occurred in these trade flows: EC exports rapidly decreased from more than 46 000 tonnes in 1988 to a mere 6 000 tonnes in 1991, and imports from the CIS and the countries of Eastern and Central Europe mushroomed from about 1 000 tonnes in 1989-1990 to nearly 27 000 tonnes in 1991 and almost three times as much in 1992. Figure 2 shows this development: the net trade surplus of the late 1980's has turned into a major deficit in 1992. Within three years, not only did the EC zinc industry lose a market outlet which it had won owing to the superior quality of its product, but it also had to incur fierce inroads on its domestic market by lesser quality, low price imported zinc products.

Actually, the move of the CIS and former COMECON zinc industry towards foreign markets, in particular their currency owning EC neighbours, is a major blow to the balance of the zinc market. This has a direct impact on the supply/demand balance and resulting market prices; but, more perniciously, it also pulls the market value of zinc down as CIS and former COMECON zinc is offered at excessive discounts.

Prices

Zinc is quoted on the London Metal Exchange (LME) where demand and supply regulate the price. As production remained slightly below consumption in 1990 and 1991, the price drop, linked to business cycle factors, was stopped in 1992 and prices increased during the first months of the year until the rising of stocks forced them to drop back.

The doldrums of consumption worldwide and the exports from the former COMECON countries and the CIS created a surplus which has been heavily depressing price levels since October 1992. On 1 October 1993, zinc was quoted on the LME below USD 900 per tonne, which is the lowest level since 1987 in real terms.

INDUSTRY STRUCTURE

Table 6 identifies the EC top zinc metal refiners with reference to their 1992 production capacity. One plant was closed during 1992, the Union Minière's facility at Overpelt in Belgium.

The major EC refiners have a diversified product list as they process part of their unwrought zinc output into value added products such as rolling products (sheets and strips of various dimensions), casting alloys or speciality products such as galvanising anodes, powders and callots for the battery industry, wires for the surface treatment of steel, dust, and oxide. In the case of Union Minière and Metallgesellschaft, value added products account for 50% or more of the output value and volume. The most diversified product list is Union Minière's.

Backward integration at the mine level is limited, and none of the EC refiners can rely significantly on its own mines' concentrate supplies, if any. A significant share of zinc mine production in the EC is not dedicated to any particular refinery. In Ireland for instance, Tara Mines has no integrated refinery and sells its concentrates on the market, and the current major mining projects or developments in Ireland and Spain are not geared to the exclusive supply of any EC zinc refinery.

During the year, Belgium reduced its production as the result of the closure of one refinery while Spain and Germany increased their output by 33% and 11%, respectively.

ENVIRONMENT

According to the European Zinc Institute (E.Z.I.) the market economy countries consume about 2 million tonnes of zinc from secondary sources either as refined metal or as remelted zinc or through direct use of scrap at the fabricating stage. Estimates based on historical consumption and product life cycles indicate that a recovery rate of 80% has been reached. The recyclability of zinc is far advanced, not only as zinc metal, but also in several different forms.

Primary and secondary facilities in the EC operate under strict emission control and limit values with respect to air and water. The technology currently implemented is state of the art in this respect, making the EC production units the most environmentally friendly in the world.

OUTLOOK

The oversupply of zinc metal, due to reduced consumption and increased exports from former Eastern Bloc countries, has resulted in extremely low prices which do not cover production costs for most mines and smelters, especially in the EC.

The integration of the former USSR and COMECON countries to the international zinc market appears to be the major determining factor for the future. It might lead to some fundamental restructuring of the industry worldwide, but the EC is more specifically affected as its neighbouring position makes it the closest target for the newcomers' exports. Meanwhile, the resumption of consumption might bring some relief in absorbing the current market surplus, although zinc is a mature metal and demand growth rates are, therefore low.

Written by: Eurométaux
The industry is represented at the EC level by: Association Européenne des Métaux (Eurométaux). Address: Avenue de Broqueville, 12, B-1150 Brussels; tel: (32 2) 775 63 11; fax: (32 2) 779 05 23.

Lead
NACE 224

The EC possesses few lead mine resources, but its lead metallurgical activities are powerful and competitive. During the last 10 years, EC consumption and production have experienced only modest growth, resulting in a decrease in the EC's share in world markets. Considerable restructuring has been taking place in the lead refining industry and in its major client industry, the battery sector. The restructuring will require the building up of new relationships between suppliers and consumers. Secondary smelting is an increasingly important source of lead, particularly as environmental regulations become more stringent.

INDUSTRY PROFILE

Description of the sector

Lead is the most abundant heavy metal in the earth's crust. It is normally found in mixed ores where it is associated with zinc and small amounts of silver and copper. Lead's softness, low melting point, chemical reactivity and resistance to corrosion give it great functional value, both in its pure form and in alloys or compounds.

Mine production of lead has decreased slightly, as a result of the growing importance of recycling. Refined lead is derived from two sources: primary material in the form of lead ores and concentrates, and secondary material in the form of scrap and residue. Primary production requires the smelting of lead-bearing ores to produce refined lead bullion.

Secondary production may also require refining facilities if the secondary raw materials contain unwanted compounds. As a result of the environmental and other regulations aiming at the recycling of lead-bearing scrap, the secondary refining industry now supplies more than 50% of the lead consumed in the market economy countries. As lead acid accumulators in cars are the main source of scrap for secondary refining, this proportion will increase as the world car population increases.

Primary refining is closely linked to the economics of mining lead-zinc orebodies. The bulk of lead mine production comes predominantly from operations in which zinc, and silver to a lesser extent, are the principal profit makers; less than a third comes from the actual lead ore mining operations in which lead is the principal metal recovered.

The most important consumer of lead is the battery industry. Other uses for lead include, petrol additives (tetraethyl lead), paint, shot, glass, ceramics and plastics.

Recent trends

Consumption of lead rose significantly worldwide in the 1980's. From 1982 to 1992, consumption in the EC Members States has risen by some 13% at an average annual rate of 1%.

The EC is not a major mining region - only 123 300 tonnes of lead were mined in the EC in 1992. Metal production, however, is much higher and amounted to 1 372 000 tonnes in 1992, of which 50% came from secondary feed materials. The industry is responding effectively to potential ecological problems by recovering ever increasing amounts of lead, resulting in a steady decline of primary production.

MARKET FORCES

Demand

Consumption of lead generally follows the business cycles, increasing during periods of high economic activity and falling during periods of recession. So was it in the EC in 1991 and 1992 with the result that the average annual growth rate recorded over the 1980's dropped from 1.5% to 1% per year.

Regional trends in consumption are variable. For example, the share of the EC consumption relative to consumption in the market economy countries has fallen in recent years. The same is true for the USA. In contrast, most other areas of the world have increased their share in world consumption in recent years. Apart from the major influence of business cycles, consumption trends are largely driven by regulatory control on lead products (e.g. gasoline additives) and the cost and availability of substitutes.

Demand from the battery industry will continue to underpin consumption, largely as a result of rising demand for lead acid batteries for the automobile industry. Between 1979 and 1991 lead consumption in the battery industry increased by almost 43%, at an average annual rate of 3.25%. The vast majority of storage batteries are used in starting, lighting and ignition (SLI) applications in motor vehicles. Demand for such batteries depends on the number of vehicles built and, more importantly, on the number of batteries required to replace exhausted units. Demand has also increased for other types of batteries, such as those used in load levelling/peak sharing applications, as well as in electric-powered vehicles and standby power applications.

Environmental constraints and competition from other metals or materials have resulted in a stagnation or decline of lead demand in most of its other end-uses. Consumption rose only marginally in rolled and extruded products, shots, pigments and other compounds: these sectors contributed little to overall growth. In applications such as cable sheathing, alloys and gasoline additives, consumption has declined markedly: between 1979 and 1991 consumption in these three sectors fell by nearly 55%. By the end of 1991, they accounted for only 9% of the total, compared with 23.2% in 1979.

In the case of cable sheathing and alloys, lead has suffered both from the substitution by other materials and from the introduction of new technologies. Increasing awareness about the impact of polluting emissions on the environment is the main reason for the drop in lead consumption in gasoline additives. Over the period 1979 to 1989, consumption of lead for this end-use fell by two-thirds, and it only remains of any significance in the United Kingdom.

Supply and competition

The market for primary lead and lead products is international in scope. Large consumer markets such as the EC are significant importers of lead concentrates and bullion. North America and Australia are large exporters of the same after having met their own market's requirements. The market for secondary refined lead is more regional as secondary refining is predominantly carried out in the country where the scrap arisings occur and production is supplied directly to the neighbouring market.

With the growing importance of secondary refining from an environmental standpoint the major firms in Europe have a vested interest to be active in both primary and secondary refining. These companies are best placed to finance the investment that will be required to conform with increasing environmental legislation.

With the breaking down of the COMECON nations and the former Soviet Union in the early 1990's, increasing tonnages of refined metal of good to mediocre quality are being exported from these countries, disturbing the prevailing trade patterns on the Western European market since it is the closest outlet to the now liberalised Eastern producers. The flow of Eastern material has enhanced the downward pressure on prices which were already suffering from the slump in demand and pushed the metal stocks on the London Metal Exchange (LME) to sky-high levels. Competition from Eastern Europe is all the more damaging to the EC industry because Eastern material prices do not take into account any comparable costs with respect to environmental protection, transport, salaries, while the EC producers bear the full brunt of heavy investments in R&D and the implementation costs of anti-pollution measures and environment friendly technologies. At the resulting current price levels, the viability of the industry is at stake and even secondary refining, though directly beneficial to the environment, is seriously threatened because it is no longer economic.

INDUSTRY STRUCTURE

Companies

Within Western Europe there are ten primary smelter/refiners, ranging in size from 75 000 tonnes per year to 200 000 tonnes per year.

The primary refineries are mostly multinational, and are spread throughout UK, Sweden, France, Germany, Belgium, Spain, Austria, Yugoslavia and Italy. All plants, with the exception of Britannia Refined Metals (UK), smelt lead or lead/zinc concentrates before refining lead bullion. Britannia Refined Metals refines only crude lead bullion imported from its parent company MIM in Australia.

The secondary industry is characterised by a large number of smaller refineries, many of which are independent. There are approximately thirty secondary smelter/refiners in Western Europe producing from 5 000 to 65 000 tonnes per year. They recycle and refine scrap generated in their local area. The number of these refineries is decreasing as the large multinational companies, and the major battery manufacturing groups as well, acquire the smaller secondary facilities or set up their own new recycling operations.

The largest primary smelters/refineries in Western Europe include Britannia Refined Metals (UK), Metaleurop (F and D), Metallgesellschaft (D), Union Minière's Business Unit Hoboken (B), Boliden Mineral (S), Enirisorse (I) and Penarroya-España (E). With the exception of Union Minière's Business Unit Hoboken, all of these primary refiners are involved in secondary recycling/ refining as well. Other companies include: STCM (F), the battery producers CEAC (F) and Varta Batterie (D), Fonderie-et-Manufacture des Métaux (B) and H J Enthoven (UK).

Strategies

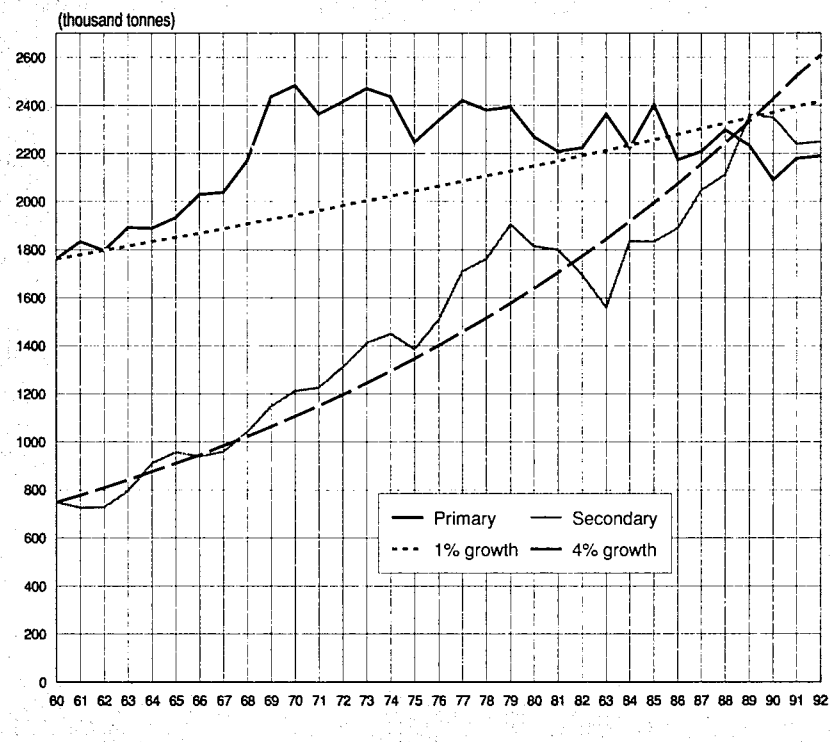
During the last three years, there has been considerable restructuring within the overall lead refining industry and its major outlet, the battery industry. The effects of such restructuring so far can mostly be noticed within the battery industry, with the emergence in Europe of five major battery groups. These groups have become very powerful in their bargaining capabilities and some are competing with the lead refiners by integrating their battery manufacturing facilities into lead recycling/refining operations: they process their own scrap collected from their own collecting networks for spent batteries, which are returned through their distributor networks.

In the future, secondary refiners will have to work more closely with the major battery companies in order to maximise the recycling rate of battery scrap and to comply with national legislation implementing the EC Battery Regulation. Government approved collection schemes will be set up hopefully in close collaboration between the refiners and the battery manufacturers. Such schemes should be harmonised throughout the EC to allow fair competition on supply of lead and lead alloys between EC Member States and other European countries with similar schemes.

Environmental legislation will also require investment to reduce lead in air emissions. In recent years several new technologies have been developed and implemented which offer more efficient, environmentally acceptable methods of smelting lead concentrates. These new technologies should rapidly gain ground because of their ability, in most cases, to handle secondary feed material as well. They integrate the smelting and refining operations, offering many advantages such as: economies of scale; synergy of the smelting and refining processes; concentration of lead production in fewer areas and the closure of environmentally unacceptable plants; and lower lead emission levels.

It seems certain that the new pyrometallurgical technologies will further increase their share of total lead smelting capacities over the next decade at the expense of the conventional blast furnace. Ultimately, looking further ahead, hydrometallurgical processes will probably make their way through, there are already signs of such development in the treatment of battery paste, in fact.

Figure 2: Refined lead
Production of primary and secondary refined lead



Source: Billiton - Enthoven Metals Ltd.

Undoubtedly, the number of operational refining sites will decrease in Europe: consolidation and rationalisation are bound to take place as companies are confronted with facts and figures relating to possible return on investments.

ENVIRONMENT

As lead is a toxic metal, it ranks high among environmental concerns. The metal has relatively little impact on ecosystems though and there has been much debate about the levels of lead which can actually cause harm: general policy is normally to restrict emissions to the lowest practicable levels given the state of technology, and recycling is normally conducted whenever appropriate and economic. Most control measures are concerned principally with human exposure (humans are most affected by lead exposure) although there are certain instances in which animals can be exposed to environmental lead.

Lead is increasingly recyclable in its major applications. Batteries, which created 49% of lead consumption in Europe in 1990, are recycled with more than 90% efficiency. Indications are that this efficiency rate should further improve in the future. Among the other uses, tetraethyl lead (petrol additives), pigments and shots have declined dramatically or disappeared completely over recent years. This has been partly as a result of environmental legislation (e.g. tetraethyl lead), partly as a result of voluntary reductions by industry (e.g. lead shots for fishing weights) and partly as a result of substitution (pigments). As far as the other uses are concerned, lead is mostly used in products from which it cannot be easily extracted such as glass, ceramics, plastics, so even in these cases there is minimal risk for ecological impact. The net result is that the uses of lead which can really affect the environment are steadily disappearing.

During the production and processing of lead there are inevitably occasions for emissions. These are kept to a minimum through the use of pollution control technologies and the strict compliance to legal limit values on the amounts which are allowed to escape. Airborne emissions are controlled through efficient filtration systems and through the implementation of design and management systems which prevent uncontrolled losses to the environment. Aqueous effluents are treated before discharge to ensure their compliance with limits imposed by water authorities. Finally, solid residues may not be disposed of indiscriminately. Depending on their lead content or their ability to dissolve into the environment, residues are designated as safe or hazardous and disposed of in authorised landfills.

REGULATIONS

Regulations affecting lead fall into three main categories: occupational exposure, emissions from plants and controls on products. Occupational exposure is addressed under EC Directive 82/605/EEC of July 28, 1992 on the protection of workers from risks related to exposure to metallic lead and its ionic compounds at work. This directive sets allowances on the level of lead in air in the workplace and on certain biological indicators which reflect the level of exposure of individual workers. The limit values are complemented by rules on the protection of the workforce providing for the use of protective clothing, respirators, washing facilities or specifying rules on eating, drinking, smoking, etc.

Emissions from lead works are normally controlled by means of national regulations relating to air or water. There are no universal European limits in these areas. However, lead in the general atmosphere is limited under Directive 82/844/EEC of December 3, 1982 which sets a limit for levels of lead in air throughout the EC. Levels of lead in water are also controlled in a number of directives relating to water depending on its type and use e.g., water intended for human consumption, water for bathing, fishing waters, etc.

Regarding products, regulations do apply to a number of non-recoverable uses of lead. The use of lead in petrol, for instance, is controlled under Council Directive 85/210/EEC of March 20, 1985. Several Member States have their own regulations which impose tighter limits or which require the availability of unleaded petrol for vehicles introduced on to the market after a certain date. Another area in which legislation is applied, is the use of lead in paints, which has been restricted under various national regulations for many years. Recently, lead carbonates and lead sulphates have been also controlled under the EC Directive, 89/667/EEC of December 21, 1989. This directive prohibits the sale of lead pigmented paints and prohibits their use in domestic buildings.

OUTLOOK

The balance of primary output versus secondary output and the cost of complying with environmental legislation will determine the strategy of the companies for the future. The price of lead will obviously be a major factor, especially as it is suffering the downward pressure caused by the exports of lead from the countries of Central and Eastern Europe and the CIS. The way in which these countries will integrate into the international market in the coming years will determine the future development of the whole industry. It is crucial to monitor such an integration with a view to ensuring that competition takes place on an equal footing and that environmental challenges be faced by the Eastern producers as well.

Secondary refined lead will grow in importance in the medium and long term, and it is expected that by the end of the century it will represent almost 60% of the supply to the market.

The battery sector will remain the major lead consumer and its share in total demand will further increase. By the end of the century, it is expected that the battery sector will absorb almost 70% of all lead consumed.

Unfavourable business cycle factors and steadily increasing LME stocks have pushed the price of lead to a seven year low. In these circumstances, secondary refiners are unable to purchase feed at levels anywhere near those needed to give realistic returns and it is no longer economic for merchants to handle scrap batteries. Governments are being made aware of the environmental implications of this development but it would seem that any action is likely to be too late.

Primary producers are suffering from depression in both the lead and zinc markets. The only way they can survive is to increase production with the aim of lowering their unit costs. This has been taking place to some extent, but is only adding to the vicious circle.

Nickel
NACE 224

The nickel industry worldwide has developed a highly concentrated structure: about 60% of the metallurgical production of nickel in the market economy countries comes from only four companies. The EC is the third largest producing area for nickel products, with three companies operating on its territory, while two other companies have facilities in Northern Europe (in Norway and Finland). With regard to nickel mine production, only two EC companies operate mining activities, one in Greece and the other in the overseas territories of France in New Caledonia. Nickel demand is still on a rising trend, determined to a large extent by the increase of consumption in the stainless steel sector, particularly in the newly industrialised countries (NICs).

INDUSTRY PROFILE

Description of the sector

The EC nickel industry processes raw materials, either nickel ore or intermediate products, into nickel products which are then used by the nickel consuming industries. The range of products for nickel is wide: ferronickel, produced by Eramet-SLN (F) in New Caledonia and Larco (GR) in Greece for use as a charge product in the fabrication of stainless steels; metal, produced by Inco Europe (UK) and Eramet-SLN (F) in the form of cathodes for use as an alloying element in various applications (such as superalloys); salts, produced by Inco Europe in the United Kingdom and Eramet-SLN in France for use mainly in the catalyst and electroplating industries.

Recent trends

Since the mid-1970s, nickel consumption in the EC has increased at an average annual rate of 2.4%. A record level of 238 000 tonnes was reached in 1990, but consumption fell by 10% in 1991 and by a further 8% in 1992, essentially as a result of poor economic activity. The metallurgical production of the EC also grew steadily during the 1980s, reached a peak in 1988 with 89 000 tonnes but decreased slowly thereafter, down to 83 000 tonnes in 1992. The number of employees in the EC nickel industry decreased by one third between 1982 and 1992, although mine production almost doubled and metallurgical production increased by more than 30%.

International comparison

Among the top four companies producing nickel in the market economy countries, one is an EC corporation, Eramet-SLN in France, another owns a factory in the EC, Inco in the United Kingdom, and a third has production facilities in Northern Europe, Falconbridge (Canada) in Norway. Table 4 shows the estimated share of the EC in world production of refined nickel. If reference is made to the market economy countries only, the EC share has diminished significantly over the past 16 years. The Canadian share decreased even more during the same period of time.

In 1992, nickel consumption in the market economy countries reached 619 000 tonnes, with the EC representing 32% of total consumption. This share of one-third has been relatively stable since the 1970s. Asia, however, increased its share of consumption from 24% in the mid-1970s to 33% in 1992, the USA's consumption decreased from a 31% share in 1976 to 20% in 1992.

MARKET FORCES

Demand

Nickel consumption in the market economy countries grew at an annual rate of 2.1% between 1976 and 1992. EC consumption increased by 2.4% per year during this period, while Japanese consumption rose by 3% per year, and consumption in the USA decreased by 1.7% per year. East Asian NIC were the fastest developing area from 1986 to 1992 with an average annual growth rate of 9.2% as new nickel consuming industries were being installed, especially in South Korea and Taiwan.

Among the various nickel uses, stainless steel plays the leading role. Nickel consumption for stainless steel represents more than 60% of total nickel demand (63% in the EC). It grew yearly at a rate of 4.3% between 1976 and 1992, while nickel consumption in the non-ferrous industry declined at a rate of 0.5%. There are two primary reasons for this rapid evolution of nickel demand in stainless steel. Firstly, the production of nickel-bearing stainless steel (austenitic) rose at a higher rate than that of nickel-free stainless steel (ferritic). Secondly, due to the improvement of the yield in stainless steel production, the rate of growth of primary nickel consumption (4.3%) was just a little higher than that of secondary nickel (4.1%).

Production of nickel-bearing stainless steel is influenced both by the overall production of capital goods and by the intensity of use of nickel-bearing (austenitic) stainless steels in the capital and consumer goods sectors.

Over the past 15 years, the use of austenitic steel has increased at a higher rate than industrial production in the OECD coun-

tries. This increased use is mainly due to the technical qualities of austenitic steel, which, for many applications, has no acceptable substitute.

Recent developments in export markets show an extremely strong growth of nickel consumption in East Asia. Korea and Taiwan were the first markets to experience rapid growth, followed by China. The Eastern European countries might become the next boom area.

Supply and competition

At the end of the 1960s, scarce nickel supplies led to a boom in investments by newcomers. Production, however, did not start until the mid-1970s. Most of these projects were located in NICs where large nickel deposits were found. As a result, Canada and New Caledonia, which were responsible for around 75% of the nickel mine production in the market economy countries in the early 1970s, accounted for only about 45% in the early 1980s.

Up to 1970, about a dozen firms were engaged in nickel production, and increases in output were the result of expanding and modernising existing installations. At that time, all producers were working at near capacity level. Maximum capacity was reached at the beginning of the 1980s, but because of low demand, and subsequently very low nickel prices, producers had to significantly reduce their level of activity after 1975, bringing about a decrease in the rate of use of production capacity. Several facilities closed after 1984, as production costs were too high to enable firms to survive the depressed period of the first half of the 1980s. Real capacity also decreased due to a lack of maintenance at most of the plants still in use.

Considerable progress in productivity has been achieved since the 1980s, including a significant reduction in energy consumption. This has enabled some companies to reduce production costs so that they are in a better position to cope with the economic ups and downs which are affecting the capital and consumer goods sectors, the major driving forces of nickel demand. Many companies still suffered heavy losses, however.

Production costs decreased in constant terms, and the average break-even price for low cost producers, which was over 6.5 USD per kg at the end of the 1970s, decreased to a level

Table 4: Refined nickel
EC share of world production, 1992

(thousand tonnes)

EC	51.5
World	837.8
EC share (%)	6.1

between 4.5 USD and 5.5 USD per kg by the mid-1980s. The most competitive producers remained the sulphide producers in Canada and Australia which were less affected by the high price of oil at that time. After 1985, production costs increased significantly. Producers treating sulphide ore (e.g. Inco) faced increases in wages and social benefits for their workers and lower ore content in their mines due to the lack of extensive mining development work.

Producers processing oxidised ore, including the EC companies Larco and Eramet-SLN, also suffered an increase in costs, but to a lesser degree. The decrease in the price of oil and the depreciation of some currencies in Indonesia, Columbia and the Dominican Republic helped these producers to reduce the gap with the sulphide producers, and in some cases to take the lead in terms of costs. The break-even price of the low cost producers was estimated at the beginning of the 1990s at 6.5 to 7.5 USD per kg, while the average price for the whole industry was between 7.5 and 9 USD per kg.

As nominal production capacity was increasing in the market economy countries, net imports from former COMECON countries were also markedly increasing, particularly from the Federation of Russia, which rapidly increased its exports to the West and especially to the EC, eagerly striving for hard currency revenues. As a consequence, the share of net imports from COMECON countries rose from less than 11% of EC consumption during the 1981 to 1986 period to 19% during 1987 to 1992. The future trend of deliveries from the CIS will have a vital influence on the supply/demand balance over the coming years.

INDUSTRY STRUCTURE

Companies

Only three companies operate nickel production facilities in the EC. Inco Europe Ltd, a subsidiary of Inco Ltd of Canada, processes matte, an intermediate product supplied by its mother company, into pure nickel and nickel salts. Inco Europe Ltd markets its production throughout the world, although Europe is the preferred market owing to its proximity. The American market is primarily supplied by Inco Canada.

Eramet is a 70% subsidiary of ERAP, which is the holding company of the French state-owned company Elf-Aquitaine. Other shareholders are Elf-Aquitaine with 15% and Imetal with 15%. Eramet is the mother company of Le Nickel-SLN in New Caledonia which produces nickel matte and ferronickel. Its plant in Le Havre-Sandouville was built in 1978 to replace the facility founded in Le Havre in 1888. Matte shipped from New Caledonia is processed in Le Havre into pure nickel and salts. Eramet's sales program worldwide therefore includes a range of products i.e. metal, ferronickel and nickel salts.

Larco, currently a state-owned company in Greece, was founded in 1963 for the mining of nickel ores and their processing into ferronickel. Due to the very small size of the Greek market, production is almost entirely intended for export. The EC market is the prime outlet for the Greek producer.

Strategies

Nickel demand grows steadily and such a growth must be met by a corresponding sustained increase in nickel supply. To allow for such a development, investment in additional capacity at the lowest possible production costs must take place. Expansion at the existing mining and smelting facilities and improvements in the productivity are preferable to opening and building new mines and production plants.

Apart from economic considerations, long term stability of adequate supply can best be provided by giving priority to investments in integrated operations. Integrated nickel producers are not dependent on an external supply of nickel ore, and have their own refining facilities with a diversified range of products. They are therefore, less dependent on cyclical market developments and are better able to withstand periods of recession. The nickel producers must keep abreast of market developments: close cooperation between the nickel producers and consumers is necessary for both industries.

REGIONAL DISTRIBUTION

The nickel market is worldwide, and to a large extent, nickel mining areas do not correspond to nickel consuming areas. Major nickel consuming countries are net nickel importers, either in the form of nickel ore and intermediate products or in the form of finished products.

Nickel consumption in the EC represents approximately one-third of consumption in the market economy countries, but the production of the three EC nickel companies accounts for only 14% of the corresponding output.

Germany is by far the largest nickel consumer market in the EC, representing 36% of total EC demand, but it has no domestic production. France is the second largest market, with a share of around 18%. Other nickel consuming Member States are the United Kingdom and Italy with respectively 14 and

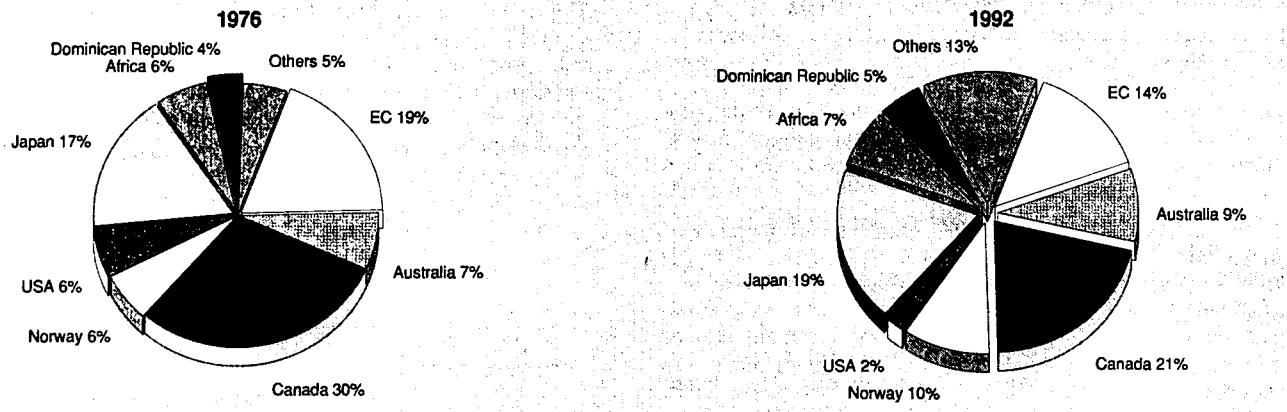
Figure 2: Nickel
Market economy countries nickel consumption by area



Source: MARKETING ERAMET

15%, Belgium 10% and Spain 7%. The other EC countries are not substantial consumers of nickel.

Since the mid-1970s, nickel consumption in the EC has grown by 2.4% per year on average, although growth rates vary widely among the various Member States. Belgium with a 14% increase per year and Spain with a 5.8% increase per year experienced the highest expansion in consumption, while demand in France increased by only 0.8% per year and the United Kingdom's demand increased by only 0.3% per year.

ENVIRONMENT

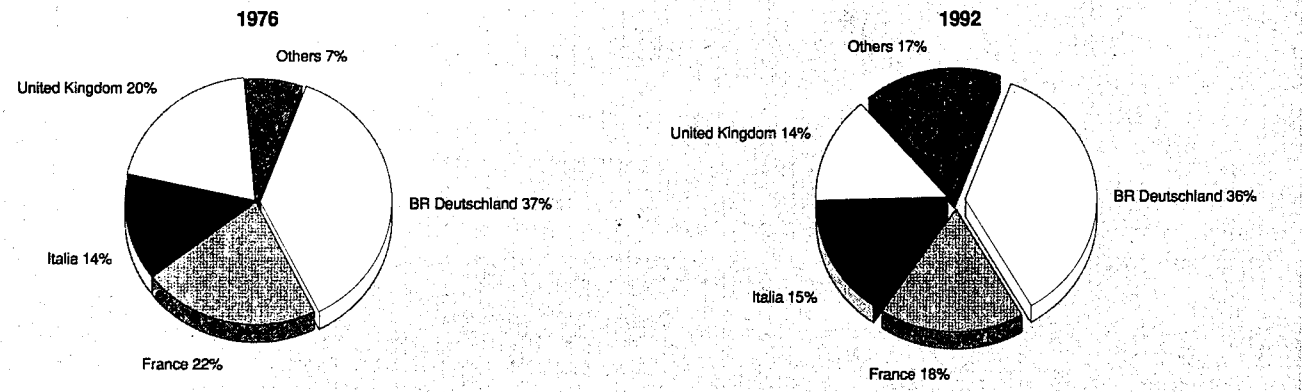
Although nickel itself does not create environmental problems, some nickel compounds have ecotoxic (dangerous to the environment) and/or toxic (dangerous to humans) properties. Most of the nickel producer and user industries have already reduced their emissions to an environmentally acceptable level. At the EC level, atmospheric emissions have been controlled and reduced by means of the installation of efficient filter systems. Liquid effluents have been under control for many years now, and their levels comply with regulatory limit values. Solid waste containing water-soluble compounds such as nickel-bearing metallic hydroxides is still a concern. In most cases, however, it is disposed in controlled landfills. Nickel-bearing recyclables (stainless steel and alloy scrap, spent catalysts, etc.) are not an area of concern with respect to their nickel content.

REGULATIONS

In spite of minimum specific risks for the general environment, nickel and some of its compounds are facing increasing regulatory pressure at the EC level. Skin-contact allergy is a clearly established risk linked to direct and prolonged exposure to nickel in some common products. The European nickel producers support the efforts of the EC Commission to establish rules for the protection of the fraction of the population at risk. Nickel is suspected of inducing respiratory cancer in workers in certain nickel refining processes. In addition, the classification of some nickel compounds as human carcinogens (Directive 67/548) will have a serious impact on industry and will require protective measures for workers exposed to these substances (Directive 90/548). This classification has been requested by the industry.

The nickel industry is also concerned about the controls which will be applied to transfrontier shipments of "wastes" in ac-

Figure 3: Nickel
EC apparent consumption



Source: MARKETING ERAMET

cordance with the Basle Convention, and therefore strongly supports the approach adopted by the OECD for "wastes destined for recovery operations". In addition, it also urges the EC Authorities to model their new "Shipments of Wastes" regulation on this OECD approach.

OUTLOOK

Nickel consumption should continue to grow at a relatively sustained rate in the medium and long term, although it will fluctuate greatly in the short term due to cyclical variations in general economic activity.

Many factors could result in the continued development of nickel consumption: growth of nickel consumption in industrialised countries in connection with the development of new applications, most of them linked with the protection of the environment (Clean Air Act in the USA, Earth Summit of Rio de Janeiro); booming demand for nickel in the newly industrialised countries (NICs), especially East Asian NICs, and in some Latin America countries due to the construction of new plants and the need for durable goods; reconstruction and reshaping of a civil industry in the former COMECON countries.

Production areas which show the greatest growth potential for the 1990s are located in the countries with the largest and richest mines, especially New Caledonia, Australia and Indonesia.

The recent creation of the "International Nickel Study Group" should improve the availability of reliable statistical information on the market thanks to the increased cooperation of the participating governments. This should help the decision process at all industry levels and significantly contribute to the transparency of the market.

The industry is represented at the EC level by: Association Européenne des Métaux (Eurométaux). Address: Avenue de Broqueville 12, B-1150 Brussels; tel: (32 2) 775 63 11; fax: (32 2) 779 05 23.

Precious metals
NACE 224

The EC has the largest refining and fabricating capacity for precious metals in the world, even though its actual mineral resources of such metals are very limited. The recycling of precious metals from scrap and industrial residues has always been an important raw material source for the EC industry. EC environmental legislation now requires all new petrol driven vehicles to be fitted with catalytic converters to reduce pollution. This has stimulated EC demand for platinum group metals.

INDUSTRY PROFILE

Description of the sector

Precious metals include such well known metals as gold and silver and the six platinum group metals: platinum, palladium, rhodium, iridium, ruthenium and osmium.

Precious metal activities can conveniently be separated under five headings: mining; refining and production of metals in unwrought forms; trading, i.e. commodity dealing, investment bars and coins; fabrication, i.e. processing, alloying and conversion of the metals into wrought or semi-manufactured forms, chemical compounds, catalysts and industrial components; manufacturing, i.e. production of goods for sale at retail level such as. jewellery, silverware etc.

Recent trends

Mining

The twelve countries of the EC now possess within their borders relatively insignificant sources of gold and silver and practically none at all for the platinum group metals. What primary precious metals are actually extracted from ores mined in the EC are mainly by-products of copper or lead and zinc mining.

Of the EC Member States, only Spain, France and Portugal appear in the world list of gold producing countries, and in 1992 they yielded only about 0.5% of total world output of 2 217 tonnes. Seven EC countries produce silver (Table 1), but only to a very limited extent: total EC production represents only 2.5% of total world annual output.

Refining and recycling

The refining of gold, silver and the platinum group metals in the EC takes place either at the specialist precious metal refining and fabricating companies or at base metal refineries equipped to treat such precious metals either as by-products of non-ferrous metal refining or by recovering them from low grade industrial residues and scrap materials. Total precious metal refining capacity of the EC firms is the largest of any one region of the world.

Consequently mines in all parts of the world still consign large quantities of precious metals in crude or by-product forms to the EC refineries. This occurs when local facilities do not exist, do not have adequate capacity or are unable to treat the mine output satisfactorily to achieve optimal recovery rates or generally acceptable commercial quality.

Despite the EC's lack of indigenous precious metal mineral sources it can count on substantial "above ground" raw material supplies in the form of scrap and waste materials sent for recycling both from within the EC and from the rest of the world. There are a number of EC companies who specialise in the collection, pre-processing and trading of such materials before the actual assay and refining stages take place. The cost of recovery and recycling is more than justified by the high intrinsic value of the precious metals contained in the scrap and residues. Typical items are discarded printed circuit

boards, obsolete computers, old photographic film, X-ray plates and solutions, spent electro-plating baths etc.

It is not just the economic aspects that encourage the recycling of precious metals but also the environmental issues where the regulatory authorities are setting ever stricter limits on the tolerable metal content of waste materials sent for dumping.

Base metal refineries with significant precious metal capacities are to be found in Belgium, Germany and the UK. These typically recover precious metals from lead and zinc, copper or nickel ores, as well as low grade scrap materials of all kinds, and they supply the pure metals in the form of unwrought "good delivery" bars or plates, grain or sponge.

The largest EC specialist precious metal refining firms are to be found in France, Germany and the UK. The specialist refiners are also fabricators and are also able to process the precious metals into alloys and chemical compounds and to supply all forms of wrought materials such as wire, sheet, tubing and industrial components of many shapes and sizes.

Trading

The major EC financial centres, particularly London but also Paris, Frankfurt and Luxembourg are significant markets for trading gold and silver as commodities and for investment purposes. The daily fixing prices quoted by the London Bullion Markets and the London Platinum and Palladium Markets are those most widely used throughout the world as reference prices. "Good delivery" gold ingots and silver bars bearing the stamps of the major EC refiners are to be found in the vaults of banks and commodity traders in all the world's financial centres and international monetary agencies. Private individuals and other financial institutions generally prefer the smaller investment bars where once again it is the major EC refiners whose bars carry the most prestigious marks which are recognised everywhere as a guarantee of quality and accurate assay.

Market forces require that trading of the main precious metals on a 24 hour round the clock basis be organised so that forward cover and location swaps be provided for international customers. This push has caused many of the leading EC traders to set up facilities in North America and the Far East to complement their activities in Europe.

Fabrication

Most of the precious metals are fairly easily fabricated either as pure metals or as alloys. Gold in particular is usually turned into specific alloys for jewellery or dental purposes in order to improve its wear-resistance or colour. Because of the high intrinsic value and the wide range of forms and alloys required, such metals are usually fabricated or processed in smaller quantities than base metals. One of the few precious metal products manufactured in tonnage quantities is silver nitrate for the photographic industry. A product that has recently entered the multi-million unit scale of production in the EC is anti-pollution car exhaust catalysts, each containing just a gram or so of the platinum group metals, and some members of the EC precious metal industry are strongly represented in this field worldwide. The EC demand trend is discussed in more detail below.

Manufacturing

Converting precious metal alloys into finished products to be sold to the retail trade, is largely the responsibility of the jewellery, silverware and tableware industries which is outside the scope of this article. These industries, however, are major consumers of gold and silver, especially in Italy, as can be seen from the accompanying EC consumption tables.

MARKET FORCES

Demand

The industrial and manufacturing demand absorbs the major share of precious metals fabrication, though gold and silver still play roles in coinage (now mostly commemorative coinage). Gold, of course, remains the main investment metal worldwide even in today's highly sophisticated financial circles, though part of its role as an internationally recognised store of value has been taken over by currency trading and futures. EC major precious metals outlets include: jewellery in the case of gold, photographic products for silver, automobile exhaust catalysts for platinum and dental alloys and electronics for palladium.

Consumption trends are closely linked to the outlook for consumer goods and industrial consumables. In the case of the platinum group metals, EC demand in the last year has, however, been driven by legislation and the Single Market. As a result since 1 January 1993 most new European automobiles have been fitted with catalytic converters to control exhaust pollution and reduce acid rain. Such devices have been compulsory since the 1970s in the US and Japan but only recently has legislation been adopted by the EC and other states of Europe.

Gold and silver are able to rely on the jewellery and tableware markets as a fairly constant source of demand, although this does fluctuate with consumer purchasing power. There is also a small but growing demand for platinum jewellery and watches in the EC. In the case of palladium, world demand has risen recently because of increased use in autocatalysts and what is probably a temporary increase in demand for dental alloys, rather than as a result of any additional needs for jewellery.

All the precious metals except gold are consumed mainly in the industrial regions: North America, Japan and Europe. These three zones currently account for 90% of Western world (referring to market economy countries) consumption of platinum and palladium, about 75% for silver but only slightly less than half of world gold consumption. More than 50% of world gold consumption in 1992 is thought to have occurred in the developing countries.

Gold

The EC accounts for just under 25% of total Western world demand for gold (Table 2). In 1992 EC utilisation is estimated to have increased by 8%, a slightly larger improvement than in previous years. It is Italy which traditionally dominates EC demand. The jewellery industry there used 461 tonnes of gold in 1992, which is about 75% of the total EC usage for jewellery estimated at 620 tonnes. Much of the Italian production is exported to North America, the Middle East and other EC States such as Germany and the United Kingdom, although it is Italy itself which is by far the largest jewellery market among EC member states, consuming some 161 tonnes of fine gold in the form of gold jewellery. Recorded demand for such jewellery rose during 1992 in France, Germany and especially Spain, but remained static or fell elsewhere such as the United Kingdom. In the first part of 1993 EC consumption weakened as recession and currency turbulence affected jewellery purchases.

There was little change in 1992 demand for gold for other purposes. The demand from the electronics industry was static but decorative applications again improved slightly. The use of gold in dentistry once again rose in Germany to meet an estimated demand of 14.2 tonnes, a 20% growth from 1991. This was largely due to an acceleration of dental treatments in 1992 to forestall changes in the health insurance programme which came into force on 1 January 1993.

Silver

Industrial demand for silver in the EC now represents about 33% of the Western world total (Table 3). One principal consumer sector in Europe is the photographic industry, where overall demand has remained steady in recent years. The other is jewellery, cutlery and silver tableware where Italy once again is by far the largest manufacturer in the world. Usage of silver in the electrical engineering and electronics industries is still declining.

Platinum

In 1992 the EC accounted for approximately 23% of Western world platinum demand, up from about 19% in 1991 (Table 4 and 5). This upward trend is primarily because of its use in catalytic converters for the car industry. As from 1 January 1993 the new EC directive on vehicle exhaust emission required all new petrol engine cars to be fitted with such catalytic systems, all of which contain small quantities of the platinum group metals. European car manufacturers prepared for this deadline well in advance. Some 66% of new petrol engine cars built and sold in Western Europe in 1992 were fitted with catalysts as well as a rising proportion of diesel engine cars. However, EC car production has fell in 1993 due to economic recession, so platinum demand in 1993 for EC autocatalysts is not likely to be as high as originally expected.

While EC industrial demand for uses other than car catalysts tends to fluctuate from year to year, European demand for jewellery purposes has been increasing in recent years with exception in 1992 when it remained stable, but in Italy which showed some growth. Demand for platinum jewellery is especially high in Japan. In 1992, 39 tonnes of platinum were used by Japanese jewellery manufacturers compared with 104 tonnes of gold, whereas in the EC jewellery trade the ratio was 2 tonnes of platinum to 620 tonnes of gold.

Palladium

EC demand for palladium represents about 17% of Western world consumption (Table 6 and 7). The use in dental alloys remained comparatively high in 1992, especially in Germany forestalling the 1993 health insurance changes, while electronics usage also increased as industrial capacity continued to expand. The volume of palladium used in the automobile industry of the EC started to increase significantly in 1992 as new technical developments began to be exploited in Europe.

Supply and competition

Gold is mined in most continents apart from Europe and is usually, but not always, the most valuable metal in its ores. The largest output still comes from the Republic of South Africa but mines with cheaper production costs have been opened up in America and the Pacific region. World supply from old gold scrap increased by almost 7% to 435 tonnes as more old jewellery was recycled in the Middle East and India and was in fact the next biggest source after South Africa's 614 tonnes of primary gold.

Silver is largely a by-product of lead and zinc mines, particularly those in Mexico and Peru so far as primary mineral sources are concerned. Some 129 tonnes out of total 1992 silver output of 482 tonnes, is thought to be derived from secondary sources such as scrap and residues from the photographic industry.

Of the six platinum group metals, it is platinum which dominates in the South African primary ores. However in the CIS and Canada where the platinum group metals are found in nickel ores, more palladium than platinum is actually recovered and the CIS is normally the largest supplier of palladium to the Western world .

Much of the platinum group metals used in industry is eventually recycled. As cars fitted with catalytic converters in the

1970's and early 1980's in North America and Japan reach the end of their useful life, a steadily growing source of platinum has been spent car catalysts, which now yield the equivalent of about 16% of the platinum currently required for new car catalysts.

The mineral sources of gold and silver are widely dispersed and mining activity is subject to only limited political risk. In the case of the platinum group metals, which rely to such an extent on the sources in the Republic of South Africa and the CIS, there is a risk that internal political events might affect supplies. However substantial stocks are held both by the refiners/fabricators of these metals and also the commodity markets which would be ample for short term needs.

INDUSTRY STRUCTURE

Companies

The principal precious metals refiners and fabricators of the EC operate on an international scale and are world leaders in their field. Prominent names are Degussa and Heraeus in Germany, CLAL in France and Johnson Matthey in the United Kingdom. The US precious metals firm, Engelhard Corporation, is also well established in several EC countries. Major EC base metal refiners with significant precious metal involvement include Union Minière in Belgium, Norddeutsche Affinerie in Germany and Inco in the United Kingdom.

The installed precious metals refining and fabrication capacity controlled by the EC industry as a whole is the largest in the world and exceeds that of equivalent US and Japanese firms. It draws its supplies from all over the world both in the form of primary metal from the mines and secondary or recycled metal. It also sells its fabricated products not only within the EC, but also in the developing countries of Africa, the Middle East and Asia.

The EC precious metal concerns form an advanced technology, high performance industry which is very strongly focused on research and development. This encompasses new uses for the precious metals as well as the discovery of techniques for economising in the quantities of precious metals used in existing applications.

Prices

The main precious metals are all traded on international commodity markets, in particular those of London, New York and Tokyo, and prices can be quoted on a 24 hour basis. Thus refiners and fabricators are able to hedge prices quoted to their customers to avoid the risk of price movements. Gold is the metal perhaps most affected by speculation and is usually sensitive to the world political and economic climate, largely because it is the precious metal of most interest to investors and speculators. Although silver and the platinum group metals are industrial metals to a much greater extent and their prices are therefore, subject mainly to supply and demand expectations, in practice they still move to some extent in sympathy with the price of gold.

For the last few years precious metals prices in US dollar terms have been dropping as supply has been ahead of demand. At the beginning of 1993 however, prices began to rise again as demand in some markets such as the US has recovered and there has been a renewal of speculative interest for investment purposes (Figure 1).

This industry is represented at the EC level by: Association Européenne des Métaux (Eurométaux). Address: Avenue de Broqueville 12, B-1150 Brussels; tel: (32 2) 775 63 11; fax: (32 2) 779 05 23.

Cobalt
NACE 224

The EC cobalt industry is the world leader in cobalt powder and oxide production, as well as a major supplier of cobalt salts worldwide. The "cradle" of special cobalt products i.e. powders, oxides and salts is Belgium, where considerable production expertise has been developed since the beginning of the century in the treatment and processing of cobalt metal and raw materials originating in the Shaba copper mines in Zaire. Today, cobalt special products are a worldwide business with products from the former Soviet Union and China appearing in western markets. However, the EC still retains a large proportion of the capacity to satisfy the market, 40 to 45% in fact, with plants operating in Belgium, Germany, France and Great Britain, directly involving at least 7 companies.

INDUSTRY PROFILE

Description of the sector

Cobalt metal is shiny, grey and brittle with a closely-packed hexagonal (CPH) crystal structure at room temperature, which changes at 421 degrees C to a face-centred cubic form. Cobalt is supplied to the end-users either as a metal in the form of pieces or powder or as a special product in the form of fine powders, oxides or salts. The metal is not used as a structural material in the pure form, but always as an alloy or a component of another system.

As the central component of Vitamin B12, cobalt is one of the 27 elements essential to humans. It has unique properties which make it extremely valuable in many industrial applications. It has a high melting point, 1 493 degrees C and retains its strength to a high temperature. It is ferromagnetic, only nickel and iron share this property. It is multivalent and easily enhances catalytic action.

As there are no longer any viable cobalt bearing ores in the EC, cobalt processors rely entirely on imported cobalt feed supplies, be these metal, mining or metallurgical residue or scrap.

All, bar one, EC special products producers have to source cobalt outside their own business. Previously, cobalt supplies in the West i.e., market economy countries, were dominated by Zaire and Zambia, indeed, 70% of metal production came from these two sources in 1990. This situation has changed during the last few years with Russia becoming a net exporter of cobalt so that in 1992, Zaire and Zambia's share had fallen to 50%.

Europe is a major market for EC cobalt special products producers, but they must also compete in export markets as capacity far outweighs European demand. The main markets are the USA, Japan, Taiwan, South Korea and other Pacific Rim countries. These markets contain indigenous competitors and other international companies compete there as they do in Europe with the EC suppliers.

Figure 1 shows the overall cobalt market structure and the EC industry within it. Consumers of cobalt use the metal, as well as cobalt special products, to produce magnets, alloys (super alloys and hard facing), soft magnetic materials, high speed steels, and other cobalt compounds.

International comparison

Demand for cobalt essentially arises in the industrialised countries. Europe, North America and Japan take the lions shares of total market economy countries demand which is currently hovering at a level of 17 500 tonnes per year. Today's geographic distribution of demand is shown in Figure 2.

Source: Union Minière

The cobalt market is a mature one. For 4 000 years cobalt has been used for ceramics; more recently, it has been used in super alloys and magnets for the past 50 to 60 years. There are many new uses in electronic recording, anodising, batteries, amorphous soft magnets, etc. However, these do not currently generate a large tonnage demand. The consumption curve has in recent years been declining, as shown in Figure 3. To some extent, this has been a technological rather than economic shift, although one must to some degree blame the uncertainty about supply which resulted from the late 70's turmoil in Zaire. Demand has fallen due to the development of substitute products which is illustrated by the following examples: nickel super alloys, albeit cobalt containing, replaced cobalt alloys, cobalt-free high speed steels were developed, ALNICO magnets were replaced by ferrites, etc.

MARKET FORCES

Demand

Until the 20th century, cobalt was only available or used as an oxide to produce blue colours. Its modern uses developed with Elwood Hayne's work on heat and wear resistant alloys (Stellite), the development of aluminium-nickel-cobalt (ALNICO) permanent magnets in Japan, and the use of cobalt as a binding agent in tungsten carbide production in Germany.

Figure 2: Cobalt

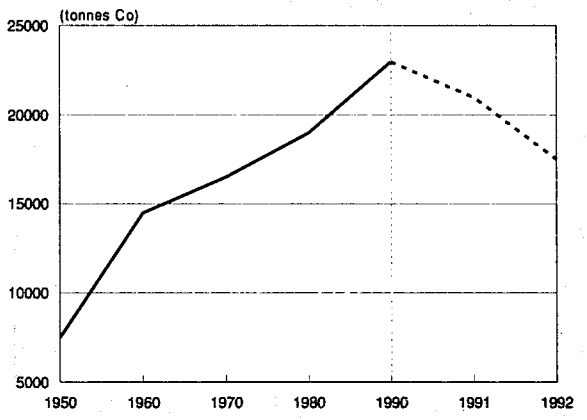
(1) Other market economy countries only.
Source: Cobalt Development Institute

Figure 3: Cobalt
Estimated cobalt demand in the market economy countries



Source: Cobalt Development Institute

Cobalt is consumed in various forms and for many different applications, which are summarised in Table 1.

About 18 000 tonnes of cobalt are consumed each year in the market economy countries. At present, demand from EC customers for special cobalt products is about 3 000 tonnes cobalt per year (estimation is based on the early 1990's), 36% is in the form of oxides, another 36% is in the form of salts, and the remaining 28% in the form of powders. This demand mainly comes from the hard materials industry consuming powders, the pigments and ceramic industry consuming oxides, the metallic soap manufacturers consuming salts, the animal feed and fertiliser sector also consuming salts and the catalyst industry consuming salts and oxides.

It should be noted that cobalt demand in the EC includes an additional estimated 3 000 tonnes cobalt per year, consumed in the form of metal by the steel and alloy industry, the permanent magnet industry and some segments of the chemical industry. As there are no cobalt metal producers in the EC, these requirements have to be imported in full.

INDUSTRY STRUCTURE

Companies

Although the EC has no cobalt mines or cobalt metal production, its industry is extremely strong in the processing of metal and of cobalt bearing raw materials into special cobalt products, i.e. powders, oxides and salts. The rated capacity of the EC cobalt processing plants can be estimated altogether at about 6 500-7 000 tonnes per year.

All the companies listed in Table 2, with the exception of Eramet-SLN (F) which processes its own mining by-products from New Caledonia, rely on feed supplies purchased on the international markets. Their output is not only intended for EC customers, but also for export, since their combined production significantly exceeds EC customer requirements. The EC cobalt processors have one major competitor in Europe, the OM Group, whose major shareholder is Outokumpu (Finland). The OM Group also competes with the EC cobalt processing companies on the international markets, chiefly in the Americas and Asia, which are significant outlets for EC products.

Although there are not many competitors with international scope, those that do operate internationally are fairly significant. Some of them supply special cobalt products as a by-product of other base metal activities i.e. Inco's cobalt oxide is a by-product of nickel-ore processing in Canada; and Rustenburg Platinum's cobalt sulphate is a by-product of platinum ore processing in South Africa.

Supply and competition

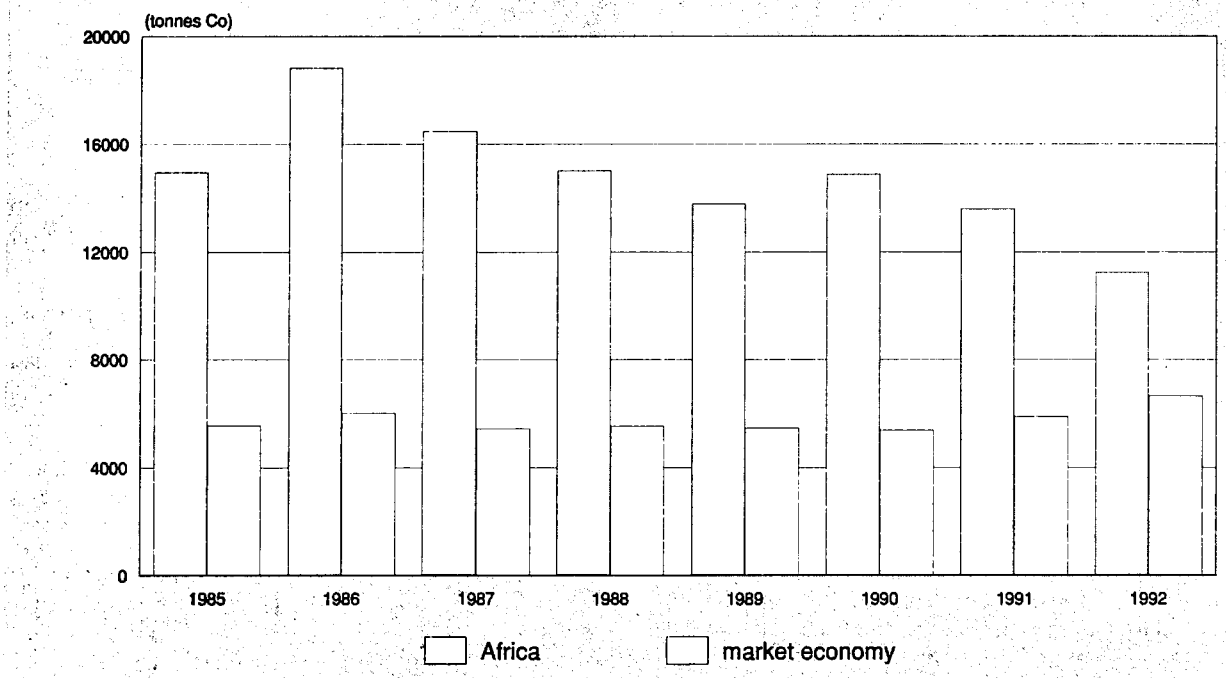
Competition between special cobalt product manufacturers is fierce in salts, strong in oxides and moderate in powders; the EC companies are world leaders in powders and oxides, while they keep up with the rest as major salt suppliers.

A summary description of the cobalt market at large helps to assess the relative position of the EC cobalt industry. The industry responds with diversity of its expertise out of consideration for the diversity of manufactured products and their industrial uses. The industry has experienced the international "spread" of its enterprises, which import their feed materials from remote countries and export their products not only within Europe, but also to all parts of the world. The industry encounters challenges which it must face in order to maintain its leadership and market share when competition is tough and demand has reached full maturity i.e., zero growth rate in the long term.

Mine production

Cobalt essentially arises as a by-product from the processing of copper and nickel ores, but it can also be associated with platinum or other non-ferrous metal ores. It only occurs as a major extracted element in the arsenide ores of Morocco currently exported to China. African mines are by far the largest suppliers of fresh cobalt units from the ground, accounting for nearly 63% of the market economy countries total output. The bulk of mine production is offered directly to the market in the form of metal which is produced in the integrated operations of Gecamines (Zaire), ZCCM (Zambia), Inco and Falconbridge (Canada). The balance of the output is supplied by the other mining concerns, either in the form of oxide or salts, or in the form of cobalt-bearing primary raw materials. Figure 4 shows the development of cobalt supply in market economy countries from 1985.

Figure 4: Cobalt
Cobalt production in market economy countries



Source: Cobalt Development Institute

Metal production

There are five major cobalt metal producers in the market economy countries. Their 1992 capacity and output are outlined in Figure 5. Since 1992, Russia has become a significant supplier of metal to the "western" or market economies market, however, but its actual output, arising at four different refineries, is difficult to assess.

About 65% of metal output is directly supplied to end-users in the special steels and alloys industry, the permanent magnet industry, and some segments of the chemical industry. The remaining 35% are supplied to cobalt processors, i.e., producers of powders, oxides and salts.

Production of powders, oxides and salts

The market for special cobalt products i.e., fine powders, oxides and salts, ranges from 9 to 11 000 tonnes cobalt content per year in the market economy countries. More than 50% of supplies result from metal processing, some 9% are the direct cobalt output of mining concerns (Inco's oxide, Eramet-SLN's chloride and Rustenburg Plat's sulphate), and the balance is produced from cobalt-bearing scrap, mining by-products or metallurgical residues.

More than 25 companies are active in the special cobalt product sector, though not necessarily supplying the full product range: competition is currently extremely fierce in salts, strong in oxides and moderate in powders. Total installed capacity is estimated at 13 000 tonnes cobalt content per year, of which 34% is for powders, 37% is for salts and 29% is for oxides.

Prices

Cobalt has for many years been a producer priced material as shown in Figure 6, with Zaire and Zambia traditionally setting the quoted level.

Free market prices are quoted by trading companies, some of which have become deeply involved in cobalt in the early 1990's. This phenomenon is largely due to the appearance of significant quantities of Russian cobalt in the hands of the trade. The volume of free market traded cobalt is difficult to assess but is probably around 20% to 25% of total supply.

ENVIRONMENT

Cobalt is classified as non-carcinogenic in the EC (15th Modification to Directive 67/548/EEC). Material safety data sheets describing cobalt products are commonly available to the users from the suppliers, on request. Cobalt metal, oxides, sulphides and carbonates in the form of powder, are listed in the Seveso Directive (82/501/EEC), but will most probably be withdrawn

from this list in the new version of the Directive currently being redrafted. Current legislation, in force or proposed, regarding Health and Safety is closely followed by the industry, especially with regard to the setting of occupational exposure standards.

Cobalt metal and oxide (Co_3O_4) are on Annex I of EINECS (European Inventory of Existing Chemical Substances) (80/C2760) and the industry is collecting data for submission to the Commission of the European Community, via a leading producer, by July 1994.

OUTLOOK

The EC cobalt industry faces several challenges. Feed stock must be imported due to the lack of indigenous cobalt sources. These sources are changing as the political scene shifts. Currently, the industry must rely on Central Africa (Zaire and Zambia), Canada/Norway (the Norwegian refinery is linked to Canadian mining operations) and Russia (CIS). This source is not new but consumption in Russia has fallen dramatically and surplus production plus stockpiles have rapidly appeared on western markets. To some extent, the new Russian material availability has made the industry less vulnerable to African instability and certainly prices have been more stable as a result.

The EC cobalt special product producers rely heavily on the availability of cobalt-bearing scrap and residue which they recycle. There is therefore great concern about the Basel Convention which, although well intentioned, should not be seen as causing the cessation of vital recycling and avoidance of disposal.

EC producers always face competition but the changes in Russia, and also China, outlined above have also paved the way for sometimes erratic competition from these areas. The industry is, however, strong and in some areas expanding.

Ferro-alloys
NACE 224

In the wake of its customer industries, steel and aluminium, the ferro-alloy industry has seen its activity stagnate over recent years. Under severe competition from abroad, Community production volumes have fallen. Company restructuring, concentration and specialisation have improved the competitiveness of ferro-alloys and will enable the industry to take advantage of the recovery of its end markets.

INDUSTRY PROFILE

Description of the sector

The ferro-alloy sector in the EC covers the production of various metal alloys, generally from electric arc furnaces by carbothermic reduction of metallic oxides.

The two main product categories are bulk ferro-alloys and special products. Bulk ferro-alloys include: ferro-silicon, ferro-manganese, ferro-chromium, ferro-silico-manganese all of which are consumed in large quantities. Special products category includes: ferro-titanium, ferro-vanadium, ferro-boron, ferro-molybdenum, ferro-niobium, ferro-phosphorus, ferro-tungsten, as well as metals such as silicon, magnesium, vanadium, chromium, and other derivatives which are consumed in much smaller volumes.

