Customised products are manufactured in smaller quantities and for more limited markets. Customisation frequently relates to the shape of the packaging (conical or irregular shapes), non-standard sizes (outsize or mini-capacity packages), or product-specific decorative effects. Typically, such customised packaging is produced by small or medium-size firms employing between 20 and 200 people. General-line cans, where product variety and limited volume requires optimal production flexibility, are manufactured principally by companies in this category.

REGIONAL DISTRIBUTION

The geographical spread of companies in the sector is largely determined by the nature of the products they manufacture.

Metal packaging offers the benefits of a comparatively low unit value (the sale price of a standard foodstuff or beverage can is currently around 0.1 ECU) combined with large volume. As the packaging requires significant space in transporting for small unit values, large-scale exporting or long-distance delivery is not very profitable. In practical terms, the maximum sales radius within which a firm can deliver its products on a competitive basis (i.e., taking account of transportation costs) is approximately 300 kilometres. It is for this reason that firms are so widely dispersed throughout every region of the EC. It is also for this reason that food can manufacturers are typically located in predominantly farming regions and general line can manufacturers in industrial areas. A wider market network is achieved as a result of the tendency for large multinational groups of manufacturers to buy up local producers and to rationalise their respective product ranges.

ENVIRONMENT

In volume terms, all types of packaging account for nearly one-third of the 100 million tonnes of waste generated by EC households.

However, metal packaging waste represents only a small part of it: by weight, all types of metal containers account for less than 2% of household waste with drink cans accounting for less than 0.5%. Nevertheless, environmental problems - together with the increasing pressure from certain substitute material - are the major challenge for the sector at present.

In recent years, the EC and most of the national governments have set up environmental policies which often focus on packaging waste. These policies typically have two aims: to increase the proportion of recyclable packaging by discouraging the sale of large quantities of non-returnable packaging; and to promote new forms of environment-friendly recycling.

These priorities have been underpinned by a series of rules and regulations, including an EC Directive dated June 27, 1985 on the packaging of food liquids.

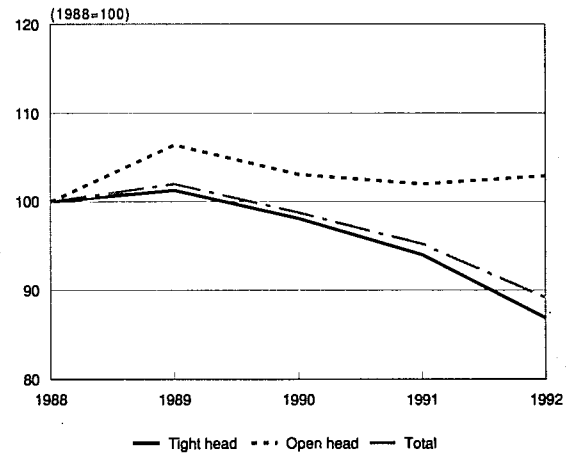
A proposed new Directive covering the packaging industry as a whole was approved by the European Commission on 15 July 1992 and forwarded to the EC Council of Ministers for final approval. This new measure aims at promoting substantial reductions in the total volume of packaging on the market and significantly speeding up requirements relating to the re-use and recycling of all types of packaging. In the long term, 90% of all packaging used in the EC marketplace will be required to be re-usable and/or recyclable.

In this respect, the metal packaging industry seems well placed to comply with future EC legislative requirements because it represents a packaging process which is ecologically sound and capable of reducing waste to a minimum. The advantages for the light metal packaging industry include: the raw materials used are in plentiful supply and will remain so for the foreseeable future; in the case of tinplate in particular, process, recycling and transport-related energy consumption is modest by comparison with other materials; and elimination of downstream consumer waste is relatively simple to achieve given that the packaging material can be selectively recovered and recycled without difficulty.

Steel substrate-based packaging has a salient advantage in that it can be separated and recovered by magnetic means. This also means that steel packaging materials can be recovered even from non-separated domestic waste or after incineration.

As a non-magnetic material, aluminium does not offer this advantage. On the other hand, its high residual value constitutes a major incentive to selective recovery and recycling, an op-

Figure 4: Heavy metal packaging
Development of the number of large drums



Source: SEFA

eration that requires only one-twentieth of the energy required for primary smelting. After recovery, both aluminium and steel are readily reprocessed by raw materials producers in smelters or furnaces to derive new products which exhibit no quality loss.

As far as metal packaging recovery provisions are concerned, certain EC Member States, such as Denmark, Belgium and Germany have already introduced comparatively stringent regulation.

In Denmark, refillable bottles are mandatory for domestic production of carbonated soft drinks, which means that there is an absolute ban on beverage cans.

In Germany, the Töpfer Packaging Ordinance makes distributors responsible for reuse and recycling of packaging outside the public waste disposal system. These obligations are waived for manufacturers and distributors taking part in a "Dual System" organisation which collects, sorts and passes on used sales packaging free of charge for recycling. All collection and sorting costs are financed through the use of an on-pack "Green Spot" symbol. Metal packaging manufacturers participate in this scheme. The ordinance also fixed some collection targets (e.g., 40% of tinplate and 30% of aluminium from January 1993, 80% of all materials from July 1995) and recycling rate targets (e.g., 65% for tinplate in 1993 and 90% in 1995).

In Belgium, an "Ecotax" (environmental tax on beverage containers) is to be introduced in 1994. Other countries have seen voluntary agreements negotiated at the level of public authorities, manufacturers and distributors. This is particularly the case in France ("Eco Emballage" system), and the Netherlands ("Covenant") etc.

As a matter of fact, almost every European country is presently introducing or preparing voluntary or mandatory national measures without any coordination, which may lead to certain difficulties once the EC directive is definitively approved and published.

The recovery rate of metal packaging waste in the EC member countries is already relatively high - around 20-30% on average - but it will show a substantial improvement with the imminent passage of the new EC Directive.

There are also grounds for optimism when one considers the situation in certain non-EC countries. In the USA, for example, more than 60% of beverage cans are now recovered and recycled. In order to improve the present recycling rates, 22 international mass-market manufacturing and user firms, including several producers of light metal packaging, have decided to pool their efforts within the framework of an umbrella group known as the European Recovery and Recycling Association (ERRA) to develop and promote ecologically-sound and commercially cost-effective solutions to the problem of waste processing.

OUTLOOK

A diverging pattern of demand in various user sectors combined with increased competitive pressures exerted by plastic packaging across a broad spectrum of applications will act as a brake on output over the coming years in the light metal packaging sector. Thus, the 1993 output is estimated at ECU 7.2 million, an increase of less than 1% compared to 1992; and output in 1994 and 1995 is predicted to increase again by 2-3% each year, provided the overall economic situation in Europe recovers.

Certain market subsectors will outperform others. The food can industry seems poised on the threshold of a growth period and there is no indication that conventional food cans will be substituted by another type of packaging in the medium term. The pet food sector is currently expanding at between 6% and 10% per year and exhibits solid prospects for the years ahead. The total market for all kinds of beverage cans is projected to increase by close to 20% between 1991 and 1995, with metal cans predicted to substantially increase their current 15% share of this market. Nevertheless, certain EC manufacturers have over-reacted to this potential demand and committed substantial investment which could, in turn, lead to an excess of production capacity in certain regions of the EC. Packaging for miscellaneous applications (such as paints and detergents) should, at best, maintain its current position.

In addition to these specific market developments, there will be significant progress in the course of the next few years in terms of product quality and production line yields. These forecasts are based on a variety of factors, including the development of new materials, the progressive ability to reduce the thickness and quantity of metal substrate as the quality of protective coatings improves, the use of laser welds, the rationalisation of production through the application of stricter standards, the introduction of more sophisticated printing techniques which enable packaging to play a more effective role in product promotion, and steady increases in productivity.

Overall, the tendency towards increased concentration noted in the metal packaging sector, both within the EC and worldwide, seems set to continue in the years ahead.

Overview
NACE 32

The mechanical engineering industry supplies almost exclusively capital goods or their components. Hence its development is effectively determined by the cyclical fluctuations in the propensity to invest. It receives additional positive momentum from progressive diffusion of the generation of computer-aided machines, a growing demand for environmental technology and an increasing service content in the products offered. The mechanical engineering industry in the European Community has so far been able to maintain its leading international position, although it is under heavy pressure from the Far East in the field of standard products. In addition, East European manufacturers are crowding on to the market with inexpensive machine components.

INDUSTRY PROFILE

Description of the sector

Mechanical engineering accounts for about 8% of the total EC industrial output.

The wide variety of products resulting from the task of supplying the means of production or their components to all sectors of the economy is typical of the industry. Its range of products extends from the smallest high-precision components such as needle bearings to complete production plants such as steel works and rolling mills. Conventional products such as lathes, excavators, cranes or circular knitting machines, and also robots or lasers for metalworking, lie between these two extremes.

With the integration of micro-electronics in mechanical engineering products and the resulting advance of the computer into production, the range of products provided by the machine manufacturers has undergone drastic changes: no longer the stand-alone machine, but the integrated machine system is now the focal point of the range, and at the same time the purchaser increasingly requires services such as advice, training, maintenance or special software. Product-related services currently already account for over one tenth of the turnover of machine manufacturers. The mechanical engineering industry has traditionally shown great willingness to solve the individual production problems of its customers. This usually necessitates abandonment of quantity production of standardised products and promotes a high degree of specialisation, which also offers good opportunities to small and medium-sized enterprises.

Recent trends

Mechanical engineering regularly experiences stronger cyclical fluctuations than most other industry groups. This is a consequence of its undue dependence on the investment activity of the undertakings, which is highly susceptible to overall economic trends and therefore displays greater movements than other demand units. This applies in particular to capital expenditure on machinery and equipment in industry, into which most mechanical engineering products flow directly or indirectly. This relationship is the key to the development of mechanical engineering in recent years.

An unusually strong investment boom additionally fuelled by pentup demand from the early eighties and the preparations of undertakings for "Europe '93" developed over the 1988-90 period in the EC. Demand for machines in the Community rose by 25% in real terms during the 1987-90 period. As this boom was part of a worldwide upturn which waned somewhat earlier, the machine manufacturers in the EC countries were presented with good sales opportunities in non-member countries in the same period. This sometimes led to bottlenecks in machine production. On the one hand, technical capacities could not be increased at the required pace despite great investment efforts, while on the other hand, manufacturers did not find skilled labour quickly enough.

The subsequent three years 1991 to 1993 were then marked by a persistent decline in investment in the EC. This compelled the mechanical engineering industry to make sharp cuts in production, so that a large proportion of the growth achieved during the preceding boom was lost. The branches supplying components suffered particularly severe set backs. The customers had built up large stocks of anti-friction bearings, gears, fluid units and precision tools during the preceding boom, because they feared bottlenecks in deliveries. These stocks were progressively reduced and demand therefore fell far be-

low installation requirements. In addition, the effect on the machine tool industry was above average, not only because it was inevitably at the centre of the downswing as a supplier to the capital goods industry, but also because it is affected by the worldwide fall in armaments production.

During the recession, machine manufacturers had to reduce their workforce drastically in line with the lower utilisation of capacity. In the course of these cuts, 160 000 jobs were lost in the mechanical engineering industry in the 1990-92 period. This figure does not yet include the high job losses in eastern Germany. The increases and falls in demand for machines during recent years have again confronted the mechanical engineering industry with the task of reacting extremely flexibly to cyclical fluctuations. There are indications that this is done particularly well by the smaller and medium-sized firms, which is also a reason why they predominate in the mechanical engineering industry.

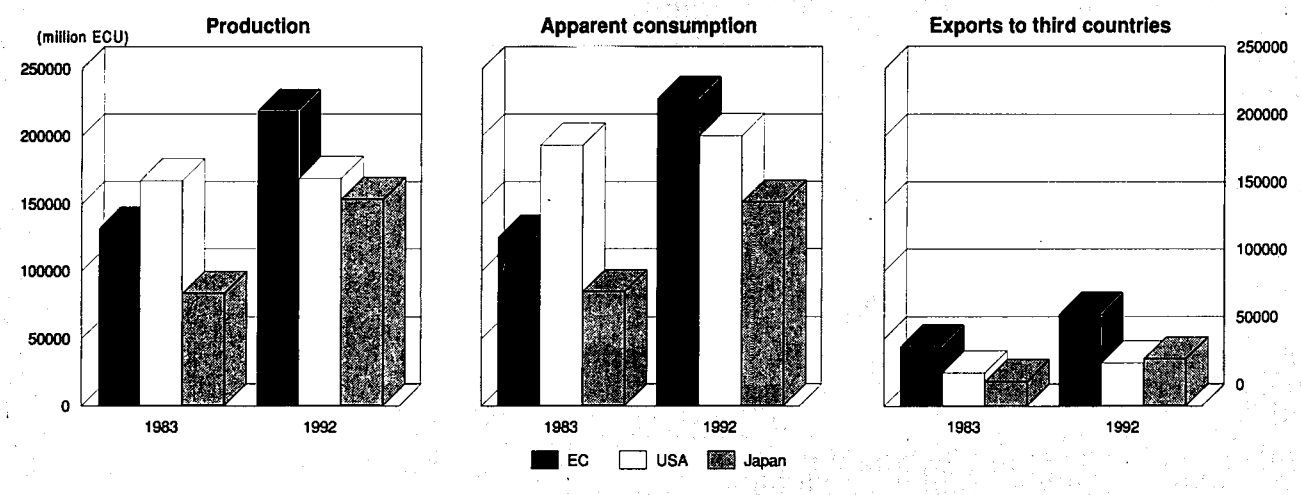
It is to be noted that production and apparent consumption's data's in table 1 (1992) differ slightly from last year's panorama edition due to previous forecasts.

International comparison

The EC is now the largest machine market in the world, having exceeded the market volume of the USA in the eighties. The Community is even more clearly the leader in machine production as, in contrast to the USA, it is a large net exporter. The latter consideration also applies to Japan, which has an output close behind the US one. Within the triad, the American industry fares rather badly because of the long-standing undervaluation of the US dollar.