A characteristic of ferro-alloys is that they are upstream of the production of other metal alloys, mainly steel and cast iron, and to a lesser degree aluminium, zinc, lead, etc. They enable alloying elements to be safely and economically introduced into metallurgical processes, thus giving certain desirable properties on to these alloys.

Bulk ferro-alloys are used almost exclusively in steel making and steel or iron foundries. Advances in metallurgy and increases in yield due to the growing use of continuous casting have contributed to limiting the consumption of bulk alloys. This trend, which has now slowed down, is counter-balanced by the growing proportion of steels using ferro-alloys, especially stainless steels, manufactured in electric furnaces.

The uses of special ferro-alloys are far more varied, and the proportion used in steel making has diminished over recent years in favour of those used in the aluminium and chemical industries, especially silicone products.

Recent trends

The consumption of ferro-alloys, which is heavily dependent on steel making, reached very high levels at the end of the 1980s. Since then, the slowdown of economic activity has hit the ferro-alloy sector and consumption has fallen steeply between 1991 and 1993.

An increasing proportion of the demand has been covered by imports, firstly from the newly industrialised countries and more recently from the East European countries and the CIS. As a result, especially over the past three years, Community production has declined. Community production mainly takes place in countries with large steel making industries. Current economic difficulties are tending to accelerate the concentration of production on a limited number of sites, especially for the larger volumes of bulk alloys. This concentration of production has resulted in continuing job losses up to 25% between 1990 and 1992. At the end of 1992, the industry employed around 6,000 people.

International comparison

The three large industrial zones of the United States, Japan and the European Community are producers of steel and traditionally also produce ferro-alloys. All three of them have experienced the same trend of a growing proportion of imports in domestic consumption of ferro-alloys over the last ten years. In addition, the European Community, at the heart of world ferro-alloy production, has always had a much higher level of export activity than the other two zones. It is now confronted with the appearance of new producers and intensified international competition.

However, external competition has frequently been unfair, especially over the last few years, and notably when it comes from countries with State run trade. The United States and Japan have reacted to this threat to their domestic sources by imposing earlier and more severe limits on imports, especially anti-dumping duties, than the Community, thereby maintaining that local resources cover 40% to 45% of their needs. Within the EC, the rate of local resources covering need has fallen to 30% - 35%.

Foreign trade

More than three quarters of EC exports are directed to industrial countries. The United States receives almost 30% of EC exports, while EFTA and Japan receive nearly 25% each of total EC exports. Overall, these volumes are falling as the Community's share of the market is eroded by the newly industrialised countries and countries with State run trade.

Imports into the European Community have grown over the last ten years to total 65% of consumption.

Although EFTA has maintained its overall market share within the EC during recent years, Latin American countries, like Brazil, and especially the East European countries have made considerable advances. These countries, especially the CIS, have an industrial base with enormous capacity, but low productivity. The collapse of their steel production has made available significant quantities of ferro-alloys which have been exported in order to obtain hard currency.

For logistical reasons most of these CIS exports are sent to the European Community. The Community ferro-alloy industry has therefore been confronted with considerable competitive pressure and has lost ground in its own market. Initiatives have been undertaken to re-establish fair competition which should preserve the future of the Community industry and enable the industrial sectors concerned to guarantee the independence of their sources of supply by maintaining significant domestic production.

MARKET FORCES

Demand

Demand for ferro-alloys is linked to the global development of its main markets, steel and aluminium making and is affected by the cyclical nature of their activities. Beyond this general observation, there are however considerable variations between the different sectors of the market.

Steel making and iron foundries

Practically all bulk alloys and one third of all special alloys are consumed by the iron and steel industries, which include steel making (sub-divided into oxygen steel and electric steel) and iron foundries. The foundries have different consumption requirements for their various types of product as well as their specific consumption.

Oxygen steel represents 67% of steel production in the Community although its share of the total is gradually diminishing. Since oxygen steel has made considerable advances in productivity in recent years with technology improvement like continuous casting, specific consumption of ferro-alloys has regularly declined. With relatively stable demand for steel, this represents a fall in the total consumption of ferro-alloys which is now below 10 kilograms of ferro-alloy per tonne of steel.

Electric steel has experienced a regular increase in its share of production, offsetting the relative decline in the production of oxygen steel. Its productivity has also increased, resulting in a fall in the consumption of ferro-alloys for a given product mix. But the increase in the share of highly alloyed steels, especially stainless steels, has more than compensated for the decline in consumption, and the demand for ferro-alloys has grown in this market segment.

Iron foundries consume a large proportion of the special alloys used in iron metallurgy and their consumption has been more or less stable. The global demand for ferro-alloys for iron metallurgy has followed that of steel, resulting in a decline in demand for ferro-alloys compared with the levels reached in 1989.

Aluminium

The aluminium industry is the second largest customer for bulk ferro-alloys and the largest customer for special ferro-alloys. It uses special alloys, mainly silicon metal and magnesium metal and today consumes almost half of all output in this market segment. Following strong growth in demand up to 1989, aluminium has been hit by recession, especially in the construction and car industries.

Chemicals

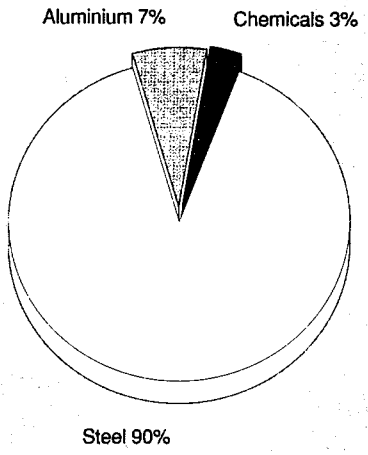
The chemical industry consumes mainly silicon metal, a raw material for silicones, which experienced a considerable growth of 80% over the last ten years. Despite vigorous growth in these products over a long period, consumption nevertheless fell slightly in 1992/93.

Supply and competition

For ten years the Community's ferro-alloy industry has been confronted with market stagnation, practically zero long term growth, and cyclical fluctuations in demand which lead to cyclical variations in price, with troughs which are more and more difficult to absorb. To tailor supply to market developments and competition, producers have undertaken large scale restructuring. Since the end of the 1970s we have seen a continuous and increasing concentration of production on the most productive plants. From 1990 to 1992 alone, 25% of industrial sites were closed in order to concentrate production. In addition, flexible working methods have been adopted, such as winter stoppages, to adapt production to the constraints of a competitive energy supply.

However, these measures have not prevented imports from growing; these imports are frequently sold at dumping prices, especially during periods of economic difficulty, which has allowed imports to continue to grow both in market share and absolute value. This has been particularly marked during the last few years with the appearance of supplies from the CIS, where there is significant production capacity. With the drop in production from 165 million tonnes in the mid eighties to less than 100 million tonnes in 1993, the ferro-alloys that the CIS steel industry no longer requires, have been redirected towards western markets, especially Europe for logistical reasons. These supplies, at prices which bear no relation to the economic costs of production, have created serious distortions of competition. European producers have made representations to Community bodies to ensure that the industry's efforts are not wasted and prevent the industrial sectors concerned from becoming fully dependant on imports. The industry in the Community has simultaneously pursued its initiative to cut costs and provide its customer industries with products and services which exotic suppliers with a different industrial tradition cannot offer.

Figure 2: Ferro-alloys
Breakdown by application, 1992



Source: Eurolliages

INDUSTRY STRUCTURE

Thirty two firms are involved in ferro-alloy production in the EC, some of which are subsidiaries of large industrial groups Viag (D), Pechiney (F) and therefore represent only a relatively limited part of the activities of the groups to which they belong. By contrast there are small companies which concentrate on production of a limited range of ferro-alloy products, or even a single product in which the company is highly specialised. All of them are committed to product quality and customer service.

ENVIRONMENT

Ferro-alloy production uses electric furnaces, generally of the open hearth type, into which are loaded natural products such as quartz, lime, various minerals, wood, etc., varying in physical and chemical composition.

For a long time the ferro-alloy industry has been committed to reducing the quantity of dust produced by the process by installing filters in its factories and recycling to the extent possible the manufacturing by-products. The concentrations which have taken place during the past ten years have speeded up this development by enabling larger furnaces to be built with greater yield, and with emissions which are more easily controlled than those of many small furnaces. These measures are costly and the industry currently devotes a quarter of its investment to environmental protection equipment, thus fully taking into account the European Community's concerns. It would be fair to request from the trading partners the same sort of measures: this is particularly the case for greenhouse gas emissions. By its very nature the ferro-alloy industry, whose basic tool is an electric furnace in which metallic oxides are reduced using carbon, is a producer of carbon dioxide (CO2). A tax on energy consumption and/or CO2 emissions would have no motivating effect since the increasing size of furnaces has already allowed high levels of efficiency. On the contrary, this tax would have a direct and unbearable effect on the competitiveness of Community producers, leaving the field open to less efficient producers in countries where there is as yet little awareness of ecological issues.

OUTLOOK

The 1992/1993 recession, particularly severe in Western Europe although not limited to the region, should give way to recovery in 1994, which would benefit the industry's main customers, the car and construction sectors.

The anticipated growth in the steel making industry will be accompanied by a search for improved productivity with a decrease in the specific consumption of ferro-alloys, although not to the extent seen in the recent past. Therefore, European demand for ferro-alloys should stabilise. Certain sectors, such as silicones, seem set to benefit from sustained growth. There will therefore be a growth in demand for the corresponding metals or ferro-alloys. The measures taken by the Community to maintain fair competition in internal markets should in addition enable Community production to benefit from better economic conditions and permit the Community industry to maintain its independence from external suppliers.

The industry is represented at the EC level by: Euroalliages. Address: Avenue de Broqueville 12, B-1150 Brussels; tel: (32 2) 775 6319; fax: (32 2) 779 0523.

Overview
NACE 24

The second half of the 1990s should prove to be more favourable for the non-metallic mineral products sector than the first if construction industry forecasts are achieved. Restructuring and modernisation activities will help the EC industry to be even more technically advanced and competitive on a world level than it is at present. Imports have been growing in recent years particularly from countries with low labour costs. The sector is a major user of fossil fuels and is thus heavily involved in environmental issues regarding atmospheric pollution. However, efforts have been made to control sulphur dioxide and dust emissions.

INDUSTRY PROFILE

Description of the sector

Non-metallic mineral products are made up of the following groups: clay products (bricks and roof tiles: NACE 241); cement, lime, and plaster (NACE 242); concrete (NACE 243); glass (NACE 247); and ceramic goods (NACE 248). The working of stone (NACE 245) is covered in Chapter 2 of Panorama. Clay products, cement, concrete, and plaster are used almost exclusively by the construction industry, which also features prominently as a major customer for lime, glass, and ceramic goods (particularly tiles and sanitary ware). Nevertheless these latter products are widely used across a broad spectrum of industries embracing metallurgy, chemicals, food and beverages, electronics, and electrical and mechanical engineering. A number of glass and ceramic items are domestic consumer items.

Recent trends

EC production of non-metallic mineral products was valued at around 90 million ECU in 1992 and involved materials measured in hundreds of millions of tonnes. The real annual growth rate over the 1983-1992 period averaged 1.5% for production and 2.1% for consumption although this hides the fact that the major growth occurred during the 1987-1990 period in response to the relative boom in construction activity. Imports of non-metallic mineral products surged during this period and have continued to grow since. It should be noted that in 1992, imports amounted to 4.5% of total consumption compared to 3.5% in 1983. As an important exporter of many of the products in this group, particularly in the glass and ceramic goods sectors, the EC maintains a clearly positive trade balance even if it has fallen over the period. The current recession in the construction industry is reflected in a marked fall in both production and consumption since 1990.

International comparison

The EC is the world's leading producer of non-metallic mineral products and its 1992 production exceeded in value those of the USA and Japan by factors of 2.3 and 2.5 respectively. The industries of both the EC and Japan have grown in real terms whilst that of the USA has contracted.

Foreign trade

Although over the 1983-92 period, foreign trade played only a minor role in the overall picture: imports average 4% of consumption and exports average 9%. It is actually much more significant in some sectors than others. For this reason the continuous fall in export-import ratio from 3.35 to 1.84 over the 1983-1992 has important implications for the EC glass, ceramic goods, and cement sectors. During the period each of these industries has experienced dramatic growth in low-priced imports: from Eastern Europe and Turkey in the case of glass and cement and from the Far East in the case of ceramic goods. In overall terms the EFTA countries and the USA are also important sources of non-metallic mineral product imports although their shares have decreased in favour of Eastern Europe, Turkey, and the Far East.

Meanwhile the value of EC exports of non-metallic mineral products has declined in real terms over the 1983-1992 period. This is mainly due to the falling contribution of cement since the level of exports for both glass and ceramic products have been more or less constant during this time. The destinations for these exports are well spread throughout the world although the EFTA countries and the USA have consistently taken between 45-50% of the total value each year. Intra-EC trade expanded rapidly during the 1980s but has since levelled off at around 14% of total activity.

MARKET FORCES

Demand

The construction industry accounts for over two-thirds of the consumption of non-metallic mineral products and thus the fortunes of the group have tended to follow the somewhat exaggerated peak and trough pattern of the past 6 years. For the same reason the current period of lower interest rates should see a renewal of construction activity which should be translated into increasing demand for non-metallic mineral products in the years ahead. Glass and ceramic goods demand is also partially affected by construction activity but overall consumption is spread more evenly across a range of industries from general manufacturing to food, beverages, and catering.

Supply and competition

Most of the products of this group are major bulk items of relatively low value that are based on local raw materials and are sold primarily to local markets. Transportation costs are always a major consideration and have generally proved a deterrent to competition from distant sources. Some of the higher value products in the glass and ceramics segments have always been exempted from such considerations but in the last decade or so major bulk items such as cement are being shipped increasingly long distances by sea. The enabling factor is the low cost of ocean transportation when large bulk carriers of 20 000 tonnes or more are involved. Thus a modern cement plant close to a shipping point can supply markets at competitive prices on the other side of the globe providing there is a bulk terminal at the other end to handle and store the product. European producers were actually among the first to take advantage of these opportunities but as former importers (for instance, in the Middle East) have installed their own manufacturing facilities not only have the markets disappeared but new exporters have emerged. Thus the market in the 1990s is much more competitive than in former decades and certain regions of the EC have become more vulnerable to competition from countries with low labour costs as in Eastern Europe or the Far East. Nevertheless most EC producers are competitive and will continue to supply the vast bulk of the EC's construction and industrial requirements. The principal threats to this competitiveness would come from any future legislation which reduced availability of raw materials or raised the costs of energy.

Production process

Europe has been at the forefront of many of the technological advances in processing methods employed by the non-metallic mineral products industries: from specifics such as the float glass process and ceramic forming and firing techniques to energy saving measures that apply to the industry as a whole. A close relationship exists between this industry and its equipment suppliers which can be expected to just as fruitful in the future as it has been in the past.

INDUSTRY STRUCTURE

Companies

The diversity of products contained in this group is mirrored in the diversity of companies involved. These range from major international construction groups with turnovers measured in billions of ECU and employees into tens of thousands to small family-owned businesses with a handful of employees and a highly regional sphere of interest. Concentration is high in some segments such as cement and glass but low in others such as concrete products, bricks, and ceramics. Concentration is also high in some countries such as the United Kingdom and France but low in others such as Italy, Spain, and surprisingly Germany. However, the pace of concentration appears to be quickening as groups acquire a more obvious pan-European status. The top six non-metallic mineral products companies: Saint Gobain (F), Lafarge Coppée (F), Holderbank (CH), RMC group (UK), Pilkington (UK), and Redland (UK) account for about 25% of total production which is low compared to other industries. Nevertheless it should be recognised that many of the smaller and medium sized companies involved in non-metallic mineral product manufacture are highly efficient, modern, and deserving of international status in their own particular market niches.

Table 6: Non-metallic mineral products

REGIONAL DISTRIBUTION

EC production of non-metallic mineral products is widespread throughout the Community. The location of production sites is often governed by the raw materials used e.g. cement factories based on limestone deposits, ceramics industries close to clay deposits, etc.

ENVIRONMENT

The non-metallic mineral products sector is one of the major users of fossil fuels and is thus a focus of attention with regard to atmospheric pollution. However, the sector has made major investments to comply with the existing legislation and has a very good record for controlling of sulphur dioxide and dust emissions. The cement industry is turning more and more to substitute fuels in order to reduce its reliance on fossil fuels. The various industries making up the sector have also been highly successful in introducing technical innovations to reduce unit consumption of energy and the glass industry in particular is held up as a model for the ecologically sound practice of recycling. Nevertheless the emission problems concerning the oxides of nitrogen and carbon are proving to be a more knotty problem. A punitive carbon tax could sound the death knell for much of the sector and thus efforts must be intensified to find a solution to treating these gases by methods which do not in themselves consume massive quantities of energy.

REGULATIONS

The EC building industry as a whole is in the throes of a major standardisation offensive through the European Committee for Standardisation (CEN). International standards already exist for many products within this sector but for others the move will help to raise standards and there should be an overall improvement in quality control and testing procedures.

OUTLOOK

Demand for non-metallic mineral products is expected to grow steadily in the latter half of the 1990s in response to the more favourable outlook for the construction industry. Although Eastern Europe has been regarded as a source of cheap imports in the past it is now being seen as a major area of opportunity for EC companies operating in this sector.

Written by: B.M. Coope & Partners

Clay products
NACE 241

Clay brick making is one of the oldest crafts in the world and the Ancient Greeks, Romans, and Etruscans can lay claim to being the earliest EC producers. Italy is still the largest producer in what is still the world's most important clay brick and tile producing region. Despite competition from a wide range of products based on concrete, wood, metal, and plastics, the modern clay brick and tile industry continues to be a major supplier to the EC building industry.

INDUSTRY PROFILE

Description of the sector

The principal clay products for constructional purposes are bricks and roof tiles. Clay extraction and treatment (Chapter 207) and brick making tends to be carried out by the brick making company itself as a single integrated operation. Nevertheless there are certain cases where large tonnages of clays are bought in from outside sources: for instance, when low cost by-product fireclays from open cast coal mining operations are available. The products are sold to the construction and civil engineering industries (Chapter 19).

Bricks are available in a wide variety of types based on size, shape, colour, type of processing, end use, etc. They may be solid, perforated (i.e. with a large number of small holes), or hollow (e.g. horizontal core). Northern climes tend to use solid bricks whereas the Mediterranean regions tend to use more hollow bricks. Perforated bricks are common along with solid bricks in Germany, Belgium, and Denmark. Another classification, particularly for solid bricks, divides bricks into commons (suitable for general building purposes, backing, etc.), facings (specially prepared with variations in colour and texture to provide an attractive appearance), and engineering bricks (high strength and low absorption for special load-bearing applications). Nor surprisingly there are strong regional characteristics in brick types as well as national ones.

Roof tiles have a special shape which facilitates roof covering. The production method is the same as for bricks. Generally it is possible to distinguish between the Mediterranean type (the roofs with a slight slope) and the north European type (for roofs with a steep slope). The brick and roof tile industry's main markets are houses, multi storey buildings and pavements. The roof tile industry covers maintenance, repair and transformation of existing buildings.

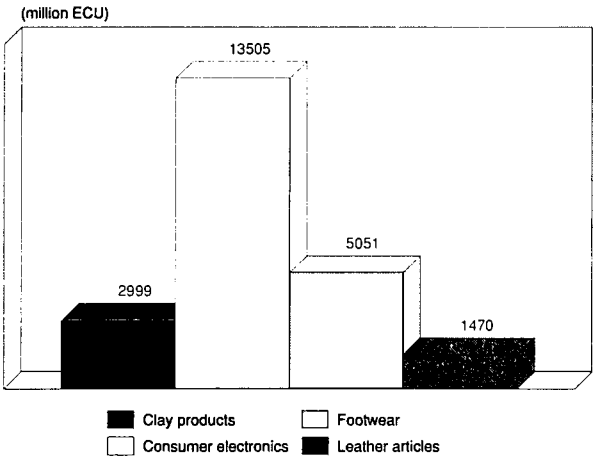
The principal producing countries in the EC are Italy, Germany, and Spain which together account for about 75% of total brick production and 65% of total roof tile output. The United Kingdom, France, and the Benelux countries are also significant producers.

Recent trends

EC production and consumption of bricks and roof tiles grew almost continuously in value terms over the 1983-92 period (at an average 3.5% per annum) although both production and consumption values remained constant in real terms during the same period. In fact the last three years have seen a marginal decline in real terms and a more marked decline is likely for 1993.

The production patterns have been different for individual countries with Italy and Germany showing strong volume growth since 1983 whilst France and the United Kingdom showed initial growth followed by a clear decline. Future growth is likely to be uneven too.

Figure 1: Clay products
Value added In comparison with other industries, 1992



Source: DEBA

International comparison

The production of clay bricks and roof tiles in the EC is an order of magnitude higher than either the USA or Japan, where other materials such as concrete, wood, and plastics are predominant. The USA has shown a clear decline over the 1983-1992 period whereas Japanese production has remained fairly constant. There are some signs that US sales of facing bricks may now be on an upward trend.

Foreign trade

Foreign trade in bricks and roof tiles normally represents only a small part of overall consumption since the products are relatively high-volume, low-value products best suited to serve proximal markets. The types of products are also designed to meet the particular building characteristics which tend to be of a regional or national nature. Thus extra-EC imports represent less than 1% of total consumption although extra-EC exports are more substantial, averaging around 4% of production in recent years. The export trade can be divided into regular trade with neighbouring EFTA countries and more single-project-oriented shipments to destinations such as the

Middle East and the Far East. Meanwhile intra-EC trade has more than doubled during the past five years, reflecting the increase in cross-border shipments in the region of north Germany, north-east France, and the Benelux countries.

MARKET FORCES

Demand

All bricks and roof tiles are consumed in building and construction and thus the construction industry is almost the sole customer; almost but not quite because there is a small volume of sales to the builders' merchants and the DIY (do-it-yourself) sector. Within construction the main market for bricks and roof tiles is the new residential building sector. As bricks tend to be ordered at the beginning of the construction process, the level of new housing starts tends to be a better guide to demand than more general construction output figures. Bricks are also used in non-residential building for exterior cladding as well as for walls, paving, etc. The maintenance market for roof tiles tends to be more important than for bricks.

Other factors affecting brick and tile demand include climate, architecture, taste, and local availability and as suggested previously there are strong regional and national differences in demand patterns.

Supply and competition

Overall there is more than adequate capacity to meet existing and expected future levels of demand for clay products in the EC although once again there are regional variations. In some areas continuing overcapacity has led to the closure of older and less efficient brickworks whereas in areas such as the former East Germany the boom in construction is likely to require the installation of new and modern brick and tile making capacity.

The EC industry meets very little competition from foreign suppliers but increasing intra-EC competition is a firm current

Figure 4: Clay products

and future trend. This has been helped not only by the process of standardisation now underway but also by a greater awareness of building practices from one EC country to another and by the increasing international nature of the companies involved. Investments made by major producers in recent years have significantly brought down operating costs through savings in energy and labour costs and through the economies of scale. The quality and the range of products have both been extended.

The most important competition that clay bricks and roof tiles have to meet is from competing materials, ranging from bricks, blocks, and tiles made from concrete or other materials through to completely different building systems.

Production process

During the past decade the brick and tile making process has undergone major technological improvements at virtually all stages of the process. A more precise understanding of the mineralogy of brick clays has enabled producers to improve properties and exercise greater control of product quality. In a modern plant, large scale mechanised extraction is followed by clay preparation that may now involve pre-treatment (e.g. weathering), blending, crushing, coarse grinding, fine grinding, and mixing. Additives may include plasticity modifiers (such as lignosulphonate to increase or crushed brick grog to decrease), wetting agents (soaps, etc.), colorants (such as manganese dioxide), deflocculants, and last but not least, water. The prepared clay may then be extruded, surface-treated, cut (by wire), and dried before firing in a tunnel kiln. Much effort has been directed in recent years to reducing energy consumption by applying best practice techniques at all stages of the process. Although extrusion offers the most flexible and economical method top produce high quality bricks (including hollow bricks) other methods are still employed. These range from large factories based on dry or semi-dry presses to small factories using hand moulding techniques.

INDUSTRY STRUCTURE

Companies and strategies

Although most of the EC clay brick and roof tile production is in the hands of small or medium sized companies, many of them still privately-owned. In Germany, France, Benelux, and Italy the bulk of production is conducted by companies with annual sales in the 20-60 million ECU range. Most of these companies are based on highly efficient units with mod-

ern plants and the relatively small size is a reflection of the localised nature of the market. Nevertheless the process of concentration is gaining momentum.

This process of concentration is most advanced in the United Kingdom where the clay brick and tile industry is now dominated by production from the conglomerate, Hanson Industries (IRL) (through its subsidiaries, London Brick Co (UK) and Butterley Brick (UK); from two major diversified construction groups: Tarmac and Redland (UK), and the large brick specialist, Ibstock Johnsen (UK). Other companies of note include Marshalls (UK), Baggeridge Brick (UK), and the building products division of Hepworth (UK). In recent years several of these companies have expanded their activities in other EC countries by acquisition. Redland in particular now operates on a pan-EC scale with its brick making in Germany and Benelux handled through a joint venture with Koramic of Belgium and roof tile activities operated through Braas in Germany and Italy and Coverland in France.

Meanwhile other prominent companies operating in the EC include Wienerberger Ziegelindustrie, Karl Bachl, Erlus Baustoffwerke, Roeben Tonbaustoffe, Josef Meindl, and F V Mueller in Germany; Guiraud Frères, Huguenot Fenal, and Sturm in France; Scheerders Van Kerchove in Belgium; and RDB Edilizia, Industrie Bitossi, and Moccia Irme in Italy. In response to increasing productivity the total number of employees in the industry has fallen from 104 000 in 1983 to less than 80 000 in 1992.

REGIONAL DISTRIBUTION

The location of brick and roof tile manufacturing facilities is governed firstly by the location of suitable clay deposits and secondly by proximity to major centres of building activity. Deposits of suitable clays are widespread throughout the EC wherever sedimentary rocks are in evidence. Thus most operations tend to be concentrated in low-lying regions rather than in upland or mountainous regions.

ENVIRONMENT

The principal environmental issues concerning the clay products industry involve the reparation of former clay workings and the various emissions from the firing process. Clay pit restoration is essentially a mining activity (see Chapter 2) thus the central issue concerns firing. Most modern brickworks tend to use gas as fuel if available although coal, oil, and certain waste materials are also used where local conditions apply. Thus attention must be paid to both gaseous and dust emissions. It should be noted that in recent years the clay products industry has successfully devoted much attention to energy saving techniques based on recycling of waste heat, insulation, and best practice operating methods.

OUTLOOK

There are signs of renewed growth in brick production and consumption in the United Kingdom, where the slump in bricks sales has been most marked in recent years. Recovery in other EC countries (apart from eastern Germany) is likely to be slower but the brick and tile industry should enjoy strong demand in later 1990s in accordance with a generally good performance by the construction industry.

Cement
NACE 242

As a result of the economic downturn, consumption and production continued to fall in 1992. The trends in both consumption and production showed marked differences between EC countries. Imports by EC countries continued to grow mainly in Germany while trade to USA dropped.
The outlook for 1994 is not bright as the overall growth in the market is expected to continue to slow down.

INDUSTRY PROFILE

Description of the sector

The activity of the cement industry is connected to construction activity which is often closely linked to the general economic situation. Cement is an important basic material for buildings and civil engineering works, representing major public and private investment.

Cement production consists of two essential phases :

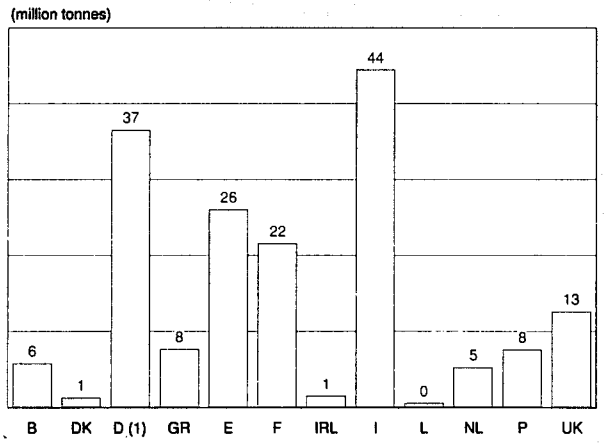
- The manufacture of a semi-finished product, so-called "clinker", obtained from the calcination in a high-temperature kiln (1 450°C) of raw materials (clay, limestone, etc.) previously prepared in paste or powder form depending on the production process used (wet or dry);
- The manufacture of cement as a finished product, obtained by the homogeneous mixture of the ground clinker and calcium sulphate with or without - depending on the type of cement - one or more additional components: slag, fly ash, pozzolana, filler, etc.

Recent trends

Consumption amounted to 171 million tonnes i.e. less than 15% of the world production compared with 21% in 1980.

After seeing a high economic growth rate in Western Europe from 1987-1989, economic activity slowed dramatically in the second half of 1990 and growth virtually ceased in the first half of 1991. Consequently 1991 and 1992 marked a heavy downturn in consumption of cement for a number of EC countries and decreased by a further 1% last year.

Figure 1: Cement
Consumption by Member State, 1992



(1) Includes former East Germany.
Source: Cembureau

Differences in countries' trends are, however, large; the United Kingdom, French and Spanish consumption decreased by about 10%, Germany, due to unification of the country, increased its consumption by 10%, but one third of the increasing tonnages was imported from East European countries. Relatively weak consumption growth was registered in Belgium, Italy, Luxembourg and Portugal.

EC cement production amounted to 169 million tonnes in 1992. As for consumption, differences in countries' trends are large: France and Spain decreased by about 10% the United Kingdom by a further 7%, Italy and Greece stayed at the same level, while The Netherlands and Irish production decreased respectively by 6 and 3%; positive percentages were seen in Germany with about 6% and in Belgium and Denmark with an increase of more than 10%.

Overall employment fell to under 60 000 employees, a drop of 25% in 10 years. On the other hand the productivity of the cement industry rose by about 30% during the same period, thanks to the introduction of more efficient and more sophis-

ticated production tools, with very advanced automation of operations requiring higher qualifications from the staff.

International comparison

World cement production has been estimated at 1 175 million tonnes in 1992 and the 10 major cement producing countries or group of countries were: China (249 million tonnes), CIS (estimated d million tonnes), Japan (95.8 million tonnes), the USA (73 million tonnes), India (53.7 million tonnes), South Korea (43.3 million tonnes), Italy (41.4 million tonnes), Germany (33.2 million tonnes), Turkey (30.2 million tonnes), Mexico (26.9 million tonnes), and Spain (25 million tonnes).

In 1992 total world production of cement (excluding China) again showed a decrease which was partly influenced by the further collapse of the CIS. The overall market curve (including China) is flat, confirming the downturn initiated in 1990. The West and East European countries witnessed a new decline while the USA and Japan showed an increase of 6 and 4% respectively.

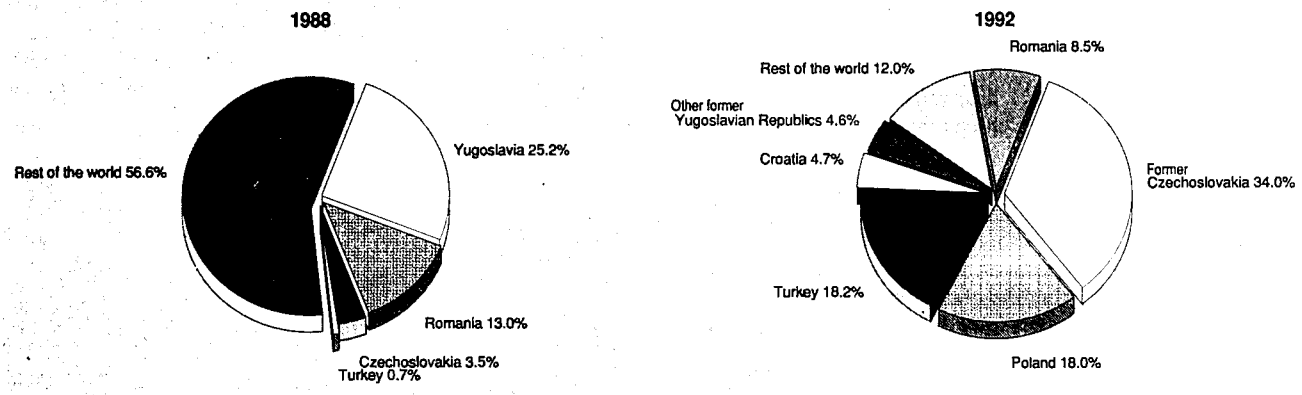
Foreign trade

The geographical distribution of the cement trade is largely influenced by the weighty nature of the product : its modest price per weight unit makes it vulnerable to the effects of transport costs, especially road transport. This is why, most often, cement is delivered to the markets that are closest to the place of production.

It also explains why world trade in cement currently accounts for about 6% only of production. Moreover, it is marked by a very pronounced geographic polarisation. In 1992, 41% of imports were recorded in only six countries: the USA, South Korea, Thailand, Germany, Spain and Italy, while nearly 40% of the world's exports came from four countries: China, Greece, Japan and Turkey. The largest quantities are mainly distributed by sea & water and consumed at a limited distance from the port.

In 1992, Japan again increased its exports by approximately 55% and export volume amounted to 11.4 million tonnes. In 1992 three countries, the USA, South Korea and Germany

Figure 3: Cement
Origin of EC imports (1)



(1) Based on volume data; excluding special cements.
Source: Cembureau

imported more than 6 million tonnes each; the amount of cement imported in Germany increased by 50% these tonnages coming mainly from Eastern Europe.

As expected, trade to the USA continued to drop and now consists of about 6 million tonnes or half that of 1990.

The application of the ITC's (International Trade Commission) anti-dumping duties continued to restrain Mexican, Venezuelan and Japanese exports in 1992.

Imports by EC countries continued to grow in spite of the general downward trend, increasing by approximately 20% in 1992 to 21.7 million tonnes and represent about 30% of total world trade. The imports from East European countries have multiplied 4 times since 1987 and represent about 11%. The largest increase of imports was reported in Germany. Import growth also continued in Spain and Italy during 1992, reaching respectively 13.2% and 8.2% of domestic consumption.

The EC's main exporter was Greece, retaining the same level as the previous year with 44% of production exported.

MARKET FORCES

Demand

As already mentioned, current consumption is linked directly to activity in the building sector and, more accurately, to investments made in residential and non-residential buildings, as well as in civil engineering works. From 1986 onwards, European countries began once again to increase their investment in building and the cement industry quickly recovered from the crisis, to reach consumption levels in 1989 that matched 1980 consumption.

Supply and competition

The EC countries' capacity is currently more than sufficient to cover internal demand. Nevertheless, there is continued exposure to cement imports from East European and developing countries at artificially low prices (dumping conditions). Unfair competition from countries where environmental and social protection is non-existent could have a very damaging impact on the areas where these imports are concentrated.

The legal resources for defence against concentrated dumping at the borders have to be reinforced. Whereas overall economic harm to the EC may appear limited, the same does not hold true at the regional level where the border dumping causes a knock-on effect.

Production process

Cement production requires large quantities of energy. The average energy consumption per tonne of clinker produced in the EC today amounts to less than 900 kcal/kg. This value may vary widely from country to country (from 800 to 1300 kcal), depending on the production method applied. Energy consumption in relation to cement manufacture also depends on the policy pursued by the different national industries as regards investment and the development of composite cements.

The second oil crisis (1979) confirmed the usefulness of the conversion of energy supplies undertaken since 1973.

The industry has continued its efforts in two directions:

- seeking cheaper energy (diversification of fuels)
- rational use of energy (new manufacturing processes, development of composite cements, heat recovery, etc.).

INDUSTRY STRUCTURE

Companies

Restructuring and market positioning of the leading companies is expected to continue.

There are no generally accepted criteria for ranking cement companies or groups, as both turnover and capacity can be defined in different ways. Published turnover in consolidated accounts may include non-cement activities, and the existence of trading affiliates can lead to different quantities of cement being produced and handled by a company. The calculation of capacity control in part-owned companies is treated differently.

Taking into account the above reservations, cement producing groups usually claimed to be the largest five operating companies in the world are: Cemex (Mexico), Heidelberger/CBR (D/B) Holderbank (CH), Italcementi /Ciments Français (I/F), and Lafarge Coppée (F).

ENVIRONMENT

As public concern for the environment steadily increases, so does the activity of the EC Commission and Parliament in tackling environmental issues.

These European bodies highly conscious of their responsibility can be seen in the Commission's strong drive to implement a European Energy/Carbon tax. EC regulatory activity is also extensive in other issues directly related to the European Cement Industry, such as waste classification, incineration of wastes, integrated pollution control, environmental auditing and liability for damages to the environment.

The Cement Industry has therefore devoted much effort to environmental issues, particularly in the finalization, in several languages, of the "European Cement Industry's Approach to the Environment". This document analyses the environmental impact associated with the manufacture and distribution of cement and advises the best way to avoid damage to the environment.

REGULATIONS

A European pre-standard for common cements ENV 197.1 was adopted last year by the Industry through the European Committee for Standardisation (CEN). The pre-standard details composition, specifications and conformity criteria for the traditional and well-tried common cements used in Europe. Cements conforming to the requirements of the pre-standard are termed "CEM" cements.

The pre-standard will now be introduced in the EC and EFTA countries for a duration of 3 (or possibly 5) years and will operate with existing national standards. During this time further work will be carried out and the changes required prior to adoption of a full European standard (EN) will be identified and clarified.

OUTLOOK

As in 1993 the European construction sector is forecasted to shrink by 2%, and the overall growth in the market is expected to slacken; even in Germany where developments in the Eastern Länder are significant, this will not compensate the decline of the rest of the country. Portugal is the only EC country where a slight increase is forecasted. Even if the economy in Western Europe picks up in 1994, there will be a time-lag in its effect on construction and therefore on the cement industry.

Precast concrete
NACE 243.2

After a general status quo in 1991, the sector recently recovered in some countries, closely following developments in the construction sector, which is virtually its only client. Steady growth can be expected for the sector in the medium term. Though the industry is mainly made up of small to medium-sized companies, some mergers and acquisitions activity has taken place. Stricter EC legislation on pollution control will also have its influence on the precast concrete industry. The limited expansion possibilities for mining and quarrying might also pose problems of supply for the industry.

INDUSTRY PROFILE

Description of the sector

The precast concrete industry is the collective name given to all enterprises that manufacture precast concrete products at specially equipped plants at a permanent location and which operate independently of weather conditions. The products are delivered to the construction sector ready to be put in place in building and road constructions, civil engineering works, etc.

Concrete is made from a mixture of sand, water, cement, gravel or other aggregates, and other possible additions. The precast concrete industry as an industrial sector is situated between the sector covering the suppliers (i.e. cement manufacturers and quarries) on the one hand and the customers (i.e. the construction sector) on the other.

The precast concrete industry embraces a wide range of products:

- products for road construction (paving flags, stones and blocks, kerbs, safety and sound barriers, sewerage and drainage pipes and accessories, etc.);
- elements for building construction (masonry units, cladding elements in architectural concrete, floor elements, beams and columns, wall elements for industrial, commercial and agricultural buildings, etc.);
- elements for civil engineering works (bridge girders, tunnel elements, etc.);
- units for various other purposes such as flood protection, urban and garden landscaping, lighting poles, agricultural installations.

Furthermore, the following general characteristics of the precast concrete industry can be highlighted:

- relatively low value-added content of certain mass-produced precast concrete units;
- strong dependence upon the efficiency of the business (i.e. the degree of mechanisation of the production process and the effectiveness of management);
- a predominance of small and medium-sized businesses (often family-owned enterprises). Though some of these businesses have recently been bought up to form bigger concerns, the number of production sites remains largely unchanged (even after the inevitable rationalisation).

In 1992, turnover in the EC approximated 20 000 million ECU and employment was estimated at about 180 000.

National and regional distribution in the precast concrete industry in the EC is very much interrelated and is influenced to a large extent by several factors such as the demographic situation, climatic conditions and the traditional use of certain construction materials.

Recent trends

In the industrialised countries, the activity of the precast concrete industry largely depends on the overall economic climate and on activity in the construction sector in particular, as 99% of the precast concrete production goes to the construction sector. However, trend differences can be observed between residential building, non-residential building and road construction (the latter absorbs roughly 30% of the precast concrete production).

The economic crisis caused a 30% to 40% drop in precast concrete production in the EC with an almost equal fall in employment from the late 1970s to the early 1980s. With the economic revival, production has increased, with figures varying depending upon the country considered.

For the EC countries (for which data are available) production in current prices has grown considerably over the last three years. In 1992, growth stagnated in almost all Member States, except Germany where continued growth was noted, and Italy and the United Kingdom where a strong downturn persisted.

International comparison

Due to climatic conditions, prefabrication is generally stronger developed in the northern countries. This explains the relatively high level of precast concrete activity in the Nordic countries. However, the recent economic crisis has had severe consequences for the activity of the sector in Sweden and especially in Finland where over the last two years a downturn of 40% was noted.

Notwithstanding some local competition from neighbouring East European countries, the production volume in Austria remains satisfactorily. Switzerland is a typically local industry with a very closed market which is probably due to the rather

heavy weight of the product and the inherent transportation possibilities.

The level of activity in the North-American precast concrete industry varies strongly depending upon the product branch. Large structural elements for industrial applications, large-diameter pipes and paving blocks seem, however, the most successful products of the last decade. Concrete masonry units seem recently to have recovered some of the attraction lost in the early 1980s.

Foreign trade

Generally, precast concrete products are heavy and bulky in relation to value. The average value of one metric tonne of precast concrete products is approximately 100 ECU (but for some standardised non-reinforced products manufactured on a large scale, this value can be as low as 35 ECU). Consequently, long-distance transportation of precast concrete products is unusual and trade is mostly limited to a single border crossing. A typical exception is, however, the technologically highly-advanced precast concrete products such as sophisticated cladding elements in architectural concrete.

MARKET FORCES

Demand

The activity in the precast concrete industry strongly depends on the activity in the construction sector, which in turn is greatly dependent on the overall economic climate. As a consequence, periods of high activity peaks in the precast concrete industry are succeeded by low-activity periods leading to costly overcapacity.

A further factor causing variations in activity levels is the financial situation of the public authorities. Approximately one third of construction activity covers public works (involving road construction, civil engineering works, etc.), a field soon afflicted by cuts when the public authorities experience financial difficulties.

Supply and competition

The precast concrete industry faces competition from traditional construction procedures with an intensity varying from country to country and closely related to the marketing skills of the local precast concrete industry.

There is indeed a wide range of substitution products offered, ranging from classical materials such as clay brick and timber to newer materials such as PVC.

Production process

Since non-reinforced concrete began replacing natural stone, timber and cast iron in many applications, the precast concrete industry has become highly mechanised. The rapid technological development of reinforced and prestressed concrete has led to the breakthrough of various plant-manufactured structural elements for building construction and civil engineering works.

Lightweight concrete was first applied in the precast concrete industry for the manufacture of masonry units, wall and floor elements.

The construction boom in the 1960s and early 1970s, as well as the increase in building costs over that same period led to a further industrialisation of the precast concrete industry. Profits were reinvested in both plants and modern machinery such as semi-and fully-automated batching and manufacturing equipment. Handling, packaging and transporting techniques were equally revolutionised.

To date, the following particular technological aspects of the precast concrete manufacturing may be pointed out:

- the manufacture at a plant with a permanent location in controlled conditions;
- the use of a proper scientific concrete technology such as the use of 0-slump concrete, hot concrete and pre tensioning techniques, particular moulding and compaction techniques and accelerated hardening techniques;
- an advanced quality control which goes beyond the checking of the fresh concrete; quality control in the precast concrete industry includes the control of: dimensional accuracy, the properties of the hardened concrete, the position of the reinforcements. This control is done before the product has been incorporated into construction;
- an advanced automation of manufacturing methods and plant, not to mention an increasing level of industrialisation and standardisation.

This specific and scientific approach of the concrete technology helps to guarantee a high and consistent quality of precast concrete products.

Basically, most "new" products in the precast concrete industry are an evolution of existing elements. Nevertheless, the industry has developed (and is successfully marketing) valuable solutions in fields relative to, for instance, environmental problems such as sound barrier walls to protect residents living near highways or railways from noise hindrance.

INDUSTRY STRUCTURE

Companies

As already mentioned, the precast concrete industry remains predominantly composed of small-to medium-sized, generally old family-owned enterprises, and this notwithstanding a rationalisation movement in recent years through the formation of company groups or the selling of family-owned businesses to a holding company.

This movement has been spurred on mainly by two concurrent factors. The first one is fragmentation of family-owned businesses (that had grown to considerable sizes since World War II) due to succession problems. The second one is, in the context of the Single Market, a trend toward increased concentration in view of allowing large construction companies to control supplies on the foreign market they entered, or

Source: BIBM

creating concrete companies large enough to deal with the big construction companies on an internationalised market.

This rationalisation movement has inevitably reduced the total number of enterprises, but not to the extent one might have expected. Even after these operations most production sites remaind in business, mainly because of the rather heavy weight of many precast concrete products and the transportation costs involved. For instance, after a company in one of the bigger countries had bought up 25 smaller enterprises, some 15 remained operational.

Even though there is not complete information on EC employment in the precast concrete industry, a reasonable estimate is around 180 000 people. The number of employees is spread over nearly 5 000 precast concrete plants, of which approximately 600 employ more than 50 people.

Following on some years of continuing growth in employment (catching up on the strong drop during the years of the economic crisis), this figure has now come to a relative standstill in some countries, while in other (such as the Nordic countries and the United Kingdom) it is falling again as a consequence of the economic crisis occurring in the countries concerned.

On the labour market, wage costs have risen in recent years as a result of reduced working hours, as well as a shortage of skilled labour. The overall average hourly wage cost in 1992 was of approximately 16 ECU.

Skilled manual workers constitute about 25% of employment in the precast concrete industry. These workers are involved in special production procedures such as reinforcement steel bending and netting, and the finishing of architectural concrete (e.g. polishing).

In several Western European countries the limited number of labourers in this field are in particularly high demand, as younger school graduates do not appear to be strongly attracted towards this occupation. To cope with this problem, the industry has set up specific programs ranging from training courses for young adults and/or unemployed people, the publication of manuals, and campaigns designed to improve both the image of the industry and the attractiveness of jobs in precasting. For instance, in recent years the industry in Germany has regularly organised a nation-wide promotion day, offering younger people the opportunity to visit precast concrete plants.

Strategies

Some degree of concentration has occurred in the industry in recent years, varying in nature and intensity from country to country, because either one or more small businesses were bought up by holdings or major industrial groups (often a large building company, a cement factory or an aggregates supplier), or because various smaller concrete businesses have merged.

Besides entering in mergers and acquisitions, the industry also aims at further increasing productivity (estimated to have risen by roughly 40% over the last fifteen years) and improving quality. First of all, the precast concrete industry has raised fixed investment by about 45% from 1985 to 1992. These investments, reflecting significant efforts toward innovation in the sector in recent years, involved not only replacement of older equipment and installations but also an increase in capacity, thus enhancing the competitiveness of plants in their region.

Secondly, precasters have become increasingly aware of the market advantages of guaranteeing the adequate durability of products (durability implying here both soundness and long-term appearance) and improved design. Hence, the active participation of the precast concrete industry in the European harmonisation, certification and standardisation work in view of the implementation of the Construction Products Directive: the CE quality label.

Technological evolution constitutes a further influential factor. Indeed, the technical realisation of new types of beams or girders with, for instance, larger spans, would automatically create a higher demand for these structural elements.

REGIONAL DISTRIBUTION

National and regional distribution are narrowly intertwined.

The precast concrete industry is particularly important in Germany, relatively important and advanced in the Netherlands and Belgium, and to some extent, in France and northern Italy. In some countries, there is a higher concentration of the precast concrete industry in certain regions e.g. the South West of the United Kingdom.

Geographical factors also played an influential role in the precast concrete industry. The more densely populated a region is, the more important and developed the precast concrete industry tends to be. These regions have a higher demand for building, water and road construction and since precast concrete products are heavy, and costly to transport, production takes place near the centre of demand. An example of this is the triangle of dense population in Belgium, the Netherlands and Germany, in contrast to more sparsely populated regions in central France and Spain.

Climatic conditions also play an important role. In general, the further north a country is situated, the more developed its precast concrete industry is. Traditional building activity in northern countries often has to be suspended during the winter due to bad weather conditions, while precast concrete products allow uninterrupted building activity.

Traditional use of certain construction materials has influenced the degree of development and strength of the precast concrete industry in the various Member States. In the Netherlands, for example, a boom began for precast concrete pavers when traditional clay pavers started to become too expensive. This secured the Dutch paving industry a strong position which allowed large-scale production at a favourable cost. Another result of this situation was that transportation beyond The Netherlands' borders became possible. By contrast, the British precast concrete flooring industry has encountered great difficulty in breaking into the traditional timber floor market for low-rise housing.

The percentage of the precast concrete industry in the total national cement consumption illustrates the actual penetration of the precast concrete products on the construction market. This shows a rather positive trend in most countries, especially in those countries where the industry has successfully commercialised its precast concrete solutions. Indeed, by producing certain construction materials at fixed plant instead of producing at the building site, construction costs may be significantly reduced.

ENVIRONMENT

EC legislation on pollution control will also have its influence on the precast concrete industry. The national legislations concerning environmental protection aim particularly at reducing emissions from the raw materials and manufacturing industries. Hence, considerable know-how and capital investments in environmental protection are required of these industries. By means of modern techniques (such as waste water treatment installations), the pollution of air, water and soil may be controlled notwithstanding a growing production; modern techniques will thus help dissociate industrial production and economic growth more and more from environmental exploitation.

In the precast concrete industry, a noise problem may occur as increasing urbanisation encroaches upon precast concrete plants. However, the industry has already recorded some success in reducing noise levels.

Increased restrictions on gravel extraction, anticipated in a number of Member States, could affect the concrete industry by rendering raw material supplies more difficult on the longer term. Raw material shortages might arise in some countries. In addition, the quarries supplying the precast concrete industry with sand and aggregates are either forbidden to extend further, or threatened with closure. Since about 80% of concrete is made up of sand and aggregates (1 m3 concrete requires two tonnes of these raw materials), this may cause serious short-term problems, not only for the precast concrete industry but also for the construction industry as a whole.

Consequently, certain research programmes are being conducted with the aim of recycling concrete debris, crushed concrete and waste concrete as raw materials. Due to requirements for high quality inputs, however, the precast concrete industry has only limited opportunities for using such recycled materials. Moreover, high-quality aggregates are also a prerequisite to meeting the stringent performances demanded as a rule of precast concrete products. Furthermore, they play an important role in one of the major advantages of precast concrete (i.e. smaller dimensions of the components which would reduce their weight, improving transportation costs).

Within the framework of BIBM it has been decided to set up a Task Group "Environmental matters" to examine and suggest answers to the various environmental challenges the industry is currently facing and will have to face in the near future.

REGULATIONS

The Single European Market and the coming into effect of the Construction Products Directive (CPD) had emphasised the urgency of the work on harmonisation, standardisation and certification.

Adoption of common standards and quality certification systems at Community level is essential for the precast concrete industry. The precast concrete industry has a preference for the most stringent level of attestation of conformity, involving product certification by an approved third party. Such certification would help to maintain client confidence in the high quality of the products, improve the quality image of the concrete products, and reduce the chances of having regulatory attestation exist next to some kind of voluntary certification system.

OUTLOOK

In general, 1993 is expected to show very mixed results in the various Member States. Steady growth is foreseen in Germany and a near status quo in Belgium, Denmark and the Netherlands. France entered a period of negative growth in 1992 and no improvement is expected in the near future. A deep recession persists in Italy and other Mediterranean countries due to severe restrictions in public spending and an overall unfavourable economic climate discouraging investments in industrial buildings and, to a large extent, in private housing. The United Kingdom suffered from deep recession since 1991 but the general impression is that the bottom line has been reached with some indications that slow growth is possible in certain areas. As already mentioned, the activity of the precast concrete industry largely depends on the overall construction activity and thus any improvement there will have a favourable impact on the economic situation in the precast concrete sector. The specific advantages of using precast concrete products for the execution of a construction will on the medium to longer term inevitably result in a larger share of the sector in the overall construction volume.

Ready mixed concrete
NACE 243.6

The year 1992 has marked the first overall fall in production in six years. Prospects for the immediate future are not good with only modest overall increases of 2% expected over the next three years.
The industry is working hard to ensure that EC regulations in being and in prospect will be those that the industry can meet in the normal course of business.

INDUSTRY PROFILE

Description of the sector

The ready mixed concrete industry covers the off-site manufacture of fresh, unhardened concrete and its transport to the location where it is placed as required. It is by definition a local industry offering little or no potential for trade even within the EC. In fact, the fresh product can only be transported for short distances, seldom more than a few tens of kilometres.

The European ready mixed concrete industry is a relatively new industry which has contributed substantially to the modernisation and efficiency of the building construction industry in each country. ERMCO members have, for the past 26 years of the organisation's existence, concerned themselves with improving the quality of their product. They have ensured that the concrete is designed for the purpose specified and have sought means of improving the marketing of the product against its main competitive products: wood, bricks and steel. Although the use of concrete goes back to Roman times, the production of ready mixed concrete from an exclusively designed plant probably started at the beginning of this century with Germany leading production in 1903, followed by the USA in 1913. More widespread use of the product developed when the United Kingdom and France established their industries in the early 1930s.

Today there are few countries in the world which do not have a ready mixed concrete industry. The largest EC producer, in volume, is Italy; Germany follows closely. Then come Spain, France and the United Kingdom.

Recent trends

Over the 1988-1991 period, ready mixed concrete production increased annually at a faster rate than that of the other EC manufactures. In 1992, a 1% decrease was recorded in all EC manufacturing sectors, ready mixed concrete sector as well.

MARKET FORCES

Demand

Total EC production for 1992 was 257.1 million m^3. Production of EC Members of ERMCO in the calendar year 1992 totalled 214.8 million m^3 (85% of the EC total), a fall of 3.57% compared with the previous year. This fall comes after almost six years of increases in production. However, following the Gulf war, the consequent disruptions arising from the break-up of the former Soviet Union and other East European states, and the even greater instability from the conflicts in the former Yugoslavia, have shaken business confidence considerably. Few countries are holding to their previous levels of production, small downturns are not unusual and there are some countries reporting severe reductions of 20% or more.

Another serious aspect of the present recession is the problem which is being caused by the growing practice of Public Administrations and Authorities to delay payments for work completed by the Prime Contractor. In turn, the Contractors are deferring payments to their Sub-contractors and Suppliers to the extent that the continued financial viability of many small enterprises is being seriously threatened.

Members of the European ready mixed concrete industry have confirmed that this is a common practice. ERMCO is actively considering the best means of representations being made to national authorities and to the EC to overcome the difficulties which are being created by this unethical practice.

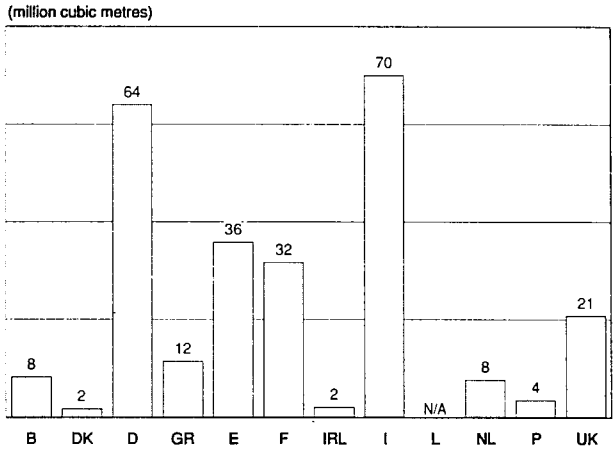
Production volume by Member State, 1992



Source: ERMCO

INDUSTRY STRUCTURE

Companies

It will be seen that, on average, there are just over 4 truck mixers to each plant. This varies by country from 3 to 6 per plant, depending on their geography.

Prospects for the immediate future are that production levels will do well to hold to the 1992 totals. Until more settled economic conditions return, no advance of any substance can be expected. At this time, the industry needs to be in a period of consolidation and investment in the infrastructure and the

environment. On the contrary, the growing unemployment debt is resulting in reduced public expenditure and a lack of investment confidence among private investors, with many major cities having large areas of unused new office and industrial space.

ENVIRONMENT

Pollution of the environment is one of the major political and economic issues in Europe today. The industry's Environment Task Group has been actively involved in studies in a number of areas including:

- Preparation of Code of Environmental Good Practice and Environmental Audit Check List
- Investigations in systems and costs of environment-related investments on ready mixed concrete plants, and the European limits on levels of air, water, and noise pollution.
- Comments to the EC on the proposed taxation of CO2 emissions.
- Compilation of EC Regulations having an effect on ready mixed concrete production.
- Studies of EC Environmental Directives
- Inter-relation of new Initiatives for Environmental Performance
- Studies of Producers liability.

REGULATIONS

The target date of 1992 set for the completion of the European common market standards and the removal of the technical barriers to trade resulted in greatly increased activity both in the years leading up to that date and subsequently. This activity has been concerned with the drafting of EC Directives covering construction products, certification and testing, and of Eurocodes and CEN (European Committee for Standardisation) standards for concrete. These documents place a great emphasis on quality and should enable the standards already achieved by the European ready mixed concrete industry to be fully recognised.

Basic policies for ERMCO Members cover the main aspects of Standardisation and Certification.

For Standardisation the same standards must apply to all types of concrete including ready mixed, site mixed, and precast concrete. For efficiency and economy whenever possible, standards are required to be expressed in performance terms. The industry's technical experts maintain a strong presence on the key CEN Committees and Working Groups and actively disseminate these policies. Difficulties have been created by the absence of a final mandate from the EC to CEN for work on concrete. Meanwhile, the CEN/TC104 Committee on Concrete has made steady progress towards achieving agreement on a new draft EN 206 European Standard for Concrete determining an appropriate Level of Attestation of Conformity; this is to be completed before the end of 1993. In those areas where a single solution has not been found, several alternative solutions have been developed as proposed by ERMCO:

- certification policy states that all concrete including site mixed (contractors) concrete, ready mixed and precast concrete should be subject to the same levels of quality control and attestation of conformity. Priority tasks in the short and medium term are:
- preparation of a quality system for ready mixed concrete which satisfies the Attestation of Conformity requirements for production control and certification in the Construction Products Directive and which is compatible with the Conformity Criteria in Section 11 of EN 206.

A CEN Committee CEN/TC 151 has been set up to define CEN Standards for the safety of construction equipment and building material machines. ERMCO is making comments on the Drafts concerning concrete and truck-mixer equipment and concrete re-cycling plans.

terranean countries, expect it to get worse before it gets better. The rising tide of unemployment is depressing the whole European economy and there will be several difficult years in the future. Recent experience suggests there should be a certain wariness of unknown crises which may lie ahead. A positive step has been the EC Growth Initiative, the plan for economic recovery with investment in the infrastructure. Already Greece, Ireland, and Portugal have submitted detailed plans for temporary loans for relevant activities.

Reacting to the demand for industry-led initiatives, the ready mixed concrete industry, through the individual members of ERMCO, is playing a significant role in establishing realistic standards for concrete manufacture, quality control and environment protection.

Glass
NACE 247

The EC is the world's largest glass producing and consuming region. After a period of restructuring and technological advance during the 1980s the EC industry is modern, efficient, and competitive in world markets. Good steady growth during the 1983-91 period has been temporarily halted but is likely to continue beyond 1994. The industry has an excellent environmental record and the container glass sector is at the forefront of recycling developments. As far as flat glass is concerned, the relationship with Eastern Europe may create some problems of low-priced for EC producers that are likely to be outweighed by the mutual benefits of an expanded European market in the later 1990s.

INDUSTRY PROFILE

Description of the sector

The glass industry can be divided into five main sections: container glass (consisting primarily of glass bottles and also known as hollowware), flat glass (consisting primarily of window glass), tableware (domestic glass), glass fibre (for insulation and reinforcement), and special glass (such as optical and industrial glassware). In tonnage terms, container glass accounted for 66% and flat glass 25% of total EC glass production which reached of 23.2 million tonnes in 1992.

The principal raw materials for glass manufacture are mineral products such as silica sand, limestone, dolomite, soda ash, feldspathic materials, and borates as described in Chapter 2. The principal consuming industries are food and beverage processors (for container glass) and construction and motor vehicle industries (flat glass), although the full range of glass products find important applications across the whole spectrum of industry and construction as well as direct consumer items. By any reckoning, the EC glass industry is a major sector, vital to the overall EC economy.

Recent trends

The EC glass industry has displayed excellent growth with production averaging 2.8% and consumption averaging 3.5% per annum in real terms for glass products during the 1983-1992 period. It maintains a healthy trade balance with an annual average 13% of production value being exported over the period. However, imports have grown faster than exports, accounting for 8% of consumption in 1992 compared to 6% in 1983. Both production and consumption were about the same in 1991 and 1992 and in 1993. However, it should be noted that different segments have behaved differently so that the domestic glassware industry has suffered a sharp fall in output between 1991 and 1992 whereas flat glass production recovered from its fall of the 1990-1991 period and container glass accounted for 66% of all glass production.

International comparison

The EC is the world's largest glass producer with a total output of 23.2 million tonnes valued at 22.2 billion ECU in 1992. US glass production was just under two thirds and Japanese production just under the half of the EC total in 1992. However, Japanese production has grown the fastest over the 1983-1992 period and has now a higher per capita output figure than either the EC or the USA.

Foreign trade

As suggested earlier, foreign trade is an important though not dominant part in the EC glass market. In value terms, the EC glass industry is a net exporter although in tonnage terms it is actually a net importer, albeit by a small margin. This can be explained by the types of glass featured in this activity, in which a major element of imports consists of large tonnages of cheap containers and unworked flat glass from Eastern Europe whilst exports contain a major contribution from the domestic glassware sector with high value sales to the USA, Japan, and the EFTA countries. However it varies depending on the countries concerned. There have been big tonnages of unworked glass from Poland, and containers from former Czechoslovakia, and local problems such as Bulgarian bottles distorting the Greek market. However, the biggest single item in imports from the former Czechoslovakia, Poland and Romania, with a larger quantity also coming from Hungary, has been in tableware. There are also increasing imports of float glass, particularly from the Czech Republic.

In recent years over 50% of the total tonnage (but only 40% of the value) imported was sourced from Poland, the former Czechoslovakia, Hungary, the former Yugoslavia, and Turkey. Meanwhile the EC imports from the EFTA countries represented in 1992 only 24% of the tonnage but 30% of the value. The USA is also an important source of imports, par-

ticularly for glass fibre but increasingly too for flat glass. The principal destinations for EC exports are the EFTA countries (nearly 40% of the tonnage and around 30% of the value), Japan (15% of the tonnage) and the USA (11% of the tonnage and 20% of the value) but the remaining 45-50% (in value terms) of total exports is spread across a wide range of countries.

Intra-EC trade became an increasingly important element of the market during the 1980s and now accounts for about 25% of total consumption. Belgium is notable as the principal net exporter of glass products in intra-EC trade.

MARKET FORCES

Demand

Glass is used by a very wide range of industries and furthermore up to 15% of sales consist of private consumer products. It is not therefore tied too closely to a single or narrow range of consuming industries. Nevertheless the fortunes of the EC glass industry are seen to be strongly aligned to developments in the food and beverages industry (for container glass) and to the construction and automotive industries (for flat glass), which together account for about 50% of all sales. Glass containers meet strong competition from other packaging materials but particularly from aluminium, plastics (mainly PET), and paper (aseptic cartons) in the beverages sector. After originally losing market share to these other materials, glass has been performing strongly in recent years on grounds of performance, cost, and ecological advantages based on its recyclable character.

Supply and competition

As the world's major consuming region for glass, the EC is a natural target for foreign companies wishing to expand their sales. In the case of the east European countries it is clear

Figure 4: Glass
International comparison of production in current prices

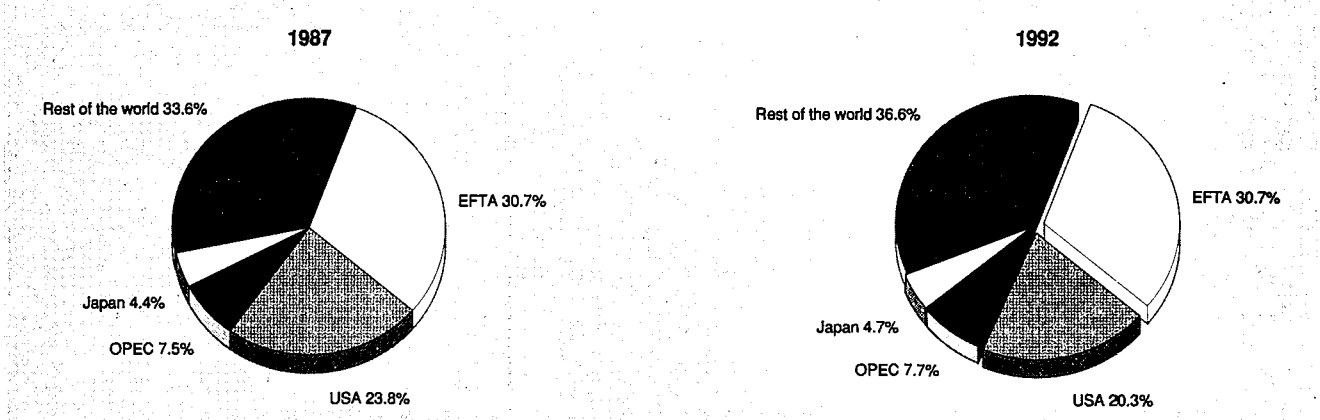
Figure 6: Glass
Destination of EC exports



Source: Eurostat

that the low labour costs and close proximity to markets have provided the platform for the growing export trade described above. In other cases foreign companies have gained major access to the market by acquisition (e.g. the Japanese producer Asahi Glass is the principal shareholder in Glaverbel in Belgium and Maasglas in Netherlands) or by building new plants (e.g. Guardian in Luxembourg). Thus EC producers undoubtedly operate in a very competitive environment although different factors come into play in the different segments of the market.

EC container glass producers meet some competition from the cheap European exports but would still see alternative packaging materials as the main threat. The rationalisation programme which was carried out in the early 1980s to combat the twin ills of industrial recession and burgeoning demand for alternative products (e.g. PET bottles) has been highly successful. Glass regained lost ground and producers operated at close to capacity levels in 1989-1991.

Flat glass does not meet the same degree of competition from alternative materials but EC producers have had to meet competition from without (imports) and within (increasing foreign involvement in EC production). The industry has moved from high capacity utilisation in 1987 and 1988 to a situation of increasing surplus capacity which will become more acute as new float glass plants are brought on stream in Poland (Pilkington of UK at Sandomierz), Spain (the Guardian Industries at Tudela, Navarra Province), and France (Euroglass) during the 1993-95 period.

Production process

In the glass container sector the past 10 years have been marked by major advances to productivity, process monitoring and control systems, and quality, as well as recycling and light weighting (the production of strong lightweight bottles). Major improvements have been made to furnace performance with regard to energy efficiency, high throughputs, and capability to take an increasing proportion of recycled glass (cullet) as feed material. The efficiency and throughput of automatic forming machines have also improved beyond recognition. Many of these factors also apply to other sectors of the glass industry including flat glass. The float glass process (originally launched over 30 years ago) continues to dominate flat glass production in Europe and has resulted in the closure of all but a handful of older technology sheet glass plants.

INDUSTRY STRUCTURE

Companies

The high degree of concentration in the EC glass industry is a reflection of the large scale and capital intensive nature of modern glass making plant. The EC flat glass industry in particular is dominated by just six companies: Pilkington (UK), Saint Gobain (F), SIV (I), Glaverbel (B, a subsidiary of Asahi Glass of Japan), and the two US companies, PPG and Guardian. Together they account for over 95% of total output.

Saint Gobain is also a major factor in the container glass industry with major manufacturing operations in 6 EC countries. However, a large number of companies are involved in the container glass sector with smaller specialist companies coexisting alongside the larger groups. Other major producers include BSN (F), Gerresheimer Glas (D), Ruhrglas (part of the VIAG group (D), Hermann Heye (D), Nienburger Glas (D), AVIR (I), PLM Group (D, UK, NL), Rockware (UK), and United Glass (UK).

The special glass sector is dominated by the German group, Schott Glas, which is a world leader in the manufacture of optical and industrial glassware. Other important companies in this sector are Corning (part of the US group) of France and Pilkington in the United Kingdom Among a large number of decorative glass producers the largest would appear to be the Waterford Crystal of Ireland although it should be noted that Venetian glass and the famous Murano producers are still highly influential in world markets. There are also Baccara, Lalique, or Crystalleries d'Arques (the latter with cheaper products, but still with high sales) in France, Val St Lambert of Belgium, Calp of Italy, Nachmann Bleikrystall of Germany.

Strategies

Although Saint Gobain and Pilkington are the principal companies operating on a European level a number of other such as BSN, PLM, Guardian, and Schott have important plants outside their home country. A number of companies operating in the EC have also formed alliances in Eastern Europe. These are notably Pilkington in Poland, Glaverbel (Asahi) in the Czech Republic (Glavunion and Obalunion), and Guardian Industries in Hungary (Hunguard).

REGIONAL DISTRIBUTION

The location of glass manufacturing facilities may be governed by proximity to raw material sources (e.g. Belgium with its abundant supplies of high quality silica sand, limestone, and soda ash) or proximity to consuming industries (e.g. where bottle factories are located in wine-growing districts or close to major breweries) or even a combination of these factors tied to good communications.

ENVIRONMENT

The glass industry is a major user of fossil fuels and is therefore subject to controls on gaseous and dust emissions. EC glass producers have a good record in dealing with the problems and operate within the limits of current legislation. The industry continues to work to improve existing practice, not only with reducing emissions but also to further improve energy efficiency. On another environmental front, recycling, container glass is probably at the forefront of all major industries in its ability to use both process waste and use of waste glass. In countries such as the Netherlands, Germany, Belgium, and Italy the recycling rate exceeded 50% in 1992 and great strides are being made by more recent converts such as the United Kingdom and Ireland.

REGULATIONS

The industry is directly affected by EC Directive 85/360 concerning air pollution and provides an ideal example of how caution and foresight must be applied when introducing pollution control measures. New measures will add substantially to costs and put EC producers at a considerable disadvantage to competitors in countries with lower environmental standards. Through products such as double-glazed windows and glass fibre insulation, glass presents major energy saving opportunities and it would be ironic if a possible carbon tax were to penalise an industry making a positive contribution to the overall carbon dioxide equation.

OUTLOOK

The EC glass industry is in good health and likely to benefit from improved industrial performance in the years ahead. Some concern is expressed concerning rising costs of complying with environmental regulations and the flat glass industry may be due for a period of oversupply due to capacity expansions in Europe as a whole. Nevertheless the potential for high growth, particularly in Eastern Europe, would soon minimise such fears.

Ceramic goods
NACE 248

The ceramic goods industry covers a range of products from tiles, tableware and sanitaryware to refractories and advanced ceramics. It is difficult to think of another EC industry in which the type of company and state of technology covers such a broad spectrum. EC industry stretches from small family companies producing clay-based products according to methods developed several millennia ago to important materials groups at the forefront of developments in advanced ceramics. Modernisation and restructuring will be necessary in some segments to maintain the EC's position as the world's leading producer of this group of products.

INDUSTRY PROFILE

Description of the sector

The principal ceramic products covered under this heading are floor and wall tiles (NACE 248.3); sanitary ware (NACE 248.5); tableware and ornamental ware (NACE 248.6 & 248.7); industrial ceramics (NACE 248.8); and refractory products (NACE 248.1). Other ceramic materials covered in other monographs of Chapter 5 include bricks and roof tiles, and pipes. The products described are based on the industrial mineral raw materials covered in Chapter 2 but in particular on the clays and other silicates (feldspar, talc, sillimanites, wollastonite, and zircon), silica (silica sand, quartz, and quartzite), and mineral oxides derived from such minerals as magnesite, dolomite, limestone, and bauxite.

They are consumed across a wide range of industries but the principal markets are building and construction (tiles, pipes, sanitary ware), domestic and leisure industries (tableware, hotel ware, ornamental ware, etc.), electrical and electronic engineering (insulators); and metallurgy (refractories). The new breed of advanced ceramics (also known as technical ceramics or engineering ceramics) are also becoming of increasing importance to the mechanical engineering sector. Thus ceramic products are not only consumer items but are also vital to a whole range of industrial processes.

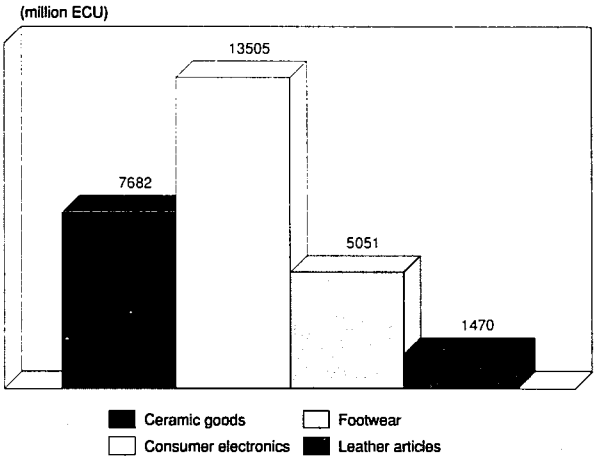
Recent trends

EC production and consumption of ceramic goods showed good steady growth during the 1983-1991 period since when there has been a decline in most subsectors. In real value terms production grew by an average 2% per annum and consumption by 2.7% over the 1983-1992 period. As this suggests, imports have grown faster than exports but the EC is a major net exporter with sales to foreign countries consistently making up about 20% of total production. The contribution of imports to total consumption has grown from 7% in 1983 to 9% in 1992. The downturn in consumption since 1991 has resulted in lower volumes and prices which are most severe in tableware and refractories segments.

International comparison

The EC is generally regarded as the world's largest ceramic producing region but it is well recognised that the fastest growing region is the Far East where Japan, China, and the ASEAN countries have all been displaying spectacular growth during the past decade. Meanwhile the US ceramics manufacturing sector has been somewhat moribund during the 1983-1992 period and indeed the USA is a major net importer of products such as ceramic tiles and tableware.

Figure 1: Ceramic goods
Value added in comparison with other industries, 1992



Source: DEBA

Foreign trade

As mentioned earlier, the EC is a highly active participant in foreign trade in ceramic goods, most prominently as an exporter but also as a significant importer of certain goods. Imports are on a clear upward trend and Far Eastern producers such as China, and the ASEAN countries have been particularly successful in penetrating the tableware and ornamental ware segments of the market. It should be noted that although EC exports still exceed imports in value terms for these segments the total tonnage imported (over 300 000 tonnes) was almost exactly double the total export tonnage. This emphasises the point that import penetration is principally at the lower priced end of the market. With regard to non-Asian sources, the EFTA countries are notable suppliers of sanitary ware and refractories whilst the USA is prominent in the areas of refractories and technical ceramics. The Czech Republic (formerly part of Czechoslovakia) is prominent among the eastern European countries supplying white ware products to EC markets.

The EC exports an enormous range of products to destinations throughout the world. The EFTA countries feature prominently across the full range of products whilst the USA is a major customer for wall tiles, tableware and ornamental ware, and refractories. Australia, Canada, and Japan also feature prominently for these items.

MARKET FORCES

Demand

The building and construction industry is by far the major influence on demand for ceramic wall and floor tiles and for sanitary ware. Demand for these products is well spread across a full range of structures and buildings, from private dwellings to public buildings and industrial structures, and is not just limited by new building. The maintenance and renovation market for tiles and sanitary ware provides an extremely important secondary market and the fact that both form a central element to interior design means that replacement takes place on aesthetic grounds in addition to the more normal reasons of wear and tear. Sales of wall tiles in particular take place on several levels, from large construction companies to the individual DIY (do-it-yourself) enthusiast, and the latter may even buy from a shop devoted to selling tiles, wall tiles, and floor tiles. Fashion trends also constitute a very important element in product replacement.

The tableware and ornamental ware segment also takes more than a passing interest in new public building and renovation schemes since hotels, restaurants, hospitals, and the like are all major buyers of tableware. Indeed the special requirements of the hotel and catering trade has given rise to the "hotel ware" sub-sector with specially designed hard-wearing ceramics. Meanwhile the private buyers in this segment tend towards some of the more upmarket products designed by artists and made in prime raw materials such as porcelain and bone china.

The refractories segment is a fascinating industry in which technical advances continuously reduce the size of the market. Refractories are vital to high temperature processes required to produce metals, glass, steel, cement, ceramics, and a range of other products but the tonnage growth of these products in recent decades has never been enough to counter the decrease in unit consumption brought about by technical advances to processes and materials.

The technical ceramics segment is to some extent based on materials and techniques developed by the refractories industry and adapted towards engineering applications. Certain products such as electrical insulators made of alumina or steatite have actually been around for some time but some of the "newer" ceramics are becoming of increasing importance in electronics, chemical, mechanical, biological, and nuclear engineering applications. Very high growth rates are predicted for materials such as silicon carbide, silicon nitride, sialons, partially stabilised zirconia, aluminium nitride albeit from an initially low volume base.

Supply and competition

The EC ceramics industry has not only centuries of tradition to draw on but also ample supplies of high quality raw materials, a strong and continuously evolving technical base, and an enormous home market. Yet it has proved itself to be vulnerable to competition from geographically distant sources of the Far East. This has been due to a combination of the low labour costs of some of these countries and the fact that producers in these countries have embraced European processing technology to boost their own production. This has exposed the high production costs and overcapacity existing in much of the EC tableware sector. The impact has been the greatest at the lower quality end of the market, causing some EC producers to concentrate on more upmarket products, others to take major cost-cutting measures to remain competitive, and yet others to go to the wall. Vulnerability to Far East competition may also be due to low environmental considerations if any, with resulting lower costs in this area. It is worth mentioning then the problem emerging when some producers send designers to Europe to copy European designs. The end result is that the customer sees on the shelf an EC made product produced to high environmental considerations, standing next to a low priced import which looks exactly the same, but has been made to low, or no environmental standards, and which costs a fraction of the price.

Source: DEBA

The current downturn in demand has certainly reduced operating margins for even the most efficient producers yet further efficiencies will no doubt be required to survive the worst in order to take advantage of the projected recovery.

Production process

Although the traditional ceramics industry, wheel and the skilful hands of dedicated craftsmen, still retains a niche at the "arts and crafts" end of the ceramic market spectrum, the modern ceramics industry is actually one of large scale, automated processes, close technical and quality controls, and a technically trained workforce. The new techniques introduced over the past 20 years are: dry pressing, pressure casting, isostatic pressing, fast firing, roller kiln firing, plus the use of robotics in glazing and decorating.

INDUSTRY STRUCTURE

Companies

The EC ceramic goods sector has total production of around 14 billion ECU and employed, in 1992, around 240 000 people involving over 2 500 companies. The figures bear out the predominance of small and medium-sized companies in the overall picture.

Some of the largest companies operate in the refractories sector where a high degree of concentration now exists and where five companies account for about 65% of total European (EC plus EFTA) production. These companies are: Didier-Werke (D), Oesterreichische Magnesit (A), Hepworth Refractories (UK), Sanac (I), and SEPR (F). Other important mainstream refractory producers include Refratechnik (D), the Wulfrath Group (D), Baker-Steetley (UK), Dyson Refractories (UK), AMR Refratarios (E), Dr C. Otto Feuerfest (D), VGT-Dyko (D). Significant specialist producers include Vesuvius International (part of the Cookson group of the UK and major manufacturer of concast refractories and crucibles), Lafarge Refractaire (F, part of Lafarge Coppee and a major producer of monolithic refractories), and the Morgan group of the UK (crucibles, monolithics, and technical ceramics).

The tableware and ornamental ware sector contains a handful of large companies amongst a myriad of small ones. Major groups include the three German companies, Villeroy & Boch, Rosenthal, and Hutschenreuther and the two UK companies, Wedgwood and Royal Doulton. Together these companies account for around 40% of total EC output. In the sanitary ware sector the two major groups operating on a European level are Ideal Standard (I) of the American Standard group of the USA and the Sanitec group of Finland whose interests now include Allia (F), Keramag (D), Pozzi-Ginori (I), and Eurocer (P) in addition to its Scandinavian activities. Other European companies of note include Blue Circle Industries (UK) through subsidiaries Armitage Shanks (UK) and Ceramica Dolomite (I), the Roca group (E), Keramik Laufen

(CH), and Sphinx (NL) which now operates plants in the Netherlands, Belgium, Germany and France.

The EC wall and floor tile industry is dominated by medium sized producers in Italy and Spain with annual turnovers in the 40-80 million ECU range. The small number of larger groups includes Gruppo Ceramiche Marazzi, Iris Ceramica, Cerim Ceramiche in Italy and Porcelanosa and Fabreza in Spain. Companies in other countries include Villeroy & Boch and ABK in Germany and H & R Johnson (part of the Norcros group) in the United Kingdom.

Companies active in the technical ceramics segment include Hoechst CeramTec, Hutschenreuther, Cerasiv, Wacker, and Didier of Germany; Saint Gobain (through its SEPR, Norton, and Stettner subsidiaries), Pechiney of France; T&N, and Morgan Matroc of UK; and Samatec of Italy.

Strategies

Of late, the segment that has been most active on the mergers and acquisitions front has been sanitary ware, particularly through the Sanitec group of Finland but followed by Sphinx (NL) and BCI (UK). It should be noted that Sanitec's expanding empire also takes in plants in Poland and former East Germany. The continuous restructuring process of the refractories industry has been evident for some time with the most recent major events being the amalgamation of the two Austrian producers, Radex and Veitscher, under the Oest. Magnesit umbrella and the purchase of Steetley Refractories (UK) by J. E. Baker of the USA.

Nevertheless it is clear from the foregoing that the process of restructuring has a long way to go in the tiles and tableware segments of the EC ceramics industry. It seems likely that further amalgamation allied to investment in new equipment will be necessary to improve competitiveness in parts of this industry. However, it should be noted that such streamlining will take place without sidelining the artistic element to this industry. Flair and design play an important role in European competitiveness on both mass production and craft pottery levels.

REGIONAL DISTRIBUTION

A large number of ceramics manufacturing companies continue to operate in regions whose traditional location was based on the availability of raw materials and fuel. Thus despite changing circumstances areas such as Stoke-on-Trent in the United Kingdom, Bavaria and the Rhineland in Germany, Sassuolo in Italy, Castellon in Spain, and Limoges in France have maintained their status as major white ware manufacturing centres. Although the raw materials availability argument also applied to the location of many refractories plants, more modern plants have tended to be built close to major metallurgical centres such as the Ruhr region of Germany and Sheffield in the United Kingdom.

ENVIRONMENT

The larger modern units of ceramics industry are well equipped to deal with existing compliance levels but further restrictions and the imposition of a carbon tax would have a major impact on the whole industry.

OUTLOOK

The consumption of ceramic goods is expected to resume its former levels of growth as EC industry in general moves out of recession. Those companies that have already modernised and restructured can be expected to perform well during the latter part of the 1990s but some of the smaller, high cost concerns will need to invest in new technology to remain competitive against imports. The technical ceramics segment will continue to grow and certain products may develop from "low volume, high value" to "medium volume, medium value" status by the year 2000.

The industry is represented at the EC level by: Liaison Office of the European Ceramic industry (Cerame-Unie). Address: Rue des Colonies, Bte. 18, B-1000 Brussels; tel: (32 2) 511 3012; fax: (32 2) 511 5174.

Advanced materials

The advanced materials industry is highly diversified as it includes at least 8 different subsectors. At the world level, the USA is the leader in most of the different market segments. Europe, however, has the biggest world market share in new steels and held, in 1991, one-third of the high-distribution composites segments. For many years, south-east Asian countries have also operated as advanced materials producers. Efforts are made in each different branch of the advanced materials industry to ease the recycling, re-use and recuperation process. Advanced materials have a bright future and many end-uses in different areas.

INDUSTRY PROFILE

Description of the sector

Advanced materials include new or improved uses or technologies implemented in the traditional materials.

Among advanced materials, a distinction may be drawn between structural materials which define the form of industrial objects and functional materials which are used for their physical skills and represent only 15% of the total market.

In this chapter, advanced materials are classified by type of material. They include:

- engineering thermoplastics: polyamides, polyacetals, polycarbonates, modified PPO (PPE-based alloys), thermoplastic polyesters, polyethylene terephtalate, very-grade plastics, elastomeric thermoplastics, fluorinated thermoplastics, new PPs and PEs, PEN;
- engineering thermosets and adhesives: phenolic resins, silicones, engineering adhesives, polyurethanes, epoxy resins, DCPD;
- glasses materials: compound glass, low emissivity glass, composite glass plasticized alloyed glass bottles;
- advanced ceramics: ceramics for catalytic converters, fine ceramics;
- new steels: tinless tinplate substitute; magnetic steel sheets, coated steel sheets, steel sheets with high elastic limit, cold-rolled thin stainless steels;
- new non-ferrous materials: refined aluminium for aeronautics, aluminium-lithium, aluminium sheets for packaging, aluminium alloys for casting, super alloys, titanium, retroactive alloys;
- high-performance composites: HP composites with organic matrix, carbon fibres, carbon-carbon composites, composites with metallic matrix, composites with ceramic matrix;
- high-distribution composites: TP and TS resins, short and semi-long fibres, RTM, SRIM, TRE.

Advanced materials cover a large variety of application areas such as: transport (for steel sheets, fixing, coachwork); building and public works (for ground coating, floors, special steels); electrical and electronic construction (for cables, electrical insulators, parabolic aerials); mechanical construction (valves); sports and leisure (high-performance composites for sport equipment, elastomers for sporting shoes soles).

Automobile, packaging and building and public works are three other important end-use sectors.

Automobile

This sector makes use of a large range of advanced and traditional materials. Evolutions related to coachwork, motors, glass and seats are numerous. They also concern electronics and telecommunications which will be highly developed in the coming years. Advanced materials used in the automobile sector are for example: new steels (HLE iron sheets, that are thicker and lighter than elastic sheets with the same resistance to the effort) or new non-ferrous steels. Plastics are going to substitute to metals because their energetic content is two times lower and their manufacture needs less energy. For motors, technical plastics improve performance as their surface is smooth and allows a better flowing of fluids. Plastics also allow lower cost of production. New glasses in the automobile area concern: a-thermic glasses which filter IR and UV; therming glass in which very thin yarns are inserted; double lateral glass; half glass and half plastic windscreen to prevent from stone projections; lightening or darkening glasses related to atmospheric conditions; head up displays visions.

Packaging

Packaging is a very important market. In 1992, production of plastics materials reached at the world level about 160 million of tons valued at 210 billion ECU. The main end-user sector for packaging is the agro-food sector which uses also most diversified forms. Plastics satisfy the majority of requirements imposed to packaging materials that are: resistance

to deterioration, impermeability, resistance, asepsis, lightness, mass colouring properties and flexibility of production process. Most of the innovations concern recycling of plastic packaging as well as lightening glass and using white steel in drink cans.

Building and public works

Advanced materials applications are numerous in this sector. Thermoplastic are used for security glass, electrical cables etc. Engineering thermosets and adhesives are used for insulation and mastic. Steels concern building equipment as thermal acoustic, insulator; glass for light façade and composites for canalisations.

Size of the sector

In 1991, the USA held more than 50% of the world market for the new non-ferrous materials and for the high performance composites. Their high share in the new non-ferrous materials market is mainly due to the monopoly they hold on aluminium sheets for pressing and spinning used in packaging. The USA were also the leader in engineering thermoplastics, engineering thermosets and adhesives and in compound glasses.

Japan, for its part, controlled about half of the advanced ceramics market. The average annual growth rate for the fine ceramics, at the world level, was estimated in 1991 at 10.5%. Europe controlled one-third of the world market for high-distribution composites, engineering thermoplastics, advanced glasses and new non-ferrous materials. For new steels however, Europe is the world leader with a share of 28% of the world market, ahead of the USA (23%) and Japan (22%).

Within the new materials, new steels represent the most important market with 38.5% on the European market share. Engineering thermosets, engineering thermoplastics and high-distribution composites come after with 16.5%, 13.5% and 12% respectively.

The average annual growth rate for engineering thermoplastics was estimated, in 1991, to around 9%. Among this category of advanced materials, high ranking pet packaging in plastics have the strongest potential growth rate. Germany represented 30% of the European engineering thermoplastics market. France and Italy followed both with 17% and United Kingdom with 15%.

MARKET FORCES

Future trends in demand

In Europe, advanced materials outlets can be found in the automotive sector, electrical and electronic engineering, mechanical engineering, building, packaging, sports and leisure and aerospace equipment.

The new glass sector is forecasted to continue its annual 4% growth in the coming years; European and Japanese markets will be likely to offer more outlets than the US market. Indeed, during the 1991-2000 period the Spanish, Japanese, French and Italian markets will record the strongest growth rate.

Automobile, railway and electric-electronic engineering are all sectors that offer the best potential of growth in high-distribution composites for the 1991-2000 period. Japan, Europe and the south-east Asian countries will increase their world market share, mainly at the expense of the USA. The world tonnage will reach 5.4 thousand tons in the year 2000.

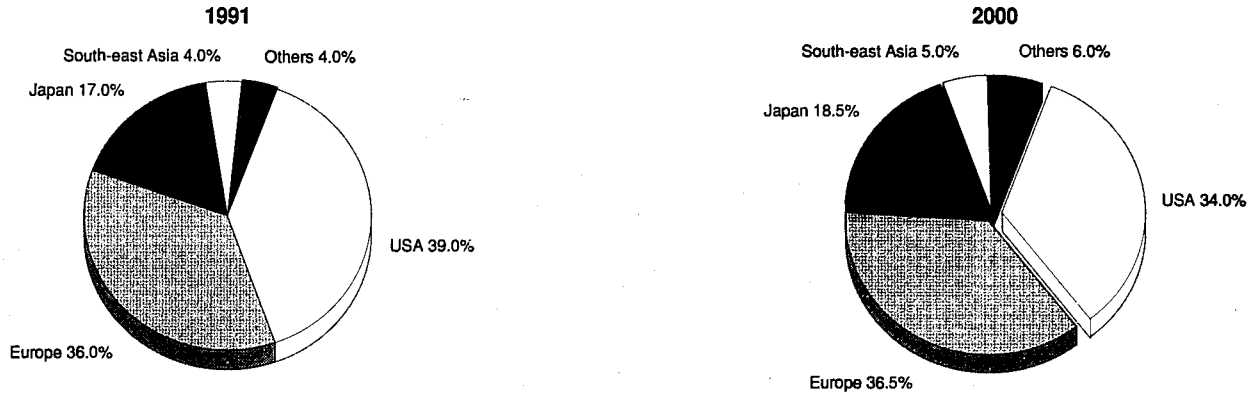
High performance composites enjoy good perspectives for a medium term growth. However, air transport difficulties might lead to a slowing down of production and the stop or reduction of a number of military projects as well as the staggering of European, US and Russian space programs are limiting the short term growth.

In the year 2000, the USA will remain the leader of the new non-ferrous materials world market by controlling a share of about 50% as they did in 1991. In Europe, penetration of aluminium is weaker but its average annual growth might go over 6% in 1996.

The market for new steels is not expected to undergo major changes until the year 2000. Europe will maintain its leadership with a share of 27%, while south-east Asian countries will marginally increase their share.

Japan will remain the leader in the advanced ceramics market and increase its share from 48% to 53%, while a sharp decrease from 32% to 26% is forecasted for the USA. Growth in Japan might be more important than the world average 10.5%, due to powerful end-use sectors and strong and structural supply.

Figure 2: Mass market composites
Share in the world market



Source: BIPE

The USA will remain the leader in the world engineering thermosets and adhesives market in the year 2000, despite a marginal decrease of its share, which will be absorbed by European and Japanese producers.

In the year 2000, the USA will be outpaced by Europe for engineering thermoplastics. The European market will indeed evolve at a faster average annual growth rate which will allow a 50% increase of the European tonnage.

Production process

Over the fast ten years or so a fundamental change in the importance of materials has been occuring. Even if materials represent a small part of the value added of a product, their intrinsic qualities constitute strategic elements for the success of a product. Technical progress has caused a reversal in the production logic and has generated a large variety of materials. Materials are now selected upstream from the specification of the product.

New materials leaders are usually large enterprises active on traditional markets, which are linked to their original know-how. However, these enterprises conceive new materials as an axe of strategic development destined to compensate present and future profitability difficulties on the traditional markets.

INDUSTRY STRUCTURE

Companies

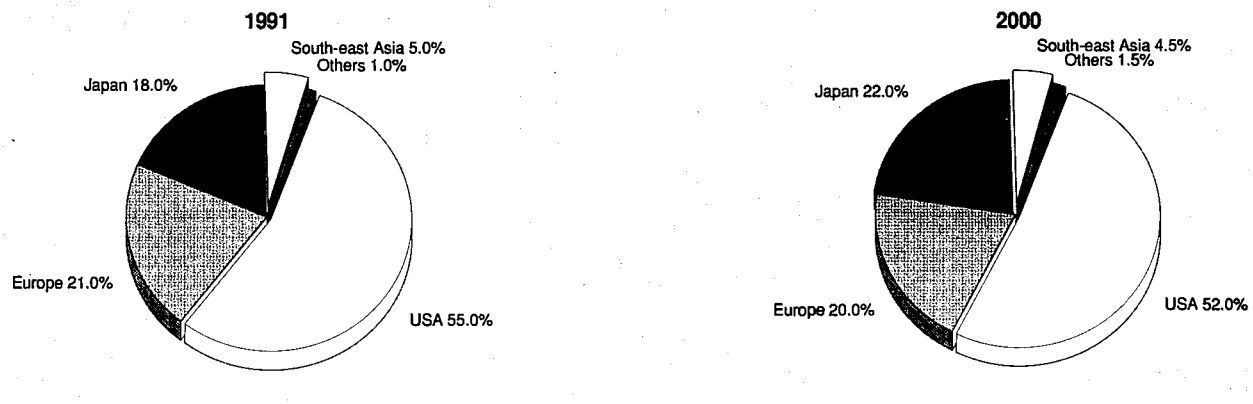
There are several producers of advanced materials. Given the diversity and heterogeneity of this chapter, a distinction between sectors appears to be necessary.

Engineering thermoplastics, engineering thermosets and adhesives are produced mainly by US companies (Du Pont, Dow and General Electric) and their European rivals (Bayer, BASF, Hüls, Atochem, Rhône Poulenc and ICI). The Japanese are also present with Mitsubishi, Ube Ind and Sumitomo, though they hold smaller capacities than their US and European competitors. At present, there is a real explosion of capacity being created in south-east Asia, which might affect the European producers in the short and medium term.

Glass supply is highly concentrated and the main producers are few. The six main ones are: PPG and Guardian in the USA; Saint-Gobain in France; SIV in Italy; Pilkington in the United Kingdom and Asahi Glass in Japan.

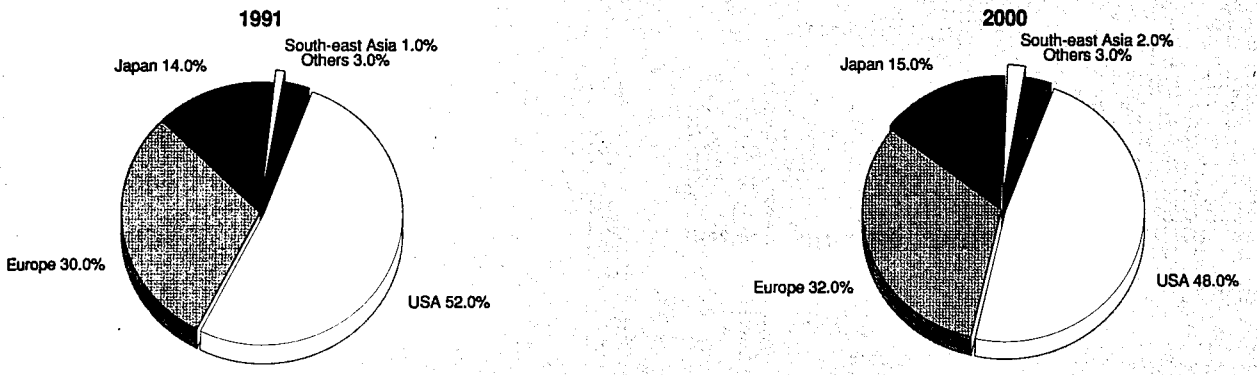
Since recent years there is also a high concentration in the supply of high performance composites to the benefit of bigger chemical groups as Du Pont de Nemours, General Electric,

Figure 3: High performance composites
Share in the world market



Source: BIPE

Figure 4: New non-ferrous materials
Share in the world market



Source: BIPE

Exxon composites (USA); Bayer, Hoechst, BP, ICI in Europe and Sumitomo and Mitsubishi in Japan.

On the other hand, high-distribution composites' supply is not very concentrated. Europe is represented by ICI, BP (UK); Ciba-Geigy (CH); DSM (NL); BASF (D). Americans and Japanese are also present in this area with Du Pont de Nemours, Dow, General Electric (USA) and Hitachi, Sumitomo, Toshiba, Asahi (JPN).

The Japanese companies Kyocera, NGK, NTK, Murata, MFG dominate the market for the world supply of advanced ceramics. Taiwan, Hong Kong or Korea are likely to be new entrants. Ceramic supply for catalytic converters is essentially constituted by the duopole NGK (JPN) and Corning (USA). Given the norms aiming to reduce emissions of pollutants in exhaust fumes and their likely hardening, ceramics for catalytic converters have a bright future with an average annual growth rate of 6% (11% for Europe) during the 1991-2000 period.

The new non-ferrous materials, for their part, are mainly constituted of aluminium for pressing and spinning and of aluminium for moulding. The first component is aimed to packaging (cans and drink) and the world supply is led by American Can (a subsidiary of Pechiney) which has also plants in Japan, Korea and Europe. In Europe, the main producers of drink cans are ANC, Schwalbach, Carnaud Metalbox, and DLM. In the year 2000, the average growth might go over 6% per year in Europe. Growth will be lower in the USA where the penetration rate is already high. Outlets for moulding aluminium mainly concern the automotive sector and remain highly dependent on the sector and on the technical developments. Main producers of moulding aluminium are Alcoa, Alcan, Reynolds, British Alcan, and Pechiney.

New steels are constituted mainly by coated steel sheets and by steel sheets with high elastic limit. The world supply of coated steel sheets is led by the Japanese (Nippon steel, Kobe steel, Kawasaki steel, Nippon, Kokan). Producers of steel sheets with high elastic limit are: for hot sheets: Japan, Europe (Thyssen (D), Usinor (F), British steel (UK)), CIS and USA (US steel, Bethleem steel); for cold sheets: Japan and USA; for production of plate: Europe, Japan, USA, CIS.

In Europe, Usinor is the world leader of flat stainless products (household equipment, industrial equipment). This market might progress by 2.5% per year in the following years.

ENVIRONMENT

Environmental problems can be encountered at each step of the life of a material. Production of certain materials can provoke healthy problems or environmental nuisances. The utilisation phase of materials may also cause the same problems. One of the most representative example is the use of asbestos in buildings. Salvage and recycling of used material generate more complicated problems as both of these operations are specific to each type of material. The OECD, for its part, has drawn up three lists of different materials on the market following their position vis-à-vis the environment:

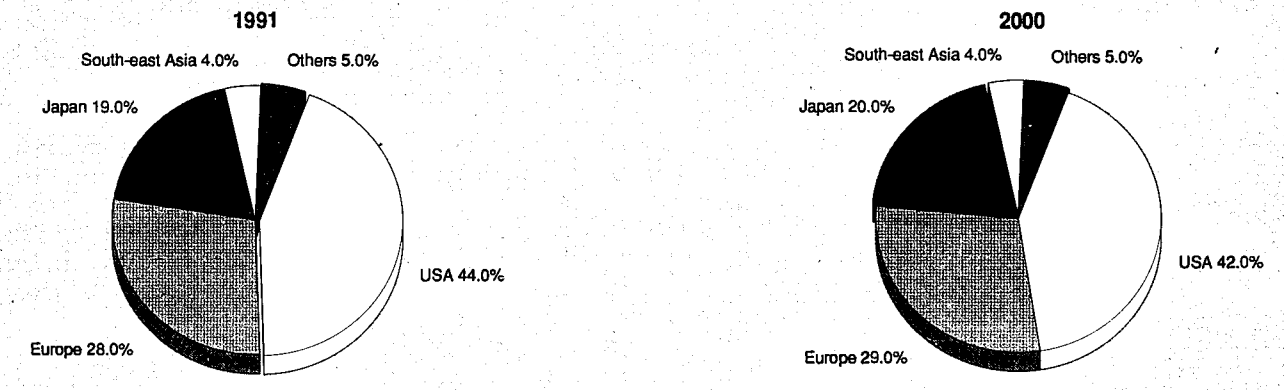
- The green list: material wastes classified under this list are not dangerous and can cross borders of OECD Member States under normal conditions of checking;
- the orange list: material wastes included in this list are bound to supervised controls;
- The red list: material wastes must be highly checked in the import level and during their displacements. The way of eliminating them is also supervised and very strict regulations have been set.

Environmental constraints oblige industrialists producing or using toxic substances to find quick solutions to answer to norms into force. For instance, the Montreal protocol of 1987 (effective since January 1988) announced a 50% reduction of production and of use of CFC for 1999 in comparison with the level reached in 1986. For that purpose, common R&D programs are often established between competing companies.

The environmental requirements in the electricity-electronics area led, for example, to the development of the use of halogen-free high-grade plastics or to a reduction of the use of PU foams. In the aerospace industry and defence, environmental constraints allowed notably the improvement of engine performance afforded by the use of advanced non-ferrous materials and ceramics MMCs, CMCs. It is also worth mentioning the new technology linked to non polluting electrical vehicles which are only in the beginning of their development but whose future is already assured. A number of R&D programs are turned to the manufacture of batteries which still are now not powerful and autonomous enough.

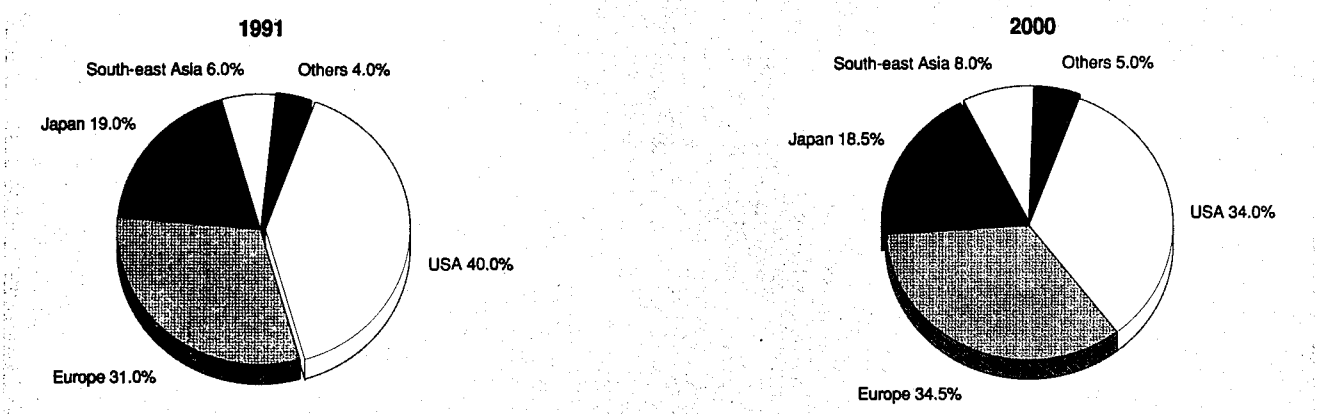
In the automotive sector, manufacturers take account of norms of pollution and energy consumption but also of the recycling or re-use character of the vehicle's components. Recycling

Figure 7: Engineering thermosets and adhesives
Share in the world market



Source: BIPE

Figure 8: Thermoplastics
Share in the world market



Source: BIPE

in this area is intricate due to the large variety of materials of different natures. It is necessary then to be aware of the recycling problem already at the moment of the elaboration of the product.

Measures have already been taken in order to increase professional recuperation and recycling. It is the case for instance of agreements between French public authorities and different inter-professional committees through which professionals commit themselves to increase the use of recycling packaging materials by taxing non-recycling products by virtue of the "pollutant-payer" principle.

Packaging in steel, aluminium, paper, cardboard and glass is easily recyclable. Recycling of plastics packaging is more complicated due to cost and technical reasons; another problem concerns the insufficiency of the collecting and selecting process for the largely used plastics.

Recuperation methods for thermoplastics are: re-use (for PET), recycling by selective collection (until now it is limited to cans), recycling by separation (currently limited to low grade-grade uses), combustion, hydrolysis, pyrolisis, degradability, dumping. Packaging materials evolve in the way of being more competitive on the market and to keep a good image vis-à-vis the environment, and number of innovations are likely to appear. The monomaterial converter has already emerged. It is also worth mentioning the apparition of biodegradable materials. This is undoubtedly the most important technological break trough in packaging.

All these examples illustrate the influence, often positive, and the source of innovation represented by environmental constraints on advanced materials. New environmental concerns create markets for advanced materials and orientate their development in a direction which is quite different of the one which would have been taken without environmental constraints. Finally, we must note the emergence of a slowing down of the multimaterial growth to the benefit of monomaterial for which recycling is easier.

CONCLUSION

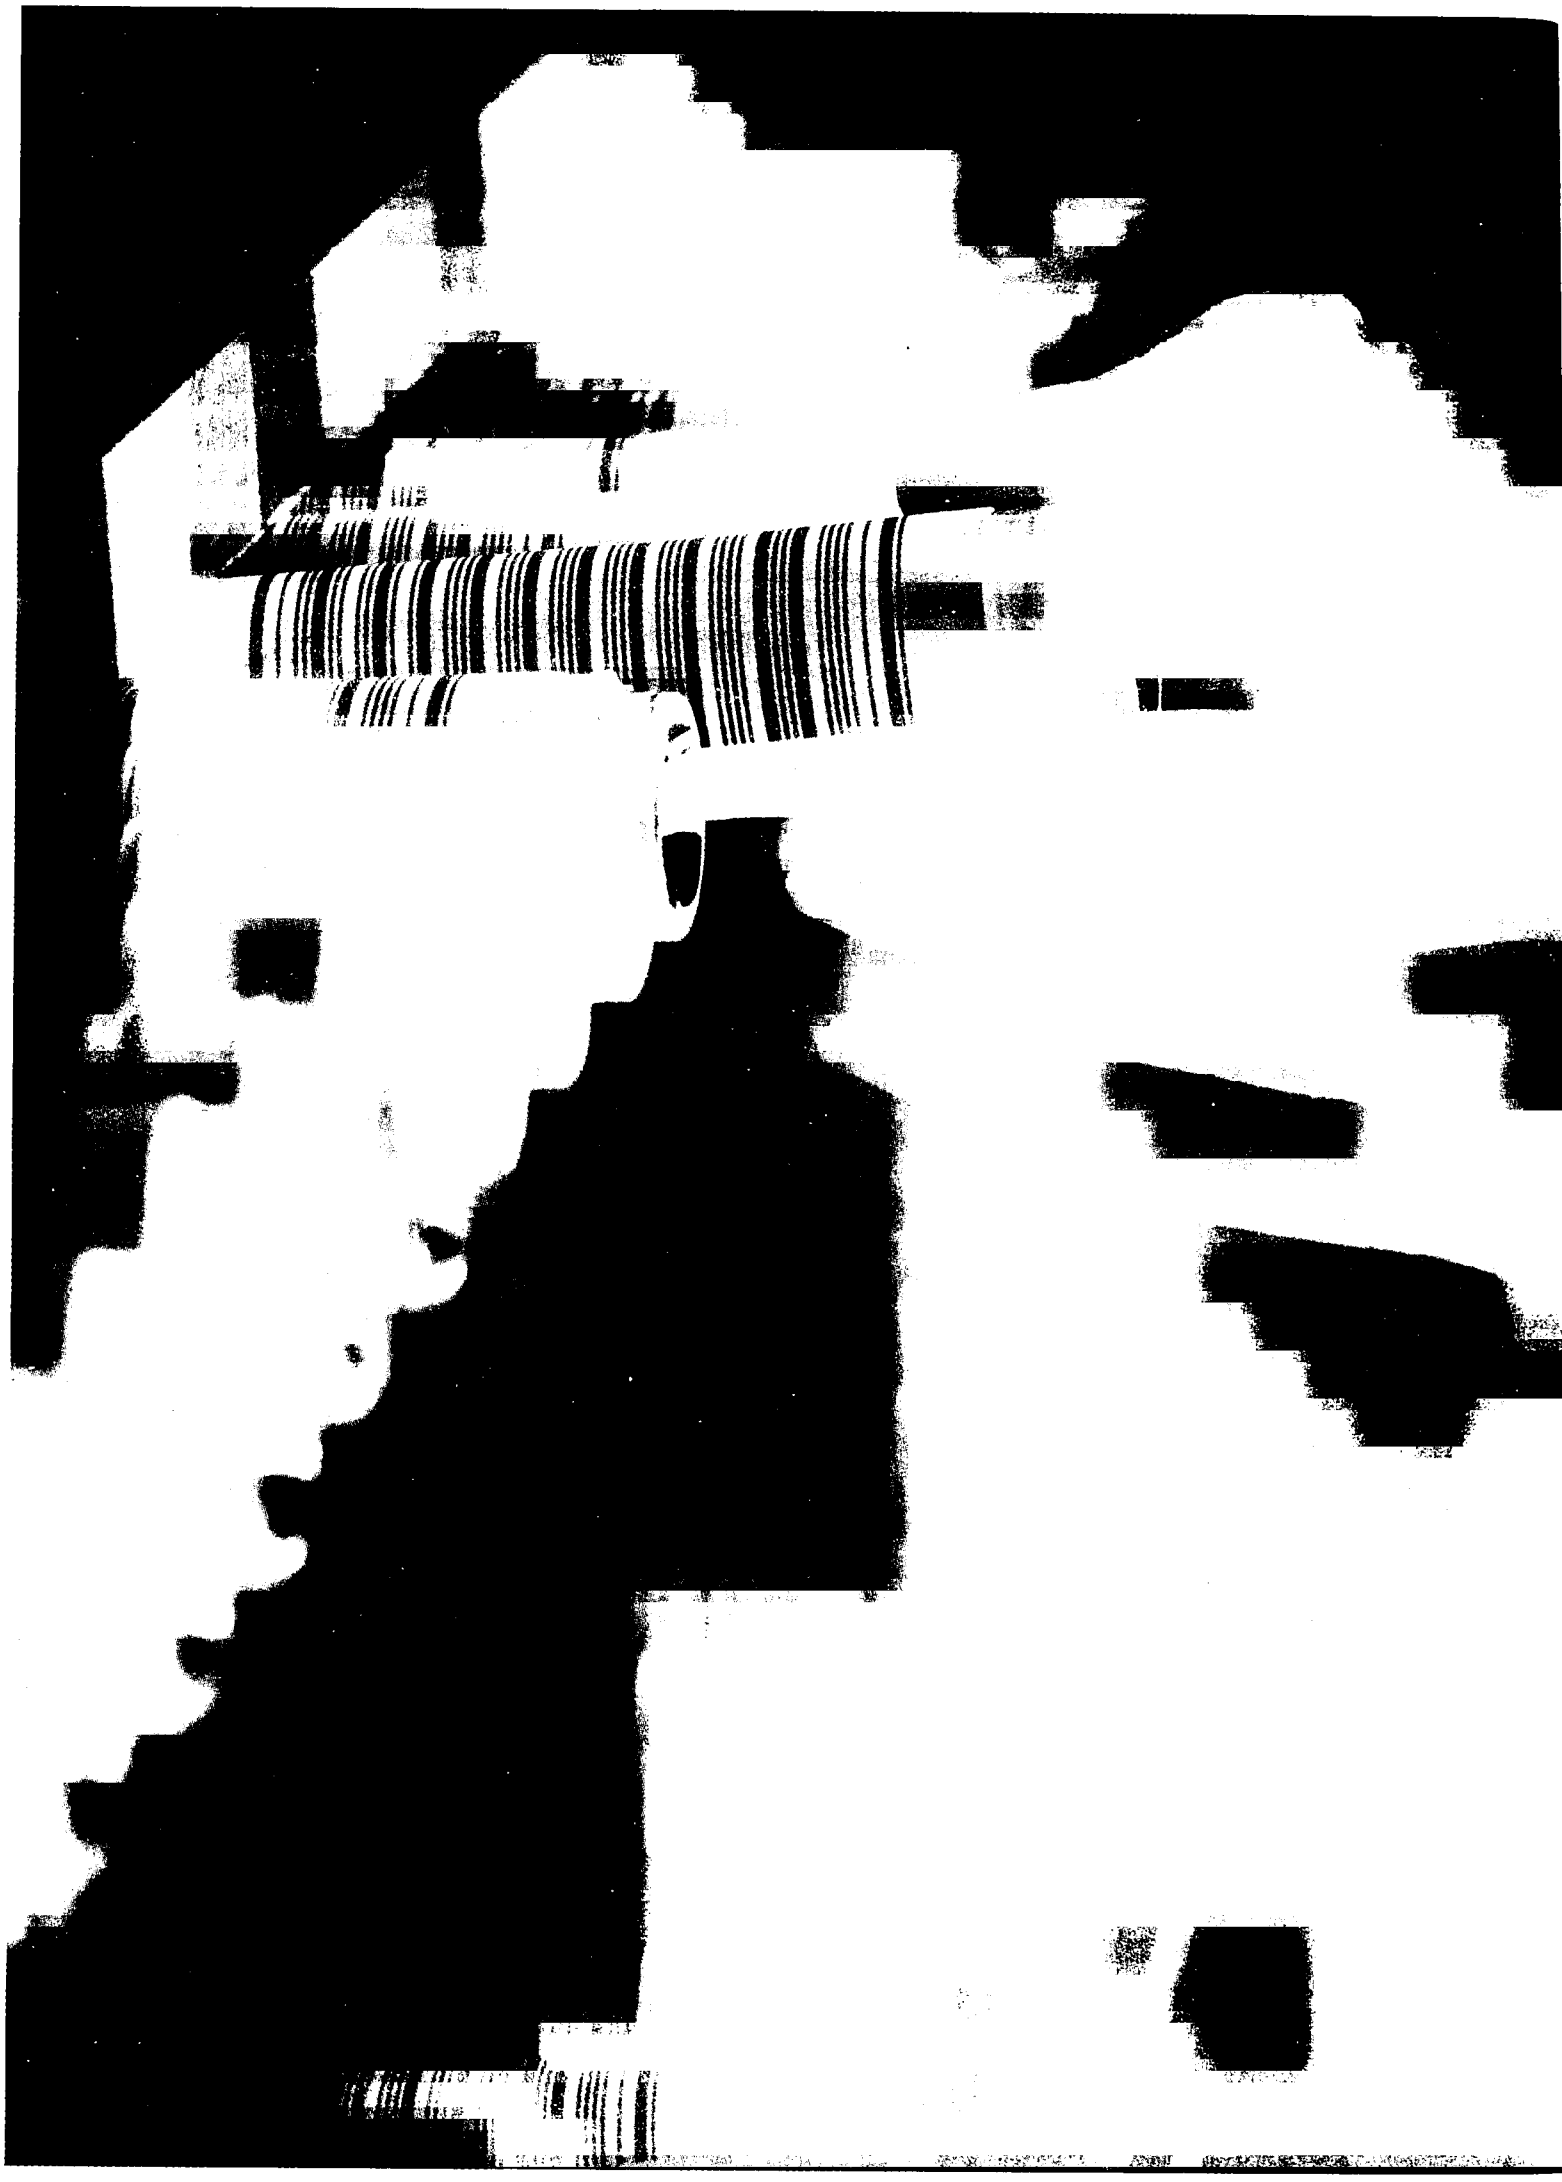
Requirements with respect to advanced materials are going to increase. These requirements concern as well the advanced materials' performance (search for structural qualities coupled with functional qualities) as their environmental acceptability or their economy (easier and cheaper transformation). This convergence between structural and functional materials becomes more and more decisive and implies major consequences in the strategy of enterprises and of public authorities. The re-conception of products and processes, respect of quality and reliability requirements, research of energy economy, creation of new industrial products or new services and decentralisation of human activities depend on control of materials as much as control of information technologies.

In order to cope with these requirements and with the multiplication of technological variables, some recommendations are made to industrialists:

- to favour the mass development of European data banking for materials and to allow a better knowledge of what exists;
- to favour European industrial partnership of the same level as well with up and downstream companies and to privilege integration;
- to develop R&D;
- to develop recuperation, selection and recycling;
- to control production tools;
- to develop industrial thesis on materials;
- to strengthen European position in functional materials and in materials with an electronic or magnetic structure.

Regarding public authorities, support in fundamental research and cooperation, development of formation programs on materials or support of few or non pollutant products are also recommended to facilitate the development of advanced materials and to allow the EC to become more competitive on these market segments.

Written by: DRI Europe, on the basis of a report produced by BIPE Conseil for the EC Commission.



Overview
NACE 25, 26

The EC is the world's most important producer of chemical products, well ahead of its main competitors, the USA and Japan. After several years of solid growth in the mid to late 1980s, depressed prices and overcapacity have characterised the performance of the industry since 1990, as the world's economies slowed down and additional production capacity came on stream. Current overcapacity (not only in Western Europe, but also in East Asia and elsewhere) is likely to continue to depress profits for the next few years. The survival strategy of major chemicals companies hinges on the creation of strategic alliances and joint-ventures to achieve rationalisation in research, production and access to markets.

INDUSTRY PROFILE

Description of the sector

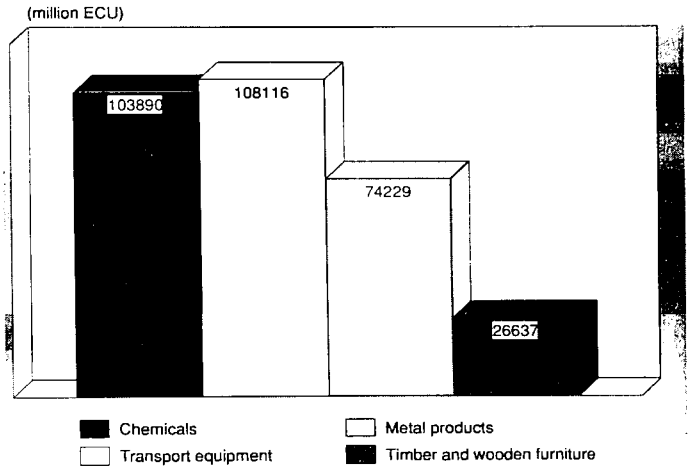
The chemical industry is an industrial branch of very heterogeneous character in which the main activities consist of chemically transforming materials into diverse substances, giving them new physical and chemical properties. For these activities, the chemical industry employs raw materials from the petroleum, mining and extractive industries such as oil, minerals, metals and certain agricultural products. The main activities of the chemical industry correspond to the following product groups: basic chemical products; fertilizers and nitrogen compounds; plastic in primary form and synthetic rubber; pesticides, fertilizers and other agrochemical products; paints, varnishes, and other similar coating products; pharmaceutical and medical products; soaps and detergents, cleaning and polishing preparations, perfumes, toilet preparations; and man-made fibres.

The industry comprises two upstream branches constituting basic chemicals (basic inorganic chemicals and basic organic or petrochemicals) and a series of downstream branches such as pharmaceutical products, agrochemicals, detergents, etc. The upstream sectors' outlets are almost exclusively the downstream sectors, which themselves supply either other industries (agriculture for agrochemicals, the plastics transformation industry for plastics in primary form), or end-users (soaps and detergents, for example).

Compared to the foregoing years, growth in all the main indicators in current prices was marginal in 1990, 1991 and 1992. 1992 saw continuing depression in prices and operating margins as global economies remained mired in recession and new capacity came on stream in Europe and the Middle East.

British, Italian and French based companies were the first in Europe to resort to severe job cuts worldwide. The German economy only came to a standstill during 1992, much later than other EC economies, as until then, German companies were able to profit from increasing domestic demand. The German "big three" (BASF, Bayer, Hoechst) all started, though to a lesser extent, to shed labour in the latter half of 1991 and during 1992, in response to the weakness in their domestic and export markets. These labour savings have resulted in improved labour productivity, but the industry is still suffering from a situation of overcapacity which, in Europe, is not expected to be alleviated before the second half of the 1990s, in the absence of any radical capacity reduction measures. The pharmaceutical sector was the only area which showed some buoyancy in 1992 with sales 5% ahead of 1991 levels.

Figure 1: Chemicals
Value added in comparison with other industries, 1992



Source: DEBA

Germany is by far the largest EC producer in terms of value added, representing almost one third of EC value added. France takes the second place, followed in that order by the United Kingdom and Italy.

Recent trends

After a rapid expansion over the 1960s and 1970s, the first half of the 1980s was rather grim, with stagnant production and overcapacity which led to a drastic restructuring of the industry. The restructuring, accompanied by huge redundancies and cutbacks in capacity, enabled the chemical sector to start off from a much stronger base when the economic environment improved from 1983 onwards. The years from 1986 to 1989 were associated with high profits and strong expansion.

Prospects changed in 1990 with the economic slowdown in Europe and North America. Demand from the main clients weakened. The fall of the dollar, which started in 1985, had already led to losses in competitiveness on foreign markets.

Imports grew, but exports stagnated. With the exception of the pharmaceutical industry, profits started weakening in the first half of 1990. Since then, significant losses have been reported by many of the EC companies, as well as by their EFTA and American competitors and in 1992 and the first half of 1993 many of the biggest chemical companies were still reporting depressed earnings as the upturn in the industry cycle still failed to materialise.

International comparison

In 1992, US production stood at 91% of EC production, and Japanese production represented some 42% of EC production.

US companies suffered declining sales and profits during 1991, with 60% of the companies showing sales and net profits lower than in 1990. On a weighted average basis, sales were down 2.4% and profits 13.5%, compared to 1990. Just as in Europe, the core of the problem was the overcapacity and the consequent falling prices of commodity chemicals, along with the specialities experiencing sliding demand, linked to the recession.

The development of the US chemical industry differs slightly from that of the EC. American companies have experienced high growth rates during the second half of the 1980s, not only thanks to an increase in domestic demand, but also due to increased exports. Thanks to the weak dollar, American competitiveness in basic chemicals was noticeably improved during the 1985-89 period. Consequently, American companies did not experience the same incentives as their EC counterparts to develop downstream in sectors less sensitive to exchange rate movements.

Markets for chemical products have developed fast, particularly in East Asia, but also in Brazil and the Middle East. Although the opportunities for the EC chemical industry are clear, new producers have appeared in these regions. The major share of world production, however, remains by far in the hands of European and American groups. Increased com-

petition from new chemical producers risks eroding the competitive position of European producers whose structural and feedstock costs remain higher than in major competing regions in the longer term. A new opportunity exists, however, for West European manufacturers to gain new markets in Eastern Europe to offset the erosion of competitiveness in Asia.

Foreign trade

The EC is the world's leading exporter of chemical products, with exports more than twice the size of those of North America. In 1992, EC companies exported 17% of their production outside of the EC. Traditionally, the EC has a trade balance surplus (along with the EFTA countries). The surplus has been deteriorating since 1986, following the fall in the US dollar and the increasing market presence of export-oriented production capacity, notably in the Arab Gulf region. In 1991-92, however, exports started to pick up again.

Overall, EC exports are specialised in refined chemicals, while imports are in basic chemicals. To a certain extent, the EC imports basic chemicals in order to export refined chemicals. Competitive discipline created by imports is therefore higher for basic chemicals than for refined chemicals.

The main destination for EC chemicals exports are the EFTA countries, the USA, the developing countries, and to a lesser extent the Pacific region, including Japan, Australia and New Zealand. Compared to the average EC trend, it appears that Germany and Denmark are more oriented towards Western Europe. The United Kingdom and Ireland export more towards North America, while the proportion of exports towards developing countries is higher in France, Spain and Portugal than in the other EC countries.

MARKET FORCES

Demand

About 65% of chemical product demand stems from industry in the form of intermediate consumption. Apart from the chemical industry itself, which represents about 36% of its own demand, the principal client sectors of the chemical industry are (in decreasing order) the rubber and plastics processing industry, agriculture, metals, mechanical and electrical engineering (the last three together), textiles and clothing, wood and derivates and construction. This considerable self-consumption is explained by the high degree of industrial vertical integration in which the downstream elements, refined chemi-

cals or specialty chemicals, are the almost exclusive outlets for components situated upstream, i.e. the basic chemicals.

The strong expansion of the chemicals sector over the last two decades can be explained in part by factors such as innovation and the replacement of traditional materials such as steel, wood, paper and glass by new materials derived from chemical processes. This substitution factor has enabled the chemical industry to experience premium growth rates, at a level much higher than the average manufacturing growth rates (10% compared to 2% over the period 1970-90). More recently, the contribution of this factor in the growth rate of the chemical industry has diminished, marking the industry's progressive evolution towards maturity.