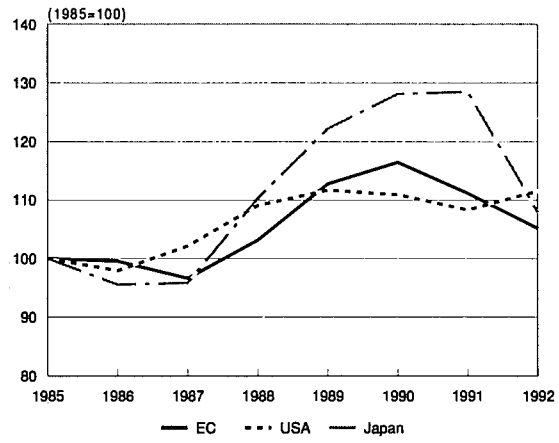
A glance at the real production trend reveals that the machine industry has survived the lack of investment better in the USA than in the EC and Japan: the USA merely sustained a small production deficit in 1991, whereas machine manufacturers in the EC recorded negative rates from 1991 to 1993. Japan had to cope with large production losses in 1992 and

Figure 4: Mechanical engineering
International comparison of main indicators in current prices



Source: DEBA, Census of Manufacturers, VDMA

Figure 5: Mechanical engineering international comparison of production in constant prices



Source: DEBA, Census of Manufacturers, VDMA

1993. The cumulative loss of production due to the recession is probably of a similar order of magnitude in the EC and Japan

Foreign trade

Although the EC countries still achieve a high surplus in machine trade with non-EC countries, this has stagnated in nominal terms since the mid-eighties, which even means a decline in real terms. Until 1990 this was essentially a result of the rapid growth in demand within the Community, which largely exhausted its own production capacities and drew in supplies from non-EC countries. In 1991 and 1992 the world-wide lack of investment then impeded exports, whereas imports initially still benefited from the surge in demand triggered by German unification. In the course of this trend the export/import-ratio compared to non-EC countries fell continuously until 1991. It rose again slightly only in 1993, because there was more demand for machines outside than within the EC.

In 1992 non-EC countries achieved a share of just under 18% in the supply of machines to the EC market, whereas this import ratio was 13% in 1983. The import share of the EC thus exceeds the 16% of the USA and the modest 5% of Japan. The EFTA countries are in the strongest position with a market share of 7%, whereas the USA holds just over 5% and Japan 3%. However, intra EC trade has also increased, i.e. the division of labour has made further progress. Intra-EC trade currently covers one third of the demand for machines in the Community, whereas the figure was only 26% in 1983.

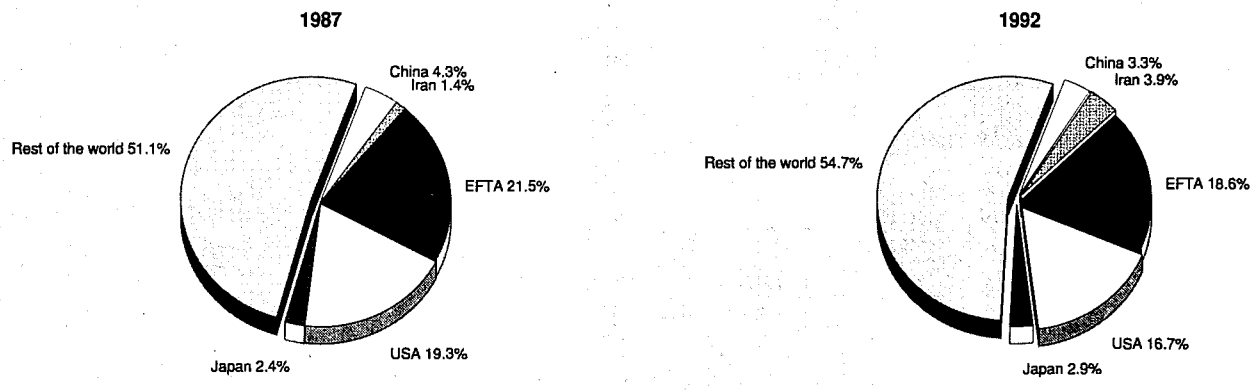
The EFTA countries together form the largest sales market for the extra-EC exports of the mechanical engineering industry, although their share has fallen slightly in recent years. By contrast the USA has again become more important, because its demand for machines has increased since 1992 (see figure 4). Despite high growth rates in the late eighties Japan continues to play a minor role as an export market.

Taken collectively, the developing countries have made up ground as customers for EC machines, thanks essentially to the sharp increase in exports to the Far East - with the exception of Japan. For several years this region has proved to be the most rapidly expanding machine market in the world, from which the machine manufacturers in the EC have also benefited. However, this must not disguise the fact that their position on this expanding market has so far been weak compared with their Japanese and US American competitors. In addition, there has recently been a positive trend in exports to Latin America, where the EC has traditionally enjoyed a better market position than in the Far East, although it is well behind the USA.

A scissor movement was observed in the export trend for the mechanical engineering industry up to 1991: whereas intra-EC exports rose faster than production, extra-EC exports lost a lot of ground. Consequently intra-EC trade, which was only just under 60% of the exports to non-member countries in 1983, almost matched these with about 90%. As this diverging trend was partly also due to different cyclical trends, this shift must not be interpreted simply as an integration success. However, extra-EC exports again rose faster in 1992, and even more so in 1993, because demand in the non-member countries expanded, whereas in the EC there was still a lack of investment. The extra-EC exports of EC machine manufacturers accounted for just over 31% of machine production in 1992 and again increased in 1993. This export ratio is markedly higher than that of Japan and the USA, which are 23% and 19% respectively.

The import of machines from non-member countries has meanwhile increased its share in the market supply of the EC to about 18%. This import ratio clearly exceeds that for the USA, which is about 15%, but is massively higher than that

Figure 6: Mechanical engineering Destination of EC exports



Source: Eurostat

for Japan where imports account for only a modest 5% share of market supplies.

MARKET FORCES

Demand

Well over half the products manufactured by the mechanical engineering industry are finished capital goods. The remainder consists predominantly of preliminary work for capital goods. This includes not only parts such as oil-hydraulic components, but under certain circumstances also an entire turbine installed as the propulsion unit in a ship, or an industrial furnace which becomes part of a cement works. Only a few preliminary products are incorporated in long-life consumer durables, e.g. an anti-friction bearing in a domestic washing machine. Finally, finished consumer durables are the unimportant exception, e.g. a domestic sewing machine, in the range of products of the mechanical engineering industry.

It is more difficult to quantify the dependence of the mechanical engineering industry on the demand from individual sectors of the economy than to describe these overall relationships, because only inadequate statistics are available. An estimate, which shows the following distribution for domestic sales of the industry, can be made for Germany on the basis of the input/output tables of the Federal Statistics Office and the investment calculation of the Ifo Institute for Economic Research: 72% of all mechanical engineering products are absorbed by processing industries, 7% by energy and water supply and the mining industry, 6% by agriculture and forestry and 5% by the building industry. The service sector accepts a total of 8% and the government 2%. As the preliminary work is highly interlinked, the mechanical engineering industry itself is its own largest customer within the processing industries and is followed by vehicle construction and the chemical and electrical engineering industries.

This pattern of dependence, which closely links mechanical engineering to the investment activity of industry, repeatedly imposes on the branch distinct cyclical fluctuations in demand. The industry's investment decisions are susceptible to changes that have already occurred or are anticipated in capacity utilisation, earnings, financing costs or in the general prevailing conditions. It is principally the capital expenditure on extensions which may increase markedly under favourable conditions but again contract sharply in the event of negative aspects.

In past boom years demand for machines in the EC already benefited from the fact that the companies in the Member States also invested on a greater scale in anticipation of the internal market. During the stagnation of investment over the 1991-93 period this factor was unimportant, because firms were largely restricted to capital expenditure on replacements in view of their high excess capacities. In the next upturn, which should occur after 1993, this situation will probably change again. The internal market will then again give additional momentum to companies' investment plans. The EFTA countries are passing through an economic cycle similar to that experienced by the EC. Here, too, investment activity slowed down throughout the 1991-93 period and the next upturn will probably start in 1994. Companies in these countries will also step up their investments with a view to the European Economic Area.

It is still difficult to estimate the sales opportunities in Eastern Europe. Investment activity is already brisk in the Czech Republic, Slovakia, Poland, Hungary and Slovene and will be intensified in future years. By contrast, all other East European countries are still affected by the structural crisis, to which no immediate end is in sight. Meanwhile demand for machines from this group of countries has fallen to such an extent, however, the positive trends will predominate in Eastern Europe.

Outside Europe, demand for machines has already developed favourably in 1993. EC machine manufacturers have thus been able to record an increasing number of orders from North and Latin America, Asia and Australia. In 1994, demand will continue to grow in these regions.

Supply and competition

The distinct investment cycles cause sharp fluctuations in employment in the machine industry. For example, capacity bottlenecks occurred in the boom of 1989 and 1990, whereas utilisation of capacity was poor between 1991 and 1993 and employees had to be laid off. If these extremes are disregarded, mechanical engineering production capacities in the EC roughly match sales opportunities. A special case is mechanical engineering in eastern Germany, which was unable to find alternative sales opportunities following the collapse of the former COMECON trade. Hence East German production capacities had to be greatly reduced. This retrenchment has now largely been completed, so that the still existing capacities

Figure 7: Mechanical engineering
Origin of EC imports

have a good chance of holding their own on the market when the next upturn comes.

Mechanical engineering in the EC is under continuous pressure on prices from Far Eastern suppliers, but recently also from Eastern Europe. The Czech Republic, which has a long mechanical engineering tradition, deserves special mention in this respect. In the EC it is principally the manufacturers of components who are under pressure, because many Western European Manufacturers of capital goods like to use the cheap supplies from Eastern Europe to improve their own competitiveness.

In the Far East it is chiefly Japanese competitors who achieve price advantages by large-scale production in the field of technologically demanding standard machines and components. However, these advantages have clearly been reduced by the strengthening yen. By contrast, manufacturers from Taiwan and South Korea are penetrating the markets with low prices in the field of simple products, although this has so far had a greater effect on other markets than in the EC.

Despite this pressure on prices EC machine manufacturers are able to hold their own in international competition. They benefit from the fact that the technology content, quality and additional services are usually more important decision-influencing criteria than the price for the purchaser of a machine. Hence the price elasticity of the demand for machines is lower than that for most other industrial products. However, machine manufacturers in the EC countries are stronger with regard to the other specified criteria.

Despite the keen international competition, producer's prices for machines generally increase at rates above the industrial average. The causes of this phenomenon are an above-average proportion of labour costs and a below-average productivity trend - both the result of highly customer-oriented production, which permits quantity production only in exceptional cases. The available profit figures show that the mechanical engineering industry usually achieves only relatively modest profits, which are also still subject to extreme fluctuations, despite its higher level of price increases.

Production process

The mechanical engineering industry is labour intensive, its labour costs in the EC being 30%. To perform its production task it requires not only a high proportion of engineers, but also a skilled workforce. Hence the availability of these skills is a general local condition for successful machine production. However, bottlenecks in the recruitment of personnel regularly occur in the upturn phases, because the labour market does not offer the required skilled workers as quickly as is desirable.

Supplies from within the industry predominate in the preliminary work purchased by the mechanical engineering industry, which accounts for almost 60% of the production value. Second place is occupied by purchases from the electrical engineering industry, which are on the increase with the advance of microelectronics. High-quality components are involved in both cases. Steel continues to be the most important starting material for the construction of machines, although it is largely purchased in further processed form (castings, steel reduction and structural steel products). No problems are encountered in the purchase of all this preliminary work, because efficient suppliers exist in the EC or worldwide purchase is possible.

The innovation process has clearly accelerated in the mechanical engineering industry in past years. Micro-electronic, which has given rise to a new generation of machines since the mid-seventies, acts as the important pacemaker here. It is characterised by the fact that production machines can be combined with conveyor systems, robots and testing machines to form computer-controlled systems, which not only achieve high output but also permit flexible adaptation to varying production tasks. Hence the use of these machines offers the investor important opportunities for modernisation. The diffusion of this technology is under way; it will support the demand for mechanical engineering products in future years. Mechanical engineering receives further momentum for innovation from the effective application of data systems technology or from production innovations within the industry. For example, computer-aided design (CAD) and computer-aided job preparation (PPS) have been realised in most firms; a feature of the actual production process is the use of flexible production cells. These technologies shorten the total transit time and also permit an even more flexible adaptation to individual customer requirements. With the increasing complexity of the machines produced the purchaser also requires more product-related services such as advice, training, software or maintenance. Hence the proportion of services in mechanical engineering turnover, which has already clearly exceeded 10%, is continuing to increase. These services are provided by the machine manufacturers predominantly under their own management, because high strategic importance is attached to them.

INDUSTRY STRUCTURE

Companies

In 1990, in the EC there were just under 120 000 companies in the mechanical engineering industry, although about 99 000 of them (82.4%) had fewer than 20 employees. Some 16 000 firms had at least 20 employees, which could be regarded as the lower limit in mechanical engineering for the industrial manufacture of complicated products. 96% of these companies employ fewer than 100 persons and 4% of them employed 100 or more persons.

This classification of company sizes shows that small and medium-sized companies are a feature of mechanical engineering. They are usually highly specialised and manufacture chiefly one-off products and small quantities, because the market segment served by them does not support large-scale production despite intensive export activity. By contrast the relatively small number of large firms is active chiefly in sectors where standard machines or components permit "large-scale economies" or the construction of complete large plants requires high labour and financial capacities.

In all concentration surveys mechanical engineering proves to be one of the least concentrated industrial groups. For example, the six largest companies accounted for a share in turnover of only 8.2%, the ten largest for 11.3% and the 25 largest for 18.7% in western Germany in 1990. It is also noteworthy here that these shares have continued to fall sharply in recent years.