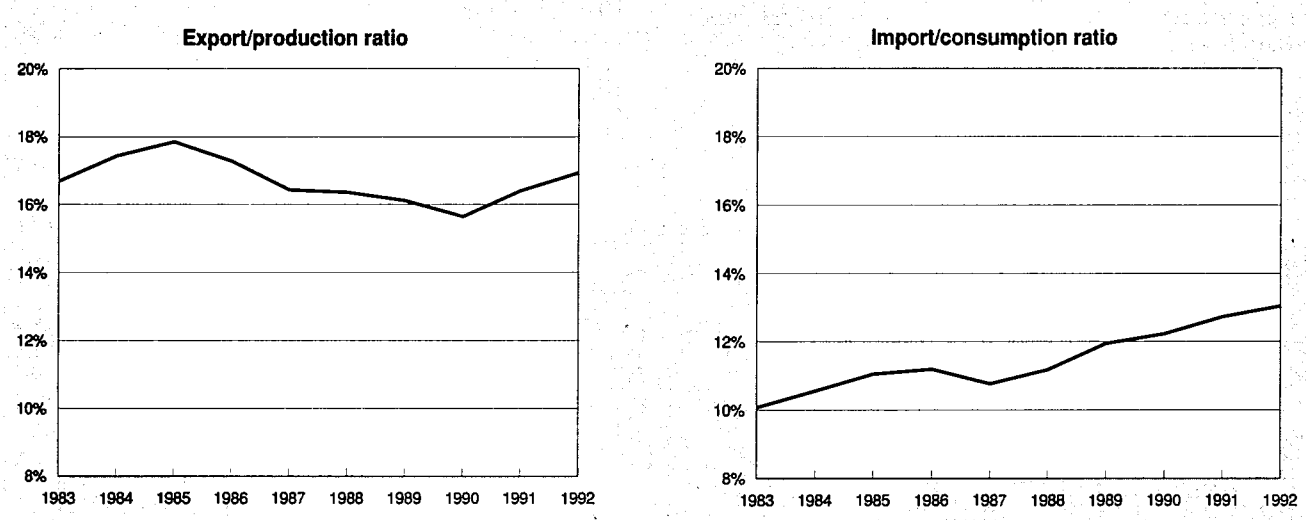
In 1992, weakening demand accompanied by the cyclical slowdown in the European economies led to a continuation of the decline in bulk chemicals' production. Similarly, the recession in North America hampered further export growth. Some industry analysts believe that the recession can be traced back to as far as 1988 when growth in the chemical industry outstripped both GDP at 2.3% and other manufacturing industry at 1.8% (average industry growth over 1980-90 was 3.4%). In 1988 the difference was much larger, with second-half production almost 7% higher than the preceding year's, while GDP was up near 3% from the second half of 1987. The result of the explosive growth was the build-up of large stocks in the chemicals chain. Sizeable destocking occurred during the first half of 1990, and then again in the first half of 1991. The same is occurring again in the second half of 1993, after stock built up in the second half of 1992 and in the first half of 1993.

Demand in other subsectors of the chemical industry continues to be high, such as in pharmaceuticals and in some of the specialty chemicals, which showed steady production growth.

Many EC producers that have established operations within the USA, in response to the unfavourable exchange rates during the second half of the 1980s, have now pinned their hopes on the recovery of demand on this market, as the two engines of growth for the US industry - the automotive and construction industries - showed signs of encouragement early in 1992. Yet industries' expectations remain cautious because consumer lead recovery is doubtful, with consumer spending not rising despite lower interest rates. Another reason for the lack of optimism, despite early signs of recovery of the US economy, is the presence of sizeable overcapacity in the basic chemicals and polymers sectors.

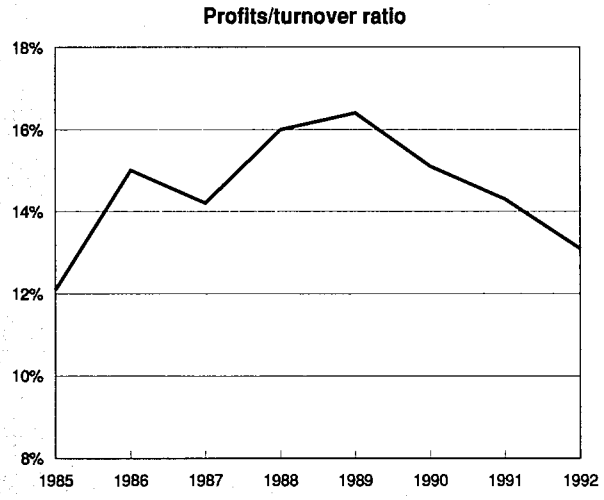
Another important factor in the creation of demand is the continuous effort towards product innovation. EC companies spent around 4.8% of their turnover on R&D in 1990. In specific sectors of the pharmaceutical and agrochemical industry, this percentage can amount to more than the double of that figure. The most innovative fields of R&D include bio-technology and new materials (advanced composite materials, polymers, plastics and ceramics). As a general tendency,

Figure 8: Chemicals
Trade Intensities



Source: DEBA

Figure 9: Chemicals
Pre-tax profits to turnover of the industry



Source: DRI Europe

R&D efforts are more and more focusing on transformations of existing products rather than on true discoveries.

Supply and competition

The future of both bulk and specialty chemicals is clouded by mounting competition. These sectors will increasingly have to focus on higher value-added and more specialised market segments in order to maintain margins.

The pharmaceutical industry will continue to benefit from rising standards of living and growing concerns for health. At the same time, the industry will suffer from government programmes aiming at checking social security costs and especially health care costs.

In basic chemicals, a remarkable part of demand is directed to foreign markets. Export intensities amount to 50% in Germany and the United Kingdom, and around 60% in France. Export markets were hit by the fall of the dollar that increased US competitiveness on markets with low or no product differentiation and high competition. The squeeze in profit margins was emphasised by the upward pressure on oil prices during the Gulf War, although these came down shortly afterwards. Also pharmaceuticals have been losing market share on export markets since 1987. In terms of competitiveness, the specialty chemicals sector is in better shape than the basic chemicals sector. Profit margins, however, shrank in 1991, as a result of growing input and unit labour costs.

Oil and other raw material prices are expected to rise at most only moderately, yet chemical producer's prices are expected to be weak in some sectors and in some countries, leading to unsatisfactory margins.

Production process

The EC chemical industry employs almost 1.7 million people. The majority of employees in the sector has a high level of qualification and training. Since 1974, the sector has had a diminishing labour force, but the upturn in production levels since 1984 has led to a stable employment number until 1990.

The greatest proportion of investment expenditure is at present directed towards productivity improvement, new product introduction, improvement of production processes and environment. In contrast to investment level growth in nominal terms of about 10% over the 1985-89 period, investments have declined since 1990.

The sector is also a big energy user. The energy use is rather concentrated in the upstream basic chemical subsector. The biggest energy user is the petrochemical sector, with electricity and hydrocarbon consumption, including the use as raw material, of 35% to 40% of production costs. Other sectors with high energy contents are plastics (20% to 25%), inorganic chemicals and fertilizers (each about 15%). The refined chemical sector is a relatively small energy consumer, but since the basic industry is its main supplier, it is bound to be affected indirectly by energy price rises. Profitability of basic chemicals is more vulnerable to oil price increases than that of specialty chemicals, since the first one can only with more difficulty pass price rises to consumers, being subject to relatively harsher competition.

INDUSTRY STRUCTURE

Companies

Six of the world's top ten chemical companies are EC based. With about 32 700 enterprises (including small enterprises, with less than 20 employees) in 1990, the chemical industry remains a concentrated sector, with 7.9% of the enterprises representing 79% of turnover. The top ten leading EC companies represented 48.6% of total turnover of the industry in 1990, with the top 5 companies taking 32.6% of turnover.

Strategies

During the 1980s, larger companies were moving into specialty chemicals in order to improve margins and profitability. Mergers and acquisitions (M&A) activity leading up to the Single Market was intense, concentrating almost exclusively on downstream chemicals (plastic containers and film, specialty chemicals, pharmaceuticals, cosmetics, fertilizers) with the objective of strengthening and expanding market share. Also, the fall in the dollar exchange rate encouraged EC companies to undertake major investments in the USA during the second half of the eighties.

In 1990, M&A activity subsided as a result of the uncertainty caused by the Gulf War, the fall in profit margins and the higher interest rates that made funding more expensive. Also

1991, which was influenced by cost reductions and rationalisations, was a quiet year for M&A activity. Fewer big deals were signed than for instance in 1989, for the same number of transactions. A lot of businesses were for sale, however, because chemicals groups considered refocusing their activity upon their core businesses, and selling off of long established acquired businesses that never or no longer fulfilled their promise in terms of profitability. These companies were facing the problem of insufficient buyer interest.

In terms of sectors, pharmaceuticals and specialty chemicals led the M&A scene in 1991. Geographical patterns in M&A still show a preference for Western Europe in terms of chemical acquisitions, which represented 57% of the total in 1991. Transactions in Eastern Europe increased slightly in number to 3% of the total in 1991, and still focus interest from Western countries thanks to the ongoing privatisation process. With a view to investments in Eastern and central Europe especially, which at first sight look like bargain opportunities, companies have realised that successful acquisitions must be based on true economic value, pointing to the importance of starting to take into account environmental expenditures required by national governments.

REGIONAL DISTRIBUTION

Proportionally to GDP, Spain, Belgium, Luxembourg, the Netherlands and Ireland have chemical industries bigger than that of other EC countries. With regard to product segmentation, the German, Dutch and French industries are more oriented towards basic chemicals and plastic materials, while the United Kingdom and Italy have a greater share of pharmaceutical and a few other every day consumer products.

ENVIRONMENT

Environmental problems are particularly noteworthy in the case of the chemical industry. Environmental costs represent some 3.5% of turnover for major European chemical companies, and 15% of new investments. This latter percentage will increase to 20% or more in the decade to come.

The problems raised by the chemical industry with regard to the environment can be separated into the pollution caused during the production process, and the downstream pollution occurring during consumption and disposal of the industry's final products. In the first area the industry is emitting harmful substances into water bodies and into the air, for example NOx and SO2, causing acid rain. The industry is also confronted with the scarcity of tipping sites to deposit solid waste. With respect to global environmental pollution, as a big energy user, the industry is a big emitter of CO2, one of the gases contributing to the greenhouse effect. The industry has solidly opposed a tax on energy use or on the carbon contents of the fuels used, proposed by the EC Commission as a means to achieve stabilisation of CO2 emissions at the turn of the century.

The chemical industry opposes any form of new tax on energy in Europe. On the other hand, in the area of the environmental auditing of industrial installations, the industry has largely accepted the core principles of an EC Commission proposal on eco-audit, according to which industry would voluntarily allow such audits, checked by accredited auditors.

Pollution linked to the use of chemical products can happen either at the time of actual use or at the time of disposal of waste. In the first case, examples relate to the use of solvents in paints and adhesives, and to the contamination of water tables by nitrates in fertilizers. In the area of solid waste disposal, the industry is faced with the successful implementation of plastics recycling infrastructure within 10 years, according to the EC proposal on packaging waste. This will stretch the plastic industry, as the recycling of plastics is generally less advanced than that of other materials used for packaging, such as paper and board, glass or aluminium.

REGULATIONS

The main legislative measures by which the chemical industry hopes for rapid progress on the road to harmonisation cover the following areas: standards, bio-technology, environment, energy, indirect taxation, fewer administrative constraints, transport de-regulation, R&D, competition, and trade policies.

Concerning trade regulations, in the framework of the Uruguay round of the GATT negotiations, much work was devoted to the tariff negotiations. CEFIC, in a joint initiative with its US, Canadian and Australian counterparts, advocates the harmonisation of chemical trade tariffs at 5.5 or 6.5% and the allowance of up to 15 years to bring existing tariffs down to this level. Other trade issues include export controls in extra and intra Community trade, the treatment of anti-dumping complaints, and the generalised system of preferences.

Internal market issues include the support of CEFIC for the EC Commission DG XXI proposal on indirect taxation in order to arrive at a truly harmonised system throughout Member States, minimising bureaucracy.

Table 8: Chemicals

OUTLOOK

Prospects for 1993 and 1994 are still depressed as the much-heralded economic recovery fails to reach expected levels, and competition for limited growth becomes more intense. Signs that the US economy will pick up remain mixed. High real interest rates are a constraint in Western Europe, where both consumer and industrial confidence remain weak. Demand is unlikely to show significant overall improvement before 1995. Meanwhile, any small increase in output will be driven by advances in pharmaceutical and in cosmetic/perfume activities. Production is likely to be flat in other areas, and continues to decline further in fertilizers. Prospects in the medium term are somewhat brighter, based upon a revival of world economic activity.

Basic industrial chemicals

NACE 251, 252, 253

The basic chemicals sector has recently been suffering from weakening demand and stiff competition from both North America and the newly industrialised countries. During the second half of the 1980s, export markets for basic chemicals were hit as the fall of the US dollar increased the competitiveness of North American producers. This squeezed profit margins, which was later emphasised by the upward pressure on oil prices during the Gulf war.

INDUSTRY PROFILE

Description of the sector

The basic industrial chemicals sector includes units exclusively or primarily engaged in the manufacture of inorganic chemicals (including fertilisers), electrochemical products, organic chemicals (including those obtained from petroleum and coal), synthetic rubber and plastics materials, mineral pigments and organic dyestuffs, isotopes etc., and in the distillation of tar and benzole. In this classification are considered not only the units producing such basic chemicals but also those units which both produce them and process them into finished products.

The data presented in this monograph correspond to the three NACE classes 251, (the manufacture of basic industrial chemicals and further processing of these products), 252 (the manufacture of chemicals obtained from petroleum and coal) and 253 (the manufacture of other basic industrial chemicals). Given the high degree of vertical integration of the chemical industry, it is difficult to provide separate data for each sub category.

Given the relative importance of the petrochemical sector (it accounts for more than the half of the basic industrial chemicals turnover), a specific monograph follows.

In this monograph particular attention is given to the plastics manufacturing sector, which accounts alone for about a quarter of total basic industrial chemicals employment

Recent trends

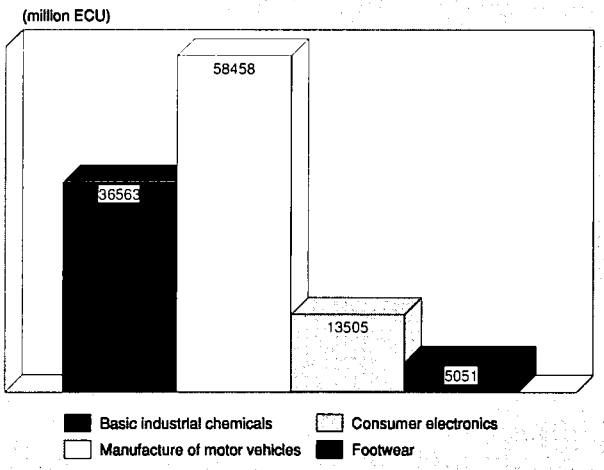
After steady growth in the first half of the 1980s, all the main indicators were affected by a sharp decline in 1986. Due to the fall in the crude oil price and a weakening of the exchange rate of the US dollar, production and consumption (in value) decreased by about 15% and 14% respectively. The continuing slowdown of the European economies since 1990, as well as the recession in the USA and Canada, depressed demand for basic chemicals. During the 1991-1992 period, production and consumption in value decreased by 2.6%.

The reduction in basic chemicals employment, which started in the early 1980s is still going on. During the 1983-1992 period employment in the sector decreased of about 43 000 units with a marked drop of 3.8% during the latter year.

International comparison

In 1992, the EC was the world's second largest basic chemicals producer although by a narrow margin. US production was less than 1% higher than that of the EC, a margin that has more or less remained steady throughout the 1980s. Japan ranks third in the world basic chemicals market, but its production is half the size than the EC and US ones. The importance of the newly industrialised countries (NICs) is steadily growing, and their competition is affecting the position of the EC industry on the world market.

Figure 1: Basic industrial chemicals
Value added in comparison with other industries, 1992



Source: DEBA

In the period 1988-1991, production growth slowed in the EC, the USA and in Japan. Among the three main producers, the EC basic chemicals industry was the most badly affected, due to weakening demand at home. The US industry was also hit by the recession, while Japan was able to maintain a positive, although decelerating, growth rate in production.

Foreign trade

The EC trade balance in the basic chemicals sector steadily decreased during the 1980s because of rising imports and weak exports; in the period 1983-1992 extra-EC imports increased by almost 85% compared to 31% for extra-EC exports. Moreover, all of these gains in export markets were made in the period before 1985, after which time exports have stagnated. The export/production ratio has been quite stable from 1983 to 1992, while during the same period the import/consumption ratio increased by 46%.

Export markets for the EC basic chemicals industry are well spread. The EFTA countries and the USA together account for about 43.2% of total extra-EC exports, and Japan for 6.7% only, while the remaining 50.1% is scattered around the rest of the world. As for extra-EC imports, they are more concentrated: about 31% of them come from the EFTA countries, 26.7% from the USA and 8.5% from Japan.

MARKET FORCES

Demand

The bulk of domestic demand in the four major economies (D, F, I, UK) comes from speciality chemicals (including pharmaceuticals and agriculture) with a 34% share. Indeed, basic chemical products are mainly used as inputs in other chemical processes. The basic chemicals sector itself accounts for another 26% of its own sales, and the rubber and plastics sector for about 16%.

Plastics

The wide range and the tailoring of their properties for specific applications have led to a vast and diversified demand for plastic materials. The main outlets are to be found in the following industries: packaging with a 38% share, construction and civil engineering (16%), transport equipment (10%), electronics (10%), house wares and toys (5%), agriculture (5%), furniture (4%), health and medical applications, paper and wood, photography and armaments.

The moderate growth in demand for plastics is attributable to the economic slump, and particularly to the deteriorating conditions prevailing in the end-user sectors such as the automobile and construction industries. Plastic materials have historically developed, at the expense of traditional materials (e.g. glass, steel, wood), in industrial and household goods production. This factor is starting to lose its importance as the market reaches maturity. However these substitution effects now occur between plastics, as with LLDPE (linear low density

polyethylene) making increasing inroads into the LDPE (low density polyethylene) market.

Supply and competition

The European basic chemicals industry has a strong technological base, and it compares favourably with the US and Japanese industry from the point of view of research and development. This represents an important strategic condition for a modern industry which depends on the use of more and more sophisticated materials and technologies.

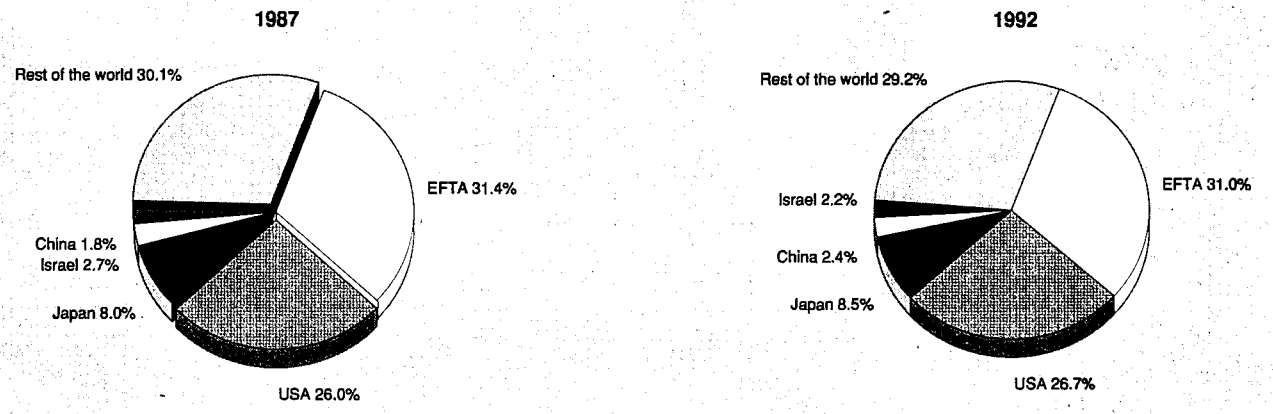
Plastics

Plastics manufacturers produce polymers and synthetic resins mixed with additives to form plastic materials. They absorb about 60% of the output of petrochemical crackers. The main thermoplastic products are: low density polyethylene (LDPE) and linear low density polyethylene (LLDPE), high density polyethylene (HDPE), polypropylene (PP), polystyrene (PS) and polyvinyl chloride (PVC). Thermoplastics represent about two thirds of total plastics production in Western Europe. By way of comparison, European production of these plastic materials is equivalent in volume terms to that of the USA and more than double that of Japanese production.

Plastic material manufacturers are not only raw materials manufacturers: they also help the entire plastic products sector by contributing to the technical and commercial development of plastics applications. Mass market plastics, which represent more than two thirds of total plastics production, have played a vital role in the plastics industry since the Second World War. However, they have been hit by sharp oil price rises and by the economic downturn during the period from 1975 to 1983, which led to production overcapacity. The mass market plastics industry actively rationalised and restructured between 1982 and 1984, adjusting production capacities and obtaining cost reductions. The more recent years have brought an upturn in demand and profits, but since its 1989 peak the market has again been deteriorating. New capacities and fierce competition are driving prices down affecting the whole basic chemicals sector.

Regarding EC competitiveness in the field of the petrochemical industry, during the 1987-1992 period the input costs were higher in Western Europe than in US and Gulf Coast countries, its principal competitors.

Figure 7: Basic industrial chemicals
Origin of EC imports



Source: Eurostat

Production process

Petroleum products and first oil derivatives are used both as raw materials and as an energy source by the basic chemical sector. Fuel and power products represent the major input costs for the basic chemical industry. Therefore, profits in the industry depend to a large extent on oil prices.

High capital investments in machinery and technology are essential in this industry and represent, along with the availability of raw materials, a significant entry barrier. High competition, low product differentiation and heavy environmental constraints also increase the difficulties of the basic chemicals activity.

Any further increase in capacity will probably be cautious, taking account of the experience of the last decade; investment plans are mainly directed towards new processes and product development, as well as towards productivity improvements in order to maintain the industry's competitiveness. Finally, factors determining investment seem to be linked more and more to the environment, notably in areas such as waste management, and to public acceptance of chemical products and chemical industry activities.

INDUSTRY STRUCTURE

Companies

Concentration is clearly higher in the basic chemicals sector, the exclusive domain of large companies, compared with refined chemicals. For example, in Germany, six producers share 80% of inorganic chemical production. Competition is however much more intense than might be believed from the strong concentration. The industry experiences a high potential for competition among the present producers on the market and the new competitors from the oil-producing countries and South-East Asia.

Among the leading EC producers in the field of basic chemicals are six firms: BASF, Hoechst and Bayer (D), ICI (UK), Rhône-Poulenc (F) and Enichem (I). Other main European basic chemicals companies are the Swiss Ciba, Sandoz and Roche, the Finnish Neste, the Swedish Dyno Industrier and the Norwegians Norsk Hydro and Statoil.

Strategies

During the 1960s and up to the middle of the 1970s, the basic chemicals groups' strategy aimed at increasing output and capacity. The 1970s economic crisis highlighted the need to restructure the industry. Company strategies were consequently modified along three main lines: first, product rationalisation, which led to major redundancies; second, increasing installation size, in order to benefit from economies of scale; third, merger and acquisition (M&A) activity in Europe and the establishment of joint-ventures in the rapidly growing Asian markets.

Among the latest joint ventures, strategic alliances and assets swaps we can cite the following ones. ICI (UK) has made such a deal with BASF(D) (polypropylene for acrylic operations). In June 1993, Statoil (N) and Neste (SF) announced an agreement to merge their polyethylene and polypropylene activities. The new company will become Europe's largest producer of polyolefins. Before that some companies had already announced plans to merge their polyolefins activities: Shell (NL/UK) with Montedison (I), and ÖMV (A) with Veba (D); BP(UK) with Enichem (I) have also announced plans to merge their styrene activities. Meanwhile groups like Solvay, DSM, Hoechst, Petrofina or Elf are carrying various negotiations.

On the acquisition, side Hanson (UK/US) purchased the US polyethylene leader Quantum Chemical in June 1993, betting on a fast recovery of the US petrochemical industry, while Solvay, Belgium's largest chemical group, acquired Tenneco's (US) soda ash business for 420 million ECU in 1992. On the European market, the situation of soda ash was deteriorating. The closure of three European plants was announced in 1993: Kalk (D) for BASF, Couillet (B) and Heilbronn (D) for Solvay. This is in line with the surge of low-priced imports from the USA into the EC which prompted the industry to file an anti-dumping case with the Commission.

ENVIRONMENT

Environmental problems are of particular importance to the basic chemicals industry. The industry itself is well aware of the pollution problems for which it is directly or indirectly responsible and has already undertaken important efforts, often ahead of legislation. Reacting to a tarnished image, the chemi-

cal industry has launched the Responsible Care programme. Its aim is to measure and improve environmental performances, in conjunction with greater openness towards people. On the technical side we witness a shift away from end-of-the-pipe technologies towards waste-minimisation. For the moment, expenditures (both capital and operating costs) aimed at improving the state of the environment represent an average of 3 to 4% of the industry's turnover (reaching up to 8% for some European companies).

As far as plastics are concerned, the main environmental issues are the consequences of plastic contact in the case of medical or food applications, plastics safety with regard to fire and the ecological consequences of plastics disposal. The recycling of used plastics is being developed in some countries, although this process still remains relatively expensive when the extra cost of waste sorting and the plastics recycling itself is taken into account. This has led other EC members to promote ecologically clean incineration of plastics with household wastes to produce energy. The Council is expected to adopt a packaging directive by 1994 which will set standards for the disposal of such wastes. The debate is still open between the merits of recycling versus incineration.

After much debate, the Council adopted, in January 1993, a regulation on the supervision and control of wastes within, into and out of the EC. This amounts to implementing the international Basle Convention on the control of cross-border movements of hazardous wastes and their disposal, which has five broad goals:

- to minimise the generation of hazardous waste;
- to keep cross-border movements of hazardous waste to a minimum;
- to achieve national self-sufficiency in disposal;
- to ensure the informed consent of the receiving country before shipping hazardous waste;
- to end trade of hazardous waste with countries which have not agreed to the Convention.

The draft European Waste Catalogue, part of the EC Directive on wastes as well as the draft Hazardous Waste List, part of the EC Directive on hazardous wastes, will define precisely these various substances.

Finally, a fierce battle is being waged on the issue of toxicity of organochlorines. Some environmentalist movements are calling for a total ban of these substances while the industry is gathering its strength to demonstrate that all but a few compounds (e.g. PCBs (polychlorinated biphenols), CFCs (chlorofluocarbons), dioxin or DDT (dichloro-diphenyl-trichloroethane) are biodegradable and do not bioaccumulate. PVC, a plastic, has been singled out because of its chlorine content.

REGULATIONS

Trade regulations are of vital importance to the basic chemicals industry given its dependence on foreign trade as a source of income. Recent years have seen the active participation of the EC basic chemicals industry in all GATT trade negotiations. The main issues under current debate are the following: improved market access for EC firms which might be obtained with the harmonisation of chemical tariffs; stronger intellectual property protection through GATT; and prohibition of the most trade distorting practices. However, an important focus of the negotiations has been devoted to tariffs. A joint framework agreement for tariff harmonisation in the Uruguay Round has been reached within international industrial circles, which provides for tariff harmonisation at 5.5% or 6.5% and allows up to 15 years to bring tariffs down to the harmonised level.

Recently, five 'essential uses' have been nominated by the United Kingdom Government, for the ozone depleting CFCs, carbon tetrachloride and 1,1,1-trichloroethane. The United Kingdom proposes for 1995-1996 a continued use of:

- carbon tetrachloride in tests to determine hydrocarbon contamination of drinking and waste water sewage sludge, tanker ballast and soils.
- CFCs 11,12,113 and 114 in metered dose inhalers.
- CFC-113 as a solvent for the active reagents (ninhydrin) used to developed. fingerprints.
- CFC-113 as an inert solvent to carry one of the active reagent used to manufacture a range of reverse osmosis membranes and
- For 1995 only, CFC-12 as a diluent for ethylene oxide in sterilisation of chloramphenicol powder used in eye ointments.

Moreover, an EC law specified the use of ozone-depleting substances. Under this law, the CFC-113 should be used as an extraction solvent in a migration test of certain plastics for food packaging; 1,1,1-trichloroethane to dewax toy samples prior to testing heavy metal migration; carbon tetrachloride in the determination of the drug ronidazole in animal feed, as the mobile phase in thin layer chromatography analysis of ground mercury compounds in cosmetics.

OUTLOOK

The future of the basic chemicals industry is clouded by rising competition from producers in other parts of the world, particularly in developing countries. Overcapacity will remain in the industry for several years to come. EC companies will continue to focus on cost cutting leading to a further reduction in employment. A renewal of the sector's former rapid growth rates is not likely in the near future.

Petrochemicals
NACE 252

The petrochemical industry represents more than two thirds of the basic chemical sector and a quarter of the total chemical industry turnover. The sector is going through a period of reduced profitability and losses after the buoyant growth experienced during the 1987-1989 period. Faced with depressed demand and global overcapacity, petrochemical companies are condemned to pursue their modernisation efforts.

INDUSTRY PROFILE

Description of the sector

The petrochemicals industry is defined as the industry that uses raw materials derived from oil or natural gas to manufacture the following products:

primary petrochemicals: unsaturated (i.e. ethylene, propylene, butylene, butadiene, acetylene), aromatics (i.e. benzene, toluene, xylenes, naphthalene), methanol, ammonia, carbon black;

petrochemical intermediates: ethylene, vinyl chloride, acrylonitrile, cyclohexane, ethyl benzene, styrene, phenol, etc.;

petrochemical products: plastics, synthetic fibres, solvents, surface active agents, additives, synthetic rubber, fertilisers and agricultural chemicals.

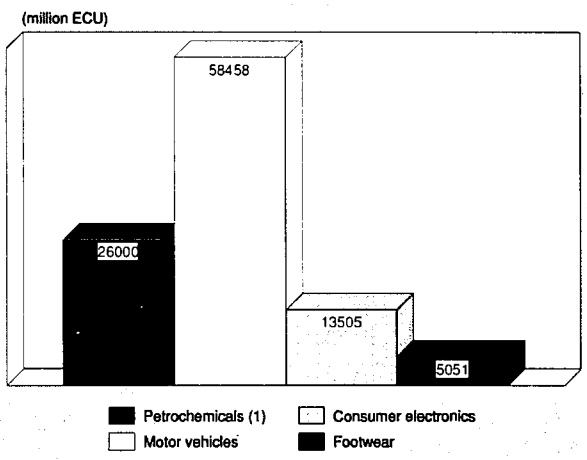
This monograph does not deal with the last category, but its elements are the subject of separate monographs in these and other sectoral chapters. The lack of a common data base for petrochemical products is the main reason for the absence of complete statistical data.

The petrochemical industry is concentrated in Germany and the Benelux countries that hold respectively 27% and 25% of the Community's olefin cracker capacity of ethylene production, followed by France, United Kingdom and Italy, with 18%, 15% and 12%.

Recent trends

During the 1983-1990 period, the supply and demand of primary petrochemical products within the EC was reasonably well balanced.

Figure 1: Petrochemicals
Value added in comparison with other industries, 1992



(1) DRI Europe estimates
Source: Eurostat

Extra-EC exports but especially imports grew steadily from 1983 to 1989. However, since then, they have reached both a plateau. In 1992, exports increased of 0.3% and imports fell of 1.0%

In terms of basic and intermediate products, the petrochemical sector accounts for approximately one quarter of the total value added of the chemical industry, that is 26 billion ECU in 1992. Total employment in the basic chemical sector (e.g. including NACE 251 and 253) reached the level of 607 000 in 1992, with a decrease of more than 8% from the 1985 peak.

An analysis of the primary petrochemical products shows strong growth for the main products. It is estimated that in 1992 ethylene production in the EC rose 5.3%, reaching 14.2 million tonnes, while consumption increased by 5.7% to 14.3 million tonnes. As for propylene, its production, which is largely dictated by ethylene demand, increased by 7.3%, reaching 9.1 million tonnes, while consumption reached 9.4 million tonnes, a 9.5% increase.

International comparison

The EC is a major player in the world market for primary petrochemicals, being the largest producer of butadiene and benzene and the runner-up, after the USA, for ethylene and propylene. EC production, in volume terms, is about twice that of Japan. New producers have recently emerged on the world scene, particularly in South-East Asia (e.g. Korea), Brazil and the Middle East.

Foreign trade

The EC's trade balance with the rest of the world is positive (about 2 200 million ECU in 1992), although it has been sharply decreasing from 1988 due to a strong rise in extra-EC imports. The exports/imports ratio had fallen from its peak of 1.73 in 1983 to 1.11 in 1990. Since then it has been more stable being 1.16 in 1992.

The breakdown by Member States shows the predominance of Germany, which is both the major exporting and importing country in the EC, accounting for 41% of extra-EC exports and 23% of extra-EC imports. In this respect, other significant countries within the EC are the Netherlands, whose figures are respectively 11% and 13%, the United Kingdom (12% and 12%), France (11% and 13%), Italy (9% and 15%) and Belgium (6% and 12%).

The EFTA countries and the USA are the main end markets for extra-EC exports as well as the main source of EC imports: in fact, together they make up 45% of total extra-EC exports and 61% of extra-EC imports. The developing countries also represent an important market for the EC, accounting for 17% of total petrochemical exports.

MARKET FORCES

Demand

The different products of the petrochemical industry are used in a variety of downstream industries such as construction, electrical industry, packaging, transport, metal working, mining, agriculture, rubber and petroleum refining.

The demand for primary and intermediate petrochemicals depends on several factors. First, the economic environment and the growth in end markets; second, inter-product competition (e.g. among different sorts of plastics or among plastics and other materials like steel); third, the emergence of new products; finally, the influence of environmental restrictions.

(1) Data includes monomers, intermediate petrochemicals, plastic resins and intermediate inorganic chemicals.
Source: Eurostat

The industry is traditionally very cyclical and since 1992 has started another depressed period that seems to be affecting all the major economies apart some in South-East Asia. In the longer run one can see that the strong growth rates of the 60's and 70's have given way to a modest expansion that could soon end up as the market reaches full maturity.

Supply and competition

The petrochemical sector is currently suffering from severe overcapacity. In fact, during the period 1986-1991, due to lower feed stocks prices and strong economic growth, the industry invested heavily in increasing capacity and flexibility of choice of feed-stocks. Removing the bottlenecks added the equivalent of three new olefin crackers, and three new ones will be operational in 1993-94.

Today, the slowdown of economic growth in the industrialised countries, the creation of capacity surpluses in the main markets and the lack of cost competitiveness of a part of West Europe's industry are a major concern in this region. As a consequence, prices and margins have been falling in 1992, and 1993 has seen no improvement of the situation. All the companies are currently losing money on petrochemical production.

Among other factors affecting the EC industry, we can cite: the presence of too many players with too many manufacturing sites; a lack of integrated pipelines; various types of companies pursuing different goals; the need to complete the integration of the European market.

The cost of raw materials used by the industry remains at rather elevated levels, notwithstanding the decrease in the price of oil that took place after the Gulf war. The price of naphtha reached a level of 152 ECU per tonne in June 1993, a price that is substantially higher than the 115 ECU of July 1990. Moreover, since feed-stock prices are fixed in USD, variations in the US currency deeply affect the feed-stock activity of the industry. This is compounded by the fact that selling prices quoted in local currencies (often linked to the DM) follow the rule of demand and supply, independently of the rate of the USD. In the 1990-1992 period, for example, the relative weakness of the dollar has given an important comparative advantage to US producers vis-à-vis their European competitors.

In the medium term, there is no real alternative to naphtha as principal feed-stock. However, at present, LPG (Liquefied Petroleum Gas), especially ethane, can represent a 20% decrease in production costs versus a typical naphtha cracker. Recently, major European petrochemical companies have sought to take advantage of rapid growth in the industrial gases' market, by setting up pipelines to feed petrochemical sites. However, LPG has volatile prices, requires high capital costs and is in limited supply. Therefore the addition of LPG cracking flexibility is attractive only close to indigenous sources of supply, where it can be selectively used during periods of intense price competition and provide a significant cost advantage.

R&D activity is another relevant cost factor in the petrochemical industry. It is estimated that between 0.8 billion ECU and 1.6 billion ECU p.a have been spent in recent years.

Production process

Product innovation plays a fundamental role in the petrochemical industry. The development of new fuels, such as unleaded fuel, is opening up new perspectives for the industry, particularly for the valorisation of aromatics. For example, several companies are investing in products based on methane, such as MTBE (Methyl Tertiair Butyl Ether), an additive used for the production of unleaded fuel

The petrochemical sector is a heavy consumer of oil products: energy-producing materials account for most of the production cost of a cracker. The growing presence of oil refining industry in the production of intermediate petrochemical products (due to the process by which fuels are reformulated) is an interesting feature of the evolution of the petrochemical industry. The process of unleaded and reformulated fuels implies a change in the share of some components. The major input for the production of intermediate petrochemicals is naphtha, a product of oil refining, which accounts (including condensates) for about 71% of total petrochemical production in West Europe. LPG comes next with a 19% share, and the remainder, 10%, consists of gasoils.

INDUSTRY STRUCTURE

Companies

Activity in the petrochemical field is performed by large-scale European and international groups, which have undergone extensive restructuring following the oil crises and the slowdowns in the economic growth that characterised the end of the 1970s and the beginning of the 1980s. The restructuring has prompted a reduction in the number of producers and sites as well as a shift in emphasis with regard to certain products. For example, during the 1980-1986 period, 8 EC producers of ethylene disappeared through the closure of 29 sites representing a capacity of 4.7 Mt. At the end of 1992 there were 46 olefin crackers operating in the EC with a capacity of 16.5 million tonnes of ethylene owned by 25 companies.

Among the five leading EC chemicals firms, four of them are involved in the production of basic and intermediate petrochemicals, (Rhône-Poulenc (F) has intentionally withdrawn from the field of basic chemicals). Nevertheless, the proportion of activities involving basic chemicals varies among the remaining four: according to 1991 data, Hoechst (D) can ascribe a share of 12% of its turnover to petrochemicals, Bayer (D) 14%, BASF (D) 20% and ICI (UK) 19%. Among the ten non-EC leaders, Dow Chemical (USA) and Exxon (USA) are firmly installed in the European petrochemical sector.

The petrochemical sector is closely related to the oil refining industry for its supply of raw materials. This has engendered the development of petrochemical activities on its own from the refining industry, as part of a strategy of downstream integration. It is worthwhile to note that among the top 15 chemical groups at the world level, four of them are petrochemical subsidiaries of larger oil companies: Shell Chemical (NL/UK), Enichem (I), Elf Atochem (F) and Exxon Chemical (USA). Traditionally these companies focus their production more on basic chemicals than on refined ones.

Strategies

The response of petrochemical firms to the challenges they confront in the market is threefold: to improve the production process and optimise costs; to increase specialisation in some particular product areas; and to implement a dynamic strategy of joint ventures and alliances.

Apart from the traditional elaboration of new products, R&D activity in the industry is principally aimed at developing processes that can increase the flexibility of petrochemical sites in order to better answer to the fluctuations of feed stock of raw materials and of demand.

In the years to come, growth rates in petrochemicals will vary significantly according to the different products. Firms are pursuing a strategy of specialisation, trying to better respond to the exact needs of customers. Producers are concentrating commercialisation efforts on some specific end-markets, such as the car industry, glues and adhesives, fuel additives, etc.

The third main strategy, pursued by firms of the sector, is to build up joint ventures, strategic alliances and assets swaps.

The section of the monograph dedicated to the basic industrial chemicals describes the latest developments, which generally encompass plastics. The new trend is clearly towards creating alliances between the major players of the market.

ENVIRONMENT

Pollution by the petrochemical industry has greatly diminished over the past two decades because of four main factors. First, the closure of plants whose environmental performance was not satisfactory and their replacement with units using clean technologies; second, modifications to the production processes to make them less polluting; third, the set-up of effluent processing plants downstream of the polluting units; fourth, the Responsible Care programme aimed at progressive improvement in environmental performance for the entire chemical industry.

Another main concern for the industry is the proposed energy/carbon tax. The industry is already facing higher prices for energy and feed-stocks than its main competitors (the USA and the Middle East) and is afraid it would be taxed more heavily than other regions in the world.

REGULATIONS

The industry's trade association (APPE) fully supports the proposal made by the whole European chemical industry at the Uruguay Round of GATT negotiations to lower tariffs on chemical goods at a level of 5.5 to 6.5%.

Other trade agreements include the Community's Generalised System of Preference (GSP) as well as Association Agreements with East and Central European states. The former was originally designed to help developing countries by granting them duty free access to the EC. The industry now complains that some of these countries have reached a stage in economic development that doesn't justify that privilege anymore.

The Association Agreements concluded with most East European neighbours aim to create a free trade area within ten years. The industry is particularly worried about the Community instances that might not have the will to apply trade sanctions whenever these are justified. These fears arose from a few cases where Eastern European imports have made spectacular progresses on the Western market (e.g. PVC, melamine). However for the chemical industry as a whole the EC has seen its trade surplus with this region grow from 708 to 1012 million ECU between 1991 and 1992.

OUTLOOK

The factor that will influence the petrochemical industry in future is a lack of competitiveness within the global market. The causes of this situation are structural rather than cyclical. An immediate problem which must be addressed is overcapacity, coupled with the existence of a number of production units in the EC with a cost structure which is no longer competitive within the global market.

The dangerous situation of overcapacity will be alleviated by the following remedies: first, an improvement in the European cost structure; second, a reduction in the number and ownership of crackers through joint ventures and alliances; third, the rise of flexible crackers able to receive propane, butane or ethane. However without significant further restructuring of the industry, this problem is unlikely to be solved until the late 1990s.

Another influence will be that investment in environmental protection is steadily increasing, and is expected to rise by about 15% between 1991 and 1994. Legislative requirements, such as the Integrated Pollution Control in the United Kingdom are the main driving force behind this increase.

Finally, during the next decade naphtha is forecast to remain the bulk feed stock, LPG playing a major role be at best only after 2010.

Written by: DRI Europe
The industry is represented at the EC level by: Association of Petrochemicals Producers in Europe (APPE). Address: Avenue E. Van Nieuwenhuyse 4, bte 2, B-1160 Brussels; tel: (32 2) 676 7229; fax: (32 2) 676 7230.

Paints, varnishes and printing inks
NACE 255

The EC is the world's biggest producer of paints, varnishes and inks, well ahead of Japan. The USA followed closely. Germany alone accounts for about one third of total EC production in volume. The value of EC production in 1992 totalled 13.7 billion ECU.
Given the structure of the industry (paints and varnishes are highly concentrated) and the importance of service linked to sales (repair work, rapid supply to the ink industry), export levels are relatively low.

INDUSTRY PROFILE

Description of the sector

NACE 255 includes paints, paint fillers, varnishes and printing inks. The sector encompasses a full range of products with various applications, of which four main categories are:

- architectural coatings, including exterior and interior house paint, primers, finishing coats, pore fillers, varnish and dyes;
- coatings used for a whole series of industrial products and consumer products (e.g. wood or metal furnishing, automotive industry, aircraft industry, machinery and equipment, household appliances, electrical insulation, film, paper and foil, toys and sporting goods);
- special coatings designed for specific applications or for use in special conditions, including products for the repainting of cars and machines, high-performance maintenance, road markings, bridge maintenance and metallic coatings;
- printing inks used for a series of printing processes (e.g. letter pressing, offset/litho, engraving, flexography, screen printing, etc.)

Paints and varnishes account for around 90% of production measured in volume and 83% of production in value of the paints, varnishes and printing inks sector. In 1992, production of paints, varnishes and printing inks reached a value of approximately 13.7 billion ECU. The indications are that it fell to 13.5 billion ECU in 1993. Germany accounted for nearly 29% of production in value, followed by the United Kingdom and France (18%) and Italy (15%).

Recent trends

Production of paints, varnishes and inks grew at an average yearly rate of 2.3% during the period 1983-88, which accelerated to 5% from 1988-92 led by an increase in consumption. Over the whole period, production grew 3.4% While consumption rose 3.7% per year.

Extra-EC imports rose at a yearly rate of 7.2% during the same period, while export growth has been sluggish particularly over the first period. In 1992, however, the Extra-EC exports reached a value of 2015 million ECU. In 1993, it is thought that extra-EC exports fell by 2.1%

The trade balance showed a surplus of about 2015 million ECU in 1992, but indications are that it was eroded to 1268 million ECU in 1993.

Employment in the sector had recovered steadily after falling to its lowest level in 1988. Indications are that employment fell in 1993, however.

International comparison

In 1983, the USA was the world market leader in paints, varnishes and inks. Its production, however, has been decreasing in recent years and an international comparison of production in constant prices shows that EC and Japanese production grew at a faster rate since 1990. As a result, in 1992, EC was the world market leader with a production reaching 13.7 billion ECU, that is 16% more than the USA and nearly the double that of Japan.

Foreign trade

Paints, varnishes and inks are not generally highly traded. However, this depends very much on the application of the product: while common house paint is sold within a few hundred kilometres of the factory, special aeroplane coatings are internationally traded. The same applies for specialised printing inks. In all the countries with large production capacities, firms chiefly serve their domestic markets. Consequently, be-

cause of their proximity, EFTA countries are the main trading partners for the EC, accounting for 31% of total extra-EC exports and 58% of extra-EC imports.

MARKET FORCES

Demand

Even if they are grouped in one common NACE category, paints and varnishes have different characteristics from printing inks.

Paints and coatings are widely used in manufacturing industries such as motor vehicles, building and construction, metal products, steelworks, wood, electric appliances, and marine equipment. As for printing inks, they are used to produce newspapers, books, advertising material, packaging and wall coverings.

Paints and coatings are quite vulnerable to developments in the demand for the products of the industry's main industrial clients. This is particularly true with regard to construction, marine equipment and car manufacturing. The vehicle refinishing market is an exception to this rule as consumers hold onto old models and refurbish them when fewer cars are produced or sold. In the level of industrial activity and the demand for durables and investment, production of printing ink is generally less affected by fluctuations than in the paints and varnish sector.

Some clear trends in buyers' preferences have emerged in the recent past. Wood care products are taking an increasing share of the decorative coating market, at the expense of paints. Powder coating is estimated to be the fastest growing paint market in the world, with volume increases averaging about 15% a year during the 1980s; powders contain no solvent and therefore there are less pollution problems. Finally, high demand for high solid paints (i.e. products with a high concentration of pigments), has produced a corresponding reduction in the use of non-aqueous solvents.

Supply and competition

Client industries require quite a long period of time before they accept new coatings. In the automotive industry, e.g. where importance of consumer tastes and the need for high quality products to satisfy requirements of resistance and functionality are particularly important, it is normal to wait at least one year for acceptance, followed by up to two years of trials. The demanding requirements of the client explain why the paints and varnishes industry is spending large amounts of money on R&D activity and advanced technologies.

The market power of the industry's major industrial customers is strong. An extreme example is provided by the EC market of coil coating, (i.e. a decorative or protective coating on freshly produced metal before the main manufacturing step or construction process), which is dominated by major metal producers such as British Steel.

Production process

During the 1980s, the paints and varnishes industry developed new products and adopted new applications driven by rationalisation in its client industries and environmental problems. "High solid" paint and powder fillers (which reduce the losses caused by over spray and allow recycling) are just two noteworthy examples.

In the recent past, production in the EC has been hampered by a technical shortage of raw materials. The shortage and sharp rise in the price of titanium dioxide, which peaked at 2.56 ECU/kg in late 1989, has been followed by a situation of overcapacity. This latter situation has caused prices to decrease to a level of 1.75 ECU/kg in 1992. This substance is at present the most widely used pigment, not only in white paint, but also in the lightning of most other shades.

Companies are also increasingly suffering from a lack of experienced technical staff, resulting from a mounting degree of complexity in the production process and the fall in the number of training facilities.

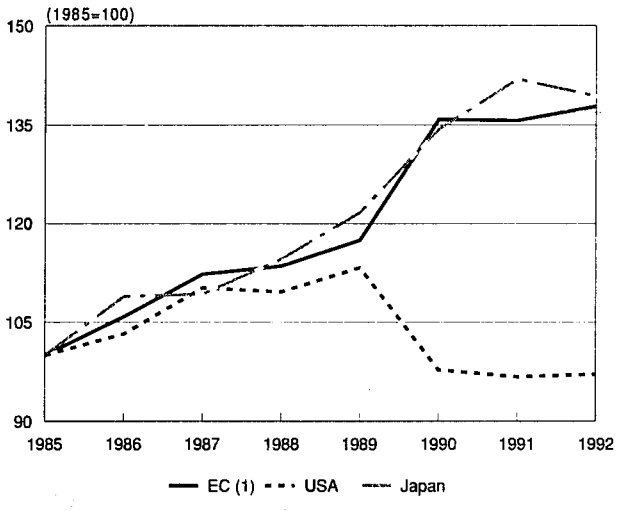
INDUSTRY STRUCTURE

Companies

All Member States have paint production plants, although a considerable number of these are to be found in the major EC countries. In 1989, the ten biggest paints and varnishes companies held about one third of the world market.

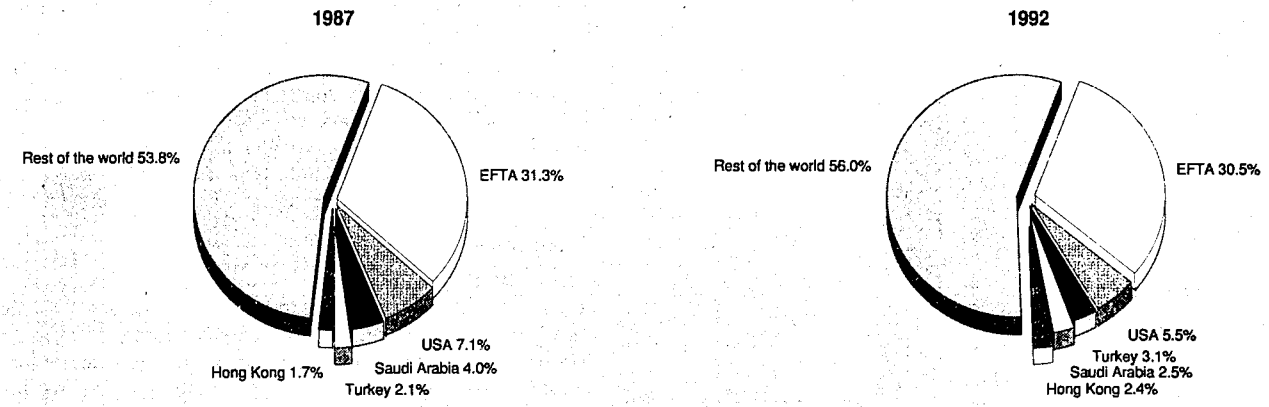
Within the EC market, the leaders are ICI (UK) which is also the world's leading producer, BASF (D), Herberts (D, a Hoechst group company), Akzo (NL) and Courtaulds (UK).

Figure 3: Paints, varnishes and printing inks international comparison of production in constant prices



(1) Excluding Greece, Ireland and Luxembourg.
Source: CEPE, Census of Manufacturers, Nikkei

Figure 4: Paints, varnishes and printing inks
Destination of EC exports



Source: Eurostat

Another major European player is Nobel Industries (S). US companies are also active in the EC: PPG (US) is a major producer, and Dupont (US) also has some production facilities.

Apart from major companies, there is still a large number of small and medium-size companies that survive through specialisation and a high quality of service.

Unlike the paint and varnish sector, there is only a limited number of multinational firms in the printing ink industry. Production units in southern EC countries are, in general, considerably smaller (and often family-run) than in the northern Member States.

Strategies

On the world market, there are four true world players in coatings : ICI (UK), PPG (USA), BASF (D), and Courtaulds (UK), while other major companies such as Akzo (NL) and particularly Sherwin-Williams (USA) operate mostly at home.

ICI paints recorded a turnover down on the previous year in 1991 (though profits increased). Similar results in other paint companies in 1991 reflect the recession that predominated in that year. 1992 was similarly badly hit, particularly in the decorative paints market due to a slow down in the housing market.

The sector has been characterised by an increasing number of acquisitions, that reflects the need to reach an adequate size to confront the concentration of distribution networks. The most important acquisitions in 1991 were Akzo's acquisition of MacPhersons' (UK) decorative business and Herberts'(D) acquisition of Becker Powders (UK). However, paint and varnish companies are also frequently using joint ventures in order to gain access to new markets. In 1991, Courtaulds and PPG set up a joint venture for aerospace and defence coating businesses in the United Kingdom and Italy. BASF and Nippon (JPN) did the same in the automotive coating business and ICI and Ferro (USA) followed suit in powder coatings. ICI paints followed a strategy of moving out of non-core activities. In 1991 ICI sold several peripheral businesses including metal pre-treatment and coatings for glass fibre.

Companies have increasingly tended to invest in the Far East. Thus, paint sales have been booming and further growth is expected in this market. Multinationals are and are likely to be the main players with United Kingdom and Japanese companies currently best placed, closely followed by the companies from Scandinavia and Holland. German and US paint makers have been slow to penetrate the market. Acquisitions in the Far East have been made by companies such as Cour-

Figure 5: Paints, varnishes and printing inks
Origin of EC imports

Source: CEPE, DEBA

taulds, Croda (UK), BTP (UK) and Jotun (N). However, in contrast to European strategies, direct investment and joint ventures are preferred in the Far East paint market as it gives them direct access to the market rather than straight technological transfer. European firms involved in Far East joint ventures recently have included Akzo (UK), Courtaulds, BASF, DSM (NL), Total (F), Becker (D) and Jotun. ICI has opened a plant in Guangdong, China in partnership with Swire Pacific development and the local development corporation

ENVIRONMENT

The main environmental issue affecting the sector is the emissions of volatile organic solvents that are used extensively in paints. Legislation in this area varies widely across the EC. German legislation calls for limits of 150 mg/cubic metre of carbon derived from organic vapours leaving the factory, while in the United Kingdom the limit is set at 50 mg/cubic metre. Although water-based paints are an alternative, they are more expensive and less durable than solvent-based varieties.

The industry is currently devoting a considerable share of its R&D expenditure to solve this problem and has already put forward some successful waterborne coatings. Another environmental concern is titanium dioxide, or white oxide. Paints, lacquer and inks represent around 60% of titanium dioxide consumption in the EC; in its natural state, it damages neither health nor the environment, but its refining is polluting.

As for printing inks, the use of non-aqueous solvents may pose problems similar to those encountered by the paint and varnish industry, even if the more limited number of professional users means that emissions can be controlled more effectively.

REGULATIONS

The EC Commission has put forward several directives on environmental pollution which concern the paint and varnish sector, all of them concerning titanium dioxide. As for solvents, they are not yet the subject of an EC directive.

In 1978, a Commission directive (78/176/EEC) was adopted with the aims of reducing pollution caused by waste and encouraging recycling. A second directive was adopted in 1982 (82/883/EEC) to ensure extensive prevention and to define procedures to control and monitor waste emissions into the environment, including the sea. Finally, in 1983 the Commission submitted a draft directive to harmonise programmes to reduce pollution caused by titanium dioxide using industries; however, in the absence of any consensus, the directive has not yet been adopted.

OUTLOOK

Although the paints, varnishes and inks industry is not recession-proof, it is certainly recession-resistant: the steady need for these products by industrial users and by private consumers (professionals or households) means that there are always returns in good and bad times. At the moment, the main concerns for the sector are the environmental protection regulations and the reliance of some raw materials upon the price of crude oil: both these elements can disrupt any increase in volume. Taking into account these factors, the growth rate for production in the paints, varnishes and inks sector as a whole is expected to average around 3.1% per year in the period 1993-97 but production will slow in the latter period while consumption should increase.

The industry is represented at the EC level by: European Confederation of Paint, Printing Ink and Artists' Colours Manufacturers' Associations / Confédération Européenne des Associations de Fabricants de Peintures, d'Encres d'Imprimerie et de Couleurs d'Art (CEPE). Address: Avenue Van Nieuwenhuysen 4, B-1160 Brussels; tel: (32 2) 676 7480; fax: (32 2) 676 7490.

Other specialty chemicals
NACE 256.1-256.7

Speciality chemicals are sold on a large number of small or niche markets, for a wide range of applications. Higher value-added, larger profit margins and growth characterise the sector, if compared to the basic chemicals. Competition is not only on price, but foremost on the ability to effectively render service to the client industries, through improving their production processes or products. Environmental concerns form another major drive for innovation in the sector. Partly because of this, the present performance and the prospects of the industry are less bleak than for many other parts of the chemical sector.

INDUSTRY PROFILE

Description of the sector

The manufacture of other speciality chemicals includes a number of products mainly destined for industrial purposes that are described below.

The manufacture of compressed gases (NACE 256.1) includes air gases, acetylene, propane, and carbon dioxide, as well as gas mixtures and various speciality gases (such as argon and other rare gases) that are supplied in smaller quantities in steel cylinders to customers primarily in the engineering industry. Applications in the medical sector include the supply of liquid nitrogen for the conservation of blood, cell cultures, bone marrow and organ transplants. It does not include the delivery of large volumes of primarily the air gases oxygen and nitrogen supplied by pipeline to the steel, chemical and glass industries, nor the gases in liquid form in medium quantities delivered to customers in road tankers.

The manufacture of glues and gelatine (NACE 256.2) includes gelatine, peptone, modified starches and glues. There are two types of glues, liquid and solid glues. Liquid glues consist of a glue-based material liquefied with a solvent, that evaporates after gluing. Solid glues have to be activated by water, solvent or air before they can be used.

The chemical treatment of oil and fats (NACE 256.3) includes the processing of animal and vegetable fats and waxes into a wide range of applications. Their uses as culture media and tablet production aids in pharmaceuticals, in cosmetics, as emulsifiers in food, as wire insulation in electronics, and for the removal of printing ink in paper recycling are just a few examples to demonstrate the variety of the application range. Other client sectors include animal feed, industrial lubricants, leather, mining, paints and coating, plastics and rubber production.

The manufacture of essential oils and of natural and artificial flavouring and perfume materials (NACE 256.4) includes essential oils such as lemon, orange and lime oils, geranium, jasmine, lavender and peppermint oils; flavourings, anti-oxidants, colourings, emulsifiers and stabilisers, and enzymes, all to be used as food additives.

The manufacture of explosives, pyrotechnic articles and matches (NACE 256.5) includes propellant powders, detonators, fuses, matches, flares and liquid gas fuels.

The manufacture of auxiliary products for the treatment of leather and textiles and the manufacture of tanning agents (NACE 256.6) include surface agents (not soaps), lubricants, leather and skin treatments.

The manufacture of miscellaneous chemical products for industrial purposes (NACE 256.7) concerns the production of activated carbon and activated earth: abrasive compounds, auxiliary products for use in mechanical engineering and metallurgy, natural resins and their derivatives, etc.

This chapter includes a wide variety of heterogeneous products, for application in a tremendous number of industrial and household uses. These chemical products differ considerably from other chemical products in the way they are produced and marketed. Indeed their production is often on a small scale, and more and more according to the specifications of one particular client. That is why speciality chemicals are a very service oriented sector and intricate understanding of the clients' products or production process is a prerequisite for successful marketing of the speciality products. R&D is not so much oriented towards new discoveries, rather towards the application of existing substances in new applications.

Speciality chemicals are also characterised by profit margins that are often markedly higher than in the commodity chemicals business.

Recent trends

A general overview of the main indicators for the group of industries included in this chapter is not available. As a general remark, it can be observed that some speciality sales have inevitably felt the repercussions during recent years of the recession in their clients' business. On the other hand, many companies active in speciality chemicals have managed to boost sales in some segments, sometimes offsetting sales volume reductions that they underwent on larger volume markets.

International comparison

Speciality chemicals, with their relatively high value-added and high margins, seem to have attracted the Japanese producers into the market, while they were rather absent, until recently, in general in the chemicals field. In the flavour industry, for example, the most significant recent growth has been in the Japanese industry that is expanding into the international market as a global player.

Foreign trade

Extra-EC exports of speciality chemicals increased annually by 4.5% over the period 1983-92. Imports into the EC rose even faster, at 7.0%. In 1989, exports increased at a faster rate than imports so that the trade balance improved steadily. Since then imports have increased at an average annual rate 5% above exports. This has led to a deterioration in the trade balance as a result of the slowdown in European economies. 1992, however, saw the trade balance recovering slightly. External trade grew slower than internal trade, which rose by 8.6% annually over the same period. The evolution of trade figures for the different countries do not show striking deviations from the general EC trend, although Germany experienced slightly higher than average import growth. Most of the exports of speciality chemicals are destined to the rest of the world and to the EFTA countries, whereas imports mostly originate from the USA and EFTA.

MARKET FORCES

Demand

Compressed gases

Though the weak economic growth since 1991 affected demand for industrial gases in general (including large volumes not part of this NACE) on the EC market, some speciality uses have fared better. Air Liquide (F) and British Oxygen Company (BOC) are the two largest companies producing compressed gases in Europe. Despite the economic slowdown, Germany remains the largest industrial gas market in Europe due to its large chemicals industry. However, the market in the United Kingdom has recently shown the highest growth.

Glues and adhesives

The industry sells to clients in four main customer groups: the construction industry, the furniture industry, the paper and packaging industry, and miscellaneous, which includes the automotive, electronic, shoe and cigarette industries. The manufacture of glues for office and household uses is included in NACE 259 (see the chapter on other chemical products). The sector experienced strong sales growth up to 1989, generated by the favourable economic situation worldwide. Other factors influencing the sales of glues are the development of new products, such as highly specialised metal and plastic glues, sold on niche markets where they replace common methods of connecting like nailing, screwing and welding. The application of glues in these sectors does not merely constitute a substitute material, but often becomes the starting point of technical innovation in the client sector; for instance, since gluing allows the usage of lighter and thinner materials, the construction of cars and aeroplanes with lighter materials becomes a possibility. Such increasingly targeted markets, in which customer needs are well understood, offer large sales potential and good growth prospects, even in periods of economic weakness.

Chemical treatment of oils and fats

Worldwide consumption of basic oleo chemicals (fatty acids, fatty alcohol's, glycerine) is estimated to be over 3.5 million tons. More than one third of this is produced in West Europe. Basic oleo chemicals are only an intermediate step in the total oleo chemicals industry, a provider of jobs for up to 10 000 people in West Europe alone.

The diversity of markets for the oleo chemicals is an important factor for the stability of the industry. The chemical possibilities of renewable oils and fats are rapidly being more and more exploited to take advantage of their ecologically safe properties. One example of current development includes ecologically safe lubricating and hydraulic oils (natural fatty acid esters that will replace non-biological base oils in important applications such as in agricultural machinery, forestry saws, outboard motors, etc.). Legislation enforcing their use in certain applications is already in place in Austria, and Germany and Switzerland are toughening environmental legislation that will improve sales. By the year 2005, it is estimated that lubricants based on natural oils will account for 12% of the West European lubricant market.