Strategies

The decline in machine production from 1991 to 1993 reflects a lack of investment within the Community and in important nonmember countries but it is not the result of reduced competitiveness of EC manufacturers. This is also demonstrated by the fact that the Japanese mechanical engineering industry suffered a decline in production of the same order of magnitude. However, this general finding does not preclude the fact that the structural problems of individual firms also become apparent in economic troughs. The industry has endeavoured to overcome the recession by rigorous cost management, which also provides a favourable starting point for the next upturn. In addition many firms have stepped up their product innovation, because this is the most important cornerstone of competitiveness in mechanical engineering.

The majority of machine manufacturers expect the completion of the internal market to increase competition, but many also hope for improved sales opportunities. Most companies are planning additional strategic measures to enable them to hold their own in this situation. The expansion of EC-wide sales is clearly in the forefront, but increased innovation is also important in this connection. In addition a minority of them is aiming to achieve cooperation for a better opening up of the market.

The investment activity of the mechanical engineering industry depends heavily on the economic situation of the industrial group; its investment ratio ranges between 4 and 5%. The companies substantially increased their investments in the late eighties; the expansion of capacity was an important reason for investment in this phase. In the 1991-93 period, there was an undue emphasis on modernisation projects predominantly with the aim of curbing the increase in labour costs.

In addition to investments, expenditure on research and development forms the second pillar in the safeguarding of the future of the companies. This expenditure accounts for 2% of turnover in the EC mechanical engineering industry. Experience has shown that this ratio is also highly stable in the economic cycle.

REGIONAL DISTRIBUTION

There is no doubt that Germany is the centre of the EC mechanical engineering industry: in 1992 western Germany accounted for just over 50% of value creation in the Community. Eastern Germany, which is not yet included in the EC figures for statistical reasons, achieved about 5% of the western German value at the same time. The other major machine production countries are United Kingdom with an EC share of 15%, Italy with 13% and France with 10%, followed by a group of countries with shares of about 2 to 3%, which include Spain, the Netherlands, Belgium and Denmark. In all EC countries there are also main regional centres of machine production. In Germany these are Baden-Württemberg and North Rhine-Westphalia, in Italy Lombardy and Emilia-Romagna, in United Kingdom the South-East and Midlands regions, in France the Bassin Parisien and the Region Rhône-Alpes. This distribution shows that the mechanical engineering industry is always located in the industrial heartlands, because it has traditionally sought to be near its main customers.

ENVIRONMENT

The production of machines usually does not cause serious environmental pollution. The noise generated by metalworking was a problem in the past, but it has been greatly reduced by modern machine tools. Further pollution was caused by surface treatment processes such as hardening and electroplating, but these are now generally carried out on a commission basis by specialists outside the machine industry. On the whole the costs of environmental protection are low in the mechanical engineering industry.

On the other hand the mechanical engineering industry is one of the main suppliers of environmental technology. Only the building industry benefits more from investments in environmental protection. With the increasing environmental awareness, as well as with the harmonisation of EC regulations, there will be a growing demand for environmental technology. Consequently demand and also innovation will be stimulated in the mechanical engineering industry, and the high standard specified in the EC will finally also bring competitive advantages in exports to non-EC countries.

REGULATIONS

The EC Machine Directive ensures that machinery placed on the EC market measures up to uniform basic safety requirements. EC Member States'regulations, which were often wielded as non-tariff trade barriers, are being replaced by national regulations which comply with the Directive. By contrast, diverse special technical requirements, which demand additional know-how from producers, continue to exist in trade with non-EC countries. However, national export restrictions designed to prevent the supply of high technology or machines relevant to the armaments industry to specific countries often present greater problems to machine producers. Not only EC harmonisation is necessary in this case: simplification of administration is also required.

Except for Portugal and Greece all EC countries have a substantial surplus in machine trade with non-member countries. For many specialists even the EC market is too small to support an adequate production volume. The machine industry in the Community clearly benefits from free world trade.

OUTLOOK

The mechanical engineering industry in Western Europe is also expecting demand to stabilise in 1994 following a substantial increase in its orders from overseas during 1993. Machine manufacturers in the EC can thus anticipate an initial upturn in production in 1994. They then count on the cyclical upturn in investment to develop fully in 1995 and 1996. With this development machine production will again be set on a clear expansion course.

Table 7: Mechanical engineering

Source : VDMA

In the long-term trend, which eliminates the cyclical fluctuations, the mechanical engineering industry in the EC will remain a growth industry. The most important arguments in favour of this view are as follows: diffusion of the new generation of computer-aided machines is continuing and is contributing to stabilisation of demand; in addition the innovation potential of the mechanical engineering industry remains high thanks to microelectronics. Environmental protection requirements offer additional spheres of activity. The internal market and the "European Economic Area" will also provide industry with additional investment incentives in future years. In the longer term it can also be assumed that there will again be better sales opportunities in Eastern Europe, which will probably benefit the mechanical engineering industry in eastern Germany in particular. On the whole EC machine manufacturers will have good opportunities to assert their international competitiveness again. This is indicated, for example, by the patent statistics, which show that the EC is clearly ahead of Japan and the USA with regard to patents relevant to mechanical engineering.

Agricultural machinery
NACE 321

Reform of the Common Agricultural Policy (CAP), standstill of the GATT negotiations, the pace of the current trend is fast and unpredictable. European farmers who are faced with such momentous disruptions prefer to postpone their productive investments. this situation has aggravated a structural downtrend of the European markets generated by a saturation of the agricultural machinery fleet. This phenomenon can also be witnessed in other industrialised countries such as the USA, Canada, Australia or in the EFTA countries.
The growth potential represented by East European countries is as yet too uncertain for the European agricultural machinery industry to expect an improvement of the sector based on a solvent demand from these countries. The same applies to developing countries. The main outlet for the European agricultural machinery industry remains its internal market. The recent shocks which have upset the European Monetary System still add to the confusion.
In this context a further decrease in the EC production of agricultural machinery and its markets must be expected.

INDUSTRY PROFILE

Description of the sector

The diversity of animal and vegetable farm products as well as the different stages of processing ranging from simple cleaning to the preparation of marketable products in the vicinity of production sites have led the manufacturers of the farm machinery sector to cover a wide range of equipment totalling around 450 different types of machines manufactured in Europe alone.

The main machines produced are: agricultural and forestry tractors; motor cultivators, motor hoes and motor mowers; machines and implements for soil preparation and soil working; machines and implements for sowing, planting and distributing fertilizers; machines and implements for crop and root harvesting; machines and implements for crop protection or irrigation; machines and implements for cleaning, grading or treating farm products; dairy and cattle-breeding equipment; forestry machinery; transport equipment; storage equipment; lawnmowers; other agricultural and horticultural machines and implements.

The extreme diversity of the equipment offered enables a large number of small and medium-sized companies, which are often specialised in the manufacture of a single type of machine or a range of agricultural machines used in a specific agricultural area of production, to exist side by side with a small number of large multinational or international companies which essentially manufacture tractors and self-propelled harvesting machines.

The agricultural machinery sector in the EC is divided into two segments of similar size : tractors on one side and other agricultural and horticultural machines and implements on the other.

The sector of agricultural and horticultural machinery and tractors is one of the most important of the European mechanical engineering industry, representing about 6% of the total production.

Germany, with 36% of the total added value, is the largest producer of agricultural machinery in the EC, followed by Italy (19%), France (18%) and the United Kingdom (6%). The other countries represent approximately 20% of the total EC added value.

Recent trends

The situation of the sector has substantially deteriorated over the last decade. Over the 1983 and 1988 period production decreased by 1.9% annually in real terms. Since then the annual rate of decrease has reached 6.9% in volume with a notable aggravation in 1993.

Simultaneously the EC demand for agricultural machinery which had increased by 3% in value per annum during the 1983 and 1988 period, has been declining at an annual rate of 7.3% in volume since 1988, with a recently sharp downturn.

In addition to this depressed European market a decline in EC exports (-1.9% per annum in real terms 1992/1988) has been registered together with an increase in extra-EC imports (+0.9% per annum in real terms 1992/1988).

International comparison

The two major American manufacturers of agricultural machinery have recently introduced re deployment schemes or have resorted to temporary shutdowns whereby European production sites have been relocated in the USA in order to

profit from the exports incentive provided for by a weak USD. The effect of these different measures is beginning to show and should enable the North-American agricultural machinery industry to catch up with the delay accumulated over the years 1990-1992 (-8 % per annum in real terms).

Japan for its part is confronted with the problems affecting its agriculture which is heavily subsidised (more than 12 times the European average per hectare) and with the revaluation of the yen. The uncertainty over the outcome of the GATT negotiations has an adverse effect on the sales of agricultural machinery in this country (-8 % in real terms in 1992 against 1991).

Foreign trade

In 1993, EC companies have exported 22% of their production outside the EC. Total exports, including intra-EC trade, exceed 50% of the total production. Extra-EC exports which had dropped significantly throughout the 1981 and 1987 period, had registered a slight recovery until 1990 but have been deteriorating again notably in the recent years (-29% in volume between 1990 and 1993).

The major EC export markets are the United States (24%) and EFTA countries (20%). It is worth mentioning that Japan now absorbs almost 5% of extra-EC exports.

At the same time, imports have continued to increase annually by almost 3.6% in average in real terms during the 1983 and 1992 period. However, the EC remains a net exporter of agricultural machinery as extra-EC imports represent less than 50% of extra-EC exports. The share of the United States in extra-EC imports has increased from 32.2% in 1987 to 42% in 1992 to the disadvantage of the EFTA countries and Japan whose combined share still reached 52% of the total imports in 1987 but has decreased to 42% in 1992.

MARKET FORCES

Demand

Following the trough observed in 1986 and 1987 European demand for agricultural machinery had slightly recovered in 1988. Since then, a sharp and steady deterioration of the markets has been noted.

As farm income can only partly explain this collapse, a parallel must be drawn between the purchasing behaviour of European farmers and the general environment of the CAP (Common Agricultural Policy) reform which, in addition to the uncertainties it generates, leads many farmers to reconsider their habits in terms of production methods.

An event of such outstanding proportions can be viewed in two different ways : on one hand, the emphasis will be put on the danger of a weakening of competitiveness resulting from a drop in investments; on the other, there will be the temptation to take it as the harbinger of a trend towards the improvement of capital productivity in agriculture.

Irrespective of the angle under which this phenomenon is considered, the fact remains that it is occurring in an unfavourable environment generated by the difficult and lengthy negotiations over the settlement of the farm deal resulting from the Washington compromise compounded by the monetary problems arising from the floating of European currencies and the chronic undervaluation of the USD.

Markets, growth areas, production or distribution chains as well as the customers' behaviour are changing more rapidly than before.

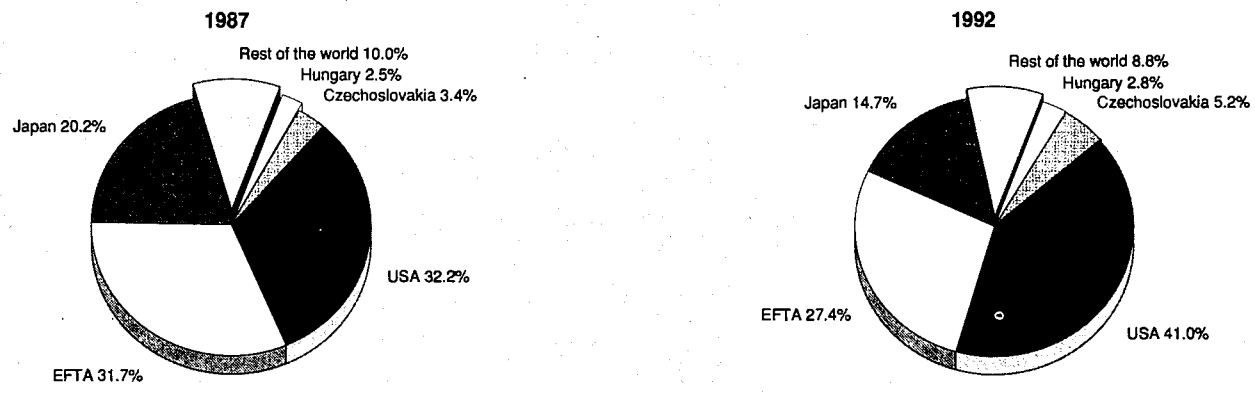
Supply and competition

Europe is the most important world market for farm products although it only represents 6 % of the world's population and 5 % of arable land.

The abundance of outlets as well as the gradual development of EC agriculture owing to the implementation of the CAP have enabled the EC agricultural machinery industry to accompany this development over the years, thus reaching the world's top echelon in the sector. However, it is to be noted that North-American companies' subsidiaries rank among the largest producers of the sector in the Community.

In direct proportion with a decreasing, demand productivity is shrinking every year (-13.5% between 1990 and 1992)

Figure 7: Agricultural machinery
Origin of EC imports



Source: Eurostat

whereas the sector is faced with an excess output capacity which burdens its profits.

Although it is obvious that crises have the virtue of exerting unmatchable pressure owing to the struggle for survival so that what seemed inconceivable yesterday appears possible today, it is however beyond doubt that this negative trend should continue over the next years.

Production process

For many years the European companies belonging to this industry's sector have been investing in robotics and in machining centres in order to optimise their production techniques and facilitate work. Most of them have already implemented the principles of the "just in time" and "stockless" production.

Computer-aided design (CAD) has been introduced in the largest firms, whereby the software is taking charge of the design of tools, forging bolsters and of programmes necessary to the manufacture of the different components of a machine.

In direct proportion with the above-mentioned, a rapid increase in internal investments in the order of 8 % per annum has been observed in the recent period.

Up to now however all these endeavours have only resulted in a 16 % decrease in the added value over the 1988 and 1992 whereas unit labour costs increased by 24 % over the same period.

Nevertheless the conditions for obtaining productivity gains do exist, as soon as a recovery occurs.

INDUSTRY STRUCTURE

Companies

As the companies belonging to this Industry's sector produce a wide range of machines (approximately 450 different machinery types) it is difficult to give an overall picture of the European farm machinery industry.

A large number of small and medium-sized companies (around 4 000) specialised in the manufacture of a machine type or a range of machines are present in the Community beside a few large multinational or international companies.

Most of these large companies produce tractors and self-propelled harvesting machines. The main European manufacturers of this category of machines are FIAT-Geotech (I) which in 1991 has taken over Ford-New Holland, a company established in Belgium and in the United Kingdom, SAME (I), Renault Agriculture (F), KHD and Fendt (D) and the German firm Claas producing combine harvesters and balers.

The large American companies are also established in Europe: Case International Harvester, John Deere and Massey Ferguson.

The activity of the large companies generate around 60% of the turnover in the profession. In order to fight the unavoidable fall of the markets these companies have been led to conclude cooperation or manufacturing agreements with some of their competitors on the world market such as Deere with Zetor-Brno or Massey Ferguson with Iseki (after AGCO, Landini, Steyr and Valmet) to quote the most recent.

When production processes within a group are planned at European level, it often implies exchanges "within the family". For instance, a German plant buys from a "sister" plant in France an intermediary product designed to be fitted into a German product which will be sold in Italy. Such a production circuit requires a minimum amount of precautions as far as cost price planning is concerned : just the opposite of what the current monetary fluctuations offer.

These uncertainties combined with a depressed market entail a certain disruption of the production process which has resulted in a 36% drop in employment figures between 1985 and 1993 and a decrease in the number of companies operating in this sector.

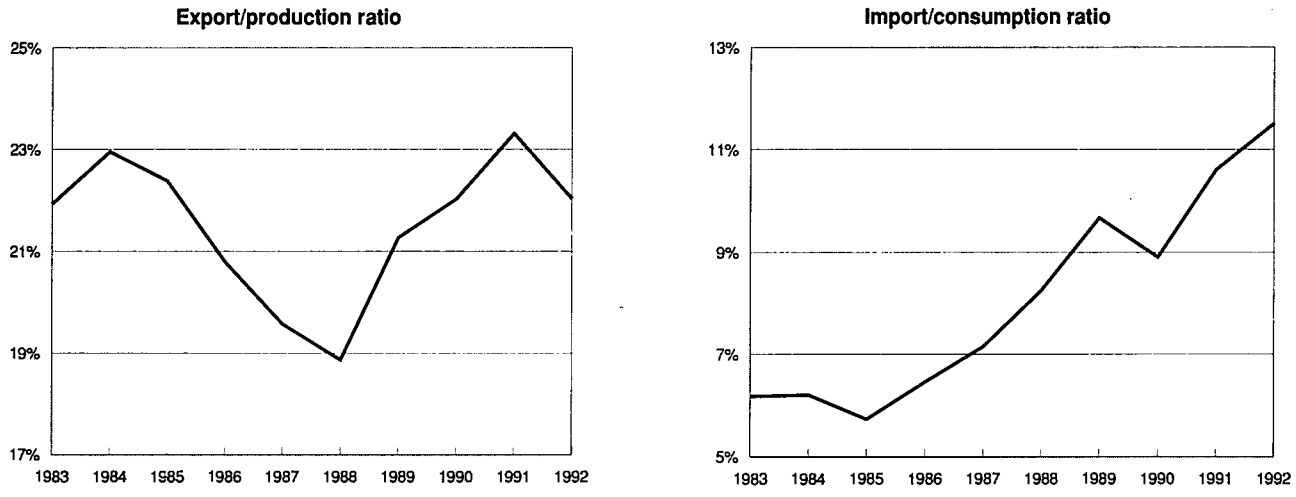
REGIONAL DISTRIBUTION

In 1992 the largest producer of agricultural machinery in the EC was Germany with 31% of the total EC production, followed by Italy (22%), France and the United Kingdom with approximately 15% each.

Germany is also the most important extra-EC exporting country with 42% of the total exports, followed by the United Kingdom (21%), Italy (15%) and France (9%).

In terms of intra-EC trade Germany's share represents 29%, followed by Italy (20%), France (14%) and the United Kingdom (12%).

Figure 8: Agricultural machinery
Trade intensities



Source: DEBA

REGULATIONS

The importance of standardisation in the agricultural machinery industry is always increasing. The implications at commercial level and therefore in the conception and design phases are becoming very real. This is to say that the time when standardisation was considered a side-issue belongs to the past.

This new orientation results from several factors :

- Liaisons (mechanical, hydraulic, electric, electronic couplings) between the tractor which remains the mostly used energy source and the machine are becoming more sophisticated. Their standardised characteristics must be observed if one wants to make tractors and driver machines interchangeable and compatible among them.
- Farmers always require more data on the performances of their machines. These performances must be determined through clearly defined methods, i.e. in standards.
- It is considered that agriculture is polluting the environment owing to the animals' production of organic dejections and the use of chemicals in treatments and fertilising. Construction standards which will enable farmers to measure precisely what they distribute are under current study and will be implemented in practice.
- The "New Approach" principle which has been introduced in Europe to implement EC Directives gives a particular importance to standards.

The importance of this issue has resulted in the abandonment of a strictly national standardisation in favour of a European or international standardisation.

The activity in this field can only increase in the coming years.

All types of agricultural machinery are subject to the Directive 89/392/EEC (modified in particular by the Directive 91/368/EEC which will be totally applied from 1995 onwards), which specifies the essential security and health measures to be respected.

Agricultural tractors are either subject to Directive 74/150/EEC (which deals with four-wheeled tractors with limited maximum speed) and several derived norms, or to the Directive 89/392/EEC.

Table 5: Agricultural machinery
Expected real annual growth rates

(%)	1993-94	1993-97
Apparent consumption	-5.2	-5.0
Production	-5.6	-5.7
Extra-EC exports	-2.6	-2.6

Source: CEMA

OUTLOOK

As the major outlet of the EC agricultural machinery sector remains for nearly 80% an Internal Market faced with a deep and apparently durable crisis and if the various shocks that the European agriculture (CAP reform, GATT negotiations) will endure are taken as an indicator, it would be unreasonable to expect anything else than the continuation of the 1987-1993 trends for the different markets.

The production of the EC sector and its apparent consumption should further decrease between 1993 and 1997, at an annual rate of 5.7% for the production and 5% for the consumption. Over the same period extra-EC exports would decrease by 2.6% per annum.

Machine tools
NACE 322

Generally investment goods suppliers face a strong cyclical demand. The machine tool industry that supplies above all machines to investment goods manufacturers enjoys and suffers even stronger booms and slumps.
Several factors that induced a strong demand for machine tools during the latter half of the past decade had gone. Among these were intense investment activities driven by the objectives to introduce new technologies, to prepare for the Single European market and to expand capacities.
These factors disappeared during the current recession and - worsened by a cyclical reaction to the former boom - the machine tool industry in most industrialised countries is hit by a severe recession.
An essential requirement for the EC-machine tool industry's success in this context lies in the economic policy. The Commission of the EC plays a key role in creating an adequate economic frame by reducing capital - and labour costs, as well as supporting a joint European initiative to improve the qualification of the personnel and to expand the efforts in research and development (R&D).
EC machine tool suppliers have a strong technological position in markets for special machinery and systems. However in standardised machines they have lost market shares to their Japanese competitors that have got a strategic price advantage derived from economies of scale and lower factor costs that currently are partly reduced thanks to the appreciation of the Yen against most other currencies.
In the tough competition of the standard machinery market the EC performance could only be improved if economies-of-scale will be increased by co-operations, by further automation of the manufacturing processes and through a reduction of costs.
Success in the standard machine tool markets is of great importance because of the inter-relations with other machine tool segments. Above all this concerns the use of common preliminary components, as controls, spindles etc. If they are manufactured in high numbers, production cost are lower to the benefit of standardised and tailor-made machines. Thus, further market losses of European standard machines suppliers provide a cost disadvantage for suppliers working in other segments and reduce their price competitiveness.
The deep recession is expected to come to an end in 1994 and a moderate recovery could take place. A forecasted macro-economic upswing in the medium term will induce a growing demand for machines, although a boom comparable with the latter half of the 1980s is not expected.

INDUSTRY PROFILE

Description of the sector

The industry provides machines for the processing of metal. Machine tools can be divided into two broad product groups. The first group, cutting machine tools, which accounts for about 70% of the supply, includes among its main products turning machines, milling machines, grinding machines, gear cutting machinery and machining centres. The second group, forming machines, comprises among its main products presses, bending machines and shearing machines.

Nonmechanical manufacturing processes have gained more importance during the 1980s. Especially the demand for electrical discharge manufacturing (EDM) and laser cutting grew stronger than total demand for machine tools.

The industry's supply not only consists of standalone machines. Automated production, using flexible manufacturing systems, flexible manufacturing cells (FMS/FMC) and transfer lines are also provided. They include controls, data processing equipment for the application of computer aided design (CAD), production planning systems (PPS) etc. Therefore, machine tool firms provide critical technology to manufacturing companies and play an important role for the efficiency of the production in a broad range of industries.

Recent trends

During the second half of the 1980s European machine tool companies enjoyed a strong growth of the domestic market. The major factors underlying this development were the supply of advanced production technology, the preparation of manufacturing companies for increased competition in the Single Market and the necessity to expand capacities in growing economies. Additionally the poor investment activities in the 1970s had led to an overaged capital stock that required replacement.

In the latter half of the 1980s all these driving factors merged together and demand for machine tools boomed. Within a couple of years the client industries' capital stock grew younger

and the increase of capacities enabled companies to meet growing demand.

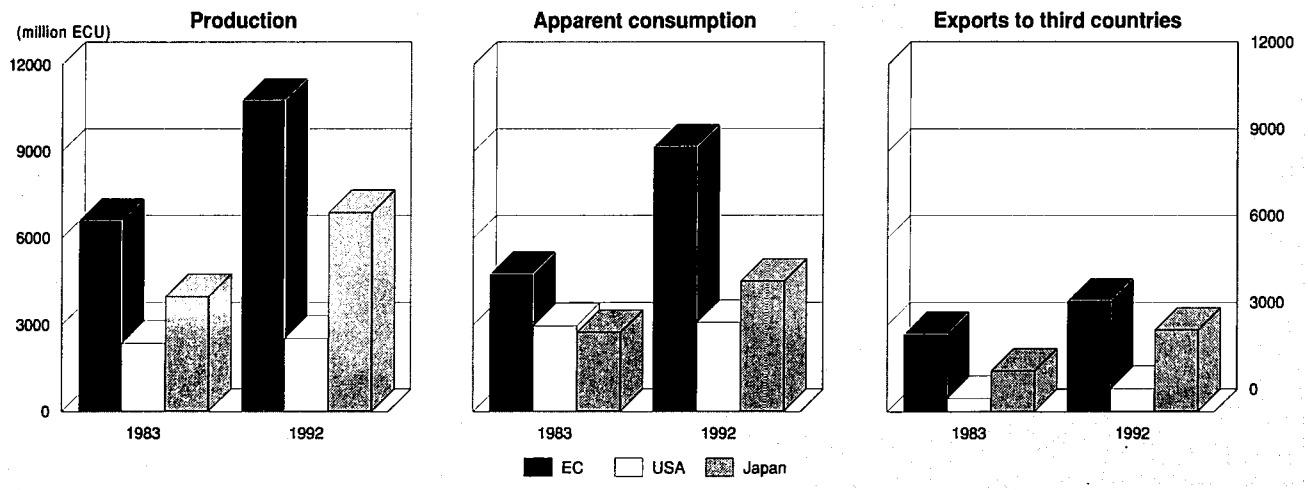
This development took place in nearly all European countries and pushed the demand for machine tools, which grew at a real compound annual growth rate of 7.1% from 1983 to 1988. Deliveries to other markets did not perform that well. The USA, the most important overseas market, went into recession, and total exports only grew by 2.6% over the same period.

In mid-1990, the situation for the EC machine tool industry started to deteriorate. Due to a domestic stimulus induced by the unification, Germany had been the only exception and went into the recession one year later on. The overall economic slowdown led to a reduced utilisation of machinery and equipment in the machine tool manufacturers' client industries. A decrease in profits forced a reduction of the investment budgets and the replacement of old machinery could be delayed because of the capital stock's renewal during the past years.

Generally speaking, since the beginning of the 1990s nearly all capital good suppliers have been facing a severe recession. This down swing took place in nearly all of the industrialised countries. The machine tool suppliers provding machinery and equipment above all for investment good industries have been in the centre of that development. Even the Japanese machine tool industry - most successful during the 1980s - was severely hit. In 1990 its production volume had reached an all time high, but shrunk until the end of 1992 by 30%. In comparison, the EC's and the US' machine tool industry shrunk by 23% and 20%, respectively.

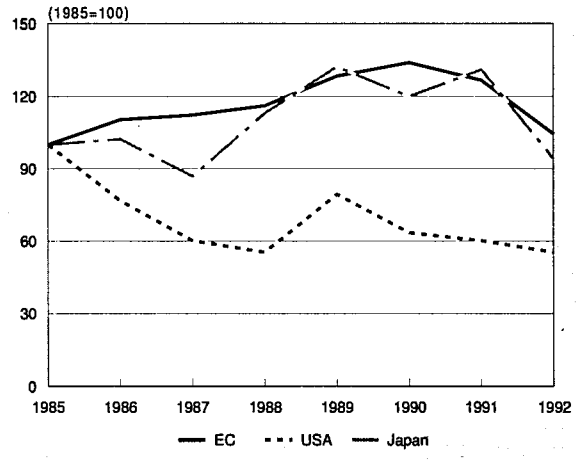
Currently, the United States have experienced a recovery, just gaining momentum. Within Europe only the United Kingdom has seen anything else than a substantial slump in the demand in 1993. The same is to say for East Europe. In the beginning there was optimism that the dissolution of the socialist economies would stimulate demand for machinery and equipment. But the expectations have not come true so far.