A great deal of research is going on to produce new ecologically acceptable surfactants for the detergent's industry, such as new non-ionics, combining oleo chemicals with other natural molecules. In this way markets are created for oleo chemicals through technological advances and sometimes through surfactant substitution. Given the environmental pressure on several varieties of surfactants, specifically related to the toxicology and biodegradability of the product, there is a growing trend to use more natural feed stocks based on plant derivatives rather than petrochemicals. Such products are believed to be less environmentally damaging and are said to lead to milder consumer products for the domestic and personal care sectors.

In 1990, for Europe, the market for speciality surfactants was estimated at 840 million ECU, out of a total surfactant market of 1.82 billion ECU. Although growth in the overall surfactant market is steady, generally matching that of GDP of 1% to 2% per year, speciality surfactants average growth rates of 6% per year on average, with some sectors registering growth of up to 10% per year. Of the total surfactant demand in West Europe, about one third (500 000 tons) goes into industrial applications, many of which can be classified as speciality. End-use sectors include textiles, polymers, petroleum additives, metal working fluids, agrochemicals and food.

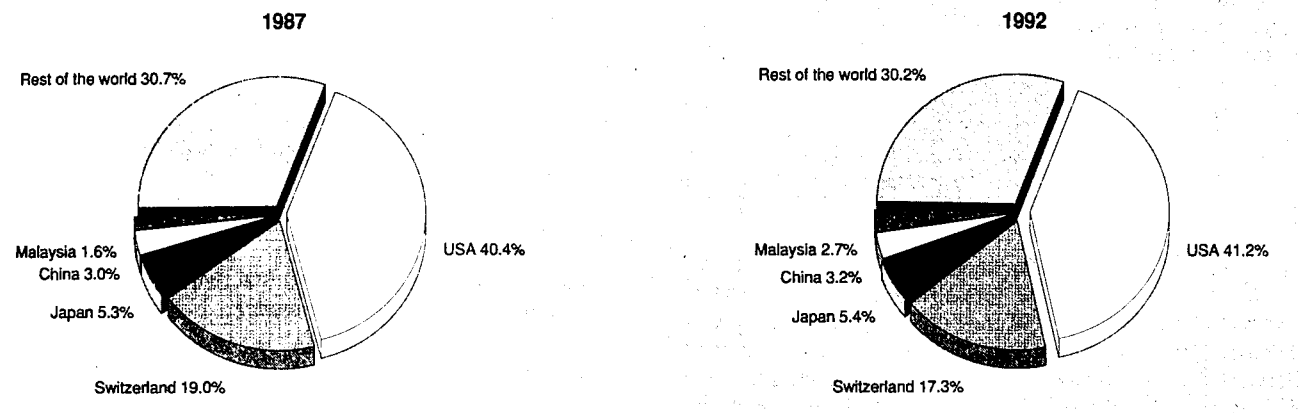
Essential oils, flavouring and perfume materials

Company results show growing demand in this area, deviating from the weaker results of the commodity chemicals divisions in 1990 and 1991. Since the 1960s, the sociological revolution in the kitchen for convenience and speed has driven food flavourings industry growth. In 1990, the worldwide flavour market was valued at some 2.4 billion ECU. Demand, and the industry itself, is fragmented, taking into account of the large variety of flavour profiles and their parameters for technologically efficient application (standardisation, purity, ease of handling, life time, etc.).

Explosives

The development of the explosives industry is strongly linked to activity in the mining sector. In Europe, the mining sector is in a situation of long term decline, hence the outlook for the European explosive's market is poor. Companies are mov-

Figure 2: Other specialty chemicals
Origin of EC imports



Source: Eurostat

ing out of Europe to regions of higher demand and higher growth prospects such as Australia and Asia Pacific.

Auxiliary products for the treatment of leather and textiles

Dyes for the textile industry have recently faced decreasing sales; sales of colourings to other industries show a mixed and sometimes more positive picture (printing inks, paints, plastics, etc.). The business in chrome chemicals, especially tanning agents for leather, is suffering from intense competition.

Supply and competition

The characteristics of the speciality market are the high functionality and specification of the product and lower volumes. On the whole, the speciality end of the market is not feeling the same degree of competitive pressure as the commodity end of the business. Product costs and sales prices are typically higher in speciality chemical business, as are value-added and margins. Purchases of speciality chemicals are often based on performance rather than on price. Technical development, especially product quality and consistency, is becoming one of the leading factors influencing competition on the market at present.

Speciality chemicals are manufactured according to precise specifications related to their final use. The products are constantly evolving to follow innovation in the client industries' products and processes. Detailed knowledge of the client's business, anticipation of the development of his market segment, and fast reaction to his needs are the clues to successful marketing in the specialities segment. For instance, the development by speciality chemical manufacturers of new stabilisers, that substantially increased the fluidity of plastics, have enabled plastics manufacturers to increase their production rhythm. In the same way, the formulation of liquid ultraviolet absorbers has enabled paint manufacturers to simplify production and to reduce costs.

Innovation in the speciality chemicals industry is characterised by minor transformations to existing products rather than by new inventions or breakthroughs. Another important driving force of innovation in the speciality chemicals industry, is the urge towards the controlling of the toxic characteristics of the products, with clients increasingly eager to create a green image for their products.

When the product cycle reaches maturity, even the highest performance additives eventually see their prices drop on the market. This may open new markets for the product. This has happened for the ultraviolet stabilisers, that, originally developed for the plastics industry, have now diversified into the rubber industry.

INDUSTRY STRUCTURE

Companies

Both fully integrated, large companies as well as small niche players are present on the speciality chemicals markets. By means of example, some of the larger companies present include ICI (UK) and Henkel (D) (speciality surfactants), Rhône-Poulenc (F) (flavourings), Atochem (F) (polymers for leather and textiles), Elf Aquitaine (F) (elastomers), Bayer (D) (dyes, pigments, optical brighteners), Hoechst (D) (food additives, pigments, industrial gases), and Tessenderlo Chemie (B) (food additives, gelatine). Fuchs (D) is the largest producer of lubricants based on natural oils.

Strategies

Marketing strategies differ across companies. Some companies follow a product-based approach whereby they try to use their chemical expertise to sell the product in an as wide range of end-products as possible. Another strategy is to focus on end-markets, such as agrochemicals or textiles, rather than on products. This has the advantage of a closer rapport with the client industry, which is important given the service orientation of much of the specialities business.

Product innovation strategies are directed towards minor transformations of existing products, rather than on true discoveries. The research is often oriented in the direction of a better controlling of the toxic consequences of the products and their adaptation to automated production processes. To remain profitable, the companies have to decline or to reject the possible development of a lot of products and extend the possible application range of those they do develop.

The speciality chemicals and materials division of one major producer have been undergoing a process of restructuring since a disappointing year in 1991 when turnover fell principally due to the European recession. In the area of colourings and surfactants, the labour force has been reduced and the product range limited as a mean of cutting costs. Divestments were also made in the areas of surfactants. At the same time strategic investments were made in niches such as biocides and resins.

ENVIRONMENT

In the industry of speciality chemicals, environmental protection constitutes one of the foremost lines of action to steer research and development of new products. Minimising toxicity has become a criterion for innovation that is as important as efficiency. The industry is bound to follow and even anticipate EC and national environmental regulations that are becoming ever stricter under pressure of the public opinion.

A lot of products containing solvents (e.g. adhesives, paint) have already been abandoned, and pigments based on heavy metals are undergoing the same fate. The strict legislation in these areas has become a real stimulus for researchers to find substitutes or alternatives for lead, cadmium and molybdenum. The same holds for additives for paint, varnish and plastics. The use of plant-based surface agents instead of petrochemicals is another example of the use of renewable raw materials leading to a less toxic end product.

REGULATIONS

Developments on regulatory matters at the EC level concerning the industry included work on the control of movements of waste (e.g. the transport of spent carbon for activated carbon producers), the harmonisation of food additive regulation developed by the EC Commission (flavourings, gases for use in the food industry), and the EC directive on plastic materials that come into contact with foodstuffs (fatty acids). The explosives industry has advised the EC Commission on a harmonised base for approval by the EC Commission for release on the market of explosives for civil use. This would include an effective system of transborder control after abolition of current border controls. Legislation affecting the industrial gases subsector includes the pressure equipment directive (industrial gases), the standardisation of gas cylinders by the technical committee CEN TC 23 (industrial gases), and the drafting of guidelines by EIGA to comply with EC classification and labelling directives.

OUTLOOK

Speciality chemicals face a bright future. The industry is expected to realise high growth and profit margins, similar to the pharmaceutical industry, and unlike the commodity chemicals. One factor at play in the success of the industry is the general tendency towards more technologically oriented products that is believed to be maintained in the future. Public demand for more environmentally friendly products is a second factor that tends to favour speciality production growth. Lastly, the industry has not fully exploited the excellent possibilities in product development, which is a major factor in the expansion of existing markets and in the development of new markets. Production is expected to increase by an average annual growth rate of around 3.1% to 1997, while consumption should increase at an average of 3.3%. Extra-EC exports should see relatively high rates of growth.

Agrochemicals
NACE 256.8

The EC is the world leading producer of agrochemicals for crop protection. The EC also maintains a favourable balance in world agrochemical trade, with exports almost twice imports. Growth is forecast in the European crop protection product production, driven in particular by a continuing increase in demand from the developing nations.

INDUSTRY PROFILE

Description of the sector

According to NACE 256.8, the agrochemicals industry can be defined as the manufacture of chemical products for agricultural purposes. There are two major branches within agrochemicals: fertilisers and chemical products for crop protection. This section of the Panorama discusses the latter of these two branches.

Chemicals designated for crop protection include insecticides, fungicides, herbicides, and plant growth regulators, and in future new biotechnological products used to protect plants against disease and pests, currently under development.

The EC is the largest producer of agrochemicals designated for crop protection, with France constituting the major EC market and the third biggest national market in the world, after the United States and Japan. In 1990, the West European plant protection market was estimated at around 5 374 million ECU, that are 26% of the world market. In comparison EC production was 6 204 million ECU representing about 30% of the world market.

International comparison

The EC is the leader in the market of agrochemicals for crop protection. France, Italy, the United Kingdom, Spain, West Germany, Denmark and the Netherlands constitute the major markets in the Community. In terms of real growth, EC countries accounted for five of the top six agrochemical markets in 1990. The EC share in the world's market represented 30%. The USA was the runner up with nearly 24% of the world market. Assuming that volumes and prices in the world market remain more or less stable and proportional to crop acreage, the EC should continue to be the world leader in the crop protection market in the 1990s.

In 1992, however, regarding sales, USA represented 29% of the world total when west Europe was about 27%. Japan came after with a share represented 14%.

Foreign trade

Since the peak in 1985 (1 307 million ECU) the trade surplus showed a steady decline during the second half of the 1980s. More recently the surplus has begun to grow again, but is still far below its mid-1980s level currently standing at about 884 million ECU.

Extra-EC exports in value decreased about 6% in 1992. However, the EC remains a net exporter of crop protection products, mainly of insecticides.

Destination of EC exports has changed. Indeed, while in 1986 the Soviet Union was the EC's most important export market, this region's share of total EC exports had almost halved to 11% by 1991. The OPEC and EFTA countries are now at the top of the list of EC export markets. The "rest of the world", however, remains the biggest destination of EC exports.

Imports decreased 20%. The most important competitors for EC agrochemical firms are the EFTA countries (with just under 50% of total extra-EC imports), followed by the USA at 31%. Extra-EC imports consisted mainly of herbicides.

MARKET FORCES

Demand

Demand for agrochemicals is directly linked to the dynamism of the agriculture sector, which represents almost its only end-market. Demand will thus benefit from any implementation of new techniques in the farm industry, which are aimed at improving the acreage yield. Economic and regulatory factors represent other important parameters influencing demand for agrochemicals. Indeed, demand will be constrained by measures exerted on the farm industry, like the reform of the Common Agricultural Policy, which have direct effects on the volume of agricultural production. Economic factors such as labour costs in the farm industry may contribute to a varying picture of demand across countries: for example, herbicides, which are the largest product group and also the most rapidly growing market segment in Europe, are particularly useful (and largely used) in countries where labour is expensive.

Indirectly, population growth constitutes a major factor influencing demand for agrochemicals, that provide a certain guarantee to maintain sufficient food resources for the growing world population. Climatic conditions have also a significant effect on demand for agrochemicals. Indeed, insecticides for example are more used in southern EC Member States such as Spain and Greece than in northern countries (especially orchards). On the contrary, fungicides that are used to control fungal diseases mainly in high value crops, are increasingly used in north Europe experiencing high rainfall and a cool climate.

Supply and competition

Competition among companies is particularly tough in the crop protection industry. The EC manufacturers hold a strong advance in terms of research and development, thanks to important investments in this activity. Numerous take-overs occurred during the recent years, through acquisitions and mergers, with plant biotechnologies as main targets.

Production process

The main feature is the increasing share of research and development in total sales. On average, the top twenty companies committed 9.7% of total sales revenue to R&D in 1990. Biotechnology has emerged as a key area of research. The main thrust of this research is in the area of plant genetics and the development of biopesticides. Genetic engineering techniques have made traditional plant breeding far more efficient and sophisticated. New plant varieties are being developed with features such as: resistance to pests and disease; resistance to herbicides; resistance to frost or drought; and improved product quality.

Research in biotechnologies will not noticeably reduce total agrochemicals' sales, but will cause modifications to the type of products and to the competitiveness of those involved. The products distributed will be safer for the environment and give stronger pest control, whilst the first results of biotechnology research should appear on the European market early this decade.

INDUSTRY STRUCTURE

Companies

Taking into account the research and development capacity and the production levels or distribution network, the number of companies of importance in the agrochemical industry was estimated to about 40 worldwide in 1985. The majority of agrochemical manufacturers are located either in the USA, Japan or western Europe. Nearly all these firms are multinational chemical companies whose agrochemical segments represent a relatively small part of the total sales of the group to which they belong.

BASF (D) and Ciba-Geigy (CH) are considered as the largest European Companies.

Strategies

As farmers demand more and more environment-friendly chemicals to treat their crops, agrochemical industrials are committed to ensure they meet new higher regulations. As this constraint is particularly costly in terms of R&D, not all of the industrialists are keen on investing in this field. As a result, restructuring is most likely to take place, mainly in the form of joint ventures, at least for the largest groups. Restructuring has, actually, already begun and groups are looking at the possibility of building up niches either in particular product area or geographical. There have been further developments and mergers, including the Cyanamid (USA)/Shell (USA/NL) agreements and the Hoechsts (D)/Schering (D).

Source: Eurostat

REGIONAL DISTRIBUTION

France, Italy, the United Kingdom, Spain and Germany are the largest producers in the EC, and are also the largest consumers of plant protection chemicals, using about 95% of the herbicides, 97% of the fungicides and 77% of total pesticides consumed in Europe.

France, together with the USA and Japan, is one of the three countries representing half the world herbicide's market, and accounted for 10% of the world herbicides' sales in 1990. Today, the largest EC market is herbicides, except in of Italy, where fungicides sales exceeded herbicides in 1990.

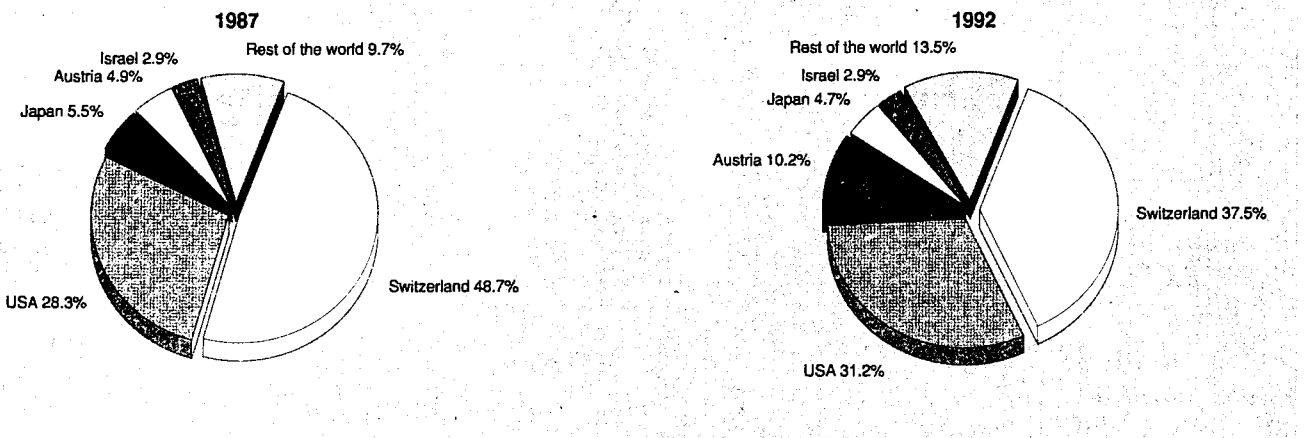
ENVIRONMENT

Whilst respecting environmental needs, the industry must also balance its role of crop protection and the maintenance of reliable food supplies. Advances in the agrochemicals industry are critical in order to limit the risk of agricultural disasters but also to limit the already important losses recorded in potential food production worldwide, due to pests' diseases and weeds (about 30% of the total). The big challenge facing the industry now is thus to find an adequate balance between the respect of green policies and the production needs of modern agriculture. Major resources are invested by the industry each year in this objective. In fact, for every new compound tested, only one in 15 000-20 000 is marketed.

REGULATIONS

The most important concern facing the agrochemicals industry is the recently adopted reform of the Common Agricultural Policy (CAP). The core of the reform is a shift away from price support mechanisms, in favour of direct compensatory payments to farmers. These measures that cover for the moment about 75% of total farm production under CAP regulation, entail full compensation to arable farmers for price reductions provided they participate in a set aside scheme for cereals, oilseeds and protein crops. This combined with the view that compensatory payments should give less incentive to raise production than high support prices, reform of the CAP could

Figure 2: Agrochemicals for crop protection
Origin of EC imports



Source: Eurostat

cut agrochemical sales by about 20%, according to industry sources. Nevertheless, Agra Europe, an independent agency, is casting some doubts on this conclusion. According to Agra Europe, the reform is unlikely to bring about steep falls in EC production of cereals, and thus have such a dramatic effect on agrochemical sales.

This reform, along with the establishment of the Single European Market is going to increase competition in the agrochemical field. As a result, the number of participants is likely to decrease. Also, it is hoped that some cost gains can be achieved by the industry through regulatory harmonisation and efficiencies to offset the expected lowering of prices foreseen in some Member States.

The EC's agrochemicals registration directive, adopted by the Council in July 1991 (another directive set up in the view of the Single European Market), is expected to bring about significant changes in the regulatory control of crop protection products. This measure is aiming at harmonising approval procedures across Europe, setting a European system for active ingredient registration and encouraging mutual recognition of national product approvals by the remaining Member States. So far, the diversities of national product registration requirements have represented important costs for the industry when launching new products.

OUTLOOK

Lower growth of agrochemicals is expected in the European countries, as a result of the CAP reform. Competition among companies will continue to increase, all the more so as R&D costs are becoming increasingly important. Further concentration will occur through mergers and acquisitions, principally in the field of biotechnologies.

Other equally important issues for the future will be the environmental pressures, particularly the general water quality debate and the aspects of intellectual Property Protection, and more specifically Patent Term Restauration/Supplementary Protection Certificate, similar to the one introduced for the Pharmaceutical Industry.

The industry is represented at EC level by: European Crop Protection Association asbl. Address: Avenue Albert Lancaster 79a, B-1180 Brussels; tel: (32 2) 375 6860; fax: (32 2) 375 2793.

Fertilizers
NACE 256.8

The prospects are rather different in the field of fertilizers compared with agrochemicals where the EC is confronted by stiff competition from East European and North African countries. The depressed market, along with the crisis of overcapacity continue to affect the performance of the European fertilizer industry, which is committed to further restructuring in order to improve profitability.

INDUSTRY PROFILE

Description of the sector

According to NACE 256.8, the agrochemical industry can be defined as the manufacture of chemical products for agricultural purposes. There are two major branches within agrochemicals: fertilizers and chemical products for crop protection. This section of the Panorama is concerned with the first of these, fertilizers.

The fertilizer industry produces and markets both single nutrient fertilizers (comprising either nitrogen or phosphate) and various compound fertilizers (containing mixtures of nitrogen, and/or phosphate and/or potash). The largest market is for nitrogen fertilizers (about 50% of the total), followed by phosphate (accounting for around 25%).

The vast majority of sales are in the form of solid fertilizers (about 90%), the remainder being liquids. The main reason for this is that liquid products require special handling and storage facilities.

Recent trends

The market for fertilizers has been depressed for years, and has suffered from problems of overcapacity as well as weak demand. Consumption of fertilizers was static or declined sharply in the EC in the last four years, and this trend is likely to continue due to the reform of the CAP (Common Agricultural Policy). Another reason for this decline is environmental legislation. The fertilizer industry is also suffering from an increasing trade deficit. Extra-EC imports, which grew steadily, reached 1.19 billion ECU in 1992 and were about two and a half times the level of extra-EC exports. In 1991 nitrogen output was below 9 million tonnes, and phosphate output was 2.9 million tonnes.

International comparison

The European fertilizer industry accounts now for 12% of world fertilizer production and is the fourth largest world producer after the former Soviet Union, the USA and China.

Foreign trade

A trade deficit has existed since the late 1980s, but has widened in the past few years, reaching 788 million ECU in 1991. In 1992, it fell back slightly to 688 million ECU. The worsening trade balance is due both to rising imports and falling exports. In 1992, extra-EC imports exceeded 16% of demand while the share of extra-EC exports in production was about 8%. Both trends look set to continue with particular pressure on the import side. The main reason for this is the difference in the cost of natural gas, a key raw material in the production of nitrogen fertilizers, between the EC producers and their competitors, in particular the CIS.

MARKET FORCES

Demand

Demand for fertilizers is directly linked to the implementation of the CAP reform; for example the 15% set aside policy for eligible arable land will have a significant impact. Furthermore, environmental legislation, like the Nitrate Directive, will have a substantial impact on the demand.

Supply and competition

Profitability has been very low for EC manufacturers for many years. Massive restructuring and downsizing have already taken place. Employment in the EC stood at 140 000 in 1983. By 1991 this had been reduced to 40 000, a fall of almost two thirds. EC production capacities have fallen since 1980; very strongly for compound fertilizers, much less so for ammonium nitrate. On the other hand, capacity has increased in the rest of the world although ammonium nitrate has seen much less growth. The EC has retained its share of the world capacity for the latter product but seen a large decline for urea, sulphates of ammonia and compound fertilizers.

The fertilizer industry is very sensitive to the vagaries of world supply and demand and to global competition. Given that natural gas constitutes a large part of the input costs, the main competitors tend to come from regions with access to cheaper gas. In recent years east Europe and in particular the former Soviet Union have become increasingly important players, the reasons being, firstly, a subsidised gas supply, and secondly, a desire to earn foreign capital. Countries with large reserves of phosphates are key competitors in that section of the market.

Given the state of the market the question of fair international trade is becoming increasingly important. In the past, cases of dumping have been proved, and this is still clearly an area of concern to the industry.

Production process

Fertilizer plants are often large integrated operations that process raw materials into inputs for other industrial sectors. These inputs include ammonia, nitric acid, urea, ammonium nitrate, sulphuric acid and phosphoric acid.

The industry is highly dependant on its supplies of raw materials, hydrocarbons (particularly natural gas) and natural phosphates. The sector manufactures heavy and low value added products: from a chemical point of view, the production of fertilizers is a fairly simple process. However, state-of-the-art plants producing high-quality fertilizer products are difficult to engineer and to operate, if they are to have low costs, especially low energy consumption, and to meet environmental legislation. Fixed costs are an important element of the cost structure as the industry is highly capital intensive. On average, they account for about 50% of total costs.

INDUSTRY STRUCTURE

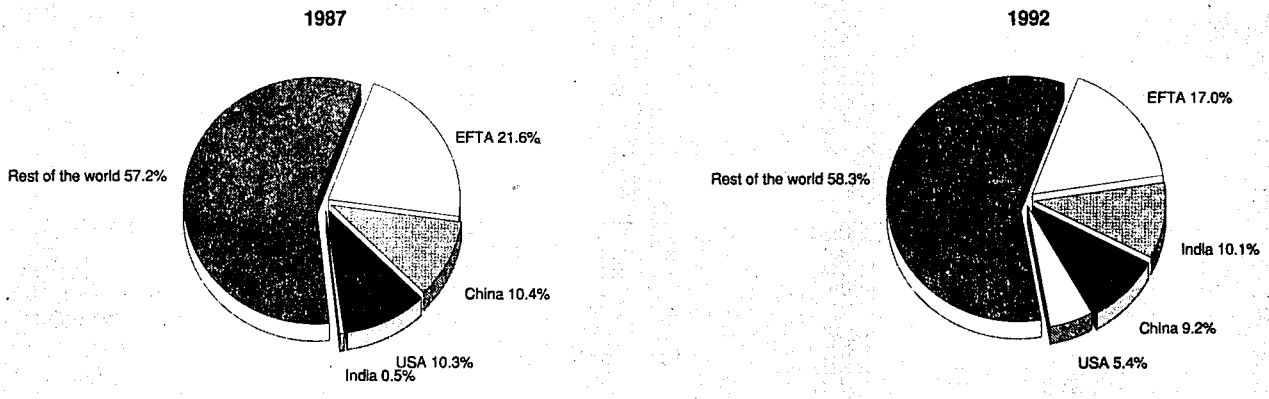
Companies

As a result of the restructuring and downsizing during the 1980s the fertilizers industry has become increasingly concentrated. From 1980 to 1991, the wave of mergers and acquisitions led to an industry where seven companies were responsible for more than 80% of European production. These seven are: Norsk Hydro (N), Kemira Oy (SF), BASF (D), Grande Paroisse (F), Enichem Agricoltura (I), DSM (NL) and Tertiberia (E). Norsk Hydro and Kemira have the largest capacities in Europe.

Strategies

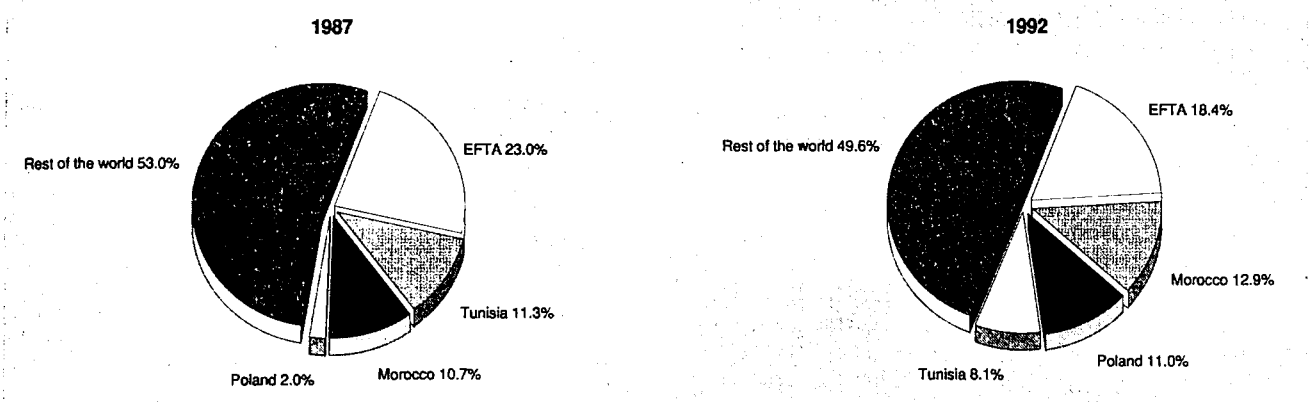
Given the increasing competition from regions that enjoy considerable competitive advantages and reduced demand, further restructuring of the European fertilizer industry is expected.

Figure 2: Fertilizers
Destination of EC exports



Source: Eurostat

Figure 3: Fertilizers
Origin of EC imports



Source: Eurostat

The EC fertilizer industry is committed to a huge restructuring and rationalisation process both within national borders and at EC level. Sales networks have been developed in all countries. Plants have been shut down and production concentrated at the most favourable locations in terms of supply and outlets. Investments have been made in order to improve efficiency and productivity (especially to optimise the use of energy) to produce the best fertilizers and market them in the best way.

REGIONAL DISTRIBUTION

Production capacity for each type of fertilizer is widespread across the Community. However, this is less true now than in the past due to the rationalisation of the industry. This had the effect of concentrating production for the different types of fertilizer in a smaller number of countries. In general those countries that were historically small producers have now largely stopped production completely.

In terms of total capacity across all nitrogenous fertilizers the Netherlands and France have the largest capacity accounting each for 18% of EC total. Other significant producers are Germany, Italy, Spain and the United Kingdom.

ENVIRONMENT

Since the early 1980s there has been considerable concern about the impact of agricultural chemicals and fertilizers on the environment. In particular there has been concern about the level of nitrates in water supplies and phosphorus in water sources and the sea. At the same time farmers have come under increasing pressure to increase yields in order to maintain profitability that has led them to increase the use of fertilizers. However their use is intended to match plant uptake (and in the case of phosphates to correct deficiencies). If they are spread in the right amount and at the right time, the fertilizers cover the plant's nutritive needs and are absorbed nearly completely. The problems caused therefore demonstrate the relatively low capacity of the environment to absorb excess amounts of these materials.

The EC has sought to remedy the situation by placing restrictions on the use of nitrogen in zones vulnerable to pollution. In this context an important document is the Council Directive concerning the protection of waters against pollution caused by nitrates from agricultural sources (91/676/EEC). In annexe 3 of this document the maximum amount of manure applicable per hectare has been fixed at 210 kgN/hectare (170 kgN/hectare after four years). For its part the industry is concentrating on producing high quality products that ensure even distribution of fertilizers and therefore minimise the leaching of excesses into the environment. However, the consumer (farmer) also has to use fertilizers in a appropriate way in order to have the best "environmental result". Reform of the CAP, to reduce the size of surplus, will also help to reduce the amount of fertilizer used in farming.

The environmental impact from using nutrients in agriculture will be reduced due to improved technology and implementing codes of best agricultural practice. Special attention has to be paid to the rapidly increasing environmental costs imposed to the European fertilizer industry by national and European legislation.

REGULATIONS

Regulations exist, covering most aspects of fertilizer production and use, and EC level legislation is becoming more common as standards are harmonised across Europe. In addition to normal health and safety regulations, fertilizer producers are subject to emission standards and product quality specifications.

The application of fertilizers is not yet subject to EC wide legislation, and given the importance of local factors such as soil quality, crop and climate, this may no be appropriate.

The fertilizer industry has developed its own code of practice and is willing to contribute to the development of legislation concerning the use of its products.

The fertilizer industry is also considerably affected by other legislative measures such as the CAP. Indeed the most important concern facing the industry is the recently signed Common Agricultural Policy reform. The core of the reform is a shift away from price support mechanisms, in favour of direct compensatory payments to farmers. This measure, which covers about 75% of total farm production under CAP regulation, entails full compensation of farmers for reduction in prices. To further limit supply, it is accompanied by a compulsory land set-aside scheme for cereals, oilseeds and protein crops. Indeed, recognising the fact that compensatory payments could give less incentive to raise production than high output prices, reform of the CAP will reduce fertilizer consumption significantly, according to industry sources. However it has been suggested that the reforms may not bring about steep falls in EC production of cereals, and thus to have such a dramatic effect on agrochemical sales.

OUTLOOK

The CAP reform, along with the establishment of the single European market, is going to increase competition in the fertilizer field. As a result, the number of participants is likely to decrease. However, it is also hoped that some cost gains can be achieved by the industry through regulatory harmonisation and efficiencies to offset the expected lowering of prices foreseen in some Member States.

Unless action is taken to curb imports, the European fertilizer industry will have to make further cuts in capacity in order to maintain profitability. Further changes in the ownership structure are therefore to be expected.

Soaps and detergents, perfumes and toiletries
NACE 258

The combined sector of soaps and detergents, perfumes and toiletries was characterised by steady growth during the 1980s. From 1988 onwards there has been a slight deceleration in real output and consumption growth despite the introduction of some innovative products (e.g. liquid laundry detergents, enhanced skin care products). Demand for the industry's products is closely linked to the standard of living, but also to individual tastes and fashion, hence the relative importance of marketing and R&D activity.

INDUSTRY PROFILE

Description of the sector

NACE 258 is divided into two product categories:

- the manufacture of soap and synthetic detergents (NACE 258.1) which covers toilet, household and industrial soaps and washing products, surface cleaners and washing powders; and,
- the manufacture of perfumes and toilet preparations (NACE 258.2) which covers hair products, beauty products, toiletries for men and women and alcohol-based products.

Although being grouped in a common NACE, the two subsectors differ substantially in terms of industry structure and recent trends and will therefore be considered separately when possible.

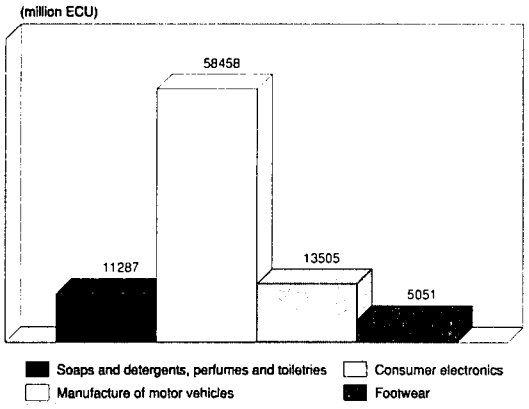
Recent trends

Production in the soaps and detergents sector is dominated by laundry and surface cleaning products, which together account for nearly 90% of NACE 258.1. Among surface and scouring products, liquid products and laundry washing powders together represent more than 90% of total production. The five main EC countries (respectively, by share of production, Germany, the United Kingdom, Spain, France and Italy) account together for more than three quarters of total production of soaps and detergents.

The breakdown by country reveals that Germany, France and Italy (in this order) are the largest markets for perfumes and toiletries, with respectively 26.9%, 23.7% and 18.3% of EC sales. France remains the first producer and has the highest per capita consumption at 72 ECU (ex-factory prices) compared to an EC average of 49.5 ECU per capita. The breakdown by product line in value shows that hair products account for 26.3% of ex-factory sales, followed by toiletries (20.4%) and beauty and care products (19.7%). In 1992, consumption grew by 2.2% to 17 billion ECU, but this figure doesn't fully reflect higher growth in local currencies (e.g. in Spain and the United Kingdom).

From 1983 to 1992, the combined sector of soaps and detergents, perfumes and toiletries performed well: all the main indicators increased steadily, with the exception of employment. Apparent consumption was growing at an annual real average rate of 4.0%, production at 4.1% and employment at a modest 0.8%. In 1992, these indicators had respective growth rates in current terms of 7.1%, 7.7% and -3.0%. The decrease in employment stems from increased automation which led to a strong increase in productivity (+7%).

Figure 1: Soaps and detergents, perfumes and toiletries Value added in comparison with other industries, 1992



Source: DEBA

International comparison

The EC is the world's largest producer of soaps and detergents, perfumes and toiletries. In 1991, EC production was some 40% higher than that of the USA and nearly four times the size of Japan. Figure 5 shows that, during the 1988-1991 period, EC production grew at fairly strong rates of growth of more than 4% per year in volume, while production growth in both the USA and Japan was more variable. In the perfumes and toiletries sector alone, the EC market is first just above the USA and about two times bigger than Japan.

Foreign trade

The EC industry has widespread export markets for soaps, detergents, perfumes and toiletries. Among the most important export markets are the developing countries (which absorbed about 47% of total extra-EC exports in 1992) and the EFTA countries (about 27% in the same reference year). As for extra-EC imports, the EC's main external suppliers in 1992 were again the EFTA countries (above 45% of total imports) and the USA (about 32%).

In the soaps and detergents segment, the level of foreign trade is relatively unimportant, although the exports/imports ratio is far above unity (about 5.1). In 1992, for a total export

Source: DEBA

value of 1 107 million ECU, the EC imported soaps and detergents to the value of 215 million ECU. Intra-EC trade grew sharply in 1992 compared to 1991, reaching a level of 1852 million ECU, an increase of 21% over the previous year.

The internal structure of trade has remained unchanged in the last two decades: the EC mainly exports washing, surface cleaning and scouring products and toilet articles, but very few domestic and industrial cleaning products. With regard to imports, washing, surface cleaning and scouring products account for about 50% of the total.

By contrast, the perfumes and toiletries segment is more export-oriented, and in 1992 it accounted alone for 73% of the sector's total extra-EC exports. Although its exports/imports ratio is the same as the soaps and detergents segment (5.1 in 1992), extra-EC exports totalled around 3 000 million ECU in 1992, while extra-EC imports almost reached 600 million ECU.

Overall, the combined sector of soaps, detergents, perfumes and toiletries is much more export intensive than import intensive. Close to 10% of EC production is exported, a share that has remained fairly steady throughout the 1980s while the share of imports in consumption is still less than 3%, although slowly growing.

MARKET FORCES

Demand

The great majority of soaps, detergents, perfumes and toilet products is sold to households and individual consumers, although for the soap and detergent industry hotels, restaurants and institutional outlets are also important end markets. For both subsectors, marketing and sales promotion play an important role in defining consumer needs. Advertising, which resorts to television as its main medium, is increasing its use of satellite TV in order to promote Eurobrands targeted at the supranational market.

Soaps and detergents

Soap and detergent consumption is closely linked to the standard of living, but is also influenced by the introduction of new products. During the last few years emphasis on energy conservation combined with the need to take great care of delicate materials has produced a marked trend towards washing laundry at lower temperatures, using detergents in a more concentrated state. The introduction of products operating at lower temperatures has reinforced this evolution in demand. Liquid detergents in particular, which are easy to use, provide such an example. In 1992, concentrated products (liquids and powders) have grown at an increasing pace and they currently account for 40% (in value) of the EC market of detergents. The development of concentrated products has also led to the use of dosing devices to disperse the product better, thus improving its efficiency.

In addition to changes in consumer tastes over time, EC manufacturers must deal with wide differences in habits depending on the country in which they are selling. History and climate conditions can considerably influence consumer needs and demand.

Perfumes and toiletries

The sector of perfumes and toiletries is characterised by a strong link between individual product consumption trends and living standards. Fashion and advertising also have a considerable influence on sales. The main consumer trends that became apparent during the 1980s have led to greater product diversification. For example, the promotion of a more natural look for women, together with the introduction of products such as gels and fixing mousses, explains in part the increased popularity of these products. The initial changes in product patterns in the hair care market influenced the make-up market during recent years.

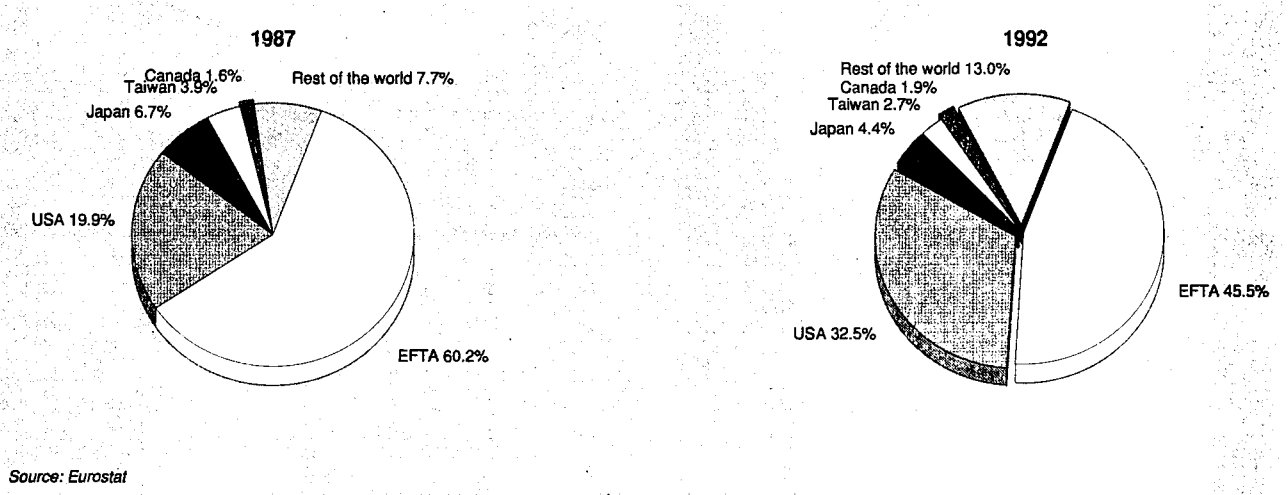
Supply and competition

In addition to inter-industry competition, which is common to both subsectors in the EC, there is external competition in the soaps and detergents sector from distributors, and in the perfumes and toiletries industry from foreign competitors.

Soaps and detergents

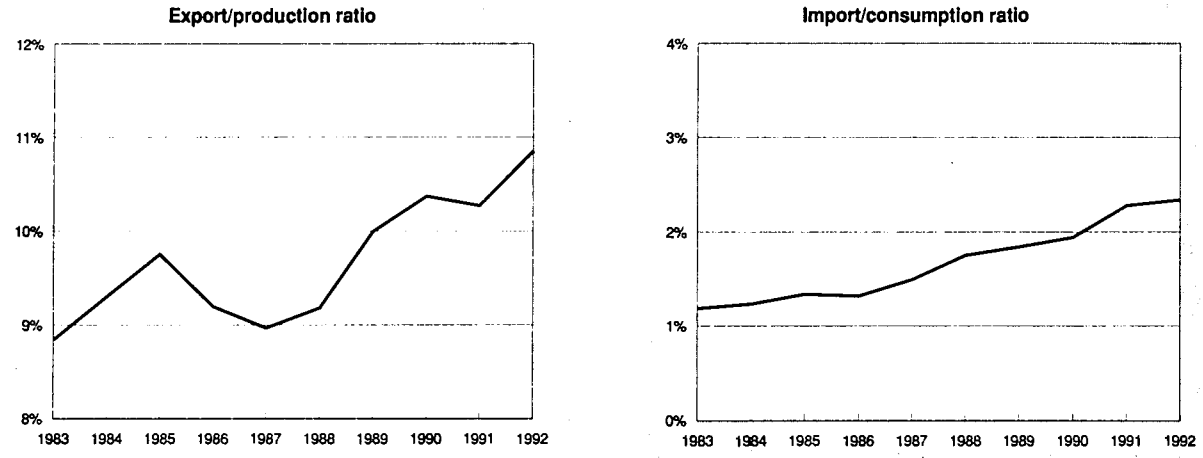
The EC soap and detergent industry operates in a very competitive environment but benefits from considerable potential in developing countries. While the supply of raw materials

Figure 7: Soaps and detergents, perfumes and toiletries
Origin of EC imports



Source: Eurostat

Figure 8: Soaps and detergents, perfumes and toiletries Trade Intensities



Source: DEBA

is widespread, the finished product is distributed by a few northern multinational companies. Within the EC, there is a relatively mature market in the northern Member States, while a sharp growth in the use of cleaning products is taking place in the southern countries.

Over the last twenty years the emergence of hypermarkets has considerably modified the distribution system of the industry. Manufacturers in the soaps and detergents sector have now to face more powerful buying groups. Furthermore, over the last few years, distributors have launched their own products (own label brands) onto the market, thus heightening existing competition.

Perfumes and toiletries

During the last few years, the growth in products for men has been quite sharp, with as yet no indication of any decline. Although such growth is mainly the result of attracting a group of new consumers, the successful promotion of product "loyalty" has stabilised sales. Fashion dictates the trend in new products, demand for which is generated by the general concern for improved grooming and care. Marketing, which focuses more and more on skin hygiene and the protection of the environment, is also responsible for these developments.

Foreign competition has made forays into the industry, with products manufactured by Japanese companies like Shisheido becoming increasingly available on the EC market. The Japanese firm has recently set up a cosmetics factory in the Loire Valley, which reflects the internationalisation of the perfumes and toiletries industry.

Production process

In both sectors, research and development and marketing are an important part of company operations, given the competitive advantage of anticipating future demand on the part of the consumers.

Soaps and detergents

In this very competitive industry, considerable funds are allocated to R&D (on average 2.5% of turnover). Enzyme technology continues to develop and "fat busting" enzymes have begun to appear in premium quality products. Recent innovations have responded to consumer concerns about the environment. The introduction of liquid formulas and the increasing of the concentration of liquids and powders improve cleaning effectiveness and save water and energy.

Perfumes and toiletries

The major companies have been restructuring production to concentrate production in plants specialising in one type of product. They are also investing in new techniques that allow the fabrication of ever expanding ranges of products on a single production line manned by a decreasing amount of workers. In 1992, L'Oréal (F) inaugurated an entirely new factory based on these principles, in the vicinity of Paris.

INDUSTRY STRUCTURE

Companies and strategies

Both subsectors are characterised by the presence of major multinational companies, which are often active both in the soaps/detergents and the perfumes/toiletries segments. Another common characteristic is the strong interest shown by companies for the East European market.

Soaps and detergents

In Europe, the soaps and detergents sector accounts for about a thousand manufacturing and distribution companies, which vary from those that only supply the local market to large international companies that serve the world market. The European and American multinational companies possess a large number of production units within the Community.

The world market for cleaning products is led by five major multinational groups, of which three are EC-based: Unilever (NL/UK), Henkel (D), Benckiser (D), Colgate Palmolive (USA) and Procter & Gamble (USA). At present many of these companies are intensifying their efforts to penetrate other markets, notably by buying out or buying shares in companies often placed downstream of their production process.

In 1992, Central Europe was still a major target for M&A or alliances. Both Benckiser and Henkel created joint ventures in Poland, while Unilever in collaboration with Ferruzzi (I) (with a 20% share) took over a Hungarian company for 100 million USD. There was also activity in fast growing markets. For instance Unilever bought an Argentinean company active in dry detergents and Henkel acquired Sociedad Nacional de Saboes in Portugal.

The industry is seeking a removal of duties applied by East and Central European States on fabric detergent raw ingredients. The industry association (AIS) has been instrumental in drawing to the attention of the Commission the advantages of such a move, since both local companies and joint-ventures

would benefit from improved quality of raw materials at lower costs.

Perfumes and toiletries

The following five firms dominate the world market: L'Oréal (F), Unilever (NL/UK), Shisheido (JPN), Avon (USA) and Procter & Gamble (USA). Among the other important EC firms are Sanofi (F), Wella (D), LVMH (F) and Schwarzkopf (D). Although the major groups grew in strength over the past few years, smaller companies have also managed to maintain their independence, particularly at the national level, operating in niche markets. For instance, The BodyShop (UK) targets the environmentally conscious customer.

After the boom in acquisitions which characterised the late 80's, the sector is continuing this strategy but at a slower pace. In 1992, Elf Sanofi (F), the health-care subsidiary of the petroleum giant Elf, took control of Yves-Rocher (F) a successful mail-order company with a strong "green" touch. In April 1993, Sanofi acquired Yves Saint-Laurent (F) thus becoming number three in the world in the perfume sector after L'Oréal (F) and Estée Lauder (USA). Meanwhile, SmithKline Beecham, the Anglo-American pharmaceutical group sold its bath and body care brands to Sara Lee (USA) and its haircare business to Wella (D). The major multinationals operated on the east European market as well: for example L'Oréal (F) started the production of a perfume in Russia.

ENVIRONMENT

Soaps and detergents

The use of soaps and detergents has at times been associated with water eutrophication, i.e. a decrease in oxygen which engenders an abnormally high level of aquatic vegetation. Water eutrophication continues to be a cause of public concern. It is, however, generally appreciated that detergent ingredients account only for a minor fraction of this form of pollution, which mainly originates in industrial, agricultural and human waste. The view on phosphates has moved significantly and this well researched ingredient is now preferred by a number of respected authorities.

The detergent sector has been active in developing several packaging prevention measures.

The use of more compact product formulas resulted in more compact packagings; separately, reuse has been encouraged by the introduction of refill bags and ecobags. Several companies are actively participating in collection and recycling schemes and have already started to use recycled plastic in detergent bottles.

Perfumes and toiletries

In the last few years, environmental problems have become an important issue both for producers and consumers. All manufacturers within the sector are investigating ways of reducing the effects of their products on the environment. At present, attention is being focused on three specific possibilities: the biodegradable properties of toiletries and cosmetics, the incorporation of preservatives in their manufacture, and the recycling of containers (plastic bottles, aerosols cans, etc.).

Problems relating to aerosols (particularly deodorants and hair fixing products) which contain ozone layer damaging CFCs (chlorofluorocarbons), have already been solved by replacing CFCs with environment-friendly components like butane or propane. The following stage is to use air or nitrogen as a propellant, since they don't present any risk of explosion.

Finally, there is a great industry concern about the current debate on animal testing. The harmlessness of perfumes and toiletries needs to be tested before they are sold to consumers, and so far the only legal way of doing so is animal testing. In its vast majority, the perfumes and toiletries industry refuses a prohibition of such practices until new testing methods are introduced, and at the same time supports R&D efforts to discover alternative methods.

REGULATIONS

The soaps and detergents industry agreed at the end of 1990 on a voluntary agreement with the EC (89/542/EEC) covering the labelling of nineteen substances in detergents. Progress in ensuring compliance within the industry has been self regulating and is regarded by the EC as a textbook example of responsible industry in action.

OUTLOOK

In the medium to long term, growth in the soap and detergent sector depends to a great extent on consumer behaviour and the development of other sectors such as textiles and household equipment. At the same time, protection of the environment and product safety will play an ever increasing role in industrial development. Expansion in sales volumes may be expected with the growing economic prosperity of former East bloc countries, where heavy investment is being made by the major manufacturers. Finally, within the EC, there still remains a considerable growth potential, notably in the South countries.

Table 5: Soaps and detergents, perfumes and toiletries

(%)	1993-94	1993-97
Apparent consumption	3.3	3.2
Production	3.3	3.4
Extra-EC exports	5.1	4.4

Source: DRI Europe

As for perfumes and toiletries, the prospects for growth vary in accordance with the wide range of products within this industry. Market saturation is likely to slow the sharp growth in hair care products that took place in the EC market during recent years. On the other hand, growth in beauty and skin care products is set to continue, as well as for men's toiletries. In terms of volume the market could soon reach saturation, however, through market and scientific innovations its value should keep growing.

Pharmaceuticals
NACE 257

The EC is the world leader in terms of pharmaceuticals production and exports. Total EC output amounted to 64 billion ECU in 1992, of which non-prescription pharmaceuticals accounted for a share of about 20%. The sector is also characterised by a constant trade surplus, as well as by a rapid growth of intra-EC trade.
R&D accounts for a large part of investments in the pharmaceutical sector, and its R&D/turnover ratio is one of the highest in the EC industry. The pharmaceutical industry is adapting itself to meet the challenges presented by new developments in technology (biotechnology), politics (upheaval in East Europe), economics (emergence of new competitors), demography (ageing population) and legislation (plans to curb health-care spending).

INDUSTRY PROFILE

Description of the sector

Within the EC, medicinal products are defined according to Article 1 of Council Directive 65/65/EEC (see Official Journal L 22, of 9.2.65 for more details):

- Proprietary medicinal products: any prepared medicinal product placed on the market under a special name and in a special pack;
- Medicinal product: any substance presented for treating or preventing disease in human beings or animals;
- Substance: any matter irrespective of origin (i.e. human, animal, vegetable, chemical).

Medicinal products can be divided into two main groups according to the way of purchasing: the first is prescription pharmaceuticals, which need to be prescribed by a medical doctor to be purchased; the second is over the counter (OTC) pharmaceuticals, which can either be prescribed by doctors or bought spontaneously by the consumer without a prescription (the true self-medication market).

Pharmaceuticals are mainly made from chemicals, but since the mid-1980s biopharmaceuticals (i.e. drugs produced from biotechnological processes) have appeared on the market. They now command an estimated 4% of world sales.

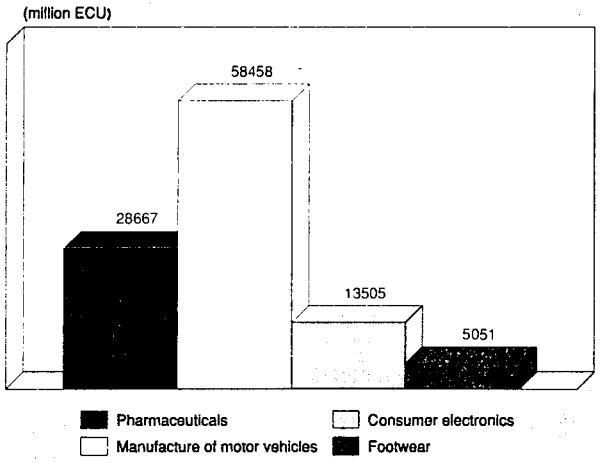
It is not easy to translate the concept of medicinal products into economic terms; until recently, each Member State had its own classification. To avoid confusion, the sector has adopted a grouping of data according to heading 54 of the Standard International Trade Classification (SITC) of the OECD. This heading comprises the entire "medicines" section, as well as the sections covering specific active substances. The key figures presented are based on this definition. Missing data have been completed, wherever possible, with Eurostat data compiled on the NACE 257 definition. The data reported are approximate and therefore should be considered as trend indicators, providing an acceptable basis for comparison.

Recent trends

In 1992, the production of pharmaceuticals in the EC grew in current prices by 5.0%, with all Member States but three enjoying an increase. Most notable were the rises registered in Germany (8.1%) and France (7.8%). In 1993, production growth is estimated to reach 8%.

Total EC consumption of pharmaceuticals increased by 4.5% in 1992 and will continue to grow in 1993.

Figure 1: Pharmaceuticals
Value added in comparison with other industries, 1992



Source: DEBA

During the same period, employment in the EC decreased, for the first time in ten years, by 1.3%. All Member States recorded diminishing or stable employment figures except for Ireland (+7.9%), Denmark (+5.0%) and Germany (+4.1%). In this context, it is important to note that official employment figures are constantly revised. Some countries therefore report strong year-on-year employment growth, but this does not necessarily mean that growth took place in the current year.

Production and consumption in the pharmaceutical sector both increased rapidly from 1983 to 1992, at an average real rate of around 7% per annum. As for trade, growth in extra-EC exports was 2.6% p.a., while growth in extra-EC imports has been stronger, at an average of 5.4%. Extra-EC trade was particularly buoyant in the second half of this period. Altogether, the pharmaceutical sector has enjoyed much higher rates of growth than those of overall manufacturing activity in the EC during the period 1983-1992.

International comparison

In the world pharmaceutical market, the EC is the leading producer. In 1992, the value of production was about one third higher than that of the USA, and about the double of that of Japan. Moreover, compared with the level of 1987, the EC recorded an increase in production of 44% (measured in constant prices) at a time when USA and Japan increased 8% and 17% respectively.

The Japanese pharmaceutical industry has long been focused on the domestic market, an attitude encouraged by the national health insurance system, which has provided the entire population with access to low-cost health care. This has prompted patients to see their physicians frequently, resulting in growing demand for medicinal products and steady expansion of the pharmaceutical industry. In order to control spending on the national health system the government reduced its official drug reimbursement prices by 8.1% in April 1992. This policy is progressively reducing profits on all drugs. As a reaction to declining domestic product prices, the Japanese industry is developing new markets in the USA and Europe, and acquiring foreign firms. Nevertheless, when it comes to medical research, Japanese manufacturers remain far behind their counterparts in the USA and Europe. Well aware of this problem, Japanese companies are investing heavily in R&D in a bid to catch up with their foreign competitors.

Foreign trade

The EC as a whole is a net exporter of pharmaceuticals in the world market. Within the EC, the major players are Germany with a share of 27% of extra-EC trade, followed by the UK (17%), France (16%) and Italy (11%). Only Italy has a negative trade balance, which dates back to the early 1980s. However, if calculated at ex-factory prices, the cover ratio (production/consumption) for Italy was 1.14 in 1992.

During the period 1983-1992 the export/import ratio of the industry has declined steadily from 2.6 to 1.9. These figures indicate that, although the European pharmaceutical industry remains the world leader, it has been losing ground on foreign markets.

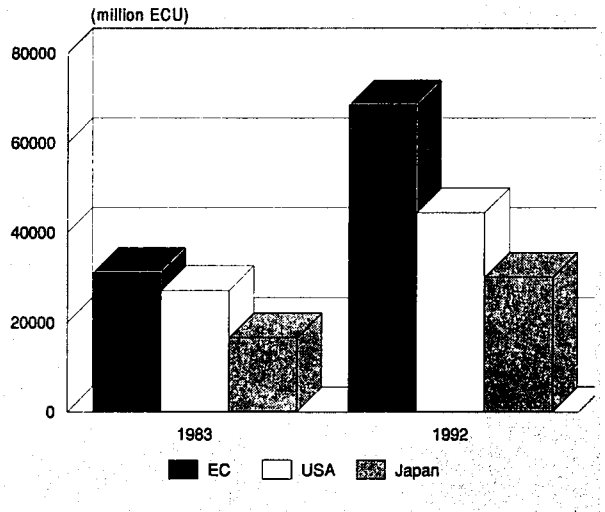
Extra-EC imports come overwhelmingly from western industrialised countries, with the USA and EFTA countries accounting together for 85% of total imports in 1992. On the other hand, export markets for the EC pharmaceutical industry are more dispersed. Developing countries, together with the category "others" (e.g. mainly Middle East and South and Central America), take up for more than half of extra-EC exports, but their share is slowly decreasing due to the growth of the USA and EFTA countries as end markets for the EC.

Intra-EC trade, measured in current prices, show that it has more than trebled in size, rising from 3 176 million ECU in 1983 to 9 945 million ECU in 1992.

ENVIRONMENT

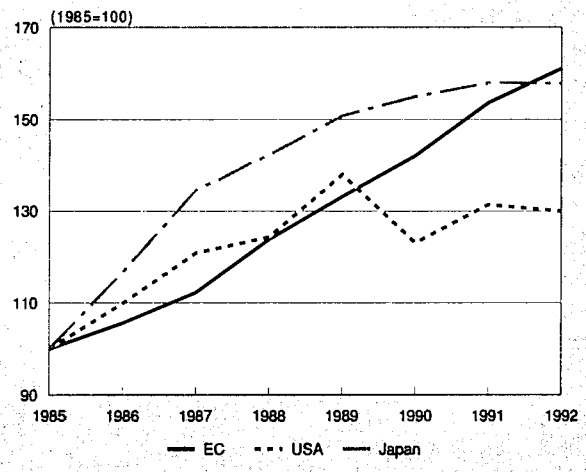
The current discussions on the reduction of packaging and packaging waste can not be separated from the need to provide the consumer with comprehensive information and the need to protect the product.

Figure 3: Pharmaceuticals
International comparison of production in current prices



Source: DEBA

Figure 4: Pharmaceuticals
International comparison of production in constant prices



1993 are Eurostat estimates.

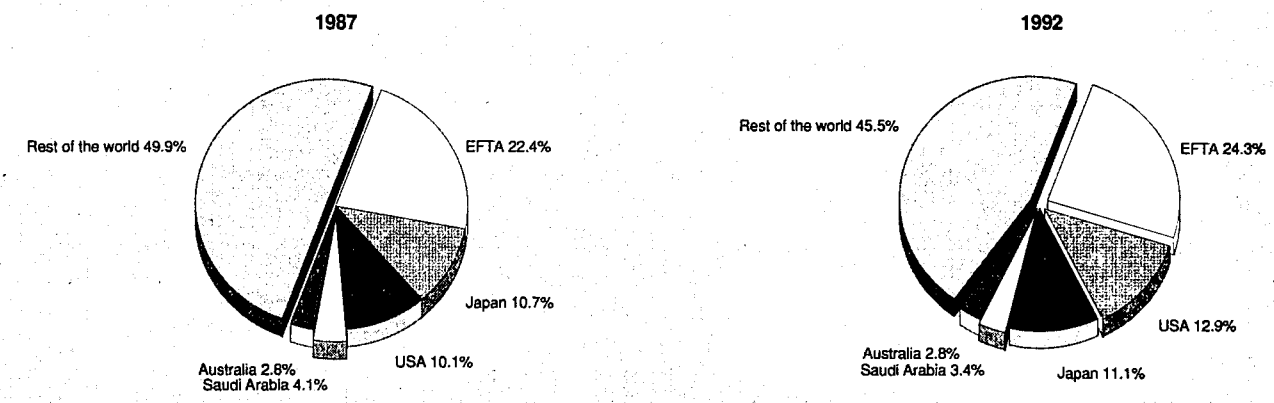
Figure 5: Pharmaceuticals
Destination of EC exports



Source: DEBA, Census of Manufacturers, Nikkei

Since the product information is contained either on the label or in the patient leaflet, it is essential that product and packaging are kept together until the final disposal of the product. Any measures in the area of packaging recycling or packaging waste reduction must therefore be balanced against these two requirements.

As far as the debate on the reduction of the use of ozone-depleting substances is concerned, account must be taken of the fact that ozone depleting substances may only be used as a means of delivery for drugs in essential use categories. Nevertheless, they should be replaced by non ozone depleting substances as soon as their quality and safety has been demonstrated.

REGULATIONS

The pharmaceutical sector is doubtlessly among the industrial sectors which are subject to the strictest regulations and controls in the industrialised countries, because of obvious public health and social reasons.

The unification of the European market for pharmaceuticals required a prior harmonisation of the essential health protection rules, of the appropriate mechanisms for a rapid access to the single market and of the socio-economic conditions which are compatible with the free circulation of medicines. All the initiatives programmed in 1985 by the Commission in the field of pharmaceuticals, contained in its White Book, were adopted by the EC Council.

EC regulations on pharmaceuticals cover all industrially-manufactured medicaments, including vaccines, emoderivatives, radiopharmaceutic products and homeopathic products. The existing EC provisions which can be applied to medicaments include binding provisions (regulations, directives), orientative guidelines on the testing procedures prior to the marketing of products, a recommendation directed to those asking for an authorisation for introducing new products in the market, and a detailed guide of good practices of manufacturing. All these provisions have been gathered in the series of volumes entitled "La réglementation des médicaments dans la Communauté européenne", which is available at the Office for Official Publications of the EC.

The legislative framework for pharmaceutical products was definitively changed with the adoption, in March 1992, of the regulation and three directives constituting the future system of authorisation of medicaments: the Council regulation (CEE nº 2309/93), establishing Community procedures for

the authorisation and the surveillance of medicaments for human and veterinary use, and instituting the European Agency for the Evaluation of Medicinal Products; and the three directives 93/39/CEE, 93/40/CEE and 93/41/CEE which modify or abrogate the prior existing directives to complete the picture.

After the European summit which took place in Brussels in October 1993, London has been designated as the seat of the European Agency for the Evaluation of Medicinal Products. In 1995, the procedures for granting Community marketing authorisations will come into force.