Figure 4: Machine tools
International comparison of main indicators in current prices



Source: CECIMO, American Machinist, Vieweg

Figure 5: Machine tools
International comparison of production in constant prices



Source: CECIMO, American Machinist, Vieweg

The EC deliveries of machine tools into the CIS shrunk by 40% between 1989 and 1992. The deliveries into the other countries of East Europe stagnate since 1989, except those to the former Czechoslovakia.

The current situation in the machine tool markets is marked by a worldwide slowdown in demand, with only a few exceptions to the rule. Orders from the Far East are increasing especially from the P.R. of China in 1992 and 1993, and to a lesser extent from the other newly industrialising economies. Growth had also been noticed in the Middle East in 1992 and in Mexico in 1992 and 1993. Since mid-1992 the orders from the United States have increased.

International comparison

The EC is by far the world's largest supplier of machine tools. Its share of worldwide production has increased from about 35% at the beginning of the 1980s up to about 40% in 1992. Second in this ranking is Japan with 25% in 1992 against 14% in 1980. The United States' machine tool industry declined sharply during the past decade and its share on the world production was only 9% in 1992 with better trends over the past two years. The differences in the countries' performance were mainly due to the development in the domestic market.

From 1983 to 1992 the Japanese production of machine tools grew at a compound annual rate of 6.3% stronger than the 5.6% of EC output. Japanese companies also enjoyed a much stronger growth stimulus from foreign than from domestic markets, whereas for EC companies it was quite the opposite.

Foreign trade

During the past decade, the extra-EC exports were much less dynamic than the domestic demand due to poor new order bookings for machine tools from non-European countries, especially the United States. At the beginning of the 1990s the demand from East Europe broke down and put a further damper on exports.

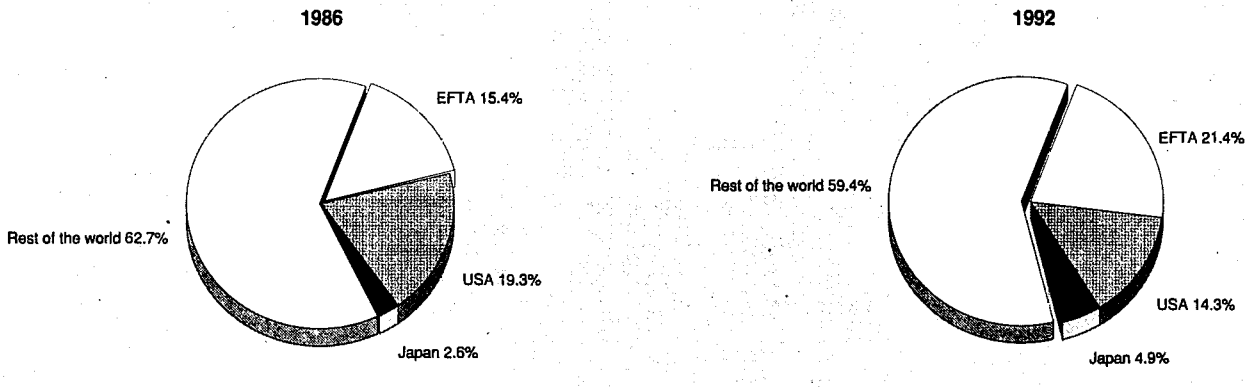
The demand for machine tools in the Far East, in Japan as well as in other countries, boomed during the second half of the 1980s. But the benefit of this development for EC-companies was not that important, because their market shares are lower than in other regions. For instance, the market volume for machine tools in the Far East is more than double as high than that of the NAFTA, but the EC's deliveries to both of these regions are on comparable levels, round about 20% of all EC-exports.

Dependency of EC machine tool industry on foreign demand decreased during the 1980s, partly due to the booming internal demand. In 1992 36% of production was delivered outside the Single European Market compared with about 40% at the beginning of the 1980s. On the other hand, the dependency on foreign supply grew. Currently about one quarter of the EC's apparent consumption is procured from abroad, compared to one fifth ten years ago.

The EC's trade balance with machine tools remained stable during the past decade. Nevertheless, the position of the EC in international trade worsened, because the companies were not able to improve their position abroad as their foreign competitors increased their market shares in the Single European Market.

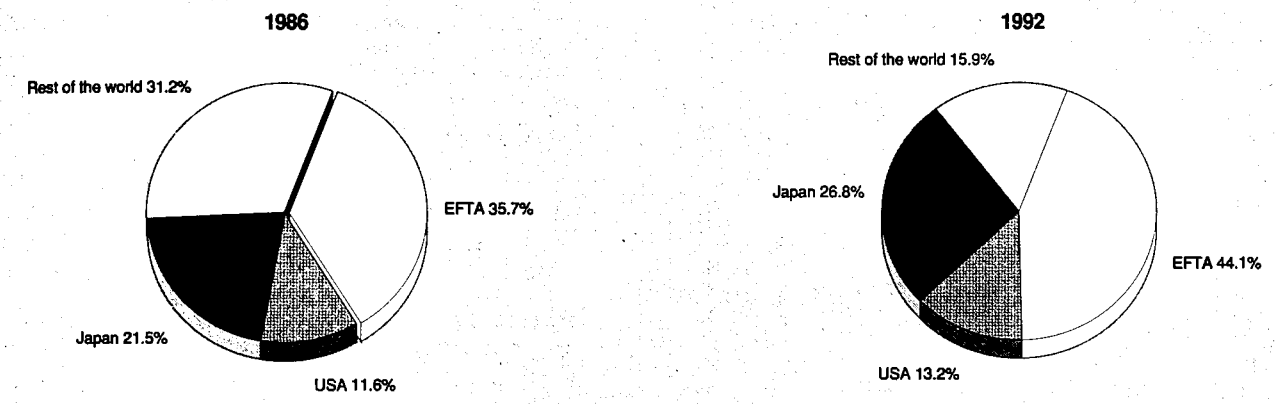
EFTA is the most important origin of machine tools imported into the EC. This is mainly due to the strong position of Switzerland in international markets, a country, whose companies export about 85% of their production and they were able to increase their share on total EC-imports.

Figure 6: Machine tools
Destination of EC exports



Source: CECIMO, Vieweg

Figure 7: Machine tools
Trade Intensities



Source: CECIMO, Vieweg

The next major exporter of machine tools to the EC is Japan. Both countries were able to increase their shares on total EC imports. On the contrary, since 1986 US producers have lost their former importance in the European market.

Japanese companies changed their strategies to penetrate the EC-market during the 1980s. Until 1984 they expanded their shares through imports, but since then this share on the EC-market has remained stable. In the latter half of that decade Japanese suppliers strengthened their position through inward investment. For two years one observes cases of de-investment and postponements of planned activities because Japanese suppliers have also been severely hit by the recession.

Since 1986, US manufacturers have lost their former importance in the European market.

MARKET FORCES

Demand

The EC accounts for 37% of the world machine tool consumption. As in production, the EC is leading in demand. Japan and the United States are second and third respectively.

The industry supplies capital goods above all to the manufacturing industries. Most important is the mechanical engineering industry with a share of one third of total EC demand. Second is the automotive industry and third the electrical products industry, with shares of one quarter and one tenth respectively. The aerospace sector is above all important by the demand for advanced technology.

At the end of the 1980s, the deliveries of machine tools to the automotive industry were particularly strong. This development resulted from a growing demand for vehicles and from strategic investments by European car producers to meet the challenges of the Single European market. Currently, the machine tool suppliers are strongly affected by a slump in the demand from this industry as a reaction on the recession in the automotive market.

Supply and competition

The description of the machine tool market requires at least a distinction between two segments with totally different environments. In the past decade the market for standardised machinery has evolved to a volume market with global players. Japanese companies are in the lead, where the price has become a key factor for purchase decisions.

(1) Vieweg estimates
Source: CECIMO, Vieweg

In this market European companies have difficulties to withstand the tough competition and recorded losses during the current recession. For instance, leading suppliers in the milling and machining centres market had to cut equity and mergers will be necessary to survive.

Because of high investments in production facilities there is excess capacity in some market segments for standardised machines. Even if demand grows strongly, the utilisation of the facilities will stay low for many years. This is mainly due to Japanese investment in Japan, but also in the United States and Europe.

In the volume market European companies face a strategical disadvantage. Their abilities to exploit economies of scale are lower compared to the Japanese and the ongoing price competition caused by the excess capacity poses a threat on them.

In the markets for special or tailormade machinery and production systems European companies maintain a strong position. Because of an increasing level of automation in client industries, which requires a specialised supply of manufacturing processes, software and engineering, these markets grow in importance.

European, especially German, Italian and Swiss strength is built on know how and highly qualified personnel. A specialisation of Japanese machine tool industry on standardised products and of European suppliers in special machinery and systems could evolve in the future. These specialisations can be a danger for European manufacturers, because many specialised machines require key standard components for which some of them must be manufactured in high numbers to reduce costs. Therefore, a further loss in the standard machine markets would make European machine tools more expensive.

Because of the appreciation of the Yen against all other European currencies currently Japanese wages per year are higher than European. However, due to longer working hours the labour costs per time unit are markedly lower. In comparison with Germany Japanese workers offer 40% more hours per year, inducing 30% lower labour costs per hour (1991: ECU 14.5).

Furthermore the dual economy allows Japanese machine tool manufacturers to procure components at extremely low prices. These goods come from subcontractors that only pay minimum wages and require even longer working hours and do not meet usual regulations for the workers' security.

Calculated on a yearly base the labour productivity of the big Japanese companies is higher than the productivity of their European counterparts by roughly 100%. About 40% is due to longer working hours. 20 to 30% are caused by the dual economy providing enormous advantages to the big machine tool manufacturers. The reminder is induced by different factors, as economies-of-scale, standardised products and to a lesser extent organisational advantages.

In addition Japanese machine tool manufacturers derive advantages from an excellent supply of advanced controls. Mainly they are delivered by Fanuc (JPN), the world's leader in numerical controls (NC) with a market share of 50% and by Mitsubishi. Others are of minor importance. Few machine tool companies manufacture their own controls. Especially standard machine manufacturers procure complete packages containing all electric and electronic components and thus enjoy a price advantages.

Production process

The technological progress in electrical drives and controls induced a substitution of mechanical components as gears and transmission units by electrical components. The new components are no longer produced inhouse but generally procured from specialised suppliers. The value added share of total turnover had been decreased.

The procurement of electrical and electronic devices is most advanced in Japan. Although some large machine tool manufacturers prefer the inhouse production of these components many others procure complete packages which reduce the engineering requirements. In contrast, most European companies prefer the procurement of components to their own design and adapt them to their needs. This process causes high costs in research and development (R&D).

European companies lead in research and development and the expenses as a percentage of total turnover is higher than for Japanese companies, (4.5% and 3.2% respectively). But it must be kept in mind that European machine tool suppliers spend a higher share of their R&D funds on a specific design than on basic research compared with their Japanese competitors. An analysis of the most important innovations proves that EC companies are technologically at the fore-front, although in some advanced technological fields as electronics, new materials etc. Japanese competitors are on the leading edge. If the ongoing integration in electronic components will result in a one chip NC-device, Japanese suppliers would enjoy the advantage first.

INDUSTRY STRUCTURE

Companies

In 1992, the European industry consisted of 1 300 companies, of which about 300 had less than 20 employees. The typical machine tool company is medium sized and employs on average a workforce of 118. But there are significant differences in the number of employees. The average German company employs 249, whereas the average Italian company only employs 67 workers. EC firms are small compared with their Japanese competitors. They have on average half as many employees, and a comparison of average turnover indicates an even larger difference. In comparison with US firms, the average EC firm has only 75% as many employees.

The European industry is not dominated by large companies. The top five enterprises account for 17% of the EC machine tool production. For comparison Japan's top five enterprises account for about 30%. The latter were very dynamic during the past decade. At the beginning of the 1980s their share of total Japanese production accounted only for 22%.

Strategies

EC machine tool suppliers expanded their investment budgets by about 50% in the latter half of the 1980s. As a percentage of the turnover the expenditures reached 7%. The major objectives were to meet booming demand, to automate production processes and above all to invest in foreign markets, especially in other European countries. Many companies were not able to finance all these activities with their cash flow and had to open up new financing sources. Some became joint stock companies, others increased their equity or raised loans.

The current recession has hit the entire industry. Especially companies that had strongly invested the preceding years suffer most under the high financial burden.

Losses and the shrinkage of equity induced companies to search for affiliations. They have been looking for strategic alliances in an attempt to stave off bankruptcy. With the help of cooperation agreements companies try to use synergies in production and distribution to achieve cost reduction.

Companies that are working in the volume market must decide with respect to the long term prospects. In view of the competitiveness of Japanese suppliers and overcapacities for many years, the tough price competition will be continued even during the expected upswing. Therefore, the forging of large groups will not be a one-way road to success.

As such, European suppliers in the volume market are strongly dependent on the conditions set by the economic policy. Important fields are social costs, interest rates, qualification of the labour force, R&D and trade policy. In the past Japanese companies enjoyed the benefit of a more favourable policy than the European manufacturers.

REGIONAL DISTRIBUTION

Germany and Italy provide three quarters of the EC machine tool production. Next are the United Kingdom and France. The Spanish industry, fifth in this ranking, has competitive prices and has caught up in the technological development.

In Germany the production of machine tools is concentrated in Nordrheinwestfalen, a traditional region for heavy engineering, and in BadenWürttemberg. The unified Germany comprises another important region, Saxony, situated in the South of the new Länder. In Italy, most of the industry is located in the North, in Lombardia, Piemonte, Emilia-Romagna and Veneto. French suppliers are concentrated around the Ilede-France and RhôneAlpes. In the United Kingdom the machine tool industry is located in the traditional industrialised region of the Midlands, in the SouthEast and in Yorkshire/Humberside. Spanish companies are centring in Euskadi and Catalunya. In Portugal the industry is concentrated around Oporto. In Denmark, Belgium and the Netherlands there are no particular areas of concentration.

ENVIRONMENT

The manufacturing of machine tools mainly consists of mechanical processes as turning, milling, boring, drilling, grinding and assembling. Most of the preliminary products are of metal, and the input of energy is of minor interest. Therefore, the major threat for the environment lies in the use of cooling and lubricating liquids which cannot be easily disposed other than by filtration which allows for a reuse of the liquids. Currently new kinds of cooling liquids, posing a smaller threat on the environment, are being developed.

Hardening and galvanising are used to increase the durability and rigidity of materials and special surfaces such as slides. As hardening by heat treatment is not sufficient, chemical processes are necessary. Most of the machine tool companies do not have their own capacities for these processes and employ specialised subcontractors.

The technological progress has induced some changes in the products themselves. Advanced machine tools are equipped with controls, motors etc. New materials are used as composites and compounds for parts of the machines. Therefore, it is no longer easy to scrap an old machine. The recycling of its components will only be possible if the machine is adequately designed. Companies are beginning to comply with such requirements.

REGULATIONS

The most important regulation in international trade of machine tools is the COCOM rule which was introduced to hinder exports of advanced production technologies to the countries of the former East bloc. In spite of its dissolution this regulation has not been abolished and hampers Western machine tool suppliers from increasing their exports. Although some improvements were made this regulation remains a major handicap.

For intraEC trade there is no major hindrance, although the suppliers must apply for a safety approval in order to deliver their machine tools into other countries. The newly adopted Machine Directive ensures free circulation of machinetools throughout the EC, reduces unnecessary administration and avoids duplication of essential safety requirements. Compliance with the directive is likely to reduce costs for manufacturers who meet harmonised standards.

Other regulations, such as the electromagnetic compatibility directive and the agreements on interfaces between data processing facilities, set standards that ease the combination of products of different EC countries. These regulations are prerequisites for the Single Market and very important for the set up of automated manufacturing processes.

OUTLOOK

A drop of demand for investment goods took place in most industrialised countries. Only the USA and to a lesser extent the United Kingdom, which went into the recession earlier, show signs of a recovery. In fact, for the US the take off has obviously begun, whereas for the United Kingdom leading economic indicators just indicate a stabilisation of the demand, while for other European markets the downward trend continues.

During the first half year of 1993, new order bookings for EC companies declined at a double digit rate compared with the preceding year. German companies suffered most losses, about one third of the orders. French suppliers benefited from

Table 6: Machine tools

Extra-EC exports	-2.0	3.0

Source: Vieweg

some major foreign orders during the first three months and Italian companies could stabilise their business activity also by foreign new orders. The depreciation of the Italian lira has stimulated exports.

The breakdown of the economies in East Europe had a negative impact on the machine tool industry. The medium term perspectives for deliveries to the CIS remain poor. The lack in convertible currencies and the inability to quickly overcome the political difficulties will hamper the demand. The other East European countries with the exception of the Czech republic suffer under a burden of foreign debts, and the trade with Western countries has been affected by the recession. Due to this framework prospects for deliveries into these countries must not be regarded as very bright in the short term. Therefore the transition of the East European economies will not provide a compensation to the overall slackening of demand.

For the second half of 1994, a recovery for the West European economies is expected. If this comes true, the demand for machine tools will increase too, but presumably there will be a delay as usual in an upswing phase. With regard to the breakdown of the production in 1993, the recovery will not be sufficient to hinder that - calculated on a year by year rate - in 1994 the production volume for machine tools in the EC will be lower than in the preceding year.

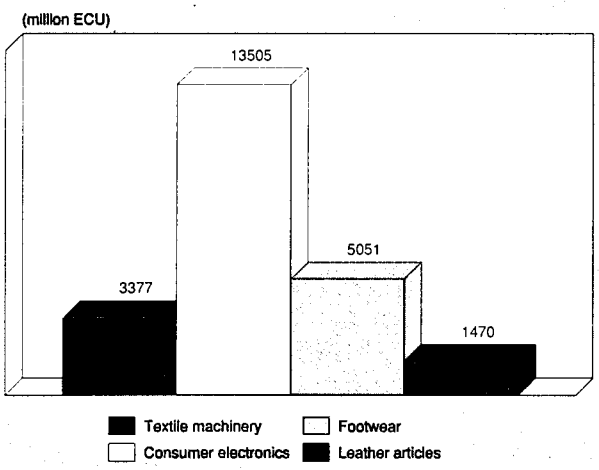
The industry is represented at the EC level by: Comité Européen de Coopération des Industries de la Machine-Outil (CECIMO). Address: Rue Capitaine Crespel 9, B-1050 Brussels; tel: (32 2) 502 7090; fax: (32 2) 502 6082.

Textile machinery
NACE 323

The EC textile machinery is global rather than regional in nature. Also, it has a high degree of specialisation, which refers both to broad product categories such as spinning, fabric forming, etc. and to specialities. Until 1990, the industry achieved double-digit growth rates (in current prices), but in the beginning of the 1990s, the sector had to cope with depressed demand, the fall of the US dollar and overcapacity. This led to a production decline in 1991. Remarkably, in 1992 producers succeeded in increasing their non-EC sales significantly, which prevented a further fall in production. Competition on the world market is strong, especially from Japan and from the NICs in the Far East and South East Asia. This concerns mainly standard machinery. EC manufacturers will respond to increasing competition by rationalisation and standardisation. Also, they specialise in high-quality and flexible machinery. Since economic recovery is not expected before 1994, in the short term the sector will develop less favourably than in the medium term.

Figure 1: Textile machinery
Value added in comparison with other industries, 1992



Source: DEBA

INDUSTRY PROFILE

Description of the sector

NACE 323 covers the production of machines for textile processing and accessories for such machines. Its main products are: short staple spindles (for short-staple fibres, e.g. cotton); long-staple spindles (for long-staple fibres, e.g. wool); open-end rotors for spinning; shuttle looms for weaving; shuttle-less looms for weaving. These machines spin (natural and synthetic) fibres into yarn; weave or knit the yarn into fabric; dye, print and finish the resulting fabric; and produce garments or other fabric products. NACE 323 also includes the manufacture of sewing machines.

Recent trends

During the 1983-1990 period, EC consumption and production of textile machines in current prices increased continuously at double digit growth rates of some 12% per year; employment rose at an average rate of 1.2% per year. Remarkably, it grew fastest between 1985 and 1987, reflecting the recovery of the sector as a result of a restructuring process. In 1991 the industry had to cope with problems such as depressed demand, the fall of the US dollar and overcapacity. These problems caused a drop in consumption of 23%. Since the imports decreased twice as fast as the exports (16% versus 8%). In 1991, production fell less than consumption (16% in value and by 18% in volume). The set-back in economic activity influenced employment adversely too; employment dropped in 1991 by 6%. In 1992 EC demand continued to fall and so did employment. Because producers succeeded in increasing their non-EC sales significantly, a further drop in production could be avoided, although the 1992 production level was still considerably lower than in 1990: 12% in current prices and 16% in constant prices.

In 1992, due to a sharp rise in exports (13% in current prices), EC production increased by 5%, the export increase outweighed the 6.5% fall in domestic demand. In constant prices the production increase was 2% in 1992. Unlike production, employment declined by 8%.

Germany is by far the largest producer in the industry, accounting for 63%, in value added, of total EC production; Italy followed with 15%. The development pattern of production differed from one Member State to another. In Germany and the United Kingdom the production increased by 6% and 18% respectively, whereas Italy, France and Spain witnessed a drop in their production in the range of 9% to 23%; in Belgium the production remained unchanged in 1992 as compared to 1991.

International comparison

The EC is the world's largest producer of textile machinery, but its traditional predominant position is seriously affected by the rapid growth of the industry in Japan and the NICs; in 1983 EC production of textile machinery was 81% higher than that of Japan, whereas in 1992 the difference was only about 58% Japan's exports are mainly destined for Asian markets. In 1992 EC imports from Japan covered some 8% of total EC demand; the market share of the USA was 3%. Unlike Japan the USA was coping with declining production; over the past 5 years its production in current prices declined on average by about 0.5% per year. In constant prices US production declined in 1992 for the third consecutive year; the production fall was remarkably strong in 1990 (19%).

Foreign trade

Foreign trade plays a major part for textile machinery in the EC. Regarding an export rate of over 60%, the sector can be characterised as highly export oriented. Import penetration is much lower; about a quarter of EC demand is covered by non-EC suppliers.

Throughout the period 1983-1992 the EC was a net exporter of textile machinery. Moreover, with the exception of 1991, exports have grown continuously since 1983 (in current prices on average by 10% per year). Until 1990 imports recorded a similar growth rate, but then fell strongly; the 1992 import level was 25% lower than that of 1990.

The development of the foreign trade flows gave rise to a significant improvement of the trade balance, which nearly tripled between 1983 and 1992. The export/import ratio increased from 2.9 to 4.5.

The vast majority of extra-EC exports are destined for the Rest of the World. The major destinations in the developed world have decreased in importance; in 1987 their joint share was almost one third of total EC exports, whereas in 1992 it was reduced to one quarter. Especially the EFTA countries and the USA contributed to this reduced share. As a result the share of the developing countries increased from two thirds to three quarters. Among these the largest market is to be found in Asia, where manufacturers in countries like India, Indonesia, Korea, Taiwan, Pakistan and Thailand invest heavily in replacements and new factories. East Europe and the Commonwealth of Independent States (CIS), where domestic machinery manufacturers are unable to meet the demand both in terms of volume and required technology, are other promising markets. The market in North and South America (Brazil) shows a stabilisation or even a decline.

The EFTA countries, Japan and the USA allow for the overwhelming part of the extra-EC imports: in 1992 their joint share was 82%; in 1987 it was 87%. The decline is particularly due to the drop in the share of the EFTA countries, by far the number one origin of the extra-EC imports: their share dropped from over 50% to almost 40%. This decline could

partly be compensated by the increase of the market shares of Japan and the USA.

MARKET FORCES

Demand

Demand for textile machinery is naturally linked to developments in textile manufacturing. Since the EC accounts for some 10% of the world's textile manufacturing capacity it is clear that EC manufacturers depend heavily on the demand for textile machinery from non-EC countries. This is reflected in an export share of over 60%. Particularly Asia, with about half of the world's textile manufacturing capacity, is relevant in this respect. Conventional (short staple and long staple) spindles still account for three quarters of world deliveries. They produce superior yarns for some end uses, especially in finer count ranges. The shift to open-end rotors seems to have come to a halt or has even reversed.

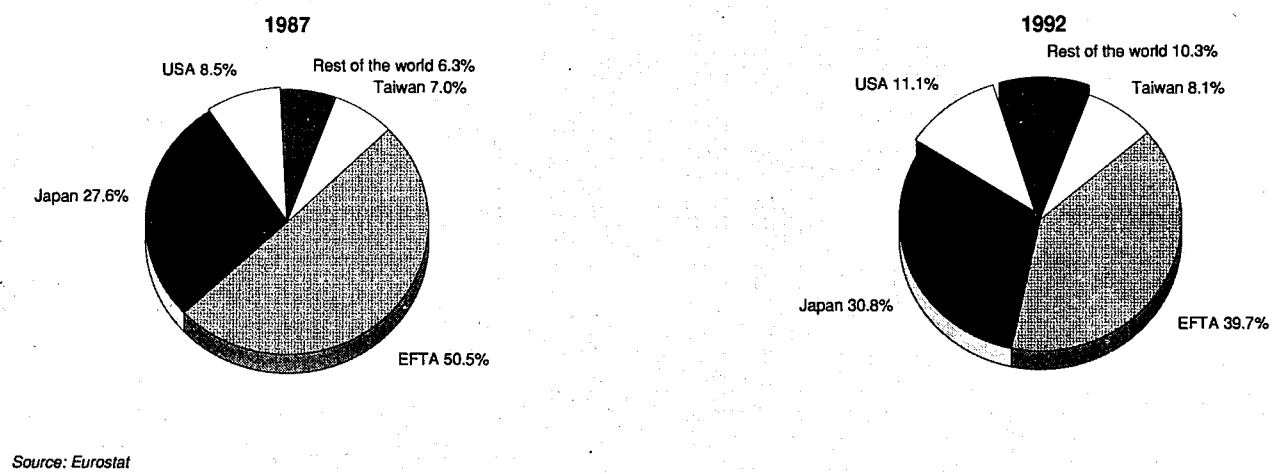
The demand structure for textile machines varies significantly by region. Asian countries are strongly investing in spinning machines with short staple spindles: EC manufacturers mainly require long staple spinning machines used for high quality yarns. The demand for weaving machines reveals a similar picture: nearly all shuttle looms are procured by Asian countries, whereas textile manufacturers in industrialised countries mainly concentrate their purchases on advanced shuttle-less looms, especially rapier/projectile and air-jet spinning machines.

Within the EC Italy is by far the most important market for textile machinery. Over 30% of EC demand for spinning and weaving machines comes from this country. In particular Italian textile companies invest considerably in long staple spindles: 60% of their investments are in these machines. Important customers for open-end rotor spinning machines are in Italy, Germany, France and Spain. EC demand for weaving machines is focused on shuttle-less looms. Again, Italy is the most important in the demand for this type of machinery.

Sewing machines

The bulk of sewing machine output goes to the industrialised countries. European producers sell about 70% of their output to customers in these countries. Germany as a supplier of mature specialised technology sells about three quarters of its exports to these countries; the remaining quarter goes to developing countries. Japanese manufacturers sell about half of their exports to industrialised countries; the other half goes

Figure 7: Textile machinery
Origin of EC imports



Source: Eurostat

to developing countries. PR China is especially a growing market for Japan.

Supply and competition

The EC is by far the largest producer of textile machinery in the world, but non-EC competition is increasing. Price competition in textile machinery manufacturing is fierce. Competition is also complicated due to sometimes volatile currency exchange rates and customers demanding 'soft' credit schemes.