Starting from 1995, there will be three marketing authorisation procedures, corresponding to the specific needs of each company and to the public health requirements in the EC:

- a decentralised procedure, covering the large majority of medicaments, based on the mutual recognition principle. This procedure will enable a company which has obtained a marketing authorisation in one Member State to apply to have it recognised in one or more others, and provides for binding arbitration by the Community if they refuse. After three years, during which the decentralised procedure is to remain optional, it will become mandatory whenever authorisation is sought in more than one Member State;
- a centralised procedure, which is mandatory for biotechnological and veterinary medicinal products and is optional for others. The applications for authorisation will be submitted directly to the Agency, and the authorisation will be valid in the entire single market;
- a national procedure, limited in principle to the applications of local interest concerning a single Member State.

These new Community procedures are aimed at easing the free circulation of pharmaceutical products, while at the same time reinforcing public health protection. In particular, they will allow a more rapid access on new products to the whole of the EC.

The newly created Agency will consist of a secretariat of about 150 persons, who will provide the various committees and working groups with the necessary technical and administrative support; moreover, they will grant a good circulation of information among the 3 000 experts and national delegates.

The Agency will allow a better collaboration between national authorities and will work in cooperation with the best European experts for each of the fields it covers, thus granting a very high scientific quality to its recommendations. These will be then transmitted to the Commission which will adopt, after consulting the company concerned, a final decision.

The Agency will also be charged of reinforcing the surveillance of any undesirable effect of medicaments after their introduction in the market, and to coordinate national or Extra-EC inspections.

Finally, a regulation establishing the Supplementary Protection Certificate (SPC) was adopted in June 1992 and came into force on the first January 1993. This measure applies to all products subject to an authorisation in any Member State, i.e. both to prescription and non-prescription pharmaceuticals. The main aim of the SPC is to compensate for the period of effective patent protection lost while a medicinal product undergoes research and development (it takes an average of 12 years from the moment a patent is applied for to the day the product is launched on the market, leaving only a limited

exclusivity period to the innovator to recoup its investment in R&D before imitations appear on the market). The SPC, which may not exceed five years, enables the protection period to reach 15 years from the date of the first market authorisation.

Lately, many governments have introduced regulations in order to curb the spiralling rise in health-care spending. Cost containment measures have included price cuts (in Germany, the UK, Italy and Japan), limits on the value of doctor prescriptions (Germany) or tight controls on the industry's advertising practices directed at physicians (France). The pharmaceutical industry has reacted by pointing out that spending on pharmaceuticals represents only a small proportion of total public spending on health in West Europe and that such controls are putting at risk the development of innovative drugs.

Prescription pharmaceuticals

MARKET FORCES

Demand

Pharmaceuticals are bought mostly on a doctor's prescription, although a distinction has to be drawn between prescription pharmaceuticals and OTC products: prescription pharmaceuticals can be sold only in pharmacies, while OTC products can be sold, in some countries, in pharmacies only, in others in drugstores and sometimes even in food stores. Apart from consumers, other categories of purchasers are medical doctors, hospitals, and other institutions operating in the health-care system.

The demand for pharmaceutical products has recently been greatly influenced by two main factors. First, the ageing of the population, which partly originates in improved medical care and products, is slowly changing the pattern of production to adapt to the specific needs of the elderly. Secondly, the opening up of East Europe has created new market opportunities for the EC industry. The need for more advanced medicinal products has resulted in a growing trade surplus of about 360 million ECU with East Europe in 1992 (+20% compared to 1991, and +112% since 1990).

Finally, the recent initiatives by some governments to control the growth of health-care spending through cuts in the price of medicines is leading to a reduction in demand, which is already noticeable in Germany and Italy over the first five months of 1993.

Supply and competition

Production is very diversified as it meets specific and very diverse demands. It varies in its degree of integration (from the synthesis of basic chemicals to the preparation of finished products) as well as in the type of dosage formulation produced (e.g. tablets, pills, injectable ampoules, or capsules).

Production must meet the demand for both widely prescribed medicines for the treatment of common illnesses, as well as for medicinal products to treat certain rare conditions. In both cases the legislative framework is the same: production standards are very strict and high quality is essential.

Biodrugs, which in less than a decade seized a 4% share of the world market, are the fastest growing segment of the industry. Companies have invested heavily in this domain, either directly in R&D or through participation in emerging biofirms.

Domestically, the EC pharmaceutical industry faces problems of various regulatory environments, pricing policy and patent laws which differ from country to country in the EC. Internationally, it faces strong competition from the United States and Japan.

Production process

Medicinal products depend heavily on research for progress. In 1991, EC pharmaceutical companies invested over 7 billion ECU in R&D, which represents about 11% of the industry's turnover, and is among the highest R&D/turnover ratios in industry. From 1987 till 1991 gross investment remained stable between 5% and 6% of production. As a result of these investments, 97 new molecules have originated from Europe in the period 1988-1992, against 63 for Japan, 52 for the USA and 5 for the rest of the world. Research costs, at about 200 million ECU per licensed medicine, are constantly rising. This evolution is partly due to an increasing regulatory burden

combined with new technologies such as biotechnology and gene therapy.

INDUSTRY STRUCTURE

Companies

In 1991, three EC companies were among the ten worldwide pharmaceutical leaders: Glaxo (UK, n°2), Hoechst (D, n°5) and Bayer (D, n°9). SmithKline-Beecham, which is the result of the merger of Beecham (UK) and SmithKline (USA), can be added to this group in the fourth place. Of the remaining six, two are Swiss (Ciba and Roche) and four USA-based companies (including the number one, Merck). Within West Europe, other leading companies are from the United Kingdom (Wellcome, Zeneca), Switzerland (Sandoz, n°12) and France (Rhône-Poulenc Rorer, n°11).

Strong competition exists both in Europe and worldwide and no single company has a dominant position: the ten largest companies represent only 22% of the world market.

In biopharmaceuticals, the world top companies are mainly from the USA. In 1992, Genentech had sales (including licensed-out products) of about 1.1 million ECU followed by Amgen with 0.7 million ECU. In the EC Novo Nordisk (DK) is the main player.

Strategies

In order to face new challenges in terms of R&D costs, increasing competition and market diversity, new groupings of major companies have emerged through mergers and acquisitions. This was mainly the trend of the late 1980s. Since then the focus has switched towards alliances between OTC and prescription drugs producers. In July 1993, Warner-Lambert (USA) and Wellcome (UK) announced the creation of a joint-venture to combine their OTC medicines business. Simultaneously, Warner-Lambert concluded an alliance with Glaxo (UK) to market its prescription drugs once they are switched to OTC status. Meanwhile, Merck (USA) agreed to buy Medco Containment, the largest US mail order distributor of drugs, and formed an alliance with Johnson & Johnson (USA) to market OTC products. This illustrates the new strategy of some major prescription drug companies, which have made a strong commitment to enter the OTC market.

In June 1993, ICI (UK) finally demerged its bioscience (pharmaceuticals, agrochemicals and specialty chemicals) business under the name Zeneca. According to 1992 figures, pharmaceuticals represented 40% of its sales and 83% of its profits.

On the R&D side some big traditional companies have decided to bet on biotechnology either through direct investment (Roche (CH) owns a majority stake in Genentech (USA) since 1990, Sandoz (CH) followed with SyStemix (USA) in 1992) or through agreements on individual projects as those concluded by Glaxo (UK) or Merck (USA) with smaller partners.

Pharmaceutical wholesalers, which control 90% of the delivery of prescription drugs, are pursuing their concentration trend. In July 1993, Gehe (D), after a protracted battle, finalised the take-over of OCP (F), which controls 40% of the French market. Three alliances at the West European level have gained 50% of the market in the United Kingdom, 55% in France, 45% in Germany and 20% in Italy. Prescription companies are worried that the wholesalers, with the benediction of governments, could become a driving force in the drive towards lower prices.

OUTLOOK

The last years have seen a shift from strong to moderate growth. The pharmaceutical sector will remain among the fastest growing sectors over the 1990s due to growing concerns for health and an ageing population. However, the widening move towards cost-containment will entail a structural change favouring the cheaper products. This will result in consumption and production growth rates below those that were observed in the 80s. Exports and imports will grow at rates of about 5% per year in line with the recent past. Biopharmaceuticals will keep ahead of the pack with growth rates about 2% higher.

Non-prescription pharmaceuticals

MARKET FORCES

Demand

OTC products can be prescribed by a doctor or purchased directly by the patient without being prescribed by a doctor. Non prescription pharmaceuticals which are bought directly by the patient without being prescribed by a doctor are commonly defined as OTC products or self-medication products. Non prescription pharmaceuticals can be considered as OTC products if they can be advertised to the public and if they are used for minor ailments.

OTC products are generally used preventively and for benign disorders. OTC-purchasing is a well established practice, which brings the following advantages: it reduces the financial burden on the state health-care system; it reduces the doctor's workload in taking care of health problems which do not require medical treatment; and it promotes personal responsibility on issues which affect a person's own health.

There is a certain degree of confusion in the determination of market size for OTC products. The rules governing these products' classification, reimbursement and sales outlets, vary considerably from country to country. The same product is sometimes supplied only on medical prescription in one coun-

try and over the counter in another. There are also several products which may be sold without a prescription but are nevertheless reimbursed or partially reimbursed if prescribed by a doctor.

AESGP/IMS estimates show that the total market for non-prescription medicines in 1992 was about 17.8 billion ECU, while the size of the self-medication market (OTC market) reached 10.1 billion ECU, i.e. 56.7% of the total non prescription pharmaceuticals market. The latter is dominated by cough and cold products and analgesics, and has grown at an average rate of 9.9% since 1987. This compares with an average growth of the total non-prescription market of 9.3% in the years 1987-92.

The importance of the non-prescription potential and the self-medication turnover varies greatly from country to country. The practice of self-medication is well established in the northern Member States including France, while it is quite underdeveloped in the southern Member States. Until recently, OTC products were, at least officially, an unknown phenomenon in Greece.

INDUSTRY STRUCTURE

Companies

OTC products are manufactured both by large companies, which in general also manufacture prescription-only medicines, and by smaller more specialised enterprises. Until recently, the majority of companies in the sector were national companies supplying their respective domestic markets because of differences in Member States' legal requirements and consumer habits. This explains why the market is still fragmented and that there are only very few "Euro-brands" (i.e. OTC products sold under the same name all over Europe). In 1992, the top three companies were Bayer (D) with a share of 3.8% of the European OTC market, Sanofi/Sterling Health (F/USA), with a share of 3.7% and Procter & Gamble (USA) with a share of 3.3%.

Strategies

With a view to obtaining the necessary critical mass to operate effectively in the Single Market and on exports markets, the OTC products industry has also been affected by a certain number of mergers and acquisitions (M&A) operations. The most striking deals have involved prescription drug companies seeking to enter the market for OTC drugs. This has been illustrated in the section dedicated to prescription pharmaceuticals.

OUTLOOK

The demand for OTC products is likely to increase at a steady pace in the following years. This is confirmed by the fact that many pharmaceutical companies are developing their OTC activities. Governments are increasingly recognising the need to support self-medication by pro-active measures. This trend is also affecting the growing market of Central and East Europe.

Maintenance products
NACE 259.2

The maintenance products industry caters for a vitally important section of the domestic, institutional and industrial market. It covers a much wider range of product classifications than most other trade groups and is committed to keeping the product range up to date, efficient, competitive and environmentally acceptable. It provides advice and guidance together with manufacturing and packing facilities to the multiples selling their own brand products. The industry includes divisions of multinational groups together with many large and small companies.
The standard of employment is high, with well trained and competent operators in marketing, commercial and technical fields. In recent years demand increased as a consequence of some changes in the demographic patterns. The future of the maintenance products industry is reassuring as figures forecast a continuous growth, for cleaning products, in most of the European countries till at least 1996.

INDUSTRY PROFILE

Description of the sector

Maintenance products are defined as preparations designed to meet the cleaning, preserving and protective requirements encountered in a wide range of domestic, institutional and industrial situations.

They are normally marketed ready for use or may require dilution with water and they are presented in a variety of forms of packaging designed to meet their simple and efficient usage.

The evolution of the European market is essentially an amalgam of the markets in individual Member States. Moreover, within the EC there is considerable variations from country to country in product types and market shares. As a result, a large range of products exists: cleaners and polishes for wood, floor coverings, leather, shoes, metals, cooking appliances, windows, mirrors and motorcars; stain removers, dressings, and household starches; scouring preparations and scale removers; household disinfectants and deodorisers; household insecticides and anti-parasite preparations; hypochlorites and similar preparations for household and industrial purposes; industrial cleaning and maintenance products; all other domestic maintenance products.

Other products are made in some, but not all, EC countries. These include: stain removers, washing and ironing aids and dressings for fabrics; antistatics, mould release agents, defoamers; sanitary ware and drain cleaners; water and effluent treatment products; deodorants and air fresheners; chimney cleaners and firelighters; miscellaneous products, including adhesives and anti-rust agents.

The products concerned cover the following general application areas: maintaining, cleaning or visually improving household articles and domestic, communal, institutional, industrial living and working areas; destroying or repelling insects or animal pests that are detrimental to health or a nuisance in domestic environment; removing, preventing, or masking unpleasant odours; preserving and visualising improvement of materials such as wood, metal, plastic, glass, leather, fabrics, etc.; destroying or inactivating bacteria or fungi that may cause disease or spoil food.

All the products covered by this range are required to achieve and maintain the high standards of domestic health and hygiene deemed necessary in the modern household, institutional and industrial environment.

Recent trends

Over the last decade, imports boomed at around 10% in real terms on average per year, while exports stagnated during the second half of the eighties. However, in 1992, extra-EC exports in value were 30% up on the year 1988.

During the 1988-92 period, extra-EC imports remained low though their growth was important (53%). This kept the trade balance positive.

Foreign trade

The EC is a net exporter of maintenance products. In 1992, the EC's world market shares in value were respectively 48% and 45%, mainly for the exports of coachwork polishes and metal polish products. Most of the EC exports goes to developing countries and the EFTA countries.

Regarding EC imports, other polishes represented in value about one third of the world imports in 1992.

As for the origin of EC imports, an important change has occurred since 1988. In 1988, extra-EC imports came mainly from Switzerland (54,5%), while the US was the runner-up with about 20%. On the other hand, in 1992, there was a

Source: Eurostat

shift in favour of the US exports towards Europe as they increased their share to 40%, while imports from Switzerland fell to 28% of total EC imports. This may be explained as the result of the important depreciation of the US dollar vis-à-vis the European currencies.

MARKET FORCES

Demand

The long term development of the demand for maintenance products is linked to a number of demographic factors. The ageing of the population brings with it the need for more intensive use of space and thus more frequent maintenance. The number of households is increasing, with more smaller (e.g. single person) households, pushing up demand. The increasing number of women working outside home has changed the nature of demand: more practical products are demanded, designed to help save time.

Consumption of maintenance products varies regionally from one country to the other, according to climate and local customs.

To illustrate this, one may consider the different trends reported in the "Consumer Europe 1993" for the cleaning products sector. In the surface cleaners and scourers subsector (for which European sales amounted to 1 987 million ECU in 1992), the highest per capita consumption in value was in Italy (8.75 ECU) and in Switzerland (7.71 ECU) while the Swedish and the English consumed the largest volume (8.1 kilos and 6.7 kilos, respectively). On the other hand, per capita sales of bleaches and lavatory cleaners (a market worth of 1 387 million ECU) were the highest in Luxembourg (7.01 ECU), Belgium (6.36 ECU), Spain (5.46 ECU) and Italy (4.54 ECU). The main users of air fresheners and insecticides (for which the sales in Europe are estimated at 500 million ECU) are the Greeks (2.27 ECU), French (2.12 ECU) and Portuguese (2.06 ECU). Finally, in 1992, Belgium and Sweden were the two countries where per capita sales of shoe polish (209 million ECU as European total value) were the most important (1.47 ECU and 0.96 ECU, respectively).

Supply and competition

Competition on the market for maintenance products is not only on the quality of the products, but also on ease of use, which is linked to packaging and preparation of the product (e.g. ready to use products rather than products that still need to be diluted with water). R&D in this sector is often geared towards achieving exactly these aspects of product marketing.

Production process

The maintenance products industry implements a continuous programme of R&D to provide new effective products re-

Table 4: Maintenance products

flecting the latest technology. Consumer safety and environmental considerations are major in product development.

Developments in packaging and manufacturing processes require a flexible work force, employing well paid, high calibre personnel, subject to on-going training programmes. Consumer safety and environmental considerations are always influential factors in product development. Packaging and labelling are conceived to make the product easy to use and safe and to facilitate recycling and disposal.

INDUSTRY STRUCTURE

Companies

The total number of companies and employees is difficult to assess precisely as a significant number of them operate in other consumer related product areas alongside their maintenance product sections, and this leads to some overlap.

It is estimated that the total number of companies active throughout the EC in manufacturing and selling maintenance products is around 600. This includes major international companies operating worldwide as well as many smaller companies supplying their home market. The wage and salaries in the industry are in general above the industrial average.

The total number of employees in the sector remains fairly stable, estimated to be at least 25 000; increased consumer demand has been met by improved productivity.

ENVIRONMENT

In the maintenance products sector, major efforts have been made to develop new types of propellant for aerosols and containers that do not involve the use of pressure. Better labelling, in accordance with EC regulations, should assure consumer safety.

One must be conscious that in a very limited number of usage situations a possible hazard can arise from the improper use of hypochlorites. This can occur if these products are mixed with other cleaners of an acidic type in use.The Hypochlorites Commission caters for approximately 1 million tons of products per annum that provide, at low cost, essential and very effective protection in the public health field The Hypochlorites Commission has strongly supported improved labelling to ensure that hypo chlorites are not used incorrectly, together with a public information programme on their benefits and safety when used correctly.

It is unlikely that the use of maintenance products would be reduced, given their strong integration into many aspects of daily life.

Growth in the maintenance products industry is therefore expected to be modest but constant as it has been the case in the past decade. According to our forecast, production and consumption of maintenance products will increase by about 1% to 1.5% per annum during the 1993-97 period.

Man-made fibres
NACE 26

The manufacture of man-made fibres in the EC is confronted with intense competition particularly from developing and industrialised countries. The European industry is thus turning its attention to higher value added products, while pursuing an investment policy aimed at specialisation and research and development.
The crisis in the textiles and automotive industries, along with the economic gloom which has characterised recent years, brought about a marked fall in demand in 1992. The European industry won't recover in 1993, and will probably record a low level of growth in the latter part of the 1990s.

INDUSTRY PROFILE

Description of the sector

The chemical fibres (or man-made fibres) industry covers three different types of fibres: synthetic fibres, cellulosic fibres, and mineral fibres.

Chemical fibres mainly consist of synthetic fibres which accounted for 85% of world chemical fibre production in 1992. The main synthetic fibres, ranked in with their share of total 1992 world production, are polyester (52%), polyamide (20%), polypropylene (15%) and acrylic (13%) fibres. Cellulose-based fibres include acetates, rayon, rayon staple fibre and viscose. These artificial fibres, which are derived from natural sources such as cellulose, account for the remaining 15% of world chemical fibres production. Although mineral fibres are also part of the chemical fibre sector, they are excluded from the statistics presented in this chapter.

All of these fibres are divided up into sub-categories according to their physical form. Filament is a continuous polymer which is remilled in its molten state via a fine strainer and then solidified by cooling. It is then spun in a variety of ways, depending on how it is to be sold. It can also be cut up into short fibres for use in the manufacture of fabric using traditional machines designed for natural fibres. These short fibres often have very similar characteristics to those of natural fibres.

The preponderance of synthetic fibres over cellulosic products is becoming more and more pronounced. Short synthetic fibres represent the bulk of EC production, with about 55% of the total. Synthetic filaments come second with 34%. Cellulosic fibres, which represented about 22% of total chemical fibres in 1980, now represent a mere 11%.

Among the EC Member States, the largest producer of man-made fibres is Germany (33% of EC production in 1992), followed by Italy (24%). The Benelux and the United Kingdom are also important producers, each accounting for 11% of EC man-made fibres production.

Recent trends

Since 1983, EC production of man-made fibres has grown at an average annual rate of 1.7%. In 1992, EC production in volume decreased by 3.9%, the first decline since 1986 (-1.2%). This production performance was mainly driven by an equal fall in consumption due to a downturn in the textiles and clothing, and the automotive industries in 1992. This output fall is significant when compared to world production which grew at 4.6% in 1992. A sharp growth in Extra-EC exports (9%) didn't prevent capacity rates from decreasing quite significantly.

In 1992, employment fell by 10% to 69 600 units, thus more than offsetting the 7.7% growth rate recorded in 1991 due to the inclusion of eastern Germany.

The EC chemical fibres industry has undergone extensive restructuring since the late 1970s. The low rate of increase in European textile consumption during the late 1970s (following the first oil crisis) contributed to this structural change. Among the other motives for this restructuring were the growing deficit on the EC's textile and clothing trade balance and the development of chemical fibre production capabilities in the rest of the world, not to mention the numerous investments made by EC firms in other parts of the world.

In fact, two waves of production capacity reduction have occurred since 1978. During the 1978-85 period, over 900 000 tonnes, or one-third of the total West European capacity, was cut. Another prominent development has been technological changes which reduced manpower requirements. As a result, employment levels in the chemicals fibres sector collapsed, recording a 39% cut from 1980. This decline was accompanied by a significant upgrade of apparent labour productivity.

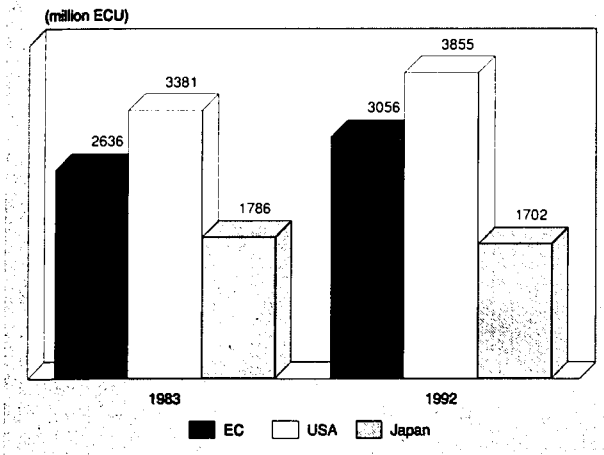
International comparison

Compared to 1977, the EC man-made fibres industry has been losing ground in the production of all kinds of fibres. This is particularly the case in the field of synthetic filaments, where the EC represented less than 12.4% of world production in 1992, down from 20.6% in 1977.

The Japanese man-made fibres industry represents only 9% of world production, while the USA remains the world's leading producer with about 19% of world output, although its position is weakening. Production of the newly industrialised countries (NICs) accounts for an increasing share of world output, displacing the former pre-eminence of both the USA and some EC Member States. In 1992, the combined pro-

Figure 2: Man-made fibres
International comparison of production in volume



Source: CIRFS

duction of Taiwan, China and South Korea reached 25% of world output.

Indeed, the newly industrialised countries are becoming crucial actors in the man-made fibres industry: the most dynamic region is South-East Asia, among which are Taiwan, South Korea, China and the ASEAN countries. For example, while the East Asian countries represented only 22% of world production of polyester in 1980, this share jumped to 40% in 1992 and would be able to rise to 60% of world production of polyester by 2001. Overall, South-East Asian industry should see its share of synthetic fibres grow from 28% in 1992 to 31% in 2001.

In 1992, Japan's production of man-made fibres was stable, while it grew by a steady 3.6% in the USA. Production in the newly industrialised countries continues to rise strongly.

Foreign trade

The EC has a strong rate of import penetration, while the share of its exports in production remains weak. The EC trade balance on man-made fibres has declined steadily since 1983, falling into deficit in 1988 when imports jumped 18% and exports fell 3.7%. Combined with growing imports, at an average annual growth rate of about 10%, in volume, over the period 1983-1992, this has resulted in a steep fall of the cover ratio (exports/imports) which fell from 1.72 to 0.70 over these ten years.

Extra-EC exports, after as modest increase of 2% in 1991, fell back to negative growth rate in 1992 (-4.2%) thus resuming a downward trend started in 1986. 1992 extra-EC imports were stable (+0.7%). Declining demand, along with increasing supply from other regions of the world, put pressure on prices as the weakness of the dollar continued to negatively affect extra-EC exports.

Germany is by far the largest exporter of man-made fibres, accounting for 53% of extra-EC exports. Germany is also the leading importer, with 19% of extra-EC imports. Italy (15% of exports, 19% of imports) and the United Kingdom (13% of exports, 16% of imports) are also big trade players. Only Germany recorded a trade surplus outside of the EC in 1992.

The USA is the EC's foremost national trading partner. Although imports from the USA increased their share over the 1987-92 period, EC man-made fibres exports lost ground in the US market.

Eastern Europe has been an important EC export market. Until 1990, this region had been more important in terms of exports (with about 25% of total extra-EC exports in 1986) than the EFTA countries. Since 1990, however, EC exports to Eastern Europe have fallen drastically.

Although EC manufacturers export less than 15% of their production on average to non-EC markets, extra-EC imports are gaining an increasing share of consumption in Europe, a share which rose to almost 20% in 1992. Extra-EC imports are mainly coming from the EFTA countries followed by the USA. Imports from Japan have increased by 48% from 1987 to 1992.

In 1991, intra-EC trade represented about 71% of total EC imports, which illustrates the high degree of trade between the Member States. Intra-EC trade has been raising slowly since 1987.

MARKET FORCES

Demand

Chemical fibres represent an important share (approximately 66%) of total fibres consumption in the EC. The main end-market for these fibres is the clothing industry, with 47% of total consumption, while fabric for interior furnishings represent another 35% and industrial applications 18%. As consumers account for an important share of demand, overall economic activity and personal disposable income are overriding factors in the dynamics of the man-made fibres. The situation downstream also has a significant influence on the man-made fibres industry. Since 1986, the large increase in imports of textile and clothing products (which has more than doubled in the last 6 years) has hampered the activity of the textile processing industry, thereby reducing EC market shares for textile products.

Looking at consumption of man-made fibres compared to textiles and clothing demand, similar trends emerge, but somewhat lower for fibres. The growth recorded throughout the 1980s in the textiles sector mirrored the overall increasing trend in the consumption of man-made fibres. The relative downturn registered since 1990 in the textiles industry is also noticeable in the fibres sector. The reduction of the European market for man-made fibres has indeed been driven by the disappearance of several of its European clients that have shifted operations to developing countries.

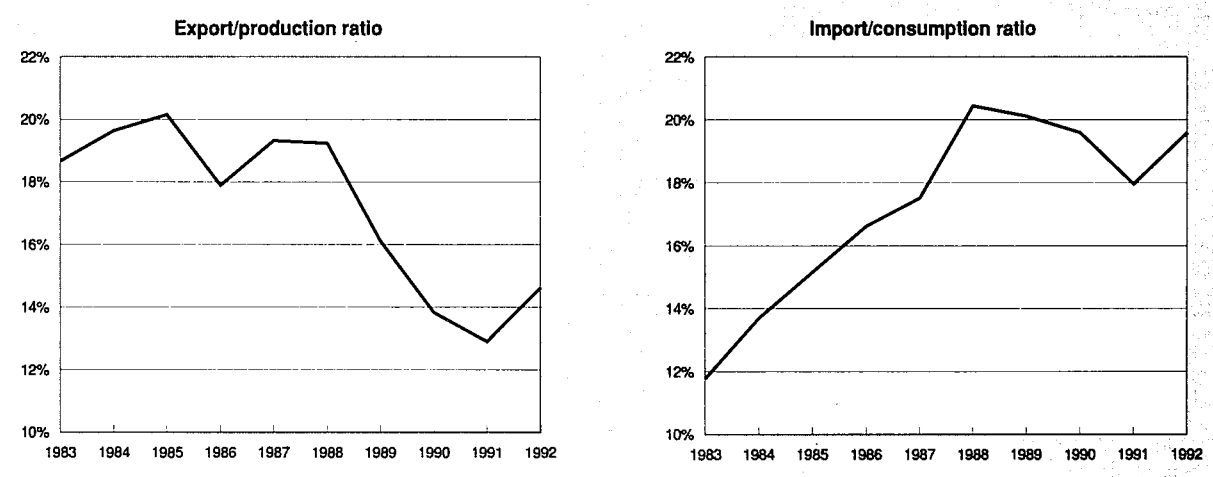
The upturn recorded in European consumption throughout the 1980s has also been a positive factor for the man-made fibres industry. Demand for these products has been driven not only by demographic factors, but also by increased earnings which directly influence the main markets for man-made fibres.

Supply and competition

In the countries for which statistical information is available, the EC industry's competitiveness is put in jeopardy by stagnating productivity growth. Despite the continuing fall of employment levels, unit labour costs have continued to increase in all the Member States, driving down the industry's competitiveness. The integration of the former East Germany in the EC has put another strain on capacity. In this region, many plants have already closed or are facing heavy problems.

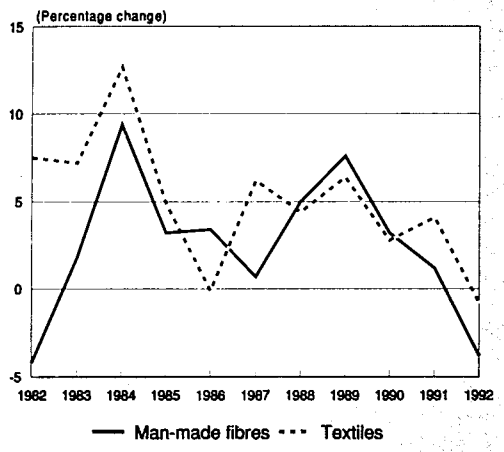
The code that forbids the use of any state subsidy to finance increases of capacity within the EC has been regularly renewed since 1977. This code is well appreciated by an industry suffering from low rates of utilization of production capacities.

Figure 5: Man-made fibres
Trade intensities



Source: CIRFS, Eurostat

Figure 6: Man-made fibres
Apparent consumption growth of man-made fibres versus textiles in the EC



Source: CIRFS, Eurostat

Since 1990, exchange rates have also been a factor in the industry's declining performance in Europe. The weak US dollar continues to benefit US exports to the EC. In contrast, European producers do not only suffer from the dollar's weakness, but production for external markets is often lost when a local producer is established.

The resulting decline in output and the under-utilisation of production capacities has led to a significant fall in EC industry earnings, especially in the second half of 1992.

Production process

Enhancements in the technology of yarn and fabric manufacturing have been a major factor of the increasing dominance of synthetic fibres over natural fibres. Some processes, such as tufting for carpet manufacture, were initially made possible by developments in synthetic fibres technology. Given their particular suitability for a variety of end-uses, man-made fibres, and in particular synthetic fibres, have been able to capture a significant part of the fibres market.

The production process is increasingly capital intensive, following the need for higher technology products. This feature is the main factor that drives up unit labour costs in the sector, as the industry requires a highly skilled workforce.

Two recent innovations have been developed for the clothing industry. Monofilaments (which have properties similar to silk) are geared towards casual wears, whereas Tencel, a new man-made cellulosic fibre developed by Courtaulds (UK) over a period of 14 years, is aimed at the high fashion market. The latter's manufacturing process is a considerable chemical simplification over that of rayon, and environmentally more friendly (through the use of a renewable raw material and the recycling of solvents).

INDUSTRY STRUCTURE

Companies

The man-made fibres industry is dominated by a small number of big companies. Companies are specialised in particular fibres, concentrating on speciality fibres in order to avoid competition from developing countries.

With a production capacity of 1.1 million tonnes, Hoechst AG (D) is the world's largest producer of polyester. Its turnover in chemical fibres amounted to 6 945 million DM in 1992. In polyamides the joint-venture between Rhône-Poulenc (F) and SNIA Fibre SpA (I) control about a third of the West European market, followed by DuPont (USA) with 25%. The latter is also the first world producer, followed by Allied Signals (USA) and BASF (D). For acrylic fibres Enichem (I) and Bayer (D) are the world main producers, recently joined by the joint-venture between Courtaulds (UK) and Hoechst (D). As far as polypropylene is concerned, two EC companies belong to the world top ten, Moplefan (I) and Danaklon (DK). Bemberg (I), and Asahi (JPN) are the world leaders in cellulosic fibres. Courtaulds (UK) and Lenzing (A), Akzo Fibres (NL) and ICI Fibres Ltd (UK) are other major players in the sector.

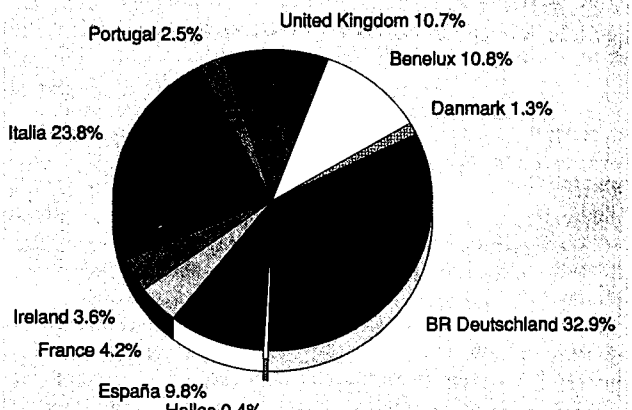
Strategies

The major firms in the man-made fibres industry operate with a very global perspective. Not only do non-EC companies have activities in Europe, but EC companies are present throughout the world. A good example is Hoechst which has a tyre cord capacity of 110 000 tonnes in North America. Meanwhile, the company is also present in the Far East and in China. In terms of sales, Hoechst realises about 85% of its turnover outside Germany.

The new strategy which appeared in 1992 and is still going on in the first half of 1993, is one of specialisation in one type of fibre through asset swaps, sales and alliances. For instance in two separate deals ICI has acquired the acrylic businesses of DuPont and BASF. These two companies have respectively received ICI's polyamide and polypropylene businesses in exchange. In polyamide alliances have been concluded between Allied-Signal and Akzo and between Rhône-Poulenc and SNIA. Another important joint-venture, announced in May 1993 between Courtaulds and Hoechst, concerns both their acrylic and viscose operations. In viscose the new company will command a strong position both in the industrial and textile end-uses. It will also provide Courtaulds with a wider platform to launch its new Tencel fibre on the European market. BASF is a good illustration of this drive towards specialisation. After divesting from viscose, sold to Lenzing in 1992, and acrylic, to ICI, it is now planning to do the same for its polyester operation in the USA in order to focus on polyamide. On the eastern front, Rhône-Poulenc set up a joint-venture with Chemlon SP of Slovakia, the leading producer of polyamide yarn in Central Europe.

Until now, none of these agreements have led to rationalisation of production, despite the capacity crisis which is appearing in certain sectors.

Figure 7: Man-made fibres
EC production in volume, 1992



Source: CIRFS

REGULATIONS

The new strategy of asset swaps and acquisitions in the industry is subject to the approval of anti-monopoly authorities at the national or supra national level. For instance both the European and the US Federal Trade Commissions have approved the ICI/DuPont swap, but in the USA ICI will have to divest parts of its downstream acrylics activities.

The industry is following carefully extra-EC imports to detect any case of "unfair" trade. Under the auspices of its industrial association, CIRFS, it has already won several anti-dumping cases. In 1992 it raised a new one concerning imports of polyester staple from South Korea and India. It is also considering the renewal of old cases that are reaching the end of their five-year term.

OUTLOOK

The EC man-made fibres industry is expected to perform slightly better in the near future. The bulk of the growth will be accounted for by synthetic fibres, especially polyester and polypropylene. Demand for cellulosic fibres will continue to decline.

Table 5: Man-made fibres
Expected real annual growth rates

(%)	1993-94	1993-97
Apparent consumption	1.9	2.5
Production	0.9	1.2
Extra-EC exports	1.5	1.0

Source: DRI Europe

Demand from the industry's main clients is expected to improve in the second half of the decade. The textiles industry will witness a slight increase in production while import growth will lose momentum. The automotive industry is expected to start recovering by 1995, thus contributing to a stronger production performance in the man-made fibres industry.

Written by: DRI Europe
The industry is represented at the EC level by: Comité International de la Rayonne et des Fibres Synthétiques (CIRFS). Address: Avenue E. Van Nieuwenhuyse 4, B-1160 Brussels; tel (32 2) 676 7455; fax (32 2) 676 7454.

Biotechnology

Biotechnology is a small but fast growing, high technology field. At present, most commercial biotechnology production occurs within the pharmaceutical sector. Other areas of increasing importance are the agricultural sector, the food processing sector, renewable energy production and environmental and waste management. Currently, the EC is an important player in the world biotechnology market. Comparatively favourable market conditions in terms of regulation, public acceptance, financial arrangements and intellectual property protection in the USA and Japan threaten EC competitiveness. Investment in the EC by European biotechnology market leaders totalled 1.1 billion ECU, 0.3 billion ECU more than they invested in the USA. The trend for investment in the USA and Japan is for faster growth than in Europe. A significant number of EC companies are specialising in the agricultural sector whereas US companies are tending to specialise in pharmaceutical and diagnostic agents. Japanese companies are specialising in industrial applications.

INDUSTRY PROFILE

Description of the sector

Biotechnology can be broadly defined as the application of scientific and engineering principles to the processing of materials by biological agents. Biotechnology consists of two segments. Classical biotechnology is comprised of fermentation and preservation processes used in the production of beer, wine, cheese, bread, vinegar, etc., where advances have been made predominantly without the use of genetic engineering. Modern biotechnology is characterised by the utilisation of genetic engineering and is a small but rapidly growing segment. Only modern biotechnology will be considered here. Modern biotechnology is based predominantly on recombinant DNA (rDNA) and cell fusion techniques and has considerable potential for a wide range of applications. Major impacts are expected in pharmaceuticals, agriculture and food processing, health (diagnostics), renewable energy, environmental management (including waste management). Large growth in biotechnology equipment is expected to impact on relevant high-technology fields of the electronic engineering sector .

The economic weight of the biotechnology sector is not easy to measure as there are many spin-offs and intangibles. However, at present, commercial biotechnology is virtually confined to the pharmaceuticals' sector. In terms of investment, biotechnology is worth roughly one eighth of the EC pharmaceutical sector.

Recent trends

Over the 1980's there was a 10.6% per year increase in the number of patent applications in the area of biotechnology in the EC. The structure of biotechnology inventions (i.e. those with patent applications in at least two countries) remained roughly stable over the second half of the 1980's. While Germany had the highest share, this fell slightly towards the end of the decade and the United Kingdom was among those that increased their share.

A significant and growing share of Research, Development and Demonstration (R,D&D) is in the agricultural sector, though sales have been relatively small. Worldwide, sales of biotechnology-derived agricultural products total less than 170 million ECU each year. New agro-biotechnology products include a rot resistant tomato and BST (a milk production hormone) with an estimated potential US market of around 180 million ECU. Other agro-biotechnology products in the pipeline are: PST (a lean pork hormone), insect-herbicide-resistant corn and cotton plants, low caffeine coffee and, this year, the first field tests for a genetically engineered apple took place.

International comparison

In 1992, the European market leaders invested 1.1 billion ECU in biotechnology in Europe, 30% more than they invested in the USA, showing a preference for the European biotechnology market over the US. European investment in Japan was relatively small at around 0.2 billion ECU. However, in 1992, the US had approximately 17.5% more companies involved in biotechnology in the world market than did Europe. This represents a reversal of the situation in 1989 when European companies outnumbered US companies by almost 24.0%. In 1987, public R,D&D expenditure was 56% higher in the USA than in the EC, and in addition the USA benefited from the much larger use of venture capital.

European companies have historically tended to specialise in different product areas than their US and Japanese counterparts. There is a major shift underway towards agriculture and chemical production in Europe (22% and 18% of the total number of biotechnology companies respectively), whilst the USA are focusing on biotechnology equipment (23%), pharmaceuticals (25%) and diagnostic agents (21%). Also, 8% of European companies are involved in development of biotechnology for energy / environmental uses compared to 6% in the USA. Japan is concentrating on developing energy saving processes in chemical and other industries.

In the pharmaceutical market, all three main players are developing and using rDNA and cell merging techniques to produce proteins for a wide range of pharmaceutical products. In the agro-biotechnology market, there are marked differences in product specialisation. European expertise is fairly broad but particularly strong in the area of agro-chemicals. The USA is superior in its level of development in seeds, geared towards to oil and cereal crops. Japan concentrates mostly in fermentation products and biotechnology directly related to horticulture.

Foreign trade

At present, trade in biotechnology-derived products is principally for pharmaceutical applications. Compared with the pharmaceutical sector as a whole, where slightly less than half of extra-EC exports goes to countries outside the USA and EFTA, biotechnology derived pharmaceuticals are much less traded with countries outside these two foreign markets. The biotechnology pharmaceutical products tend to be high value, specialist drugs designed for ailments prevalent in the developed world. Trade in agro-biotechnology is small in comparison and is largely of seeds. Non-compliance with intellectual property rights is a barrier to trade.

Demand

In general, biotechnology is driven by the following factors: rapid advances in knowledge in the basic sciences, particularly molecular biology and molecular genetics; technological advances, which feed back and in turn create a strong demand for high-tech biotechnology equipment; strong demand from the pharmaceutical industry in particular.

Factors hindering demand include the following: concern over the safety of genetically engineered organisms on the natural environment; infringements of international intellectual property rights.

The industry is tightly regulated at present but simplified procedures are currently in force as a precursor to a new directive that will enable an EC -wide system to operate.

In Europe, the non-uniformity of intellectual property rights remains a stumbling block for producers of biotechnology derived products, within the EC domestic market and also in many export markets. The very high levels of investment that are necessary to bring the product to the market necessitate some form of generic licensing enforced through patents. In the past, an estimated 14.5 billion ECU per year have been lost on the world pharmaceutical market due to the non-recognition of patents by many large export markets such as Brazil, Hungary, India and Thailand. If international intellectual property rights were enforced it could increase world pharmaceuticals' sales revenues by up to 8.5 billion ECU.

Agro-biotechnology for food production is presently aiming at increasing both quality and productivity through genetic modification of selected crop plants. In the future this trend should continue, accompanied by a reduction in the cost of agricultural inputs. Non-food uses of animals and plants will become important for the production of antibodies and therapeutic proteins. Recently a patent has been granted in Europe for the use of modified bovine haemoglobin as a human blood substitute.

Agro-biotechnology products have taken longer to be brought to the market than biotechnology derived pharmaceuticals for at least three reasons. Firstly, there are stricter regulations on the release of genetically modified organisms (GMO's) than of biotechnology derived pharmaceutical products. Secondly, in the EC and other developed countries, high technology pharmaceuticals are part of a more profitable and faster growing sector than the agricultural sector. Thirdly, basic research in agro-biotechnology takes longer than for bio-medical products, partly because of the scale (genetically altering a whole organism compared to cells used to produce proteins for a new drug) but also because testing of new strains of crop is limited by seasonal factors and in animals, testing is constrained by the gestation cycle.

In agriculture and food processing applications, regulations are strict. The Deliberate Release and Contained Use Directives issued by the EC have been interpreted in a wide variety of ways. Germany, however, adopted very strict regulations under the 1990 Gene Law that was adopted before the approval of the EC directives by the EC Council of Ministers and contained very strict regulations. So far around 400 GMO's have been released into the environment worldwide. Within the EC the difference in the number of GMO's released by Member States is marked.

An estimated 686 transgenic plants have been released worldwide to date. France, Belgium and the United Kingdom accounted for 74% of the 282 releases in the EC/EFTA region. Oilseed rape, potato, tobacco sugar beet and maize accounted for 84% of the releases. The purpose of the genetic modification has been predominantly to engender herbicide resistance. About 42% of transgenic plant releases in the EC/EFTA region had this trait enhanced.

Source: PIP Newsletter, September 1993

Biotechnology also has the potential to provide solutions to many environmental problems and demand is likely to increase with the growing concern over the environment in the EC and the rest of the world.

At present the market for biotechnology derived products is almost totally in the USA, EC, Japan and EFTA countries. The market fails to take advantage of developing biotechnology products, pitched at demand from the developing world for two main reasons. Firstly, the return on the large investments in R,D&D that would be needed to bring the products to commercialisation would be too small to justify. Secondly, if the product was brought to commercial status, the risk attached to non-compliance with international intellectual property rights would be very high. Technology for equity deals may be one viable way forward as a mean of technology transfer in the less high-tech industries, particularly agro-biotechnology.

Supply and competition

The world leader in the biotechnology-derived pharmaceuticals' market is Amgen (USA) with sales of its best selling drugs Neupogen and Epogen totalling 1.3 billion ECU. In Europe, Switzerland (with La Roche), Germany (with Bayer and Hoechst) and Denmark (with Novo-Nordisk) are particularly well placed in the market. As far as attracting investment is concerned, the Netherlands, where many US owned companies have settled, is amongst the most attractive business environments. Germany, with its strict Gene law, has one of the worst.

Production capacity for biotechnology derived products in the EC is increasing rapidly. Since the main driver for biotechnology is advances in basic science, it is important to look at regional investment in R,D&D as an indicator of market potential.

Several factors contribute to the preference for European companies to invest in biotechnology outside the EC. Firstly, the level of bureaucracy that is high compared to USA and Japan. Also, EC and Member State encouragement is relatively low compared to the USA and Japan. In the ten year period before 1992, the EC provided 600 million ECU in consecutive programmes to improve basic knowledge and reinforce biotechnology in Europe. Public mistrust and interest group opposition, both higher in Europe than in the USA or Japan,

are the third factor: lastly, trade barriers, such as a relatively low level of intellectual property protection, are relatively high.

Production process

Biotechnology has made great strides in the field of human health since 1980 when insulin became the first product of genetic engineering and modern biotechnology to reach clinical trials. In the pharmaceutical sector, biotechnology is used in three ways: to produce drugs and vaccines using rDNA technology, to make intelligent screens for new compounds and to apply techniques for rational drug design by understanding molecular structures. Since the early 1980's biotechnology has also branched into other areas. In the field of diagnostics, kits are available that use monoclonal antibodies (MABS) to diagnose such diseases as the AIDS virus. MABS can also be used to direct treatments or attack a target themselves which have important consequences for the treatment of cancer and other diseases. In the chemical sector, biotechnology research is mainly in the field of enzymes (which act as catalysts) with markets such as washing powder.

In the agricultural sector, developments have been in the areas of pesticides, plant and animal health and the increasing of yields. Bio-pesticides are produced using strains of a bacterium Bacillus thuringiensis. They have been in commercial use for over 30 years and, over this period, biotechnology has increased the range of target pests. Plants and animals have been selectively bred for generations to bring out useful traits. However, it wasn't until 1983 that the first rDNA engineered plant was produced. Since then there has been much research and development in the area (known as transgenic plant technology) and over 50 species of crop plant can now be genetically transformed. In addition to increased yield, biotechnology has also enabled increased resistance to pests, diseases and to herbicides, so that weeds can be removed by spraying.

In the food sector, developments have included the genetic modification of plants to improve flavour and smell, lengthen shelf life and eliminate toxins. Also, genetically engineered enzymes can be used to enhance the efficiency of certain areas of food production. For example, Bovine Somatotrophin (BST) increases milk production in cattle, and a rennin substitute (Chymosin) eliminates problems of supply and infections from animal sources of rennin.

The areas in which biotechnology could play a key role in environmental and waste management are: treatment of contaminated land and water; reducing the cost of effective pollution control for hazardous industrial effluent; a reduction in the volume of household, agricultural and industrial waste through bacterial digestion and the use of biodegradable packaging. In addition, the use of biotechnology to engineer organisms to increase the rate of digestion of woody matter would enable the yield of biogas from landfill sites, sewage works and agricultural digestors to be increased.

INDUSTRY STRUCTURE

Companies

According to the EC Commission, there are roughly 4500 bioindustry companies in the USA, Europe and in Japan, taken in a rather large definition and including traditional and modern biotechnology as well as suppliers, distributors, constructors, consultants and producers etc. Of these roughly 4500 bioindustry companies, some 1100 are in the USA, some 400 in Japan and some 3000 in Europe (EC around 2500, EFTA around 500).

The companies active in modern Biotech R&D and production are much smaller in number: some 460 in Europe, the USA and Japan, some 200 in the USA, 80 in Japan, and some 180 in Europe (150 EC/ 30 EFTA), this for a relatively narrow definition of modern Biotechnology, including genetic engineering, cell fusion, cell culture and AIDS therapeutics and diagnostics development.

In a larger definition, adding to the foregoing definition biomolecular modelling, synthesis and engineering/ biocatalysis and biotransformation, chiral compounds, immobilization technologies/ biotech downstream processing/ transgenic organisms, one arrives at a larger scope of modern biotech industry core companies, namely some 850 in the USA, Japan and Europe: some 340 in the USA, some 110 in Japan and some 400 in Europe (some 350 EC, some 50 EFTA).

These latter 850 biotech core companies, in the three areas considered, run some 1270 company activity centers in pharmaceuticals, diagnostics, agro-bio food, environment, chemicals, with 26% pharmaceuticals, 34% diagnostics, 22% agro-food, 3% environment, 15% chemicals. Pharmaceuticals and diagnostics make thus some 60% averaged over the three areas considered, the USA being slightly above this average, Japan and Europe below. The other three industry sector lines are rather close to the total average for the three regions considered.

Most companies run more than one activity center.

Because the field has a large capital requirement and relies heavily on an accumulation of knowledge (often in-house), large companies are prominent in the field. On the other hand in the United Kingdom there are a larger than average number of smaller companies due to exceptional arrangements that have been in force since 1992, allowing biotechnology companies to be floated on the London stock exchange without the usual three years record of trading profits. The smaller companies are hence able to benefit from investment of venture capital that has been possible in the US for some time. In the pharmaceutical sector, the average development costs for

Table 3: Biotechnology

a new drug in smaller companies average 106 million ECU, almost 50% of those of a large multinational. In the USA, the market is characterised by many small to medium sized companies operating along side large multinational companies. In Japan, the players on the market are almost exclusively large multinationals.

In the EC, Denmark leads the way in sales of biotechnology-derived pharmaceutical products. The company sales of Novo-Nordisk (DK) were around 288 million ECU in 1990, 37% of which was due to the company's genetically engineered rDNA insulin (Novolin), produced in yeast. In 1991, Novolin sales were up 24% to lie at around 370 million ECU. Of the European companies involved in Biotechnology, La Roche (CH) has the largest share of the market. Its alpha-interferon drug brought in 170 million ECU in 1991. It also holds a 60% share in Genentech (USA) whose two best selling drugs Alteplase (tPA and hGh-r) gave sales revenues of 324 million ECU.

Strategies

Alliances or minority shareholdings are generally preferred over acquisitions in the biotechnology field. Large companies see these as a way of allowing smaller, innovative companies the freedom to bring a novel technology to the market, whilst widening their technical knowledge and increasing the opportunities for spin offs. During the late 1980's, European companies spent about 2-3 million ECU sounding out the US biotechnology market by investing in small, specialised Californian companies. The testing period ended when La Roche (CH) acquired a 60% share of Genentech (USA), adopting an aggressive apprenticeship strategy. Since then, European activity in the USA has been increasing. In 1992, La Roche and Genentech together accounted for over 50% of patents filed in the USA.

Three distinct investment strategies can be identified on the part of European companies:

The apprenticeship route, whereby the company brings teams of scientists into contact with the commercial environment in the hope that this will generate other favourable developments for the corporation. Companies following this strategy invest highly abroad. Investment in Japan is motivated by the quality of the market, academic ability, a favourable climate for technological progress and the strength of the Japanese in industrial biotechnology. In the USA, the main factors are academic excellence and a highly attractive regulatory and financial environment;

- The cohabitation route, whereby European companies take a neutral view to international alliances. This strategy is pitched more towards securing existing product and marketing bases than actively to encourage innovation;
- The Euro-centred strategy is practised by large European companies whose market is predominantly in the classical biotechnology industry. Also, those companies with a particularly risk averse strategy will tend to remain Euro-centred.

The consequence of the trend of companies forming strategic alliances in the USA has meant that 71% of product and technology flow from the USA to Europe. Thus, jobs and innovation resulting from European investment are created in the US and not in Europe.

ENVIRONMENT

Biotechnology has the potential to radically transform the environment. While applications of biotechnology include improving environmental and waste management and improving the yield and health of plants and animals, there is also a safety issue over the release of GMO's into the environment. The pharmaceutical sector is presently the largest market for biotechnology and this application has the least impact on the environment. The potential for agricultural biotechnologies and biotechnologies to improve environment and waste management is very great. The market for these applications is growing fast.

Biotechnology can benefit the environment directly in several ways. Using biotechnology to improve the ability of bacteria to digest woody material could improve biogas production from sewage works, landfills and agricultural digestors, boosting renewable energy production. It could also reduce the volume of waste from domestic, agricultural and even industrial sources. Bacteria could be designed to provide effective effluent pollution control at much reduced costs. The decontamination of polluted land and water is another possible application. In oil spills, for example, the use of detergents and the consequent detrimental effects to the environment could be avoided through the use of biotechnology.

In agricultural applications, biotechnology could transform modern farming methods with mixed consequences for the environment. Genetically engendered resistance to pests and diseases could reduce the necessity for artificial pesticides (and improve the environment), while the genetically engendered resistance to herbicides could increase the quantity of herbicides applied (and a corresponding decrease in environmental quality).

The safety of GMO's on the environment is another important issue. The industry is highly regulated, both in R,D&D and in the clinical or field testing of genetically engineered organisms before commercialisation. Currently moves are underway to make it easier for biotechnology derived products to be brought to the market.

REGULATIONS

On one level, biotechnology is a new set of techniques that modify the way in which a number of industrial sectors are approaching R,D&D and production. It is therefore subject to all pre-existing regulations controlling those industries.

There have also been various Council directives and regulations specifically in the field of biotechnology.

Registration of biotechnology-derived pharmaceutical products has been the responsibility of the Committee for Proprietary Medicinal Products (CPMP) and the Committee for Veterinary Medicinal Products (CVMP) as regulated by Council Directive 87/21/EEC. In January 1993, these two bodies were due to have become part of the European Agency for the Evaluation of Medicinal products (EAEMP) when their views would have become binding on Member States. This has been delayed and simplified procedures are operating as a temporary measure.

In the area of health and safety at work, Council directive 90/679/EEC has been adopted to protect workers against the risks to their health and security from exposure to biological agents and to promote the harmonisation of the regulations applied by Member States in this area.

Council directive 90/220/EEC and 90/219/EEC respectively cover the deliberate and contained release of GMO's into the environment. The former directive requires that a risk assessment should always be carried out before any deliberate release of GMO's into the environment. National approval is required for experimental release, thereafter community approval is required for commercial release. After receiving EC approval, the product can circulate freely in the EC. Directive 90/219/EEC requires a risk assessment to be performed on installations carrying out work on GMO's. Flexible precautionary procedures reflect the level of potential risk.

As concerns the juridical protection of intellectual property, the Commission is currently considering three proposals: a directive on legal protection of biotechnological inventions; a regulation on a supplementary protection certificate for medicinal products and a regulation on community plant variety rights.

In the latter, the ruling on whether farmers have the right to re-sow seeds produced by means of biotechnology must be in line with GATT. Additional proposals under consideration refer to the law pertaining to genetically modified animals, animal productivity enhancers, novel food ingredients and processes and transport of biotechnological organisms and micro-organisms.

A move by the European Commission in 1992 established standards in the field of biotechnology with a program conducted by the European Committee for Standardisation (CEN). The standardisation will help support existing legislative actions and in other areas not under specific legislative control. By building a common approach on technical questions, the program should strengthen the competitiveness of the European biotechnology industry. In the past, community support has been given to the biotechnology industry through a number of programs, including BEP, BAP, BRIDGE, ECLAIR, FLAIR, HUMAN GENOME ANALYSIS, VALUE, and MONITOR, that have been designed to improve basic knowledge and reinforce biotechnology in the EC.

OUTLOOK

Given the front-ranking position of the USA, it is expected to continue to act as a magnet for investment. The Japanese industry, too, should experience high growth. Investment is likely to continue to flow out of Europe. By 1995, it is estimated that European investment in Japan and Asia will more than double (albeit from a small base) while investment in the USA should be around 40% higher. An increase of about 30% is expected in Europe.

Overview
NACE 31

The European Community is the world's largest producer of metal products. The industry's products serve mainly as intermediate commodities for other industries such as mechanical engineering, construction and the automotive industry. Although comprised of a large fabric of small companies, the metal products industry ranks among the largest manufacturing employers in the EC, with a workforce of over 2.1 million.
Due to the present recession in the sector's downstream markets, metal products suffered a significant drop in activity in 1992. Production and consumption are not expected to resume before 1995, as the near term outlook is not quite encouraging for the sector's main customers in the EC.

INDUSTRY PROFILE

Description of the sector

The metal products industry as defined by NACE 31 includes the following sectors:

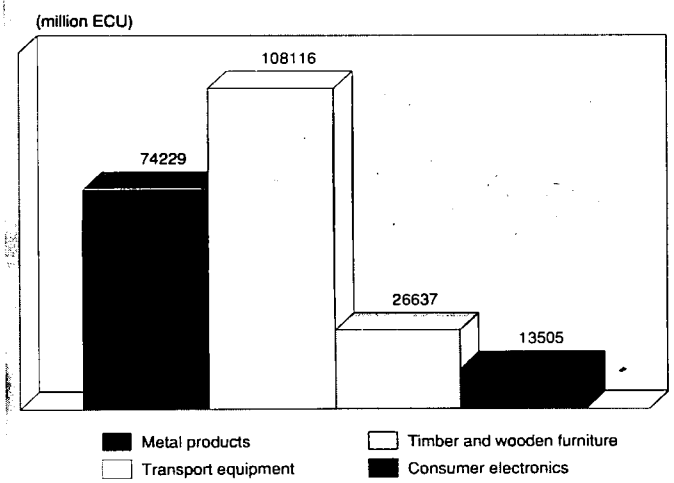
- Foundries (NACE 311), include iron and steel foundries which produce cast iron, ductile cast iron, etc., and non-ferrous foundries which produce copper cast, aluminium cast, etc.;
- Forging (NACE 312), includes transforming semi-finished metal into forged metal products through the use of a die;
- Secondary transformation of metals (NACE 313), involves the production of articles such as lathes, nuts, bolts, springs (excluding furniture and watch springs) and chains (excluding articulated link chains). The sector also includes such processes as galvanising, anodising and enamelling of metals and general mechanical engineering on a sub-contract basis;
- Structural metal products (NACE 314), include the production of metal bridges, frames, doors, windows, railway tracks, etc.;
- Boilers and metal containers (NACE 315), include the manufacture of various boilers, fittings, water tanks, and pipework, etc.;
- Tools (NACE 316), include hand tools, tools for joinery, fixing tools for construction and metal saws, cutlery, metal packaging;
- Other metal workshops (NACE 319).

Of the sectors of the industry listed above, tools are the largest with an output of 71.3 billion ECU, or 39.6% of EC production of metal products. The secondary transformation of metals, with 24.5 billion ECU of output, is also an important sector of the metal products industry.

Recent trends

The European Community is the largest producer of metal products in the world. Of the Member States, Germany is by far the largest manufacturer of metal products, with value added output of above 30.5 million ECU in 1992. As such, Germany provides 41% of the EC metal product value added. The EC four leading Member States represent the bulk of metal product output, as they account for 83% of value added within the EC in 1992. Spain is also a sizeable producer, with output reaching 8.4% of the EC value added.

Figure 1: Metal products
Value added in comparison with other Industries, 1992



Source: DEBA

The metal product industry also ranks among the largest employers in the EC. With a workforce of over 2.1 million, the sector accounted for 9.7% of EC manufacturing employment in 1992.

In 1992, the metal product industry experienced its first drop in production value in ten years. This cut followed a year of slower growth in the value of production and apparent consumption in 1991, compared to the unusually strong boom reported in the 1988-1990 period. Recessionary conditions in the sector's downstream markets (mainly engineering, transportation equipment and construction) have reversed the booming demand which characterised the industry at the end of the 1980s. Employment figures also feature the halt reported in activity, as the number of employees decreased for the second year in a row, with 79 000 workers axed between 1990 and 1992. This sharp cut in employment follows a two-year period of fast growth, when the industry built up a numerous workforce to answer the strong market upturn reported in 1988-1990.

International comparison

World production of metal products is clearly dominated by the European Community, followed by the USA and Japan which rank as EC's closest competitors. EC's industry of metal products managed to maintain a better rate of production growth than the USA, but has been outstripped in terms of growth by Japan until 1991. Last year however, Japan's metal product industry joined its major competitors in the downward trend, and cut sharply production to answer plummeting demand.

Competition is also increasing from other parts of the world, mainly from East Asian countries such as Hong Kong, Singapore and South Korea. Several East European countries have also joined the group of EC's significant competitors in the manufacturing of metal products. These countries are particularly competitive through pricing, and are formidable .

Foreign trade

Although EC countries continue to net a trade surplus, that position has declined recently as a consequence of a halt in exports combined with an increase in extra-EC imports. The metal product industry is not particularly open to trade: external trade accounts for a mere 7.6% of total production. Imports, on the other hand, are growing at a faster rate than exports: the export/import ratio has been steadily decreasing from 3.28 in 1983 to 1.49 in 1992.

The largest importers of metal products from the EC are the EFTA countries with 33% of total extra-EC exports, and the USA with 11.2%. The "rest of the world" represents almost half total extra-EC exports, which gives evidence of the large number of small foreign outlets for EC metal products.

The major importer of metal products into the EC are also the EFTA countries, with a share of about 40% of total EC imports in 1992, followed by the USA with 13% and Taiwan with 7.6% (when excluding the "rest of the world"). Most

competitors lost shares on the EC market during the last five years. EFTA countries, in particular, lost as much as 7.4 percentage points of market share, and Japan 2.3%, to the advantage of an increased NIC's presence: China and Taiwan increased their joint market share from 10% in 1987 to 14% in 1992. Subcontracting to the automotive industry is particularly affected by imports. For example, Japan's plants in Europe are mainly supplied by imports of metal products originating in NICs such as South Korea.

Intra-EC trade has been increasing substantially over the past years and amounted to more than 23 billion ECU in 1992. This high level of intra-EC trade evidences the local nature of the metal product industry, which traditionally supplies national or even regional markets. Intra-EC trade actually represents above 71% of total imports; furthermore, imports from outside the European Community represented a mere 5.3% of EC consumption of metal products in 1992. However, the analysis of recent trends signals increasing inroads of foreign manufacturers into the EC metal product market. Since 1990, extra-EC imports have been severely outstripping intra-EC trade in terms of growth, giving further evidence of an increasing penetration of non-EC metal products into the European Community.