Japanese manufacturers are increasingly becoming a competitor on the world market. They are not only strong in producing machinery of traditional technological standards, but they have also obtained considerable strength in highly advanced machinery. Japan exports the larger part of its production: in 1989 53%. The Japanese have already succeeded in acquiring strong positions in the Asian markets, where demand for standard technology machinery is prevailing. Some 60% of exports go to these markets. Their importance on European and American markets is also growing.

There is also expanding competition from local companies in the newly industrialising countries in the Far East and South-East Asia. These companies produce standard technology machines at low prices and become more and more an important competitor on the Far East and South East Asia markets. In developing countries, companies manufacture machinery under licenses of EC manufacturers, that represents essentially an import substitution policy.

Sewing machines

In terms of supply the most important manufacturers of sewing machines are located in Germany, Japan, the United States, Sweden, Switzerland and the NIC's in Asia. Within the EC Italy and Spain are of limited importance next to Germany. Japan and Germany together account for over 50% of world trade in sewing machines. The NIC's like Taiwan, Hong Kong, Singapore and South Korea have become serious competitors imitating Japanese technology, but selling at lower prices. Industry in PR China is developing and may soon capture the domestic market or even enter the international market.

Production process

Expenditure of EC enterprises on research and development have been significant (5% to 10% of turnover) to guarantee continuous technical and product innovation. Further, marketing costs have also proliferated due to the need to attend international textile machinery exhibitions, especially to have promotion in developing markets.

Innovations have occurred in various fields, such as: new automatic bale feeders, aerofeed systems, high-draft spinning, texturisation, shuttleless looms, needle punch machines, transfer printing, rotary screen printing and computer-integrated manufacture. This led to new machinery in all stages of the textile production process: material handling, yarn spinning, fabric weaving, dyeing, printing and finishing. It also led to automation of machinery functions.

Technological innovation has improved productivity in textile manufacturing a great deal. Over the 1983-1990 period, labour productivity (in current prices) increased continuously at an average rate of 11% yearly. In 1991, however, it fell significantly, by 11%, due to a sharp slump in demand, as employment was not reduced accordingly. In 1992 productivity growth picked up 10%. Unit labour cost increased namely by 7% during the 1983-92 period. This was less than the growth of total unit cost, which rose annually by about 9% on average. This reflects the growing capital intensity of the sector.

INDUSTRY STRUCTURE

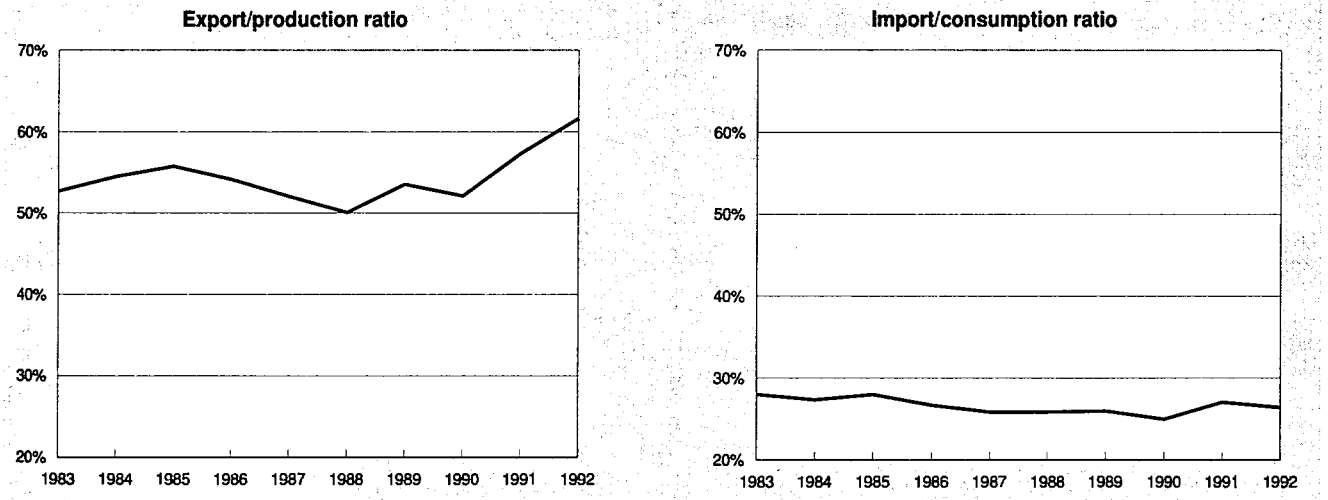
Companies

The EC textile machine industry encompasses some 1100 companies. Many of them are small or medium-sized enterprises. The largest textile manufacturers in the EC by type of machinery are:

- spinning machines: Platt-Saco-Lowell (UK/USA) and Schubert & Salzer (D);
- weaving machines: Dornier (D), Jumberca (E), Picanol (B) and Somet (I);
- knitting machines: Mayer Albstad (D), Stoll (D), Sulzer Morat (D) and Terrot (D);
- dyeing, printing, finishing: Adrioli and Co. (I), Kusters Corp. (D), Stork (NL) and Zimmer (D);
- all categories: Schlafhorst (D), Bentley (UK) and SAMT (F).

The overall structural features of the EC textile machinery industry are determined by two main factors. First, the global

Figure 8: Textile machinery Trade Intensities



Source: DEBA

rather than regional nature of the industry. Most major European textile machinery manufacturers have cooperative agreements in important markets like the United States and the Far East. Such agreements may even be joint-ventures with local companies or fully or majority-owned subsidiaries. Via such agreements they have a basis to service markets like Canada and Latin-America from the USA and the Far East from Asian countries. Second, the high degree of specialisation, which refers both to broad product categories such as spinning, fabric forming, etc. and to specialities within these categories. Pressures on order volumes and profit margins, and increased local competition in some developing markets have encouraged specialisation. Examples are Schlafhorst (D) with a good reputation in spinning machinery, Barmag (D) in spinning machinery for synthetic fibres, Van der Wiele (B) for carpet weaving and Stork (NL) for printing machinery.

Competition from outside the EC comes from large companies in Switzerland (Benninger, Rieter, Rüti, Saurer, Sulzer) and Japan (Fuhuhara, Howa, Murata, Nissan, Shima Seiki, Toyoda). Both countries are key players in the world market. With high efficiency and technologically advanced products they are able to capture a large market share even in countries with strong indigenous textile machine-making capacities.

Strategies

Some major manufacturers have adopted a strategy to reduce the number of variations of machine types within a particular product category or group. This enabled them to optimise the production of machine parts and to match production and orders in a better way.

The industry has also been confronted with internationalisation involving acquisitions, mergers and other forms of cooperation not only within the EC, but also at the international level. In this way specialised individual textile machinery manufacturers aim at becoming a complete supplier to meet with the growing demand for fully equipped, highly automated production plants. Examples are the French SAMT (merger of SACM and ARCT), Rieter (CH) acquiring 51% of Schubert & Salzer (D), Saurer (CH) having taken over Volkmann (D) and Schlafhorst acquiring Zinser (D).

REGIONAL DISTRIBUTION

Germany, a country with a long tradition in machinery manufacturing (some 25% of the total number of EC companies is settled), accounts for some 55% of EC employment in the textile machinery industry; Germany's share in the industry's value added was 63% in 1992. This reveals that the largest textile machinery companies within the European Community are mainly settled here.

In Italy, the second largest EC producer country, the manufacturers are on average substantially smaller; Italy allows for most (30%) of the companies in the EC textile machinery, but for 15% to 20% of EC employment, and for 15% of EC value added. The relatively small size seems to allow maximum specialisation and close customer relationships. For France, the third EC producer of textile machinery, the shares in EC value added, employment and number of companies are virtually identical, indicating that the French 'picture' complies with that for the EC as a whole. As to the remaining Member States it is worth noting that, although Spain and Belgium have a comparable value added, Spain has 40% to 45% more labour employed. Spain reveals the lowest labour productivity in the EC.

REGULATIONS

Regulations on machine safety and health provisions are currently imposed on machine manufacturers. Provisions concern the design, the materials used, the way in which machine operations should be illuminated, machine operations itself, safety against mechanical risks, the application of screens and other safeguarding components, maintenance and machine indications and identifications. Machines complying with the EC regulations will obtain the CE mark.

Further provisions concerning technical standardisation are relevant to the sector. The European institutions on technical harmonisation CEN and CENELEC are developing such standards applicable throughout the Community. International standards for quality control have also been developed such as ISO 9000.

Given the highly export oriented character of the sector, the liberalisation of the world trade through GATT negotiations is of particular relevance to the sector, especially regarding the trade with Asian countries. The Japanese Comprehensive Import Expansion Policy provides an interesting example. Foreign producers have already a share of some 24% in the Japanese market for textile machinery, totalling ECU 852 million in 1989. These imports are overwhelmingly (for about 90%) handled by Japanese importers. The Import Policy together with increasing sales efforts by importers may encourage EC exports to Japan.

OUTLOOK

Table 5: Textile machinery
Expected real annual growth rates

(%)	1993-94	1993-97
Apparent consumption	0.5	1.5
Production	1.5	2.5
Extra-EC exports	2.0	3.0

Source: NEI

Given the high export rate of the EC textile machinery industry developments outside the EC are particularly relevant. On both the EC and non-EC markets manufacturers will have to face increasing competition. The liberalisation of the EC market will encourage intra-EC competition; competition in the exports markets, particularly in Asia, will come on the one hand from further penetration of Japan on these markets, and on the other from import substitution in current export markets.

EC manufacturers will respond to increasing competition by further rationalisation and standardisation on the one hand and by increasingly proceeding to the production of special high-quality and flexible machinery. Technologically advanced machinery, replacing expensive labour, will generally be destined for the industrialised countries; machinery of accepted standard technology will be mainly sold in developing countries, where, as a rule, labour cost are relatively low. The development of advanced machinery includes the application of modern technology: sophisticated automation, electronics, and computer-to-computer communications. Besides technological improvement and innovation of machinery, after-sales-services will be increasingly a competitive weapon.

Despite increased competition and the prevailing global slump, EC production revealed an increase in 1992, especially due to increased exports; EC demand declined. The production development was largely due to a rise in orders of 22% of German manufacturers, who account for the bulk of EC production. For 1993 a further growth in these orders is expected. On the other hand economic recovery is not expected until 1994.

Written by: Netherlands Economic Institute
The industry is represented at the EC level by: Comité Europeén des Constructeurs de Materiel Textile (CEMATEX). Address: p/a FME, P.O. box 190, NL-2700 AD Zoetermeer; tel: (31 79) 531 100; fax: (31 79) 531 365.

Food, drink and tobacco processing machinery

NACE 324.11

Within this grouping, the manufacture of food processing machinery is the largest sector. As the European food market is maturing, not only food manufacturers, but also suppliers and manufacturers of food machinery and equipment have increasingly engaged in M&A activity. Production of food is becoming centralised, which, together with rapidly changing consumer preferences, gives rise to the introduction of more capital intensive and research intensive production methods. Demand for more efficient and flexible machinery rises. As a result, the application of robots and industrial automation systems is growing.

INDUSTRY PROFILE

Description of the sector

The market of food processing machinery includes: flour milling equipment, noodle making machines, baking machines, confectionery machines, fermenting machines, dairy product processing machines, meat processing machines, seafood processing machines, rice & barley polishing machines, fruit and vegetable processing machinery, and other machinery. Food processing machinery accounts for the greater part of the production of this NACE.

The production of food, drink and tobacco processing machinery accounted for an estimated 5-6% of total machinery production. In contrast with other machinery sectors demand for, and consequently the supply of food processing machinery is highly fragmented. Within the EC especially meat processing machinery, bakery machinery and fruit and vegetable processing machinery are important segments of the industry.

Recent trends

Germany is the major producer of food processing machinery with an estimated share of 35% to 40%. In contrast with other machinery manufacturing industries the Italian position within the industry is not so strong. Its position is comparable with that of France with an estimated share of 17%. Import penetration in the EC is some 10%, whereas the export rate is estimated at 35% to 40%.

Germany's production rose continuously over the 1980s strengthening its leading position. Dutch production increased as well. Rising exports contributed largely to production growth in Germany and the Netherlands. However, in the beginning of the 1990s German production was also stimulated by a booming domestic market as a result of the reunification. Germany and the Netherlands are net exporters.

Stagnating French production, together with increasing imports from Germany, suggests a weakening French competitive position, since demand remained high. Italian manufacturers on the other hand were confronted with stagnating domestic demand in 1991; the rise in exports was not enough to prevent a production decline in that year. The United Kingdom recorded a considerable production fall in 1991 (16% in current prices, compared with the level of 1989). However, turnover in 1992 increased (by 4% in real terms), suggesting a production increase as compared to 1991.

International comparison

Outside the industrialised countries, the food-processing machinery industry is either non-existent or of a rudimentary character. The industry is strongly concentrated in the developed countries. As the major producers, the EC, the USA and Japan apply differing definitions of the industry, a definite comparison can not always be made.

Available data suggest an isolated Japanese market; both import penetration (1988) and export rate (1989) are about 3%. For the EC, these figures are considerably higher, around 10% and between 35% and 40% respectively in 1990. The USA recorded a higher import penetration than the EC (around 20% in 1989), but its export rate was lower (about 25% in 1989).

Foreign trade

The EC is a net exporter of products classified under this NACE. Moreover, over the 1983-1992 period, the trade surplus increased at an average rate of about 4% per year. The export to import ratio, however, decreased, indicating that the extra-EC imports grew faster than the extra-EC exports: 6%

and 3.7% per year on average. Remarkably, the intra-EC trade increased by almost 9%, reflecting the increasing internationalisation of the industry within the EC. In 1983 the intra-trade was 48% of the extra-EC exports; in 1992 it was 73%.

The EFTA-countries and the USA are important destinations of non-EC exports, but their joint share declined from 27% in 1988 to 22% in 1992. The bulk of extra-EC imports originates from the EFTA countries and the USA, allowing together for 82% of total extra-EC imports; in 1987 this share was slightly higher 84%.