MARKET FORCES

Demand

Most of the industry's products are basically intermediate commodities for other industries, demand is heavily dependent upon the industry's main markets, namely mechanical and electrical engineering, transportation equipment and construction. In the case of Germany, the input/output table compiled by the Statistische Bundesamt provide a significant breakdown of the metal product industry's outlets: almost 44% of all metal products go to the processing industries, above 7% go to the construction sector, and 21.5% are directed to investment activities. Only 5.8% of metal products manufactured in Germany go to final consumers, mainly to the DIY market. Intermediate consumption is mainly accounted for by the motor vehicle manufacture (with over 20% of total sales to processing industries), the mechanical engineering (15%) and the metal product industry itself which is one of its own best customers. Almost all sectors of the metal product industry are linked to these very cyclical downstream industries, which experienced a severe downturn in the last two years: activity in the mechanical engineering collapsed in the last two years as a consequence of a slump in investment climate; the automotive

industry and construction activity were also severely affected by the economic gloom. As a consequence, domestic sales of the metal product industry declined in real terms in 1991 and collapsed in 1992. No major improvement is forecast for 1993, as the economy will remain in the doldrums until early 1995.

Supply and competition

The recent slump in demand left the metal product industry with excessive production capacity, that contributed to put pressure on prices. In the early eighties, many European producers had carried out major investment projects to improve their production facilities, and to increase their capacities. These investments helped the industry to answer the booming demand it enjoyed at the end of the 1980s.

When demand for metal products started to decline in 1992, the industry found itself with an over capacity which further dampened companies' profitability. Indeed, the drop in demand occurred at a time when the metal products industry was severely affected by strong pressure on the cost side. Unit labour costs actually rose an estimated 71% between 1983 and 1992. Such rise in labour costs has not been matched by increases in productivity, which put the industry's profitability under strong pressure.

There are, nevertheless, significant differences between Member States. For example, Greece has very low labour costs compared to Germany. Greece also reports lower production costs as regards environmental legislation than Germany. Flagrant imbalances between costs of doing business can also be found between Europe and the USA or Japan for example. Such differences make Europe's manufacturers less competitive than their major counterparts, and leave them with the necessity to increase productivity, in an aim to lessen pressure on costs. German productivity, for example, has improved significantly over the past years.

Production process

Since the early 1980s productivity gains have been achieved through greater automation of production processes. Apart from the introduction of robotics, the industry is utilising innovations such as Computer Numerical Control (CNC), Computer Aided Design (CAD) and Flexible Manufacturing Systems. As a result, the need for skilled labour in these sectors is increasing. Although firms are striving for greater mechanisation of production, most sectors of the metal products industry remain labour intensive. For example, in the forging industry, personnel costs range between 40% to 50% of total costs (most of the remaining costs being allocated to metal inputs and energy costs).

INDUSTRY STRUCTURE

Companies

The EC's metal product industry is characterised by a relatively low concentration. About 98% of all enterprises employ less

than 100 persons. These small companies employ almost 56% of the industry's workforce. As most firms do not serve final consumer markets, they tend not to have brand names recognised by the general public. At the other end of the spectrum, the number of large companies operating in the sector is very small. However, they represent above 42% of the sector's workforce and almost 55% of the sector's turnover. Large firms tend to concentrate on areas allowing economies of scale or necessitating high personnel and financial capacities.

In 1992, the foremost companies operating in the European market included Pechiney (F), CMB Packaging (F). The largest companies tend to be located in the countries which dominate the market, although the top German company only ranked as the fourth largest EC metal producer in 1992. The German industry is indeed less concentrated than France's one, which counts five out of the fifteen largest metal product companies in 1992. The ranking provided below evidences the presence of two major packaging producers, the weigh of which illustrates the higher concentration in this industry than in any other segment of the metal product industry.

Strategies

After the booming period between 1988 and 1990, EC metal products industry found itself in dire straits, with plummeting demand and the accompanying problem of excessive production capacity. Also confronted by harsh financial difficulties, the metal product manufacturers entered in the early 1990s in a deep rationalisation process aimed at cutting costs. This mainly translated into large cutbacks in employment, along with investment reductions. As a matter of fact, ORGALIME estimates that EC manufacturers cut investment by as much as 5% in 1992 and 10.5% in 1993.

As far as firms' structure is concerned, there is, contrary to most of the sector's customers, no obvious trend towards concentration. Mergers and acquisitions are quite rare in the metal products industry. Companies tend to remain independent while strengthening the links built with their traditional customers. The depression nevertheless brought about the need to lessen the dependence on few heavy clients. This concern has encouraged firms to diversify their operations. Many firms are seeking new outlets for products, not only in the European Community, but also on foreign markets. In particular, some companies are currently investing in the most industrialised East European countries, in order to take advantage of the local markets when they take off.

Meanwhile, metal product companies are also reconsidering the composition of their key activities, in order to better answer their customers' requirements.

REGIONAL DISTRIBUTION

For most of the sectors, the high weight/value ratio limits long-distance transport of goods. In order to remain profitable, firms tend to locate near their clients. Modern and efficient metal product mills tend to locate in those regions where high capacity automotive production plants or productive engineering companies are found, or more generally near the major industrial centres of Europe. Given that Germany in particular has a number of relatively large regions of heavy industry, it follows that large number of firms in the metal products industry are in close proximity to such clients. For example, German companies account for 51% of EC forging, and 80% of all German forging companies are concentrated in North Rhine-Westphalia.

ENVIRONMENT

Each of the sectors in the metal products industry has a unique environmental concern. To summarise these issues, a short description of environmental problems concerning individual sectors is in order.

Foundries are very active in recycling materials used during the production process. This sector is also focused on the subject of clean air, and often makes large investments in order to comply with strict regulations. The foundries sector is also an important energy consumer and is very much concerned with the problem of energy conservation.

The forging industry is mainly concerned with reducing noise pollution resulting from the use of forging hammers. Fur-

thermore, energy conservation has been emphasised with efforts to use more efficient electro-hydraulic systems to power forging hammers and to utilise waste heat from the forging process.

The electroplating industry (secondary transformation of metals) is particularly concerned with reducing the metal content of the effluent through the introduction of new production processes.

Apart from environmental issues related to production, the boilers and metal containers sector is concerned with the corrosion of tanks containing chemicals and oil products during underground storage.

The light metal packaging industry is presently exploring new programmes which will ameliorate the environmental impact of its products, mainly through the promotion of consumer recycling.

REGULATIONS

At present, directives pertaining to the metal products industry are primarily related to safety standards. One of the more notable examples is a study taking place which would make ISO 9000 standards compulsory not only for EC manufacturers, but also for importers.

One of the major issues confronting the metal products industry is the harmonisation of EC standards. The present difficulty for manufacturers is deciding what standard of production processes will be used in the near future (i.e. existing national standards or a future unspecified EC standard). The unpredictability associated with this situation is an obstacle in making future investment decisions.

The general upgrading of environmental requirements in the EC will have a particular impact on foundries, which might suffer a loss in competitiveness vis-à-vis third countries producers.

OUTLOOK

Improvements in the mechanical engineering, motor vehicles and construction markets are necessary for strong growth in the metal products industry. Due to the ongoing recession in these major markets, a continuing fall is expected in 1993.

1994 will not bring about any relief as the industry's customers remain in the doldrums. Employment in the sector will suffer further cuts over the next two years. Most of European producers will have to wait until 1995 to benefit from a revival in demand . Companies' profitability will be slow to recover, as they will continue to suffer from strong pressures on prices.

In the medium term the outlook is not so discouraging. Efforts to lessen dependence on heavy industry in recent years have already helped reduce the degree of cyclical downturns of demand for intermediate commodities traditionally supplied by this industry. Furthermore, innovations in production processes are also allowing sectors to become more profitable not only by reducing material waste but also by producing products with a higher grade of value added.

Written by: DRI Europe
The industry is represented at the EC level by: Organisme de Liaison des Industries mécaniques, électriques, électroniques et de la transformation des métaux en Europe (ORGALIME). Address: Rue de Stassart 99, B-1050 Brussels; tel (32 2) 511 3484; fax: (32 2) 510 2301.

Foundries
NACE 311

With an annual output of around 20 billion ECU, the EC is among the world's largest producers of castings. The greater part of this output is supplied as components to the automobile industry and mechanical engineering firms. The foundry industry is structurally composed of small and medium-sized firms. In many cases, foundries are part of larger companies and produce castings to meet that company's own needs. The customers are, for the most part, large companies.
The marked decline in employment coupled with generally constant production clearly shows the rise in the productivity of labour during the past ten years. The EC's balance of trade is, admittedly, still positive, but imports have risen much faster than exports in recent years.

INDUSTRY PROFILE

Description of the sector

Foundries are industrial subcontractors. The castings which they manufacture are normally used as primary products in other industrial undertakings. Cast end-product companies remain the exception.

Cast products acquire their shape through the fact that metals are poured in the molten state into a mould and solidify in it. This leaves the designer basically free to determine their shape, with the result that both the surface and the cavities may be very complex. Depending on whether the molten metal is given the shape corresponding to the desired product under the influence of gravity, centrifugal force or pressure, in other words, depending on the technique used for making the mould, the following types of casting are distinguished: sand casting, shell casting, chill (permanent-mould) casting, die casting, centrifugal casting, continuous (extrusion) casting, high-quality casting, precision casting and art casting.

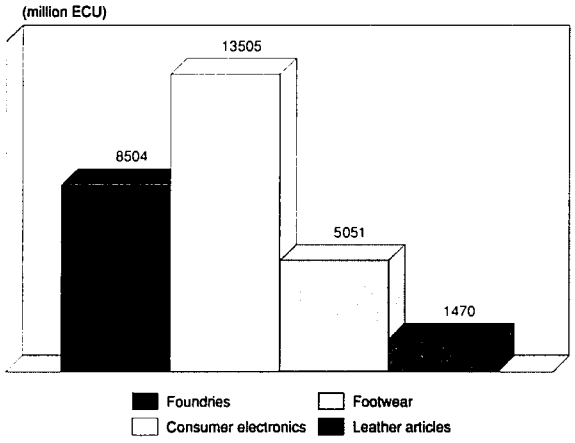
Another possible classification is to make the distinction in terms of the materials used. This classification forms the basis of this paper and also of NACE. A distinction is made in NACE Code 3110, Foundry products, between iron and steel foundries that produce grey cast iron, ductile cast iron (spherical graphite cast iron/malleable cast iron), cast steel and special cast steel (NACE 3111) and non-ferrous metal foundries that chiefly produce aluminium, copper and zinc (NACE 3112).

For each group there are innumerable alloys. Some are standardised. Many are specially developed to meet the customer's specific requirements. Foundries quite often offer up to 200 different qualities or alloys.

The availability of statistical data and their differentiation vary greatly among individual EC countries. Particularly unsatisfactory throughout the EC is the foreign trade data. Many foundry products do not have a commodity number of their own in the foreign trade statistics. They are grouped together with other products under "miscellaneous products". This applies particularly to components supplied to the automobile industry.

In the past, many foundries were established in the vicinity of coal mines or close to iron and steel production locations. In other words, the locations of the foundry industry were raw-material-oriented. Over the course of time, the raw-material orientation has been increasingly replaced by customer orientation. Concentrations of foundries are now found in areas near the locations of their major customers, the automobile and mechanical engineering industries.

Figure 1: Foundries
Value added in comparison with other industries, 1992



Source: DEBA

Recent trends

As a result of the protracted boom, foundries were able to increase their output from 1983 to 1989 by 7.9%. Since 1990 quantities produced have been declining again, at first only slightly but quite markedly since the end of 1992. It is expected that in 1993, 19% fewer castings than in 1989 will be produced in the EC.

The fall of 21% in employment from 1983 to 1992 coupled with a quantitative decline in output of only 3% clearly reveals the rise in labour productivity during that period. In terms of value added per employee, the extent of the rise in the productivity of labour becomes even clearer: expressed in 1985 ECU it rose by 28%.

This also highlights the shift towards higher-quality castings: firstly, the share of castings made of non-ferrous metals in total production has risen from 12.5% to over 16%. Secondly, cast products have become increasingly thin-walled, lighter and more complex and expensive to produce.

While the EC's balance of external trade is still positive, the surplus is dwindling steadily. In 1983, the quantity of cast products exported was 2.8 times as great as that of imports. In 1992 the corresponding figure was only 1.6.

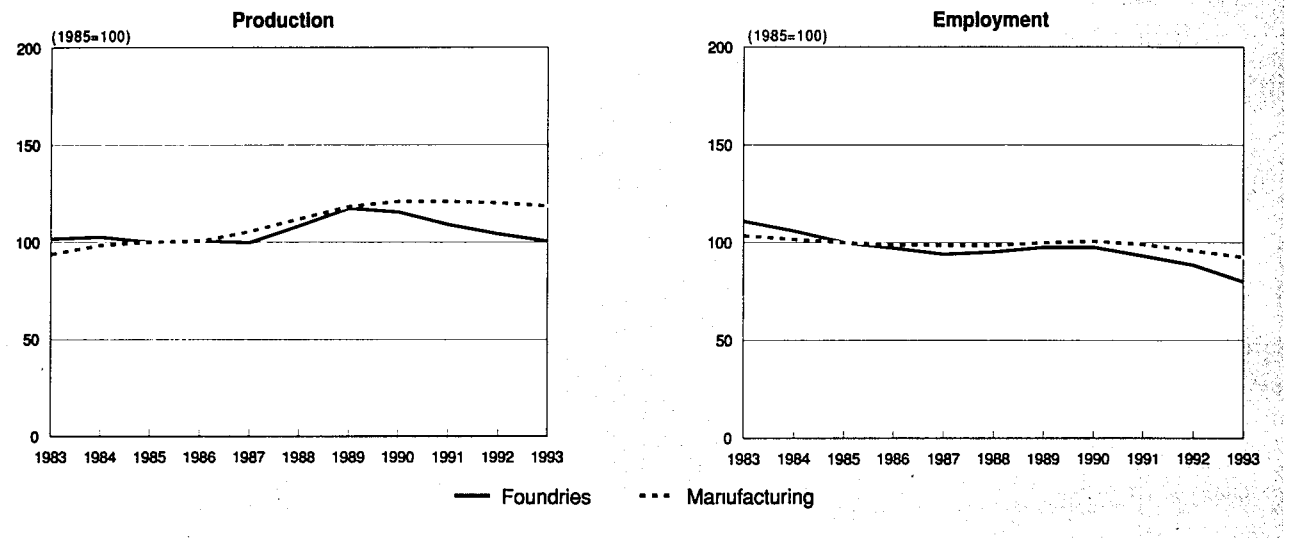
Figure 3: Foundries
Production at constant prices and employment compared to EC manufacturing



1993 are DGV and Eurostat estimates.
Source: DEBA

Regionally, the industry is strongly concentrated within the EC. The Federal Republic of Germany alone accounts for 40% of the value added of the European foundry industry. It is followed by France and Italy with 16% each, the United Kingdom with 14% and Spain with 8%. The five largest manufacturing countries account for 94% of total EC production.

Personnel costs in the foundry industry represent 50% of production costs. The ratio of the sector's value added to the value of its output is correspondingly high.

International comparison

There have been and still are great uncertainties concerning production in the USSR and its successor states. According to the latest publications, the USSR's production in 1990 was 21.3 million tonnes, 13.4 million tonnes of this was accounted for by Russia alone. There are equally great uncertainties about the production of the People's Republic of China, which is said to have risen from 8.9 million tonnes in 1990 to 10.8 million tonnes in 1991.

Consequently, any statements about the world ranking of EC production must inevitably be imprecise. One thing is certain, however: more castings are produced in the EC than in the United States or Japan. It is also certain that the shares of the individual materials are similar in these three economic areas. This applies especially to the share of non-ferrous-metal castings in total production, which is between 14 and 16% in each case.

Foreign trade

Cast products are made to order according to the customer's specifications and on his behalf. Furthermore, they have to meet increasingly stringent demands. Both these factors necessitate close co-operation and intensive communication between the foundry and the customer. In addition, consideration of the high specific and sometimes absolute weight of castings and their value to weight ratio, together with "just in time" delivery difficulties greatly restricts transportation possibilities (or trade, for that matter) over great distances. The importance

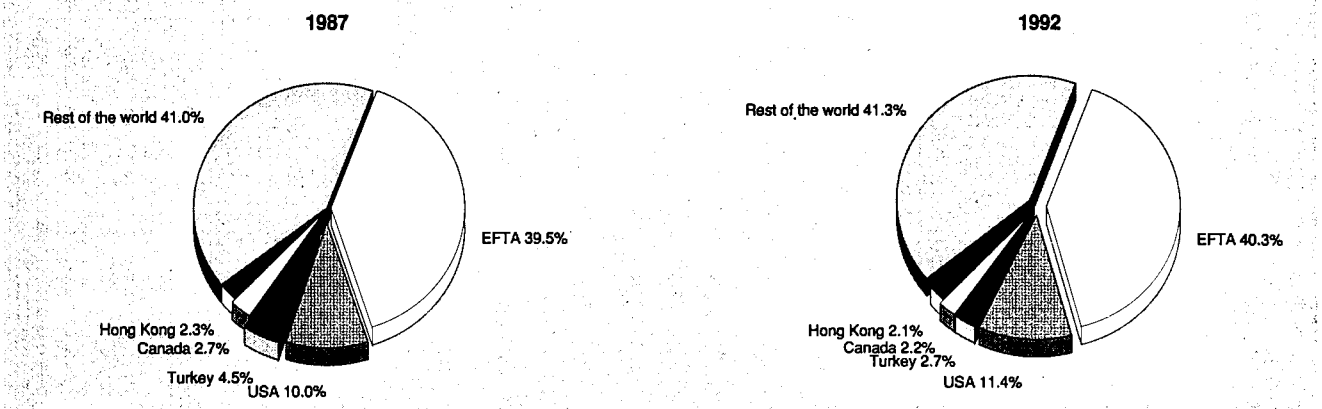
Figure 6: Foundries
Destination of EC exports



Source: Eurostat

of foreign trade is correspondingly slight in comparison with other branches of the economy. In the five most important EC countries, exports represent barely 15% of the value of output. The share of imports in consumption is less than 5%. By far the largest proportion of foreign trade takes place with neighbouring countries: either EC Member States or EFTA countries.

Shipments to distant countries are the exception. They chiefly consist of components or spare parts for plant construction and their value is, as a rule, very high.

MARKET FORCES

Demand

By far, the largest customer of the foundry industry is the automobile industry. Over 70% of the output of light-metal castings (chiefly aluminium alloys) become components for road vehicles. In the case of iron, steel and malleable iron castings, the percent of total EC production shipped to the automobile industry is approximately 35%; total German production was foremost with 42.6% consumed by the auto industry.

Next, is the mechanical engineering industry. Due to the strong world positions of the German mechanical engineering and plant construction industries, supplies of castings in Germany reached their highest levels in at the end of the 1980s (in both relative and absolute terms) but has since declined slightly. In 1992, 28.6% of all supplies of grey cast iron and spherical graphite cast iron went to the mechanical engineering industry; at the end of the 1980s this share was over 30%.

Pressure pipes, pipes and castings are the most important end-products of the foundry industry. They played the greatest role in France where they accounted for 30.1% of total output of grey cast iron and spherical graphite cast iron. Their value (ECU/kg) is, however, very low.

The foundry industry cannot actually be said to be a growth industry. If business cycle influences are eliminated, hardly any change has taken place in the tonnage produced during the past ten years. The fact that the value of production has risen during the same period reflects the shift towards higher-value castings, towards lighter, thinner-walled, harder cored and complex components and towards lighter alloys, especially aluminium-based ones.

Source: CAEF, Modern Casting

As producers of preliminary products and components, foundries are heavily dependent on the fortunes and demand behaviour of their most important customers. These are primarily the automobile industry and mechanical engineering industries. Both generated high growth rates for the foundries at the end of the 1980s. Both are, however, responsible for the recent decline in foundry output, and both will exert a decisive influence on future developments in the foundry sector.

Casting, as a basic forming process, is in direct competition with sintering. In practice, however, particular importance is attached to the processes of metal reshaping, specifically: forging (hammer forging or drop forging), rolling, pressing (extrusion), drawing and deep drawing. There are also the processes of connection technology comprised of welding, bonding, riveting and bolting.

By far the most important factor in recent years, has been the competition between metals and substitutes such as plastics. The proportion of the latter in motor vehicle manufacture, the making of household articles, pipes or connecting pieces has grown steadily in recent years at the expense of metals demand. The reasons which are leading to the replacement of one material by another include: weight, tensile strength, resistance to pressure and wear, resistance to heat or to rust and acid, ageing behaviour, price and recycling possibilities.

In the future, mineral products such as ceramics or composite materials appear likely to gain market share held by foundry products. Whether they can become generally acceptable will depend chiefly on their price and whether their ability to meet stated specifications.

Supply and competition

As material-intensiveness is decreasing in practically all branches of the economy, specific consumption of castings is also declining, as evidenced in the automobile and mechanical engineering industries. The growth rates of the foundry industry are lower than those of their main customers (as became evident, for instance, at the end of the 1980s) and resulted in an appreciable decrease in the long run quantity produced when compared to the quantities produced in 1970 or 1980.

Accordingly, the existing smelting, moulding or fettling capacities are more than sufficient to meet demand. (Surplus capacity is currently estimated at to be about 25%.) This leads to intense competition between foundries, and also makes their market position weak in relation to their main customers. Because of the overcapacity and strong buying power of the major customers, foundries do not have much leeway in price setting, thus creating a low profit to sales ratio.

In view of the EC's single market, the most important repercussions are likely to result from international calls for tender

Source: CAEF

for public contracts. This effect, in particular, manufacturers of pipe, pressure pipes and moulded conduits. Furthermore, liberalisation in the transport sector may lead to lower freight rates. Both of these factors not only widen the foundries' range of action, but also shift the competition between foundries from the national to the international plane. To ensure that this competition takes place under fair conditions environmental protection regulations and supplementary personnel expenses must be harmonised.

The making of castings continues to be very labour-intensive. Even where the production process is highly mechanised, for example in large-scale series production, the proportion of personnel expenses in the production costs is 40%. In the case of hand casting, i.e. individual production, the proportion of personnel expense to total cost is as high as 55%. As a result, efforts made to step up labour productivity and reduce personnel expenses have been correspondingly great.

Production process

Metal materials account for 15 to 25% of production costs. The range is due to the differing nature of the materials to be produced, as well as to the ore mix, which in turn depends on the smelting equipment. Factors effecting the proportion of raw material costs in the total production costs are: whether an initial melt is being produced; whether a material is merely being re-melted; and the proportion of scrap, pig iron, (ferrous) alloys or high-grade pure metals contained in the melt. Lastly, the influence of market prices should not be underestimated. In past years, the foundries benefited from a decline in raw materials prices, they are now confronted again with rapidly rising raw material prices.

The proportion of capital costs, depreciation and interest costs fluctuates between 10% and 15% of total production costs. It depends chiefly on the production technique and is naturally larger in the case of highly automated large-series production than in that of hand-moulded individual parts.

And finally, energy costs must be discussed. Here, the foundries still operating with cupola furnaces are the most economical since coke is the main source of energy. Rising quality demands, the decline in the share of grey castings and, conversely, the increase in the amount of cast iron using spherical graphite are, however, causing many foundries to switch to electric furnaces. The share of energy costs for foundries using electric furnaces can rise 15% of total production costs.

INDUSTRY STRUCTURE

Companies

The foundry industry has been able to retain its character as a sector composed of small and medium-sized firms. More than half of all foundries still have fewer than 50 employees, and many are still family-owned. Some of them, as jobbing foundries, work only for other companies. Often, however, they are also part of a larger undertaking, which predominantly produces castings "to meet its own requirements", for instance for use in mechanical engineering and plant construction.

There is no observable trend towards larger company units. Investment in recent years has been mostly for the purpose of increasing labour productivity. A breakdown between iron, steel and malleable-iron foundries and non-ferrous-metal foundries reveals that on average, the former have an appreciably larger number of employees than the latter.

Nevertheless, technical progress has the led sector to the emergence of a few large companies in the foundry For instance, the production of large series has become much more economical due to the development of automatic moulding plants. The increase in capital-intensiveness, however, has necessitated two or even three-shift operations. This has led to the creation of production plants with up to a thousand employees. These usually specialise in making castings for the automobile industry.

Strategies

Rationalisation and automation has brought about, among other things, automation of sand preparation, the development of automatic casting plants and the development of induction and holding furnaces. In the future, the greatest successes will probably be achieved by the use of CAD/CAM in pattern making and fettling.

The demands made of castings are becoming increasingly high and varied. This necessitates the development of new materials with ever-narrower dimensional tolerances. Castings are becoming thinner-walled, lighter and harder cored with the cavities and surfaces becoming more complex. Other castings are required to be made in ever-increasing size and thus of ever-greater weight. The result is that foundries, too, are specialising more and more and that the industry is steadily becoming more heterogeneous.

Therefore, one cannot speak of general or uniform foundry strategy. An important current topic is the extension of the value added chain from the raw material phase to the end product. The enterprises involved in production (in different industries) may be faced with the need to restructure the distribution of functions within the chain. For foundries, this could mean taking over research and development functions, taking over mechanical processing operations and, via the supply of ready-to-fit components, increasing their own value added.

Where foundries are taken over by other companies, they typically continue to be operated as profit centres of the new owner. The size and equipment of the production plant does not usually change much. That being the case, there are two main reasons for a take-over: the acquiring company's need for castings for their own production to make them independent of other suppliers; and the need to offer customers the complete range of the foundry sector's products, from light-metal to fine-steel castings, from hand-moulded to automatically moulded castings, and from small to large castings, etc.

ENVIRONMENT

Great importance has always been attached to recycling in the foundry industry. This applies particularly to the most important materials used, namely sands and metals. Sands are reprocessed and metals re-melted as reusable material. Used castings are returned to the production circuit as "broken castings" via trade channels.

Even so, total avoidance of waste is not possible. Certain residual materials, especially thermally exhausted moulding sands, which have to be disposed of at tips, will always accumulate. Nevertheless, the foundry industry is trying to devise economically defensible methods of further reducing the quantities of such residual materials.

Keeping the air clean, particularly dust removal, is presently the foremost environment protection measure for many foundries. Strict regulations have to be met. In some cases this will require substantial investments.

Not all foundries will have sufficient financial resources to afford the requisite investment. These will most likely have to stop production after the regulation phase-in period. For many foundries, however, earnings will deteriorate further if the costs entailed by environmental protection cannot be passed on to customers. In this respect, the regulations should be the same for everyone, at least within the EC to curtail the lose of competitiveness of foundries located in more environmentally conscious countries.

REGULATIONS

There are no specific EC directives or regulations which apply exclusively to foundries. Foundries are, however, affected by all provisions relating to: protection of the environment, incidental personnel expenses, trade with associated countries in Eastern Europe, energy prices and public charges (e.g., for waste disposal) and taxation (business taxes, property tax, corporation tax).

OUTLOOK

Foundries presently hard hit by the recession. The quantitative output in the EC in 1993 is expected to be 9% lower than in 1992. Because of non-ferrous-metal foundries' strong dependence on automobile production, their fall in production will be greater than for iron, steel and malleable iron foundries. Apparent consumption is expected to fall by just over 6% in 1993. Extra-EC exports will fall by 5%; the EC's positive trade balance in the foundry industry will also decline 5% from 991 to 941.5 million ECU at current prices. As a result

Table 9: Foundries
Employment, 1992

	D	F	I	UK	E
Ferrous metals	68 155	35 560	22 250	33 836	17 630
Non ferrous metals	35 398(1)	20 458	N/A	N/A	5 850

(1) Only West Germany.
Source: CAEF

of these somewhat gloomy estimates, total employment in the industry is anticipated to fall by 6% to 235 300.

When the fall in economic activity stops, the downward movement of foundry production will also end. This is expected to take place not later than at the beginning of 1994, so slight growth can be expected by the end of 1994, although it is not likely to be more than 2%. Production levels are expected to level off by the mid-1990s.

In the future, it will be even more important for foundries to further improve quality and develop new materials and production processes. The distribution of functions between individual enterprises participating in the value added chain from the basic product to the finished article present foundries with additional opportunities. For example, they could focus on increasing their value added by supplying ready-to-fit components.

Against the background of the labour-intensive production, investment will aim towards rationalisation, further raising the productivity of labour. Progress can be expected to result from the use of CAD/CAM systems in pattern making and fettling since both remain very labour-intensive manufacturing stages.

Reducing the production cycle length, minimising production rejects, attainment of "just in time" delivery and quality improvement will be important for the future international competitiveness of EC foundries.

Forging
NACE 312.1

The forging industry is a typical subcontracting industry with largely medium-sized undertakings. Important consumer sectors are the vehicle industry, mechanical engineering, electrical industry, aircraft construction, etc. With a production volume of just over 3 million tonnes the forging industry of the European Community surpassed both the USA and Japan in 1992. A decline in production has been observed in the forging industry since 1990, essentially due to the recession in Europe. This downward trend will probably continue through the early nineties.

INDUSTRY PROFILE

Description of the sector

The majority of forges are subcontracting plants. In addition to their own products such as universal joint shafts, clamping systems for the construction industry and pipeline fittings, they predominantly offer products manufactured according to customer drawings on the open market.

The hammer forges are sometimes manufacturing departments on a larger scale, e.g. steel mills. The structure of the drop forging shops and of the manufacture of extruded parts, flanges and pipeline fittings consist primarily of medium-sized operations. Some car and bearing manufacturers, for example, produce individual articles in their own production plants, but only where extremely large, recurrent quantities are involved.

The following product groups are covered by the term forging: hammer forgings, drop forgings, flanges and pipeline fittings and extruded parts. Forgings are mainly semi-finished products, which still require after-treatment such as heat-treatment, surface treatment or cutting at least in subsectors. Articles ready for installation can also be manufactured when special forming methods are used.

The forgings are produced with or without heating of the blank (which is usually offcuts of rectangular sections or round bars or shaped pieces made of thick plate) by shaping tools moved in relation to each other. Whereas the hammer forgings are produced by simple flat or round tools and have a machining allowance of several millimetres. In the case of the other product groups, drop forgings, flanges, pipeline fittings, and extruded parts, an attempt is made to come as near as possible to the final shape of the workpiece through a high expenditure on tools. Operating surfaces or forging products ready for installation can often be produced by a combination of different methods.

Both the most diverse steel materials and non-ferrous metals like Al, Mg, Cu, Ms, and Ni alloys, can be formed by forging. The different deformation capacity of the various materials determines the type of production method and also limits the attainable shape and accuracy. The required properties of the products with regard to strength, structure, workability, etc. are achieved either by the process method itself (heat treatment from the forging heat, cold hardening, etc.) or by subsequent operations (annealing, heat treatment, shot-blasting for strength).

The forging industry manufactures high quality products, which offer important advantages to the consumer particularly from the point of view of weight, resistance to fracture, life and uniformly high quality.

MARKET FORCES

Demand

The output trend in the EC Member States varied widely in earlier years. The countries represented in EUROFORGE produced just over 3 million tonnes of steel forgings in 1992 and thus constituted the largest forging producer ahead of Japan and the USA. The drop forging production group easily accounts for the largest proportion of forging products with just under 70%. The rising production trend observed since about 1986 in various countries has again shown a downturn since 1990. The causes are essentially the recession in the engineering industry and the decline in car production for well over 2 years.

INDUSTRY STRUCTURE

Companies

The forging industry structure consists predominantly of medium-sized companies. It has been observed for some time

that concentration and cooperation activities are expanding beyond national frontiers. The Netherlands, Ireland, Denmark, Greece and Portugal are not taken into account in this report, because they have no significant forging industry.

About 150 forging companies, accounting for just under 60% of EC production, are active in Germany, which thus occupies first place in the western world. 75% of the companies are located in North Rhine-Westphalia, 11% in Baden-Württemberg, and the remaining 14% are divided equally between the remaining western and eastern German Länder. The size structure of the forging companies is as follows: 36 forges have more than 200 employees, 31 between 100 and 200, 32 between 50 and 100, and 51 companies with fewer than 50 employees. The large companies include Thyssen, Gerlach and Peddinghaus.

Italy is responsible for 16% of EC production. Most companies are located in the north for example, in Piedmont, around Turin, in Lombardy, in the Como, Varese and Brescia regions, in Venezia and in Emilia Romagna. The most important companies are Teksid, a subsidiary of Fiat (90% production is intended for the car industry), the Erber group, Riganti and Casartelli. In Lombardy 10% of the companies account for 50% of the total production. Apart from Teksid the forging companies are typically family businesses.

In the United Kingdom who is responsible for 8% of EC production, most of the manufacturers of small forgings are located in Central England in the Birmingham area. The large forgings are generally produced around Sheffield in South Yorkshire. The largest company is United Engineering Steels Ltd. It is responsible for about 45% of UK production. Other important forges are Firth-Rixson, the INCO group and Cameron Iron Works.

France contributes 11% of EC production via 72 companies. The forges are spread around the regions as follows: 25 in the Ardennes, six in the Loire region, 14 in eastern France, 27 in the other regions. Three groups dominate the sector: Ascometall, Forges Stephanoises and Forges de Courcelles.

Spain has only 5% of EC production with 37 companies in this industry. Approximately 30 are located in the Basque region, the remainder in Catalonia, Aragon, Madrid and Galicia. Eight companies have more than 150 employees, five between 100 and 150, nine between 50 and 100 and the remainder have fewer than 50 employees. The most important companies P. Echeveria SA, La Forge Casanova SA, Forges de Villalba SA (Gekanor group) and Forges de Galicia SA together account for about 60% of the Spanish production volume.

In Belgium with only 1% of EC production, 10 companies operate in this sector, and forging is the main activity of four of them. The 10 companies are predominantly small to medium-sized and are located around Charleroi and Liège.

Figure 3: Forging
Sales by end market, 1992

Strategies

The strong pressure of competition, caused by excess capacity, discounts demanded by customers and substitutions, induced the forging industry at an early stage to develop strategies designed to safeguard the competitiveness of its products also in a larger market. These include inter alia: intensification of export activities with simultaneous specialisation and concentration on specific market segments; reduction of the large variety of products with optimisation of the products using modern computer methods (CAD/CAM/CAQ, FEM); increased productivity by rationalisation of production with the aid of interlinked or automated plants; development of new materials with the aim of reducing the costs of the material used or simplified further processing (e.g. heat treatment, workability); production of workpieces with a more accurate shape to reduce the expenditure on finishing; increase in value creation, e.g. by finishing workpieces or production of assemblies; and increase in and safeguarding of the quality standard by application of modern quality assurance methods (FMEA, SPC) adapted to the forging industry.

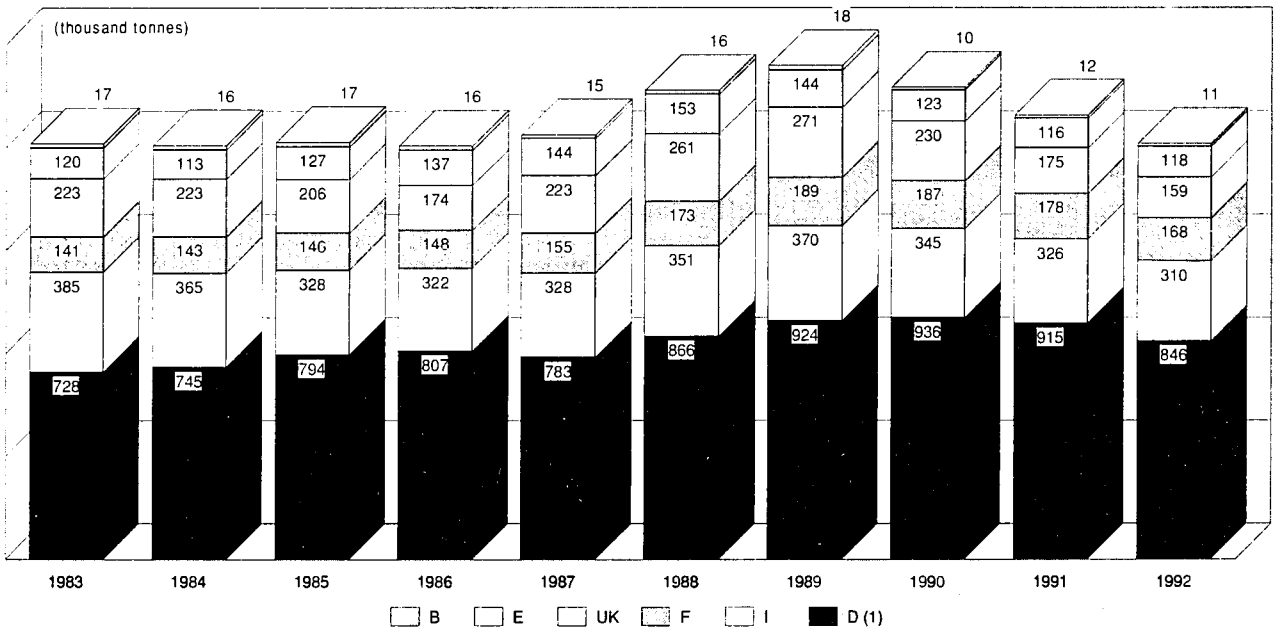
Inter-company cooperation plays an important part in the realisation of these aims. It is a necessary measure designed to safeguard the existence of the forging industry with its structure of predominantly medium-sized companies. Individual companies do not have the wherewithal to independently finance several major projects at the same time. Examples are the CAD/CAM/CAE and the quality assurance project for the forging industry as well as many plant management activities.

With the increase in just-in-time deliveries, proximity to the customer has become an important aspect in selecting suppliers. Hence, there will be an increasing tendency for the forging companies to establish branches or embark on cooperation abroad.

With the introduction of the "Single European Market" there will certainly be an expansion of exports and imports, i.e. competition for market shares will be considerably intensified. Only those companies which are able to increase their competitiveness by implementation of the above mentioned strategies will be successful.

Competition on the forging markets is additionally intensified by substitution. Cast products, sintered parts, composites and sheet metal constructions or combinations of these are suitable alternatives on a still limited scale. Choosing a product depends on several factors according to its purpose. In addition to the price, reliability, safety, weight, life and environmental friendliness are important criteria for decision making.

Figure 4: Forging
Production by country



(1) Including former East Germany from 1991.
Source: Euroforge

ENVIRONMENT

A considerable proportion of the investments in previous years was allocated to environmental protection measures in the forging industry. The main emphasis was on noise protection, energy conservation, e.g. by equipping furnaces with recuperators, replacement of the expensive pneumatic drives for hammers by electrohydraulic systems and by utilisation of the waste heat in the forging process, as necessitated by official requirements. An important advantage of the forging products is that the materials can easily be recycled. For this reason, and others, the increasing substitution by plastics parts over the last few years was again reduced.

OUTLOOK

The forges will continue to depend on their main customers despite the strategies developed. The growth rates of recent years in various European countries will probably not be achieved again in the near future. The trend towards larger company units will also continue on an increasing scale. Questions of location will also have to be discussed again, since the consumers of the forgings are also concerned with supplier proximity.

The measures taken by the forging industry to safeguard its competitiveness on the market will ensure that forging products will continue to account for a significant proportion of industrial production in future. Yet risks in the forging industry remain with their dependence on the economic growth of the main consumer industries and the intensified competition from Eastern Europe and non-member countries. Further opportunities for the forging industry exist through, innovative product development, high quality standard, flexibility and service.

Written by: EUROFORGE

Secondary transformation of metals

NACE 313

The production of fasteners and hot dip galvanising are the primary activities of secondary transformation of metals; the major outlets are the construction and automotive sectors. The industry is largely nationally and regionally oriented. After continuous growth during the 1980s, production has declined since 1990. The general economic recession and increased competition contributed to this development. Rationalisation and a switch to higher quality products are prerequisites to cope with increased competition. A slight recovery is expected in 1994. In the medium term a more substantial improvement is expected.

INDUSTRY PROFILE

Description of the sector

Data for the secondary transformation of metals industry are classified under NACE 313. The products of this industry are highly diversified and can be divided up into the following categories:

- manufacture of articles on turning machines or lathes, including the manufacture of turned screws (NACE 313.11);
- nuts, bolts, rivets, screws and related products (NACE 313.12);
- springs, except furniture and watch springs (NACE 313.2);
- sintering of metals (NACE 313.3);
- chains, except articulated link chains (NACE 313.4);
- treatment and coating of metals, including zinc coating, aluminising, anodising, enamelling etc. (NACE 313.5); and
- general mechanical engineering on a subcontract basis (NACE 313.6).

In general, the most important subsectors are the fasteners industry (the first two sectors) and the treatment and coating industry (galvanising).

Fasteners can be divided into two main categories: those which are used for construction purposes, and those which are used for assembly purposes and which do not come under stress or load. From a market point of view however, fasteners can be divided into common fasteners and special fasteners. In the first category price is important, in the second, quality, marketing and delivery time are important.

The purpose of zinc coating is to improve the qualities of the metal. This can be done by several techniques, such as electrolysis. Galvanising, formally "hot-dip" galvanising, involves coating steel with zinc by immersion in molten zinc metal.

Characteristic for the industry is its regional dimension. In general, enterprises in the secondary transformation sector are located near the major industrial centres of Europe. Because of the small scale of many of the firms, long distance transport is not viable in general. To decrease transportation costs, firms must be located near their clients. For instance, in Germany centres of the galvanising industry are in Nordrhein-Westfalen and in Baden-Württemberg.

Recent trends

Production in current prices declined by 2.4% in 1992; employment fell, too. Since non-EC trade plays a minor role in this sector - both the export quote and the penetration rate are less than 5% - the adverse development of EC demand accounted largely for the drop in production. The sector recorded a small trade surplus in 1992.

It is to be noted that data for production and employment may differ from those presented in the 1993 edition of Panorama, because of statistical reasons.

With a joint production share of nearly two thirds, France and Germany allow for the bulk of EC production; France is the leading manufacturer. Spain, Italy and the United Kingdom account together for another 30%, leaving the remaining EC Member States about 4%.

The EC output of steel galvanised as fabricated products increased in 1992 by 2% to a total of 4 million tonnes. The increase was much smaller than in the preceding years; from 1988 to 1991 the average growth rate was 7% per annum.

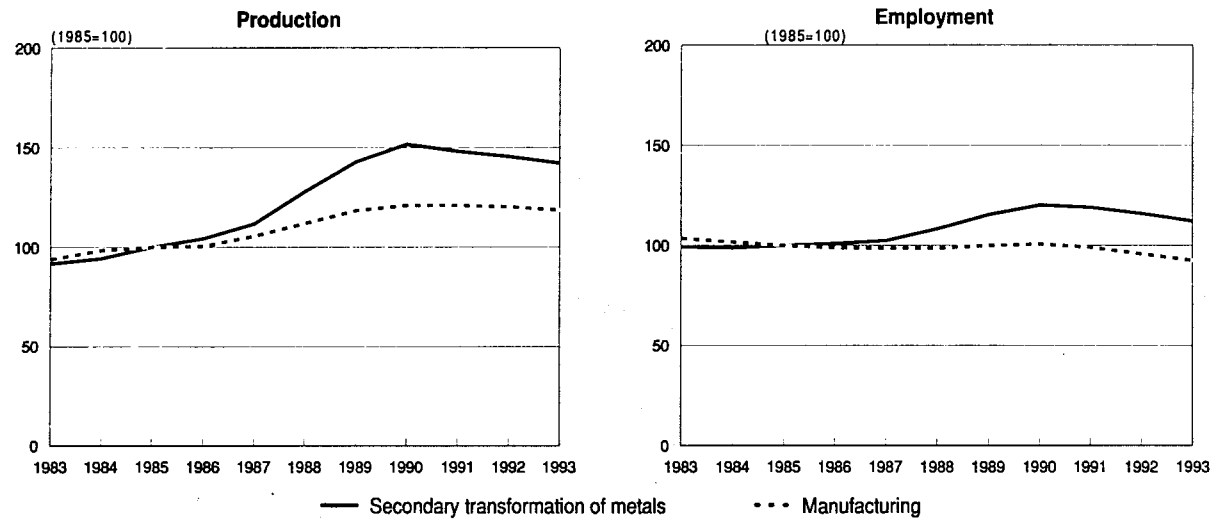
Figure 3: Secondary transformation of metals
Production in constant prices and employment compared to EC manufacturing



1993 are NEI and Eurostat estimates.
Source: DEBA

By Member State the development of the output was dissimilar in 1992; in Spain the output declined by 8.5%, and Italy revealed a stable output, whereas the output of the remaining Member States grew. As to the latter category the growth rates varied significantly: from 1.9% in France to 9.8% in Denmark, but most growth rates were in the range of 3% to 5%.

The development pattern of EC production (in current and constant prices) and consumption was similar during the period 1983-1992: a continuous and fast growth between 1983 and 1990, followed by a decline in 1991 and 1992 as a result of the general economic slow down. This had an adverse impact on the demand of main customer industries such as the automotive and construction sectors.

Consumption grew marginally faster than production, causing a slight decline (from 96.5% to 95.5%) in the market share of EC producers. Although this market share is still overwhelming, its decline reflects increased competition from outside the EC, particularly from the Far East and Eastern Europe. The export rate remained fairly stable: it fluctuated around 5% from 1983 to 1992.

Employment reached its highest level in line with production. In 1990, a record level of nearly 360 000 was attained; in 1992 it was 3.5% lower. Between countries, there is a wide divergence in average firm size. For instance, the average firm in Spain had 9 employees in 1991; in West Germany this was 129.

International comparison

Varying classification systems for industries in the EC countries, the USA and Japan, make an international comparison difficult to make. Some comparisons can be made, however.

USA manufacturers in the secondary transformation of metals industry recorded in 1992 the third consecutive year of declining production. Compared, in particular with 1990, this fall was only very modest. The weak demand from important

Figure 4: Secondary transformation of metals

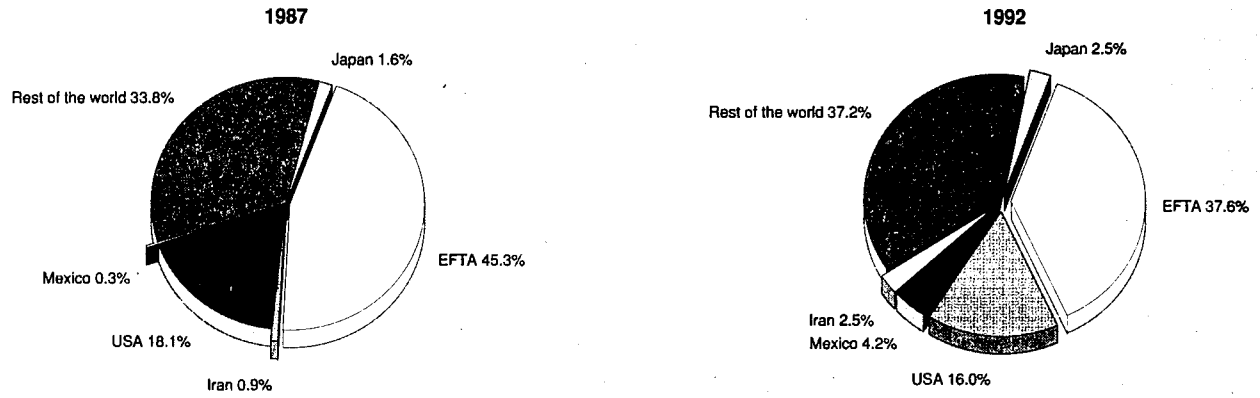
Figure 6: Secondary transformation of metals
Destination of EC exports



Source: Eurostat

domestic customer industries, particularly the automotive sector added to this effect. On the other hand, since 1985 American exports to the EC increased strongly. USA manufacturers are increasingly serving foreign markets. Most American exports are high quality products, while their imports are mass market products from East Asia, especially Taiwan.

Relatively high production cost caused Japanese fasteners to become less competitive.

Foreign trade

From 1983 to 1989, the EC experienced a continuous rise in foreign trade flows. Since the non-EC imports increased at a faster rate than the exports, 16% and 12% per year, respectively, the export/import ratio declined from 1.39 in 1983 to 1.07 in 1989. After 1989, when the foreign trade flows fluctuated only slightly, this ratio varied between 1.02 and 1.07, implying that since 1989 the trade balance has not been far from zero. The development in nominal terms was reinforced by the decrease in the terms of trade since 1988, although 1992 shows slight improvement as compared to 1991.

Import penetration increased during the 1980s: 3.5% of consumption in 1983 to 4.5% in 1992; the export rate fluctuated around 5%. These low rates demonstrate a major characteristic of this sector, i.e., its national, and often regional, orientation. The export and penetration rate remain modest if the total of intra- and extra-EC trade is considered, namely 12% each.

By far the main export markets are the EFTA countries; the USA ranks second. Together they accounted in 1992 for 54% of the total extra-EC exports, which is less than in 1987 when it was over 63%. the Japanese market is of no significance to these exports.

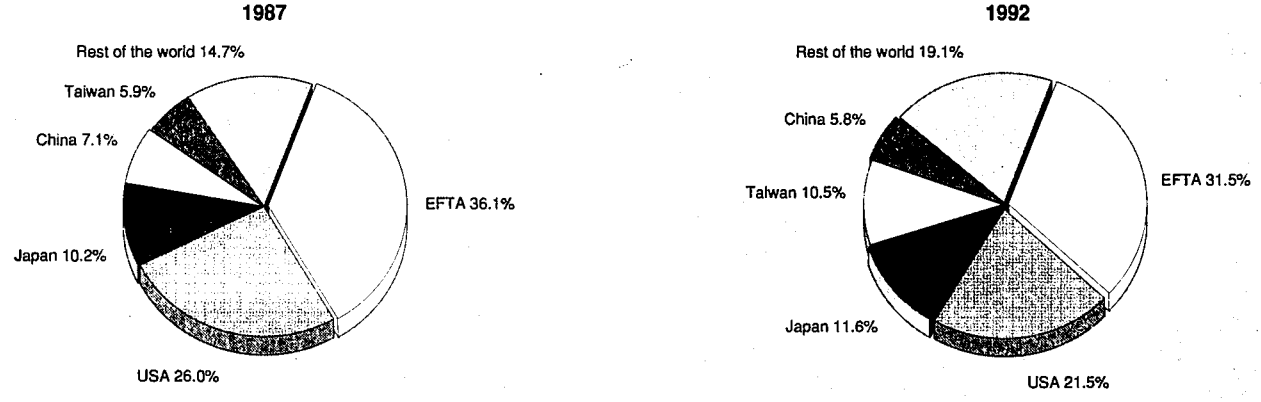
Regarding extra-EC imports in 1992, around 65% were accounted for by only three origins: the EFTA countries, the USA and Japan. In 1987, this share was still 72%, but it fell due to declining shares of the EFTA countries and the USA. Japan improved its position slightly, but its place as the third largest exporter to the EC is becoming increasingly threatened by Taiwan, which improved its position at the expense of EFTA and USA imports.

MARKET FORCES

Demand

The primary client of the fastener industry is the automotive sector. Other important sectors are mechanical engineering,

Figure 7: Secondary transformation of metals
Origin of EC imports



Source: Eurostat

furniture, household appliances, construction and electronics. There is also a relatively small amount of consumer demand for screws, etc. The EC galvanising industry serves more or less the same branches. Three markets allow for nearly 70% of the output of the EC galvanising industry (building and construction, street furniture and power transmission). The building and construction sector is by far the main single client; it takes up 40% of the output of the EC galvanising sector. This sector and street furniture showed a considerable growth between 1985 and 1992, 75% and 65%, respectively, whereas in 1992 the demand for galvanised products for power transmission was lower than in 1985.

Technical and logistical developments in the client industries have a strong impact on the fastener industry. Technologically, the ongoing automation and robotisation of production processes has influenced demand for speciality and high quality fasteners often in a negative way. Most of the standards for screws, for example, are designed for manual fastening. These standards are widely used, and producers can take advantage of economies of scale. Therefore, the price is normally relatively low. This had led to the use of these screws in automated production systems, even though in terms of quality of the end-product, the use of specially designed screws would be preferable.

Supply and competition

Both in the USA and the EC, manufacturers faced world-wide overcapacity in the mass market of fasteners in the first part of the 1980s. This led to fierce competition and price falls. Many producers were forced to leave the business.

The market power of the main clients of the secondary transformation industry continued to increase. This is particularly true for the automotive industry. Japanese competition urged the requirement of more security, just-in-time delivery and increased quality from their subcontractors and suppliers. Consequently the upstream industries bear both the costs and the risks. However, the tendency towards small, family-owned fastener producers precludes the availability of substantial R&D resources.

Further, the EC industry of secondary transformation of metals has to cope with developments in the automotive industry such as the growth of Japanese car production and the increasing use of single-sources by motor vehicle manufacturers. Japan's increasing production of cars within the EC will urge the EC fastener manufacturers to cooperate with Japanese motor-vehicle producers who have different design specifications than the European automobile industry. The increasing use of single-sources by motor vehicle manufacturers means less utilisation of subcontractors and fewer suppliers. Combined with the ongoing tendency towards concentration in the client industries, the mutual dependency of the supplier and client industries is growing.

The EC fastener industry is continuously faced with strong competition from East Asia and Eastern Europe in mass production of standard screws, nuts and bolts. In this area there is a worldwide overcapacity. Both EC and non-EC fasteners seek high volume markets, such as Germany. In the mass market there is severe price competition. The standard nuts and bolts from outside Europe are usually destined for the consumer market. The core of the competitive power of the EC industry is sophisticated, specially designed fasteners. The trend in trade is to export high value added products and to import low value added items.

As a result of increased competition costs have risen and prices have dropped. Profits in the fasteners industry reduced to a level which does not allow for necessary investments. It is difficult to change this situation as the industry depends on large suppliers of raw materials and big customers. Companies in the industry have little market power, because they are of limited size.

The galvanising industry is facing increasing cost, incurred by environmental regulation. This gives rise to a trend for mergers; larger minimum plant sizes are required to cope with the necessary investments. The environmental requirements also encourage specialisation; companies which formerly galvanised their products themselves now leave this to specialist hot dip galvanising plants. By servicing a number of companies the unit cost can be reduced.

In spite of the general economic slowdown, hot dip galvanising capacity increased in the early 1990s. The average production increase between 1988 and 1992 was 5.8% per year. The production process has also become more efficient. The average throughout Europe in 1991 was 13 tonnes of steel galvanised for every tonne of zinc consumed, while the average in 1970 was 11 tonnes of steel per tonne of zinc.

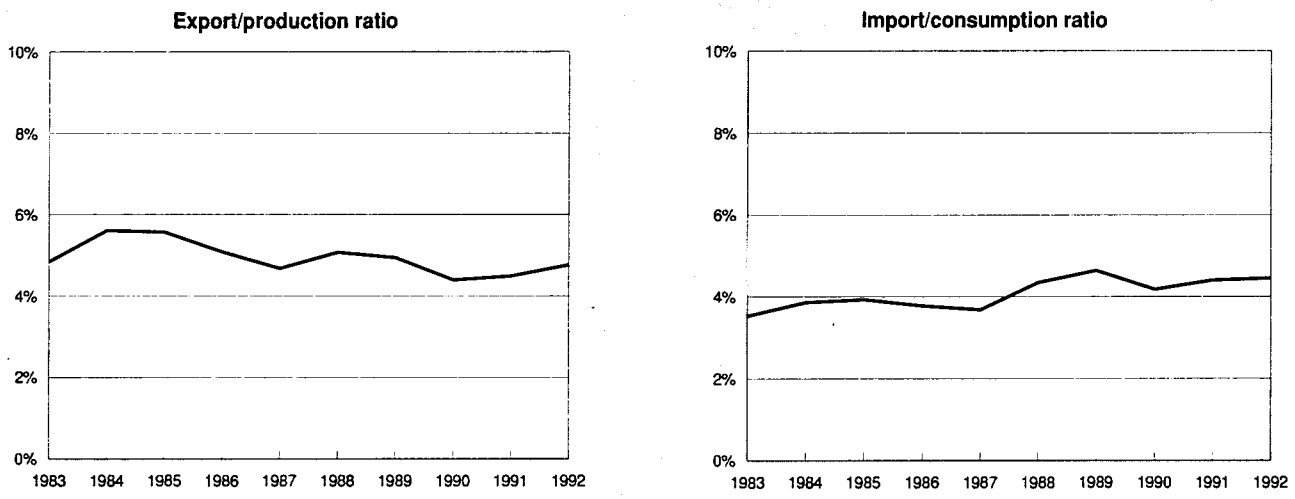
Trade intensities



Source: DEBA

Production process

Although fasteners are largely standardised products, the manufacturing of tailor-made screws is gaining in importance. An example are multifunctional screws, which can drill, tap and fasten all in one. Automation is necessary to fulfil the needs for more tailor-made fasteners.

The hot-dip galvanising industry has four separate areas: the coating of pre-fabricated products, the coating of steel sheets, the coating of steel wire, and the coating of steel tubes in automatic plants.

Electroplating techniques can be divided into three areas: upgrading of metals, plastic-galvanising and conductor plate technique. The methods include the use of zinc alloys and chromium alloys to fight rust, copper-nickel chromatising, chemical nickel and hard-chromium. The most important alloys in the conventional electroplating process are: copper-tin, copper-zinc, zinc-nickel, nickel-iron, lead-nickel and aluminium alloys. The electroplating technique has gained importance in the field of electronics and printed circuits, which has led to a more efficient use of zinc in electroplating.

Skilled labour is becoming more and more important, because of the increasing use of Computer Numerical Control (CNC), Computer Aided Design (CAD) and Flexible Manufacturing Systems. The use of these new machines and techniques is necessary to be able to produce new kinds of fasteners through cold-forming. Lack of skilled labour is especially a problem here, although the techniques themselves, in particular CNC, help to alleviate part of the problem. Increasing use of CNC can lead to a decrease in labour requirements, which results in a decline in unit labour costs.

Unit labour costs (in current prices) rose an estimated 6.1% per annum between 1983 and 1992; labour productivity in current prices increased marginally more, by 6.2%. In constant prices labour productivity increased by half these rates (3.1%). Although up to date information is lacking, there are indications that the unit labour cost differ considerably among Member States. In 1988, they were 7 600 ECU in Greece, and 24 900 ECU in Luxembourg. The productivity development has also been very dissimilar by country; for example in Greece, it declined over 20% between 1982 and 1989, while in Germany it increased with 20%.

INDUSTRY STRUCTURE

Companies

The galvanising industry can roughly be subdivided in three areas: small enterprises, using primarily hand-skilled labour; larger enterprises, operating more on a manufacturing scale, including in-house production of galvanised metal as part of the production process; and supply of zinc, machines, chemicals, etc., for the galvanising process.

The fastener industry roughly follows a similar pattern, with many small and medium sized enterprises. There are a few, however, that could be classified as medium to large enterprises, with sales over 100 million ECU. The largest companies and dealers are German, which is not surprising given the importance of the German machinery and motor vehicle industries in Europe. Italian, French and British manufacturers are not far behind, however. In the galvanising and electroplating sector, Metaleurop (D) has sales of approximately 140 million ECU in 1990, and in continuous galvanising of steel sheet, Galvanage (L) had annual sales of around 140 million ECU in 1989.

Strategies

Rising cost and decreasing prices urged producers to seek ways to lower production costs, especially through rationalisation. However, in certain segments of the mass market price reductions would not restore competitiveness, as competitors can use cheap labour. In addition to rationalisation, therefore, a switch is made in the product-mix towards quality products. Further, measures have been taken to meet logistic requirements such as just-in-time delivery. All these factors lead to increased investment in new equipment.

In the subsector of speciality products, CNC machines decrease the time and cost of change-overs. The trend toward orders for smaller lot sizes at more frequent intervals and with shorter lead times leads to increased numbers of change-overs for machinery.

The above factors have resulted in increased specialisation and product development in both fastener and galvanising sectors. Subcontracting of galvanising will also become more important, despite the preference of some client industries for single sourcing.

ENVIRONMENT

The electroplating industry is looking for ways to reduce the amount of waste created, in particular the metal content of the effluent. The metals concerned are copper, chromium, nickel and zinc. Efforts are made to develop production processes which generate less effluent by regenerating it and by extending the dipping time. Also, the use of techniques, such as ultra filtration and electrolysis, have the advantage that they do not use additional chemicals. The cascade-washing technique in combination with the recycling of metals could reduce the metal concentration in the effluent from 300 g/l to 0.3 g/l.

Furthermore, recycling of metals out of the galvanic waste disposal is an option, but only if the waste has a high enough metal content, preferably of a single metal. Currently, this is not very practical. Most of the small and medium sized enterprises use third party firms for recycling metals. Also, the traditional technique of the galvanic bath is increasingly being replaced by showering the metal plates. The main waste products of hot dip galvanising - zinc dross and zinc ash - are essential raw materials for the zinc chemicals industry.

REGULATIONS

Standardisation is very important to fasteners. The German quality standard (DIN) is normally used to indicate the quality.

Some manufacturers prefer to meet higher individual quality standards than general standards. However, in general, they support the initiative to make ISO 9000 standards compulsory not only for EC manufacturers, but also for importers.

In the galvanising industry, the possibility of standardising hot dip galvanisation of fabricated products has been studied. A draft based on ISO 1461 has been made. After a period of comment this initiative will presumably lead to generally accepted standards.

OUTLOOK

The strong orientation of the sector towards the common market makes the general economic situation in the EC very influential on its production levels. The effect of the general economic situation on the secondary transformation of metals is magnified because the activity rates of the major client industries such as the construction and the automotive industries, depends heavily on the swings in the EC business cycle.

Cyclical influences and structural factors, such as increased competition from non-EC suppliers, are relevant to the future development of the industry. Therefore, the trend towards specialisation and high-quality products will continue. It will also generate a greater demand for more skilled labour.

The EC is currently in a recessive period and, likewise, so is the sector of secondary transformation of metals. In 1992, its production decreased for the second consecutive year. In 1993 the situation will deteriorate further; whereas for 1994, a slight recovery is foreseen. In the medium term the situation is expected to improve.

Constructional steelwork

NACE 314.1

The scale of the European constructional steelwork industry may be gauged from the total tonnage of steel used which amounted in 1992 to nearly 6.2 million tonnes (mt), making the EC one of the leading world consumers of constructional steel.
Output peaked in 1990 and had fallen by 12% by 1992. It is forecast to decline by some 7% more, bottoming out in 1993. This fall does not fully reflect the overall recession in the construction industry because structural steel has mitigated some of its effects by winning market share from concrete, particularly in the commercial buildings sector, in a number of the EC countries.
Within Europe, the major consumers of structural steelwork are West Germany (1.4 mt in 1992), Spain (1.01 mt), Italy (0.92 mt), the United Kingdom (0.781 mt) and the Netherlands (0.76 mt).

INDUSTRY PROFILE

Description of the sector

Constructional steelwork is the backbone of much of Europe's building industry. It provides the supporting framework for many of Europe's major structures - massive suspension bridges as well as more prosaic road and rail bridges, power stations and transmission towers, high rise office blocks, and countless industrial, commercial and agricultural buildings. These structures are mainly fabricated from hot and cold rolled steel sections and steel plate, supplied by steel producers throughout Europe.

The industrial building sector is the largest user of constructional steelwork, and in a number of countries industrial buildings account for more than half of constructional steelwork production. Other non-residential construction, which includes commercial buildings, is another important user of constructional steelwork, particularly in Italy, Spain, the United Kingdom and France. In agricultural buildings, the Netherlands is by far Europe's largest user of steelwork, followed by the United Kingdom, Italy, France and Belgium.

The use of constructional steelwork in bridges and similar structures used in road and rail networks varies considerably from country to country. The Netherlands appears to be Europe's largest market followed by the United Kingdom and France. An encouraging feature is that a number of countries have reported good prospects for constructional steelwork for bridges - a sector where it competes almost exclusively with concrete.

Available data on constructional steelwork exports suggest that the United Kingdom (65 000 tonnes [t] in 1992), France (50 000 t), Belgium (32 000 t) and Finland (25 000 t) are the largest exporters. However, other countries for which relevant statistics are not available, particularly Germany, Spain and Austria, are known to be significant exporters.

Recent trends

Austria

Constructional steelwork for buildings fell in 1991 and is expected to continue to decline at least until 1995. In 1993 the labour force will be reduced and some production is likely to move to cheaper wage countries, particularly in Eastern Europe.

In Austria the use of steel in buildings is heavily influenced by government contracts. Positive prospects exist in infrastructure investment, for example links to Eastern Europe.

In the private sector, the recession in office and other commercial buildings has been slower to reach Austria than other countries. Steel has only about 5% of the multi-storey market, however, compared with some 20% of the single-storey industrial, agricultural and commercial building market.

Belgium

Constructional steelwork in the Belgian-Luxembourg Economic Union (BLEU) peaked at 240 000 t in 1991, and a 5% decline in 1992 was the result of a 19% contraction in the demand for industrial buildings, which is by far the most important outlet for the constructional steelwork industry. A

(1) Estimate
(2) Forecast.
(3) Consumption.
Source: European Convention for Constructional Steelwork, 1993 Statistical Bulletin (Construction Forecasting and Research Ltd, 1993)

further fall is forecast for 1993 with some stabilisation in 1994.

More than 95% of production is accounted for by three sectors - industrial (79%), agricultural (11%) and commercial buildings (5%). In 1992 there was little change in the high level of activity reached previously in commercial and agricultural buildings but new agricultural building work is forecast to fall by more than 40% between 1991 and 1994 which is expected to reduce steelwork demand in this sector by a similar amount. Demand is also expected to fall in the industrial and commercial building sectors.

In 1991, steel had the largest market share, compared with competitive materials, in two sectors - industrial and agricultural buildings. An encouraging feature is that the amount of constructional steelwork used in industrial buildings was more than 40% higher in 1992 than 1986 due not only to a strong increase in demand for industrial buildings but also to steel's improved market share.

A beneficial trend for steel is also evident in the commercial building sector. Whereas in 1986 and 1987, the consumption of steelwork was essentially for shops, showrooms and garages, there has been a growing trend to use steel framed construction for office buildings, for which there has been a strong demand - particularly in the Brussels area. As a result, office buildings accounted in 1992 for 40-45% of commercial steelwork consumption.

In the agricultural building sector, steel consumption has increased considerably since 1986 because of the material's cost effectiveness and improved durability. However, the negative effects of the Common Agricultural Policy are expected to bring a sharp decline in the market in 1993 and 1994.

Croatia

Because of the war, data for 1992 are not available and a forecast for 1993 and 1994 cannot be provided. However, production of constructional steelwork, which peaked at 53 500 t in 1989, had fallen to 29 600 t in 1991, and informal sources suggest that production has since slumped more dramatically. One major manufacturer, for example, reports a decline in production to a mere fifth of pre-war annual production.

The basic prerequisite for normal development is the cessation of hostilities and political stability.

Denmark

The Danish steelwork industry currently has about 20% overcapacity, competition in the market is fierce and prices low.

Production of constructional steelwork peaked in 1990 and is expected to trough in 1993 before improving considerably in 1994.

The building sector is expected to be weak in 1993 and early 1994. Although industrial activity is unlikely to increase in 1993, better prospects in both the public and private sectors should result in higher steelwork production in 1994 and beyond.

The share of steelwork in single and multi-storey commercial buildings is only a few per cent. There has been little investment in agricultural buildings since 1987 because of uncertainty about future government requirements for environmental protection and the level of subsidies.

Finland

Steel's market share in new construction has grown since the early 1980s from 6-7% by volume to about 15%. An important factor in this success has been the even sharper drop in the real price of steel compared with the falls suffered by competing products.

In the peak years of 1989 and 1990 production stood at 150 000 t. By 1992, the figure was down to 95 000 t, and it is forecast to drop to 85 000 t in 1993 before recovering to 90 000 t in 1994.

Exports are of great importance to the Finnish structural steel industry. At the end of the 1980s they accounted for 30-40% of total production. This proportion fell rapidly to just over 20% in 1991 but is expected to climb back close to 40% in 1994.

An overheated construction industry produced an abundance of commercial and office space in the late 1980s and there is huge over-capacity. Until 1988, steel frames had a market share in this sector of less than 5% but it has stood at 15-20% ever since and today structural steel is widely used in commercial construction, especially large shopping centres.

Industrial construction, which is also currently in a trough, is the most important user of structural steel in Finland. Steel has a market share of 40% in this sector, compared with 20% in the early 1980s, and accounts for 35% of domestic consumption.

France

Structural steel production increased by 33% from 1987 to 1990 when it peaked at 750 000 t. It has since fallen for two successive years and is expected to decline further in 1993 and 1994. Despite the slowdown in economic activity in France's trading partners, exports have held up well, accounting for 50 000 t of the total constructional steelwork production of 610 000 t in 1992.

Preliminary statistical data suggest that production of constructional steelwork has continued to fall in 1993, largely due to the collapse of the market for industrial buildings which traditionally constitutes the main sector of activity for the industry. Between 1990 and 1993, production of constructional steelwork for use in industrial buildings and complexes will have fallen by more than a third.

A continued fall in production is forecast for 1994 despite a turnaround in construction output. Steelwork production in 1994 is expected to be more than 30% below the 1990 level, reflecting steep falls forecast for office and industrial building construction in the three years 1992 to 1994.

There has been a general increase in steel's market share, and this has helped to mitigate to some extent the decline in the overall market. Steel has a predominant market share in the industrial, warehouse and agricultural sectors, and between 1991 and 1992 it increased its market share in most of the eight sectors, mainly at the expense of concrete.

In the industrial sector, market shares were little changed compared with 1992. In warehouses, steel's share rose by 6%, in retail by 16%, in educational buildings (where steel's share is small) by 50%, in sport and cultural buildings by 37% and in a very weak offices market by 23%.

Steel's strong performance overall compared with concrete reflects the increased competitiveness of the material, and cost indices suggest that it is continuing to enjoy this advantage. The future appears bright.

Germany

The economic cycle in structural steel production has generally lagged behind the overall economic cycle by about 18 months. While employment and production generally have been reduced in many sectors during 1992, with a deteriorating trend towards the end of the year, the structural steel industry has shown growth in both eastern and western Germany, albeit not as high as in recent years. In the constructional steel market as a whole, western Germany accounted for 87% of production tonnage in 1992, almost unchanged from 1991.

Compared with most other European countries, Germany's structural steel industry - the largest in Europe - was still enjoying relatively buoyant conditions in 1992. The number of firms, the number of employees and turnover were all still rising. It should be noted, however, that the production total of 2.3 mt provided by the Federal Statistical Office, IFO, DSTV includes about 0.8 to 1 mt of steelwork used in "building elements" not generally considered part of the structural steelwork sector. However, reflecting the deteriorating economic conditions in Germany's trading partners, new export orders fell in both 1991 and 1992. Capacity utilisation also fell in both years.

Calculated on a different basis to exclude steelwork in building elements and other non-structural end uses, the total production in western Germany in 1992 is shown to be 1.41 mt. The downturn in economic activity that started in 1992 is forecast to continue in 1993 and to adversely affect structural steel production. Growth should continue in the new Länder but the impetus given to reconstruction by unification will be curtailed because of generally unfavourable economic developments.

After the monetary and economic union of Germany it was quickly realised that former East German industries made only a small contribution, less than 10%, towards total German production of good and services, and that even this contribution might decline further because of the unsatisfactory state of most industries. A completely different picture was presented by East Germany's structural steel industry. Its share in German production started at over 10%, rose to 13% in 1992 (more than 300 000 t), and is forecast to rise to around 315 000 t in 1993 with a further gain likely in 1994.

A study - Structural Steel 2000 - describes in detail the conditions in the market, which have changed dramatically as a result of unification, the single European market and the emergence of new countries in Eastern Europe. An immediate effect on the German market, with its open borders, has been cheap imports which are well below German costs - especially in the structural steel production sector where there is no opportunity to expand. The study comments that importers appear to have an unrealistic pricing policy and that quality standards seem to have been forgotten. The study shows that in framework and warehouse constructions, structural steel production can be increased and is suited to withstand competition.

Italy

Constructional steelwork consumption totalled 920 000 t in 1992, down from 1.2 mt in 1991. Forecasts of 801 000 t for 1993 and 790 000 t for 1994 may be over optimistic because the corruption scandals have resulted in a virtual standstill of work in the public sector, which accounts for about 50% of production.

For steelwork, the non-residential buildings sector (commercial, education, health and other public buildings) has been one of the most dynamic in recent years, particularly retail and office buildings. A substantial tonnage is also accountable to power transmission. In the near future, investment in buildings for industrial and agricultural uses is likely to be stable, while slow growth is expected in multi-storey office buildings. Envisaged investment in large-scale distribution and the development of hypermarkets and supermarkets suggests that the retail sector should experience sound growth.

In Italy - Europe's largest cement manufacturer and consumer - cement costs about 25% less than the European average, resulting in an unfavourable price differential between steel and concrete.

In addition, a wide difference between the price of steel at the steelworks and for building companies is a major hindrance to the further development of steel in the Italian building industry. Building companies have an unfavourable attitude towards steel and have the ability to condition end users in their choice of materials. Reinforced concrete has a 71% share of the total volume built. Steel's best showing is in the important industrial building sector, accounting for about half of total non-residential building, where steel has a 20% market share.

The Netherlands

Between 1985 and 1990, the value of structural steelwork production increased by more than 40% while the number of firms in the industry employing more than 20 people rose from 219 to 280.

In the Netherlands, the production of structural steelwork is dominated by what the Project Analyse Bureau calls "Other public" building. Since this sector includes steel for frames and building structures, much of the usage is likely to be in the industrial area (although "Industrial" building is quoted as a separate sector), particularly for distribution warehouses and similar structures. In 1992 other public building accounted for 261 000 t out of a total constructional steelwork production of 760 000 t.

Structural steel's market share in buildings with two storeys was little changed between 1988 and 1991 at 50% - well ahead of concrete's 30%. In buildings with more than two storeys, steel increased its market share in the period from 7% to 12%. Overall, steel increased its share of the multi-storey market from 17% to 26% over the three years.

Norway

Production of constructional steelwork in Norway in 1992 totalled 39 100 t - only slightly down on the 1991 figure of 40 200 t - and it is forecast to rise to 46 600 t in 1993 and 48 000 t in the following year.

The market share of fabricated steelwork in buildings in 1991 was about 23%, with precast concrete accounting for 33%, insitu concrete 26% and other materials 18%. Given the depth of the recession, the tonnage of steel used in buildings has held up well, implying a gain in market share.

Spain

The Spanish constructional steelwork market is among the largest in Europe. Production increased by almost 25% to a peak of 1.3 mt between 1988 and 1990, slightly ahead of the growth in the construction industry as a whole, but fell by 20% in the two years to 1992 to 1.0 mt. A further 15% fall is forecast in 1993, reversing the gains in market share made in the late 1980s, which results from the greater volatility of the sectors in which steelwork is most used.

An improvement in construction activity is forecast for 1994 but this is unlikely to have much effect on constructional steelwork production, since it is in new residential building that the increase in output will be concentrated. However, the price competitiveness of steel compared with other materials should help it to win back some of the market lost since the 1990 peak.

Around two thirds of constructional steelwork is used in the form of steel beams. The industrial sector accounts for more than 40% of total steel beam consumption in construction, followed by offices at around 20%, and "other" building (mostly refurbishment) and "other public" building at 10%.

Steel's market share is highest in towers (90%), industrial buildings (85%), and in the retail and power station sectors.

Compared with the United Kingdom market, Spanish constructional steelwork has a low penetration in several markets, in particular the important offices sector where its share is 30% as against near 60% in the United Kingdom. In a number of other smaller markets such as bridges, health, other public building and education, penetration in Spain also lags considerably behind the United Kingdom, showing that considerable potential exists to develop the market further.

Sweden

According to figures from the Swedish Institute of Steel Construction, the total domestic output of constructional steelwork in 1992 was 70 000 t. However, that figure is based on an annual survey covering approximately 70% of total production so that the true figure for Sweden as a whole is closer to 100 000 t. Output is forecast to fall by more than 10% in 1993.

The industrial sector is the most important market but since peaking in 1988 the production of steelwork for this sector has fallen by 43%. The fall in the commercial sector since its peak in 1989 has been more than 70%. The only sector to show a positive trend has been bridges which is now the second most important market for constructional steelwork in Sweden.

An improved outlook for industrial buildings in 1994 and a continued expansion in the civil engineering sector should result in the first increase in constructional steelwork production since 1989.

Constructional steelwork has about an 80% market share in the industrial buildings sector, so the very poor performance of industrial buildings investment in recent years has had a severe negative impact. A further fall of 14% is forecast for 1993 but the expected improvement in 1994 should bring a 5% increase in output.

Investment in commercial buildings has fallen by around 25% since 1990. A decline in 1992 was particularly marked in hotel and office building but activity in the retail sector was positive, which reduced the overall fall. A decline of 15% in office and retail construction is forecast for 1993 with a further 5% fall in 1994.

Steel has won a large market share in the commercial building sector, accounting for 50% of multi-storey office buildings (as much as 75-80% in certain regions such as Stockholm), and some 80% of single-storey buildings in the retail sector.

Switzerland

Registered orders fell in 1992 compared with the previous year, with overall tonnage down by 14% and value by 15%. These falls were not as severe as those recorded by the building and industrial construction sectors, suggesting that constructional steelwork increased its market share. Exports fell almost 80% and now account for only 3% of the total volume of orders.

The private sector remains by far the most important one for constructional steelwork despite a recent decline. Steel's share of the public sector is falling but remains high.

At the beginning of 1992, order books stretched to 4.7 months. During the year they fell progressively to stand at 3.9 months at the beginning of 1993. This situation has intensified competition and the pressure on prices, which have reached their lowest levels for 20 years.

The recession will probably persist for some time even though the bottom of the current cycle has probably been reached. However, recent falls in interest rates should lead to some improvement in the construction industry from 1994, and the reputation of constructional steelwork can only improve further. Rapid construction, low price and the possibility for recycling are positive factors which are relevant to the near future.

United Kingdom

With the hoped for recovery in the construction industry failing to materialise in 1992, United Kingdom production of constructional steelwork fell by 8%, largely as a result of a fall in commercial demand.

The industrial and commercial sectors, the two largest users of constructional steelwork accounting together for 80% of United Kingdom production, both experienced a poor year in 1992.

Even with a modest recovery in 1993, total constructional steelwork production may not exceed 875 000 t - about 60% of the 1989 peak level of 1.37 mt. Most of the upturn is expected to be for the industrial sector, with a further fall anticipated for steelwork to be used in the commercial sector.

Investment by manufacturing industry in new building and works fell by an estimated 20% in 1992 while steelwork pro-

duction for this sector fell by 6%, implying a gain in market share - a trend expected to continue in 1993 and 1994.

The glut in office floor space in South East England is a serious burden on the office construction sector because traditionally the region accounts for some 50% of offices built in England and Wales. Following an estimated decline of 39% in 1992, output is forecast to fall further in 1993 and 1994.

The floor area of multi-storey buildings completed in steel fell from 7.29 million square feet (677 160 m^2) in 1988 to 4.41 million square feet (409 640 m^2) in 1992. This was notwithstanding the fact that steel had increased its market share during that period to 56.9% and for office construction to more than 70%.

For the commercial sector as a whole, steelwork production is estimated to have fallen to 217 000 t in 1992 from 413 000 t in 1989. An anticipated recovery in leisure/other markets in 1993 is not expected to be sufficient to outweigh the continued decline in orders for office building.

In 1992, the industrial and commercial sectors accounted for 80% of United Kingdom constructional steelwork demand. The other 20% was accountable to agricultural buildings, bridges, power stations, towers and public (non-housing) buildings.

An increase in demand for agricultural steelwork is forecast for 1993 but this may revert to near 1992 levels in the following year. No great change in demand for steelwork for bridges is anticipated for the years immediately ahead but there is the promise of a high plateau of activity being reached in the mid 1990s.

Structural steel has built up a considerable cost advantage over some of the materials against which it competes, and in its most important sectors, industrial and commercial, it is forecast to gain market share. In 1993 steel production in industrial buildings is forecast to increase by 5.5% compared with a fall in the market of 5% and, in the commercial sector, steel production in 1993 is forecast to fall by 4.4% compared to a decline in the market of 18%.

ENVIRONMENT

Today it is recognised that all buildings have an impact on the environment, during their construction, during their life cycle, and again at the time of their demolition. Similarly, there is awareness of the fact that all building materials and components consume energy and create by-products.

A full life cycle analysis of energy and CO_2 levels for structural steel - from extraction of raw materials, production, manufacture, construction, maintenance, refurbishment or demolition, with the further option of recycling or production of a waste product - has yet to be completed: this complex subject is complicated further by such variables as building type, method of construction, and location.

However, steel has the environmental benefit of recyclability, with reclaimed steel that is recycled into products representing 40% of total worldwide steel production. The relative ease with which the steel frames of demolished buildings can be recovered for scrap is a big environmental plus.

Another environmental advantage of a steel structure is that the majority of the construction takes place away from the site, making it a much cleaner system than reinforced concrete, and with the additional benefit that timber is not wasted on shuttering.

A particularly important environmental and practical benefit of structural steel, and one that is increasingly recognised by developers, is its post-construction adaptability. This enables many steel framed buildings to be extended or refurbished that would otherwise be demolished.

REGULATIONS

A condensed version of Eurocode 3, entitled "Essentials of Eurocode 3 - Design Manual for Steel Structures in Building," has been published by the European Convention for Constructional Steelwork (ECCS). This is designed to be simple to apply and contains only those rules needed for the normal day-to-day design of steel structures. While providing simple rules for everyday design, it aims at the same time to the make the concepts of Eurocode 3 itself, which is needed for more advanced design, more accessible.

To provide a bridge between those two documents, ECCS has also produced two supplementary publications - "Worked Examples," which gives a number of typical designs, and "Design Aids," which contains a series of tabulated values for the design equations in EC3.

The importance of making EC3 as accessible as possible is seen as a fundamental part of encouraging designing in steel. Furthermore, the harmonisation of codes is expected to greatly increase the transfer of technology between countries where steel construction is advanced to those where it is not.

The new fire code, publication of which is expected in 1994, will be of particular interest. This will disseminate economic methods of fire protection including new methods of determining fire protection thickness.

There are various ECCS initiatives aimed at promoting the use of steel as a safe material in the fire situation and encouraging use of the Eurocodes to create safe steel structures cost effectively. One such initiative involves the production of a series of normograms covering the design of steel members in fire, based on the methods in the Eurocodes.

OUTLOOK

The constructional steelwork industry, having peaked in 1990, is expected to experience its third successive depressed year in 1993. The increased market share achieved in a number of countries and the keener price of structural steelwork compared with competing materials will be insufficient, in general, to offset the downturn in steel's two most important markets, industrial and commercial buildings.

Despite the forecast of a continuing fall in construction output, however, the United Kingdom - having been among the first into the recession - is expected to experience a modest recovery in steelwork production as market shares are improved at the expense of other materials.

The poor outlook in continental Europe reflects the overall economic situation and, particularly, the excess supply of industrial and office space that exists in many countries.

On current forecasts, 1994 is likely to be a mixed year for the industry. Germany, the largest steelwork producer in Europe, has been following a delayed cycle compared with most other countries since unification. A forecast fall in its production could more than offset increases in several other countries, notably the United Kingdom and Spain. Only when the industrial and commercial sectors improve, which is not anticipated until 1995, is steelwork production across Europe likely to exceed its 1990 peak.

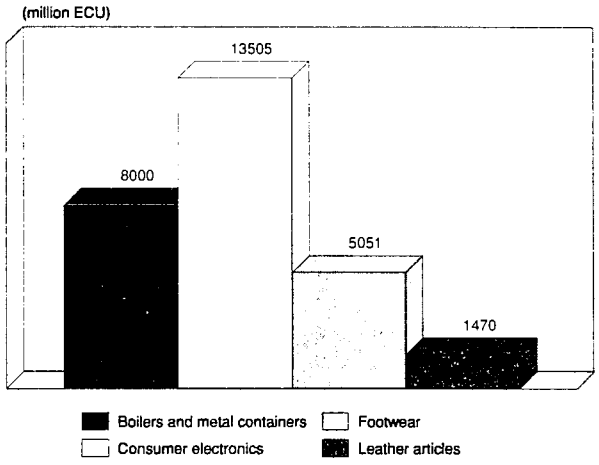
Boilers and metal containers

NACE 315

The EC boilermaking industry has a regional or national orientation rather than an international one. Nevertheless, the sector has to cope with increased international competition, both within and outside the EC. The boilermaking industry has a variety of client industries of which the energy sector and the chemical industry are the most significant ones. Cutbacks in investment in some of the client industries together with increased international competition caused the EC consumption and production of boilers and metal containers to stagnate, adversely impacting employment. The resulting overcapacity forced restructuring and diversification in the industry. If the sector is to remain strong in an increasingly competitive market, it needs to seek new outlets in rapidly growing industries and to update technical skills. In the short run production and consumption will stabilise; in the medium term a modest growth is expected.

Figure 1: Boilers and metal containers
Value added in comparison with other industries, 1992



Source: DEBA

INDUSTRY PROFILE

Description of the sector

Data for the boilermaking industry are classified under NACE 315. The products of this industry can be divided into the following categories: steam generators and boilers; nuclear boiler construction; fitting for steam generators and boilers; flat and nuclear heat exchangers and condensers for nuclear reactors; water tanks, containers and cisterns; distillation; refining and similar equipment; pipework; and miscellaneous activities, including installation and maintenance.

Since classifications differ within the EC, it is difficult to estimate the importance of the industry in each country.

Recent trends

Production in nominal terms increased by 1.2% in 1992. Consumption grew at a slower pace (0.5%). Regarding the small export rate (7.3% in 1992), EC demand largely determines production. Nevertheless, in 1992 the development of domestic demand and exports equally contributed to production growth. In volume however, production dropped in 1992 (2%). Employment in the EC boilers and metal containers industry was 2.5% lower in 1992 than in 1991.

Considering output, France is the largest EC producer of boilers and metal containers; Germany ranks second; in terms of value added the opposite is the case. Both in output and value added Germany and France accounted for two third of the total EC output in 1992. Italy and the United Kingdom accounted for some 20%.

EC production in current value grew at an average rate of 3.2% per year between 1983 and 1992. The growth was rather unevenly spread over this period; it was particularly large between 1988 to 1990 (9.5% per year), then it slowed down to around 1% in 1991 and 1992. In constant prices, production declined by 2.5% in 1991 and 1992, whereas over the period 1988-1990 an annual increase of 5% was recorded. Employment dropped on average by 1.2% per year.

Investments by EC producers fluctuated in the 1980s, with strong growth in 1987 and 1988. No data are available for more recent years, but the general view is that investment growth has declined.

Both French and German production (in constant prices) increased slowly (0.4% to 0.5% per year) from 1983-1992. In 1992, France recorded a significant production fall of 9%, whereas Germany's production increased by 11%. In the United Kingdom, production declined on average by 5% per year between 1983 and 1992, but it recovered slightly in 1992. Italy and Portugal's 1992 production level was in similar to that of 1983; the remaining Member States revealed positive growth rates over the same period. Employment declined in most Member States between 1983 and 1992. Only in Belgium, Denmark and Germany did it increase.

International comparison

The EC is by far the world's largest producer of boilers and metal containers. Its production level is three times that of the USA. Like in the EC, production in the USA is very much determined by domestic demand; in 1992, production (in current prices) was 12% lower than in 1983, which was particularly due to a considerable drop in 1990. Japanese production doubled during the period 1983-1992. However, in 1992 it was only a fraction (2% to 3%) of EC production.

Foreign trade

With export rates in the range of 7% to 9% of total production and an import penetration of 1.5% to 2%, foreign trade is of relatively minor importance for boilers and metal containers. This is also true if intra-EC trade is considered; including this trade, the export rate was 16% and import penetration 11%. These low proportions underline the rather limited geographical coverage of most of the enterprises in the sector.

The EC has always been a net exporter of boilers and metal containers. Regarding the declining export/import rate imports grew faster than exports. The trade surplus fluctuated over the years, but for the greater part it was around 1 billion ECU.

About two-thirds of the 1992 EC exports of boilers and metal containers were destined for the countries outside of the Triad, including newly industrialised countries (NICs) and less developed countries (LDCs). Within the remaining one third exported to the industrialised world, the EFTA countries are by far the major destination. In addition they increased their share in the total extra-EC exports from one fifth to one quarter. The very modest share of exports to Japan increased too, whereas the proportion of exports to the USA became declined. Regarding individual Member States, France has sold its specialised nuclear power station technology to industrialising countries, while Germany is meeting demand in Africa and the Middle East.

The industrialised world is the main of the non-EC imports. Its share of the EC market dropped from nearly 80% in 1987 to just over 60% in 1992. The EC market share of all countries exporting to the EC declined. For example, the share of the EFTA countries, by far the main origin of the non-EC imports, declined from 51% to 43%. Imports from East European countries have become considerably more important over the past five years: they jumped from 5% of total extra-EC imports in 1987 to 28% in 1992.

MARKET FORCES

Demand

The boilermaking industry supplies equipment to many branches of other industries. It produces a variety of capital investment goods for the following purposes (in decreasing order of importance): the production of thermal and nuclear power; the oil and gas industry; the chemical, petrochemical and pharmaceutical industries; the food and drink industry; the construction industry; the iron and steel and metalworking industries; the paper industry; and various other industries including automobiles, textiles, mechanical engineering, cement, rubber and electronics.

The importance of customer industries varies by Member States. In France, major downstream industries are the: energy (nuclear and conventional) industry, chemical industry, the food and drink industry, the building and construction industry, the and oil and gas; they account for 70% of the sector's output. Major client industries in Germany are the chemical, automotive, engine construction and energy industries. In the United Kingdom, the oil, energy, harbour and shipping, and iron and steel industries are primary outlets, while in Italy, the energy, automobile, harbour and shipping and ventilation industries are major clients. The market has been subject to significant changes, including shifts in the relative importance of the main clients. For instance, demand from the nuclear power industry collapsed due to sharp cutbacks in investments. New major outlets are the food and drink industry and the chemical industry.

Large cyclical and structural swings are significant features of the market for boilers and metal containers. Energy prices have a substantial impact on industry demand for boilers and in energy-saving equipment (heat exchangers), since they affect investment decisions. The relatively low oil prices since the end of 1985 were an important determinant of recent demand trends. Another significant factor influencing demand is the industry's sensitivity to the general economic development. Postponement of investments in downstream industries affects the position of the boilermaking industry. Enterprises specialising in large boilers for heavy industry, such as power stations, are particularly vulnerable to these swings.

Supply and competition

Increased competition in the export markets from emerging East Asian boilermaking firms and from Eastern Europe, together with declining investments in domestic markets and a

Source: DEBA

slow down of investments in developing and OPEC countries, affected the EC industry very badly. Estimated profitability (non-labour income in value added) declined significantly and overcapacity emerged, urging the manufacturers of heavy industry boilers to reconsider their activities. Companies try to become less dependent on their traditional clients, such as the heavy industry by switching to new, but related areas, such as civil engineering.

Production process

Unit labour costs (in current prices) rose at an average rate of 5.6% per year from 1983 and 1992. The growth of labour productivity (in current prices) was less; 4.7% per year. During the period 1989-1992, unit labour cost grew twice as fast as labour productivity: 7% versus 3.2% per year. As a result, the profitability of the industry has increasingly been put under pressure. This is the more so since labour productivity in constant prices (measured in value added) increased only at a rate of about 1% between 1989 and 1992.

Within the industry, system integrators are concentrating their activities on design, contracting and on-site installation. Much of the intermediate assembly work is contracted out to small local firms. The changing economic environment of the boilermaking industry - the need to improve productivity, for instance - increases the need for more skilled labour. Personnel training is a major concern.

INDUSTRY STRUCTURE

Companies

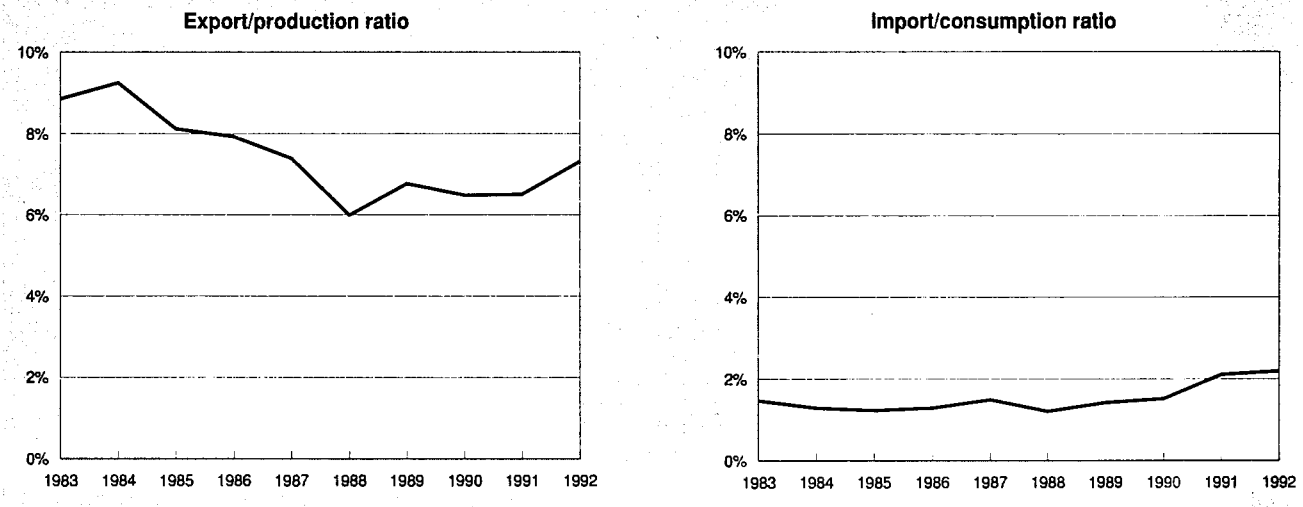
In the boilermaking industry three types of firms can be distinguished: system integrators; product specialists; and activity specialists.

System integrators are the smallest, but most powerful group. They are usually medium-sized firms or divisions of large diversified industrial groups installing systems. They focus on three activities: design and engineering, manufacturing and on-site installation. The principal feature of system integrators is the high value added content of their activities. Raw material input represents about 20% of turnover, whereas labour cost are about 45% due to large design and engineering departments with highly-qualified technical staff.

Product specialists supply equipment such as vessels, boilers and heat exchangers. Owing to the low unit costs of production they have a good international competitive position for specific products. The enterprises, however, tend to be domestically oriented. The firms are normally medium-sized enterprises. Raw material input represent over a third of total turnover. The value added content is less than for system integrators.

Activity specialists are firms which manufacture particularly specialised items, mostly from blueprint of the client. This is the most common type of firm within the boilermaking industry. They are sub-contractors of the system-integrators

Figure 8: Boilers and metal containers



Source: DEBA

and operate on a small scale. Their rather weak basis due to their specialisation hinders export activity.

Enterprises in this sector have regional or national rather than an international orientation. They can generally be found near the centres of heavy industry. the largest companies tend to be located in the countries which dominate the single market, although only one of the ten largest EC firms is located in Germany (Deutsche Babcock). In Germany, there are many medium sized enterprises. Babcock is a special case, however. If all activities of the enterprise in Germany, the United Kingdom and France are taken together, Babcock is the largest EC firm. Other large firms involved in the industry include CLN (I), Degrement (F), Sabroe Refrigeration (DK), Alsthom (F), Industria Cantieri Metallurgici (I), Dexion International (UK), which is a subsidiary of Interlake (USA), Ponticelli (F), Aalborg (DK), Cockerill Sambre (B) and Stork (NL). Both US and Japanese firms have subsidiaries in the United Kingdom.

Strategies

In this market, successful firms are mostly demand oriented, rather than innovative. The relatively weak development of demand, as well as the changing roles of the diverse outlets of the industry, has forced enterprises to reconsider their key activities. Many companies are attempting to lessen their dependence on the heavy industry as the main outlet.

Competition over labour costs forces the enterprises to turn to related areas of work: mechanical engineering, electricity and civil engineering. System integrators offer an ever wider range of maintenance services. Maintenance work is no longer lengthy and infrequent: the ageing of machines and the concern regarding the financial viability of the installations makes quick, frequent maintenance necessary. In areas which require a high level of skill, such as nuclear energy, firms are tending to broaden the scope of their services.

ENVIRONMENT

The boilermaking industry is involved with environmental problems in several ways. Because of the danger of leakage, tanks for underground storage of chemicals and oil products are of increasing concern; much research has been done in the field of corrosion containment and substitute raw materials for tanks. In the USA, about 90% of all new tanks for oil stocking are made of plastic. The discovery that metal tanks corrode not only from outside but from inside as well, stimulated the use of plastic tanks. Installation of underground plastic tanks is very different from metal tanks, and demands a completely different organisation of the work. For instance, the use of a special glue allows only a limited amount of time to connect the pipework.

The market for environmental products such as for cleaning industrial waste water or air pollution is becoming increasingly important. This creates opportunities for the boilermaking industry. Enterprises are likely to have a competitive edge in countries where environmental regulation is already very strict (e.g. Germany and the Netherlands).

REGULATIONS

Already in 1987, a directive on simple pressure vessels (87/404/EEC) was adopted. It relates to unfired vessels of a simple geometry which contain air or nitrogen. These vessels are mainly used as air receivers or braking cylinders. Simple pressure vessels have to fulfil several demands regarding safety in order to receive the CE marking. The directive does not apply to pressure vessels for nuclear installations, to pressure vessels for the propulsion of ships and aeroplanes or to fire extinguishers.

The recent liberalisation of the public procurement in power plant markets is expected to generate significant changes in electrical power equipment supplier firms. More generally, EC energy policy will have a major impact on the upstream industries of the energy sector. But harmonisation of the laws of Member States concerning pressure equipment is still required to establish an internal market for boilers. A proposal for a directive on this subject has been made.

OUTLOOK

To cope with increased competition from outside the Common Market, the EC industry will continue to diversify, and demand for higher and differently skilled labour force will increase. Training will be an important means through which firms can update technical skills. Furthermore, the changes that have been taking place in the industry structure are likely to continue. Firms will redefine their core activities and seek co-operation to survive in the competitive market. More engineering services are likely to be part of this.

Source: NEI

Regarding its low export share the sector depends largely on EC demand, which in turn is very much linked to swings in the business cycle. As a result of the current recession investments in some major client industries are not likely to pick up in the near future. This applies to the heavy and chemical industry, whereas in the short term prospects for the food and drink industry and the energy sector are neither moderate nor bright. The resulting stagnating demand for boilers and metal containers together with low growth and increased competition on the international market will entail a stable production in the short run. In the medium term the business cycle is expected to recover, which will stimulate demand for products of the boilermaking industry in general. Moreover new opportunities stemming from environmental concern in particular could stimulate demand for special boilers and heat exchangers in the medium term. During the period, 1993-1997 EC production and consumption of boilers and metal containers are expected to grow modestly.

Written by: Netherlands Economic Institute
The industry is represented at the EC level by: Comité Europeén de la Chaudronnerie et de la Tuyauterie (CECT). Address: Leicester House, 8 Leicester Street, London WC2H 7BN, United Kingdom; tel: (44 71) 437 0678; fax: (44 71) 734 2413.

Hand tools
NACE 316.11

Due to the general economic slowdown, the beginning of the 1990s recorded a decrease in average production of 3.3% per year in current prices. Due to increasing competition from outside the EC, demand was increasingly met by imports. Moreover, the export rate dropped and the EC turned from a net exporter into a net importer of hand tools.
EC manufacturers try to cope with increased competition by rationalising their production process and by changing their product-mix towards the production of high-quality products. For the short term, the outlook will remain rather dim; future prospects for the medium term are more positive.

INDUSTRY PROFILE

Description of the sector

The tools industry comprises four principal segments: hand tools, tools for joinery, fixing tools for construction and metal saws. The sector manufactures products including axes, screwdrivers, saws, files, rasps, pliers, shears, spanners, tools for drilling, taps and dies, hammers, planes, chisels, etc.

Although some hand tools can perform the same function as some power tools, they are different products, occupy different market segments and are subject to different regulations. Some hand tools more related to the industry are also treated under NACE 343.1.

Recent trends

Production in current prices declined by 3.7% in 1992. A drop in EC demand together with increased imports accounted for this decline; exports remained virtually unchanged. Imports exceeded exports slightly, continuing a slight trade deficit that began in 1991. International trade plays a major part in the EC hand tool market; 44% of the production is exported; 45% of the consumption is imported.

With a share of 43% in total EC production in 1992, Germany is by far the largest EC producer of hand tools. Other major producers are France and the United Kingdom. They each accounted for 20% of the EC production. Germany (with almost 40% of EC consumption), France and the United Kingdom are also the major consumer markets of hand tools.

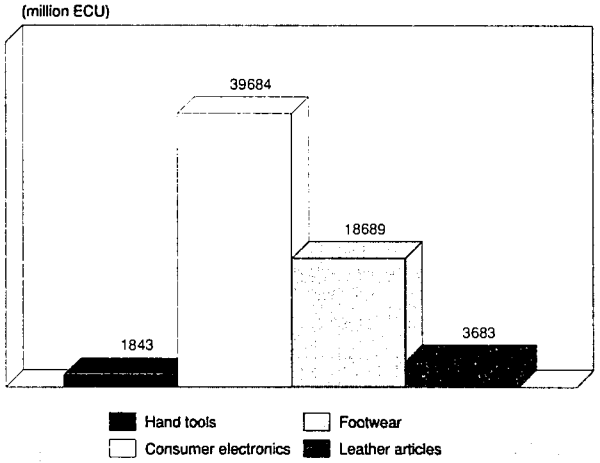
All the Member States except Belgium had lower 1992 production levels than in the previous year; in Belgium the production level remained stable between 1991 and 1992. Italy suffered the greatest production decline (13.2%), followed by France (6.3%); for the other Member States the reduction was 2.5% to 3%.

During the 1980s, production in current prices grew at an average rate of 5.5% to 6% per year. However, due to the general economic slowdown, the beginning of the 1990s recorded an average decline in production of 3.3% per year. As a result, production from 1983-1992 increased by 3.6% per year. Consumption grew at the faster pace of 6.2% per annum. Since demand was increasingly met by imports (45% in 1992 versus 33% in 1983), EC production did not fully benefit from the rise in EC demand. At the same time, the export share of production dropped from 50% in 1984 to 44% in 1992.

Practically all subsectors have to cope with weak demand. One of the more faster growing segments of the market was that of electric power tools. Major consumer countries were Germany (almost 45% of EC consumption), followed by France and Italy with shares of 15% and 11%, respectively in 1992. A fast growing segment is the market for replacement parts and accessories for power tools; growth will probably be generated in this subsector at the expense of the power tools themselves.

Screwdrivers, spanners (mostly used for home car repair) and wrenches are the most important sectors of the do-it-yourself (DIY) hand tool market. The spanner sector was by far the most important until the mid 1980s. It has since suffered a decline due to a reduction in sales of socket sets. The screwdriver sector has been adversely affected by rising sales of cordless drills, which double as cordless screwdrivers.

Figure 1: Hand tools
Production in comparison with other industries, 1992



Source: Eurostat, CEO

International comparison

The EC is the world leader in the production of hand tools. The rise of the penetration rate and the fall of the export rate, however, reflect increased competition, in particular from China and other East Asian countries and also from East European countries. These countries are especially competitive through pricing.

Foreign trade

With a penetration rate of 44% and an export rate of 45% in 1992, non-EC trade played a significant role in the EC hand tool market. Between 1983 and 1992, imports rose three times as fast as exports: 9.5% versus 3.1%, thus creating a negative trade balance in 1991.

In 1992, more than 38% of the EC exports of tools were destined for the EFTA countries and the USA; in 1987 this was 44%. The decline was particularly due to the increase in the EFTA countries' share of their own markets. Conversely, the remaining extra-EC trading partners of the EC became more important for exports; their collective shares rose from some 56% to 61%.

Remarkably, there was virtually no shift in the relative importance of the origins of EC imports. The EFTA countries ranked first, followed by Taiwan and the USA. These countries account together for around two thirds of EC imports of hand tools.

MARKET FORCES

Demand

Demand for hand tools for industrial use is linked to the general level of economic activity. Different factors are important in this respect. In the case of saws and tools for joinery machines and metal saws, demand depends almost entirely on investments made by downstream industries (furniture manufacturers, sawmills and mechanical engineering in general). Demand for tools for construction (including anchor bolts, masonry drills and power tools) is affected by the strength of the building and construction industry, which in turn depends on the general economic climate. The explosive growth of office automation equipment is also responsible for increased demand for high-quality hand tools used in repair work.

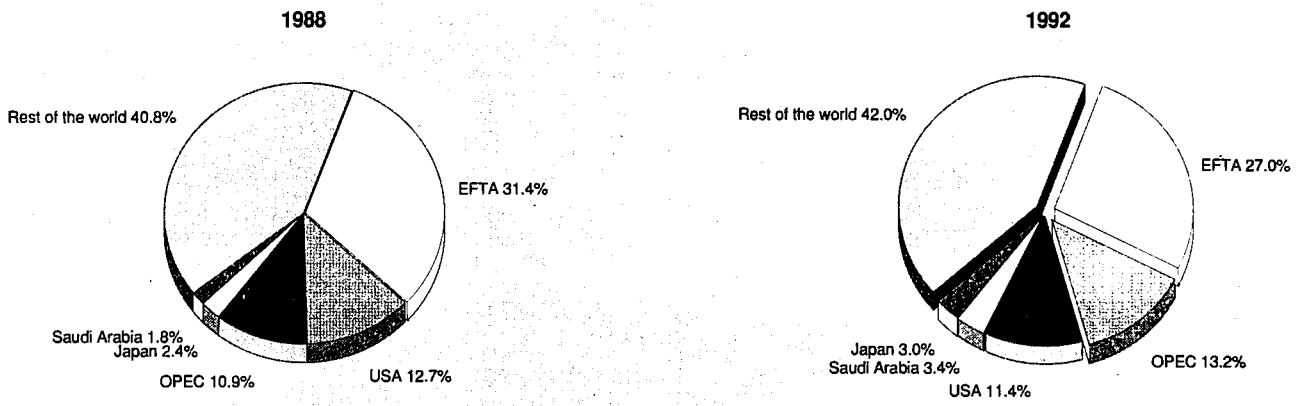
Tools for private use have, in general, a long economic life. When the economy is strong, these tools have a high price elasticity. However, declining disposable income is a strong factor in pushing demand towards the cheaper end of the product range.

The DIY sector boomed in the 1980s with rising home ownership levels. As people became more confident about tackling DIY jobs, they tended to buy higher quality tools. Manufacturers have introduced more advanced products, such as hardpoint saws, to the DIY market in response to this change in demand.

Supply and competition

Depending on the market size, the EC countries can be subdivided into three categories: 'leaders', 'developing' and 'small'. The leading countries, which are large and developed,

Figure 3: Hand tools
Destination of EC exports



Source: Eurostat

include Germany, the United Kingdom, France and Italy. They account together for some 70% of the EC market. Several intensively used distribution channels exist in these countries. They have a long tradition of tooling and DIY activities.

The second group consists of Ireland, Spain, Greece and Portugal. They accounted for an estimated 15% of the market. Modern distribution networks from the leader countries are establishing themselves here.

The small EC countries - Belgium, Denmark, Luxembourg and the Netherlands - hold the remaining 15% of the market. They have distribution channels comparable to those in the leading countries.

In the leading countries, some 50% to 60% of all sales of hand tools through the retail trade are accounted for by DIY superstores or multiples. These stores are characterised by wide product ranges, accessible presentation and competitive offers. Another 15% or so of sales go through independent DIY stores, while specialist hardware stores account for a further 18%. Tools for joinery machines and metal saws are partly distributed by retailers and partly sold directly to manufacturers of plant and machinery. In the last few years a stagnation in the DIY market has led to alterations in the distribution system. In France, the medium-sized stores (around 3000 m^2) are having difficulties. Due to a continuous flow of low priced products from East Asia and East Europe, competition has become particularly fierce in this market segment.

Production process

From 1983-1992, labour cost increased at an average rate of 5.5% per annum. The continuous rise in cost, together with a recessive market at the beginning of the 1990s, encouraged manufacturers to rationalise their production processes. At the same time growing supplies of cheap hand tools from East Asia and East Europe urged EC producers to change their product-mix, and to switch to manufacturing of products with a high value added content.

INDUSTRY STRUCTURE

Companies

In the EC, the bulk of the companies engaged in the production of hand tools is small. About two thirds of the firms have less than 20 employees. In the individual Member States, this share varies from 45% in France and Spain to 70% in Germany. Principal reasons for the abundance of small-sized companies are the low value added nature of the products, the wide diversity of the products and the small production runs per item. Moreover, many companies are family-owned, which can limit the acquisition of capital.

The few medium to large, sometimes internationally operating, firms account for the larger part of production. These include SandvikBahco (S), Stanley (UK/F), Rothenberger (D), Hilti (CH) and Facom (F). The Swedish manufacturers Sandvik-Bahco have several production facilities in the EC. This applies also to the US-based Stanley works. In the leading countries, major manufacturers often have a large market share. For instance, 50% of the UK DIY market for screwdrivers is supplied by Stanley and Draper (an importer/packager); 75% of the DIY market for hand drills is covered by Stanley, Draper and Record Ridgeway.

In power tools manufacturing, large enterprises include Bosch (D), Black & Decker (USA), Metabo (D), Peugeot (F), Makita (JPN), Andreas Stihl KG (D), Kango (UK), Hitachi (JPN), Hilti CH), Fein (D) and AEG (D).

Strategies

Fierce price competition due to the increasing volumes of cheaper imports urge many manufacturers to improve their productivity and to reconsider their product-mix. Lowering production costs and making a switch to quality products are prerequisites to remaining competitive. After-sales services are important, too. These qualities are particularly important in high-income countries like Germany. Further, quality and after-sales service are of greater importance in a booming economy than in a recessive one; in a recession, the customers tend to concentrate on price.

Manufacturers are looking for new markets. Eastern Europe can be such a market with large opportunities, provided the worst economic developments can be overcome in those countries. As an example, Stanley Works (USA) has set up a joint venture with the Polish company Fabryka Narzedi Kuznia near Krakow. This deal works in two ways. The new company will take over Kuznia's hand tools manufacturing capacity and make further investments in new equipment and facilities later on. In return, the deal will allow Stanley to manufacture Stanley branded products cheaply and sell them throughout Europe.

REGIONAL DISTRIBUTION

The sector has local, regional and global aspects. Manufacturers who are operating on a small scale and depend on the demand from downstream industries like mechanical engineering tend to be located in the area where these industries are concentrated. For instance, in Germany and Spain, manufacturers are contracted geographically. At the same time however, the big firms in the industry and those engaged in the production of DIY products have a global orientation.

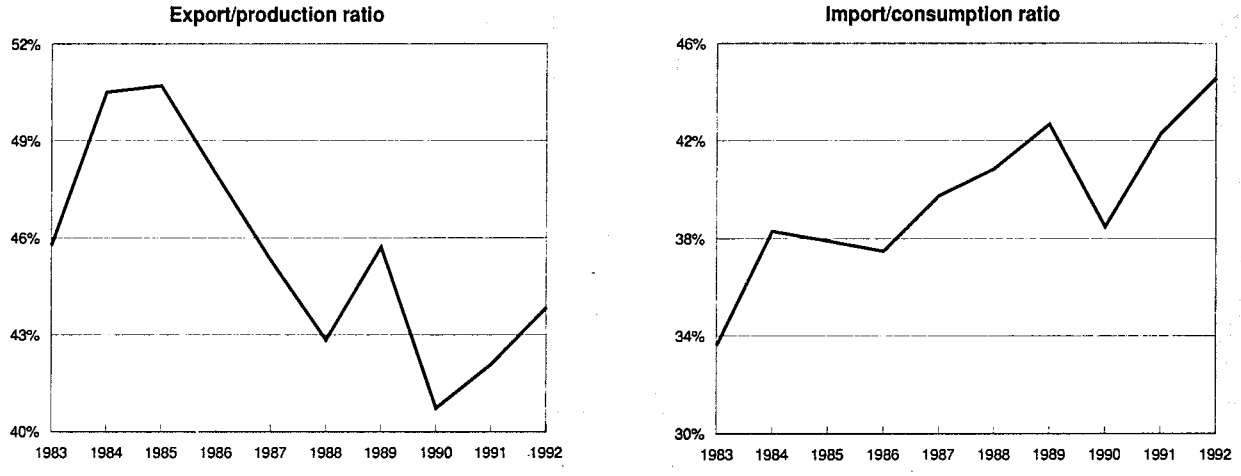
ENVIRONMENT

This subsector is not one of the major polluting branches of industry, so the remarks that can be made with respect to the environment are only general in nature. Regarding intra-EC competition, a coherent approach in ecological issues is mandatory. Otherwise, distortions in competitive power will arise. The EC has indeed become more active in this area (e.g., the carbon tax proposal, and the more general fifth action programme on the environment "Towards sustainability, A European Community programme of policy and action in relation to the Environment and sustainable development").

REGULATIONS

Two directives are of particular importance to the hand tools manufacturing sector: the Low Voltage Directive and the Machine Directive. The European norms have been adopted and published as part of the Directive on Low Voltage (adopted in 1973). With the adaptation of the Machine Directive in 1989, a certain overlap has arisen on the coverage of power tools by the two directives. Some confusion may arise as to the standards and certification procedures to be applied. Efforts are being undertaken by the European Commission, CEN and CENELEC to solve this transient problem.

Figure 5: Hand tools
Trade intensities



Source: CEO, Eurostat

OUTLOOK

Demand for hand tools is closely linked to the general level of economic activity. Due to the economic slowdown at the beginning of the 1990s, the industry was facing declining production and consumption levels. One of the main downstream industries, the building and construction sector, was severely hit by the recession. The recession also had an adverse impact on sales in the private market, although one can argue that poor economic conditions will encourage demand for DIY products as people will tend to renovate and make repairs themselves rather than employing a professional. At the same time, however, declining disposable income pushes demand for DIY products towards the cheaper end of the product range. Regarding the overall decline on retail sales, this negative impact of the recession on demand outweighed the positive one.

Besides cyclical factors, structural influences played a role in the deteriorated market for hand tools. In this respect, especially fierce competition from outside the EC is relevant. In order to enable the sector to maintain its position in the future, structural changes are required. More rationalisation to reduce cost is expected to take place, probably by way of takeovers, mergers and other forms of alliances. At the same time a switch to quality products is foreseen.

Short term prospects of the sector are dim due to the general economic situation. Hence, no quick recovery of the hand tool market is expected. This applies both to the industrial and the private market. Demand for hand tools in the professional market will not pick up soon, since the main client industries will continue to be depressed. In the private market, declining incomes will hit demand adversely.

Table 4: Hand tools

(%)	1993-94	1993-97
Apparent consumption	-2.5	1.5
Production	-2.0	1.5
Extra-EC exports	-1.0	1.0

Source: NEI

The economic outlook for the medium term is better. Regarding the industrial market, a recovery in the downstream industries is expected. At the same time, the structural measures (rationalisation and quality improvement) will have a favourable impact on demand. The economic recovery will bring about a rise in the private market demand, particularly for quality products.

Metal packaging
NACE 316.4

The metal packaging industry has enjoyed slow but regular growth over the course of the last few years. Substantial production cost savings and significant productivity increases have been achieved, principally due to technological advances. The sector as a whole is characterised by a high degree of competitiveness, given that a broad range of alternative processing and packaging options currently exist or are being developed. The impact of environmental regulations and recycling is particularly important in this sector.

Heavy metal packaging (NACE 316.41)

INDUSTRY PROFILE

Description of the sector

Categorised under NACE 316.41, heavy metal packaging, in contrast to light metal packaging, is packaging manufactured from cold-rolled sheet steel with a surface thickness equal to or greater than 0.5 mm and used in the fabrication of casks, cans and drums with a capacity of between 30 and 220 litres. They are used mainly for the transport of mineral oils, chemical products, paints/varnishes and food.

The most common packaging unit in this sector is the universally produced 210 litre (55 US gallon) steel drum with standard dimensions. The European steel industry consumes approximately one million tonnes of cold rolled steel per annum for the production of some 40 to 42 million new 210 litre steels drums. The annual value of turnover amounted to some 700 million ECU.

Recent trends

After a moderate growth of about 2%-3% per annum during 1991, a decline of similar percentages occurred during 1992 due to the overall recession and the competition of alternative packages such as intermediate bulk containers (IBCs). While the production of open head drums has remained relatively constant since 1990, tight head drum production has steadily decreased by approximately 14% since 1989.

New steel drums are all United Nations approved for the transports of both non-hazardous and hazardous products.

Steel drums, manufactured from only one type of raw material (i.e., cold -rolled steel) are either reused or reconditioned. At the end of their life-span, they are returned to the steel mills as scrap raw materials for new steel without causing any problem to the environment. So, steel drums are in a closed loop in the cradle to cradle concept of product life-cycles. Along with the new drum manufacturers, are the EC drum reconditioners who are active in reconditioning steel drums. They collect, clean, reshape and repaint the drums so that they can be reused again. At present, some 20 million drums are reconditioned every year in Europe.

Empty drums, because of freight rates, usually do not travel longer than distances of 300 to 400 kilometres. For decades, however, a vast amount of drums filled in Europe with many non-hazardous and hazardous products travel successfully all over the world.

Light metal packaging (NACE 316.42)

INDUSTRY PROFILE

Description of the sector

The term "light metal packaging" is applied to all metal packaging less than 0.49 mm thick and with a capacity below 40 litres.

The distinction between "light" and "heavy" metal packaging is by no means arbitrary: not only does it reflect the use of different raw materials as well as different manufacturing technologies, it also relates to entirely distinct consumer markets.

Within the light metal packaging sector, further distinctions apply to specific product groups:

- packaging for foodstuffs, particularly cans for food and beverages;

- various types of light multi-purpose packaging (called general line cans), notably removable-lid cans for paints and varnishes, oil cans, cans for cleaning agents, non-sealed cans for foodstuffs, decorative cans, aluminium dishes, and metal containers for specific industrial applications (e.g., electric battery cases);
- aerosol cans for use as containers for a mixture of gas and liquid, used primarily in the cosmetics, pharmaceutical and cleaning agents subsectors; and
- lids and caps, including crown corks and other types of metal closures (especially for glass bottles), and screw-on caps and lids.

Recent trends

The value of the light metal packaging sector is estimated at some 7.1 billion ECU. In 1992, the sector employed about 50 000 people in approximately 300 firms and used some 3.5 million tonnes of tinplate and 360 000 tonnes of aluminium. Net exports totalled about 340 million ECU in 1992 and apparent consumption reached 6.8 billion ECU.

Current estimates suggest that light metal packaging currently accounts for around 16% of the European packaging market as a whole, ranking it third in terms of packaging industry materials. By way of comparison, paper and board account for 30% of the packaging industry's current requirements, with plastic packaging accounting for a further 30%. The percentages for glass, heavy metal and wood are 7%, 4% and 4%, respectively.

A combination of sectoral restructuring and productivity-boosting measures has resulted in a steady fall in employment in this sector, which fell from 84 000 jobs in 1981 to around 50 000 in 1992. Productivity over the same reference period increased from 70 000 ECU per employee in 1980 (at constant 1985 values) to nearly 140 000 ECU in 1992.

From 1991 to 1992, changes in production by individual countries varied widely from country to country. Of the EC's major producers, Italy experienced increases in production (in terms of current prices) of 23% and 14%, respectively, while Germany, the United Kingdom and France had decreases of -5%, -3% and -0.6%, respectively. Greece had an increase of 23% from 1991 to 1992, however, its production represented 3% of total EC production in current prices in 1992.

Foreign trade

The metal packaging sector is not traditionally characterised by major long-distance international trade for technical and economical reasons. The EC is a net exporter in this sector. Imports, however, are growing at a faster rate than exports: the export/import ratio dropped from 7.1 in 1981 to 2.8 in 1992. Although imports currently represent a little less than 3% of market demand, they have grown significantly over the course of the last few years. Intra-EC trade is increasing substantially and amounted to more than 1 billion ECU in 1992.

MARKET FORCES

Demand

Although originally developed for food products, light metal packaging has developed an increasingly important role in everyday life, thanks to its unique properties compared with other forms of packaging. Food contained in metal packaging can be stored for long periods without any loss in nutritional value or any risk of corrosion or contamination. The primary advantage of this longevity is that products can be more readily transported and stored.

In recent years, economic growth within the sector has been relatively modest, ranging from 2% to 3% per year on average. In 1992, however, stagnation in apparent consumption and production has been observed, due to the poor overall economic situation which affected demand for several types of cans and to unfavourable summer weather conditions in most European countries. As a matter of fact, production figures of the two main types of cans (food cans and beverage cans) are significantly affected by weather conditions during the summer months, as these conditions have an important impact on the availability of vegetables and consumption of beverages. Most of the little structural growth in the metal packaging sector is attributable to developments in the canned foods industry and the emergence of new market segments in canned beverages and aerosols. As far as industrial packaging is concerned, the position is distinctly less positive; this is due to a difficult economic situation in certain consumer sectors (among them the construction industry) and to growing competition from the plastic packaging sector in terms of specific applications, notably motor oils and cleaning agents.

Overall, developments in the light metal packaging sector are strongly influenced by a number of external factors, such as:

- changes in individual consumer preferences and patterns (including a trend towards individual portion packaging in the food industry and more sophisticated methods of preservation) which have prompted an increase in demand for

packaging for sophisticated canned food, pre-cooked dishes and acrosols;

- stiffer competition from new types of packaging (such as compound plastics on impregnated board, ultra-lightweight glass and flexible packaging) and new preservation technology (e.g. deep-freezing or freeze-drying);
- psychological aversion to certain types of packaging and product presentation, particularly where long-life foodstuffs or beverages are concerned.

Production process

At present, light metal packaging production can be broken down as follows: 60% food packaging (of which around 83% is accounted for by foodstuffs and 17% by beverages); 30% multi-purpose packaging; and 10% metal closures and accessories.

Tinplate, blackplate and aluminium are the three principal raw materials used in the manufacture of light metal packaging.

Tinplate is cold-rolled steel sheet less than 0.5 mm thick and coated on both sides with a thin (3g/m2) film of tin. It is used principally in the light metal packaging industry. Some 95% of annual tinplate production (which is to say, approximately 11 million tonnes worldwide) is used by this sector. Among the various properties which make it especially useful for the light metal packaging industry are high mechanical strength, susceptibility to decoration (it accepts print readily), and the fact that a vast range of products can be packaged using this material - notably food and chemical and pharmaceutical products.

Blackplate, usually referred to as tin-free steel, is a steel substrate coated with a chrome oxide compound. Although the technical properties of blackplate are inferior to those of tinplate, it has been widely used in recent years to manufacture products to less exacting specifications. Typical examples include can bases and lids, bottle caps, and so on. The principal factor in its favour is that it is approximately 10% less expensive than tinplate.

Aluminium is the third most popular base material for light metal packaging. Currently, around 10% of world aluminium production is earmarked for the packaging sector. Major uses include dishes, small food cans for fish and meat, flexible tubing, can lids and beverage cans. Use of aluminium for light metal packaging varies significantly by region. Aluminium accounts for 95% of the can packaging for drinks market in the USA (with tinplate accounting for a modest 5%), about 40% in the United Kingdom but only 15% in Germany.

Changes in the relative cost of tinplate and aluminium largely dictate the use of these two materials in the metal packaging sector. While tinplate showed a relative stability of price over recent years, aluminium by contrast registered price increases and decreases of up to 50%, according to the short-time price trends of non-ferrous metals.

Over the long term, however, one can observe a slight move towards more frequent use of aluminium for some types of cans.

Packaging manufacturers, particularly in the foodstuffs subsector, rarely limit themselves to a single technology or to one single type of raw material. The leading groups worldwide each use a broad range of packaging materials.

INDUSTRY STRUCTURE

Companies

All EC Member States are involved in the light metal packaging sector to varying degrees. The three largest producers are the United Kingdom, Germany and France, which together account for almost 60% of total EC output, which currently equals two-thirds of US output.

The light metal packaging sector is relatively concentrated within the EC. Its structure is based on two categories of companies: large groups that manufacture predominantly standardised products and small to medium-size firms that specialise in customised products.

Standardised products (i.e., those mass-produced on highly-automated production lines) are manufactured by a small number of large companies in each country. This is particularly true with respect to standard-size food and beverage cans, caps and so on.

Several factors impact on concentration within the sector, not least of which is the capital investment implicit in large-scale production. A modern beverage can production line requires an initial outlay of up to 40 million ECU, so only major manufacturers have the requisite financial strength to make such investments. There is also the problem of access to advanced technologies. The trend towards mergers at the level of major industry clients such as food processing groups and brewers has also affected the structure of the light metal pack-

Source: SEFEL

aging sector. Finally, economies of scale implicit in mass-production are a factor in increased concentration.

Merger and acquisition activity, joint ventures and cooperation agreements between firms is becoming increasingly common. As a result, beverage can production, for example, is now largely concentrated in the hands of five European manufacturers. These manufacturers, which are also the five major industrial groups dominating the light metal packaging sector in Europe are the following: Pechiney (F), which is present in France, the United Kingdom, Belgium, Germany, Spain and Italy; Carnaud Metalbox (F-UK), present in France, the United Kingdom, Belgium, Germany, the Netherlands, Greece, Spain, Spain and Portugal; VIAG - Continental Can Europe (D), present in Belgium, Germany, France, the United Kingdom and the Netherlands; Crown Cork Cy (USA), present in Belgium, the United Kingdom, France, Italy, Germany, Spain and Portugal; and PLM (S), present in Germany, Denmark and France.