MARKET FORCES

Demand

The market for food, drinks and tobacco consumption is maturing in the Western industrialised countries. Further, consumer preferences for these products are changing rapidly and more frequently. The availability of reliable and non-perishable food products is getting more priority. Diet and health conscious consumers are reducing their intake of fats, salt, sugar, and high cholesterol foods, while still demanding flavourful, wholesome and appealing food along with greater convenience and variety. The negative publicity about smoking has caused a shift of demand towards light cigarettes. All these trends create market challenges for the food, drink and tobacco industry and, as a result, for the food, drink and tobacco processing machinery industry.

The development of new products and the implementation of new production lines by food processing companies are costly, but it is a prerequisite to keep pace with consumer trends and to cope with intensifying competition. It is only in this way that they can maintain or even increase shares in core areas, which are considered to yield high profits and long-term growth opportunities. This will result in a continuous search for new products and new processing techniques, where flexibility seems to be the key word.

Other growth opportunities could stem from the economic development of relatively less developed regions with high agricultural potential such as the former East bloc countries. Demand from the East European countries - for instance Poland - but also from China is rising. The main problem for further developments remains the lack of capital in these regions. Because of the primary character of food, the food industry and the food machinery manufacturers are expected to benefit earlier from the industrial and political restructuring processes than other industries. Furthermore, the capital problem may be solved by large food processing multinationals entering the former East bloc countries.

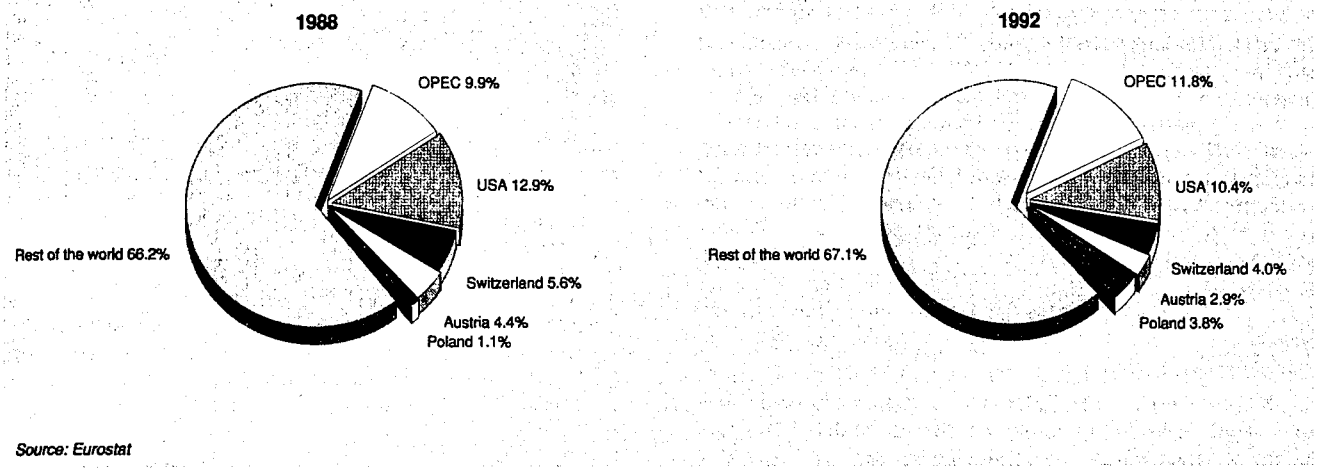
Supply and competition

Compared to packaging machinery, for example, the applications of food processing are less diverse and more limited to specific segments of the food processing industry. Supply is highly fragmented, with manufacturers operating and specialising in one market segment that can differ considerably in size. For instance, the manufacture of meat processing machinery, bakery machinery and processing machinery for fruits and vegetables are relatively large and important market segments with only very specific applications.

Machinery manufacturers have coped with the need of food processors for modern, flexible equipment by introducing more capital-intensive and research-intensive production machinery. New technologies are providing new opportunities for cost reductions, larger-scale production, a higher degree of flexibility and the development of new products.

The growing concentration in food processing urged the food processing machinery and equipment manufacturers to concentrate too. This gave rise to the emergence of large and international machinery producers. Internationalisation encouraged the growth of technology transfer, necessary for the large producers to carry out their own research and take out patents, which can be commercialised.

Figure 2: Food, drink and tobacco processing machinery
Destination of EC exports



Source: Eurostat

Similar to the packaging machinery industry, the Japanese industry is highly oriented on the large domestic market and the considerable requirements for after-sales service. Furthermore, the Japanese industry can not cope with the highly fragmented character of demand in food processing. When the industrial trend moves towards more standardised machinery and equipment, Japan could become a more serious threat on the international market.

Production process

The food processing industry is developing towards less, but larger production centres with the ability to produce a greater variety of products. Concentration of production is developing very strongly in the West industrialised countries and some Asian countries in particular. Consequently, production and process systems have to meet more stringent requirements for flexibility and efficiency. These requirements have stimulated the widespread application of CAD (Computer Aided Design), CAM (Computer Aided Manufacturing) and flexible manufacturing techniques within the industry.

To keep pace with special market demands, food processors and the machinery and equipment suppliers are developing joint R&D programs. These joint forces speed up the development, testing and introduction of new production equipment. The growing attention to R&D programs also demonstrates the importance of the quality of the labour force. In the future the focus will be increasingly on the quality of education and training of employees.

INDUSTRY STRUCTURE

Companies

Intensified competition and changing consumer demand strengthened the process of concentration in most downstream industrial food sectors. The creation of the Internal Market has also been a stimulus to concentration, since it enabled free movement of raw materials and processed goods. Customers within the Common Market can be served from one or a few plants within the EC and production can take place on a larger scale. The concentration process is expected to continue.

A large share of food processing is currently taking place in larger corporations (e.g. Unilever (NL) and Nestlé (CH)). These companies dominate the development of new processes and new products. As a result they are becoming more and more knowledgeable buyers of processing machinery and equipment. Through their transnational information and steering systems, they can obtain specifications, price information, details of materials and other relevant information which puts them in a favourable position to discuss prices and other terms when buying equipment. This could make it difficult for an equipment producer to sell the same type of specialised machinery to more than one large food corporation.

Despite a process of concentration the food machinery manufacturing industry remains fragmented due to different patterns of demand worldwide. The majority of the enterprises are medium-sized and specialise in one or more subsectors of the food machinery industry.

Within every segment of the industry one or more relatively large companies are operative. Companies with over 500 employees are especially active in international markets.

Until the beginning of the 1990s the process of concentration was characterised by horizontal integration. In 1991, however, the Swedish-owned milk and juice packaging group Tetra Pak took over Alfa-Laval, the Swedish manufacturer of industrial equipment, the second largest sector of which was food equipment. The trend towards more concentration by the merger or cooperation of specialised medium-sized companies enables them to offer tailor-made machinery and equipment to meet customer needs. After the Tetra Pak/Alfa-Laval take-over, a development towards vertical integration can also be expected among medium-sized firms.

Vertical integration increases the convenience for customers who can purchase packaging and processing machinery at the same location. On the other hand, horizontally integrated firms will be better equipped to face the future challenges in the largely untapped markets of the less developed countries and East Europe.

ENVIRONMENT

The growing importance of ecological issues is especially reflected in measures against packaging waste. For the manufacture of food processing machinery, however, no specific consequences can be recognised. The more stringent EC-regulations on sanitary conditions during the processing of foods and drinks might enhance the technical requirements for the applied machinery. In general, however, the resulting effects for the manufacturers of food processing machinery are expected to be quite modest.

The increasing number of measures against smoking has already discouraged and will further depress the use of tobacco. A possible prohibition of promotional activities by the tobacco

industry on EC-level, will undoubtedly affect the number of smokers. As a consequence, the demand for tobacco processing machinery by tobacco processors is likely to decline.

REGULATIONS

In 1993, the European Technical Committee for machinery safety and health regulations (CEN TC/153) introduced safety standards, which will also apply to the manufacture of food processing machinery. The central issue of the new regulations - self certification by the industry itself - will give the final responsibility to the various industries to set their specific standards. CEN - the European Normalisation Institute - has the final task to provide detailed European standards. Control on the use of the new standards has been given to the national governments. The European industry would like to see the CEN standards adopted by the International Standards Organisation (ISO) in order to avoid unfair competition on foreign non-EC markets.

In addition, Directive 89/392 will implement additional safety and health essential requirements for this industry, as well as for all other machinery producing sectors.

OUTLOOK

In the short term, the prevailing recession in some major markets will influence demand for food processing machinery adversely. In addition to this cyclical problem the industry has to cope with the structural problem of maturing food markets in the Western world. In response to these two factors, EC manufacturers must increase their export efforts. The markets in the former East bloc are still uncertain. Because of its primary character, however, the food sector is likely to benefit earlier from the political and economical restructuring processes in these countries than other sectors. For the same reason the current downswing of the trade cycle is expected to affect demand for machinery, classified under this NACE less than in other machinery producing sectors.

Chemical machinery
NACE 324.12

The dependence of chemical machinery manufacturing on the chemical processing industry played an important role in a number of changes that took place. Quality control and environmental concern have become increasingly important issues. In the 1980s, the chemical plant equipment industry was confronted with several drawbacks, including the fall in oil prices, the depreciation of the US dollar, the recession at the beginning of the 1980s and more competitive export markets. Currently, the industry has once again to cope with sluggish economic conditions. For 1991 the chemical machinery production was estimated at 5.5 billion ECU. Some 90 000 people were employed. The industry is a net exporter. In the short-term the prospects for the industry will be dim; in the medium-term the situation will improve.

INDUSTRY PROFILE

Description of the sector

The chemical machinery industry is classified under NACE 324.12. The products of this industry can be divided into the following categories:

- producer-gas or water-gas generators;
- centrifuges and dryers;
- filtration and purifying machinery for liquids and gases.

Important products in the three categories are: pressure vessels, heat exchangers, process towers and reactors, dryers (rotary, belt, adsorption), piping, filtering engineering, mixers, structural steel engineering, valves and fittings, heavy walled tubulars, air conditioning and jacket piles.

Several products are not specific to the chemical industry. Since classifications differ within the EC, it is difficult to estimate the importance of the industry by Member State. For instance, the production of water purification equipment is usually, but not always, classified under the heading of chemical plant equipment. Other equipment which may or may not be considered chemical machinery in national statistics are furnaces, heat exchangers and pressure vessels. Consequently data should be considered with care.

As to production, data were only available for Belgium, Germany, France, the Netherlands and the United Kingdom.

Recent trends

Production in the EC countries considered totalled 5.3 billion ECU in 1990. The available data suggest a modest production increase in value in 1991 to a level of 5.5 billion ECU. Consumption in 1990 and 1991 is assessed at 4.6 billion ECU and 4.9 billion ECU respectively. The EC is a net exporter of chemical machinery. The export rate amounts to about a quarter; import penetration is some 15%. Employment is estimated at roughly 90 000 people, which implies a productivity of 60 000 ECU per employee in 1990 (roughly the relevant figure in the Netherlands and Italy).

Like in other machinery industries Germany is by far the largest producer of chemical machinery, accounting for 45% of total production of the countries considered. Italy and the United Kingdom follow with 18% and 17% respectively. Hence, these three Member States are accounting for some 80% of total EC production. However, due to the already mentioned differences in statistics, these figures give only an order of magnitude. It is presumed that the French figures underestimate the industry as several enterprises could be subsumed under the food processing machinery industry and under boiler making. Besides Germany, all Member States recorded a production increase in 1990. In Germany, production fell by 14%.

Following the recession after the second oil crisis in 1979, a large shake-out took place in the chemical machinery industry, resulting in a decrease in production capacity, which is currently still lower than 1980 levels. The declining activity in the chemical industry was transferred to upstream industries with a small time lag. The industry faced several setbacks:

- the decline in orders from the traditional industrial countries;
- the international debt crisis which forced several developing countries to stop or postpone investments;
- the subsequent fall in oil prices which put orders from OPEC countries under pressure;
- the fall of the US dollar which started in March of 1985, and, more generally the volatility of the dollar exchange rate vis-à-vis the European currencies.

In current value EC production increased at an average rate of 7.2% per year during the 1983-91 period; in constant prices the growth rate is estimated at 2%. In France and Italy, production value increased respectively by 8% and 16% per year

over the 1983-91 period. Germany and the Netherlands revealed annual growth rates in the range of 7% to 8%, and 11% for Belgium from 1983 to 1990; the production in the United Kingdom showed the slowest growth: 5% per year throughout the 1983-91 period.

International comparison

Production in the EC is several times higher than that of Japan. No figures are available for the USA due to differences in industry classification. This is not surprising giving the weight of the European chemical, and other more general processing industries. Capital investment in the chemical industry of Western Europe is by far the largest in the world, compared with the USA and Japan. Investments in Japan, however, grew faster than in Europe during the 1980s.

Foreign trade

Throughout the 1983-92 period, the EC was a net exporter of chemical machinery, but the export to import ratio fell significantly, from 3.4 to 1.8. Non-EC exports, indeed, increased at a lower rate than non-EC imports: 11.0% versus 3.8%. The trade surplus has declined since 1990, but recovered a little bit in 1992. Intra-EC trade has become increasingly important. It has grown at an average rate of almost 13% a year over the reference period, due to the increasing degree of internationalisation of the market. In 1983, intra-EC trade represented 44% of the non-EC exports; in 1992 it was 95%.

The bulk of the extra-EC imports are originating from only two groups of countries that are the USA, the EFTA countries, and Japan. However, their joint share declined between 1988 and 1992 from 94% to 80%. In particular the EFTA countries and Japan have lost market to smaller suppliers.

The main non-EC markets for chemical machinery are the EFTA countries and the USA, accounting together for some 32% of total extra-EC exports in 1992. This figure was virtually identical in 1988, but the USA became somewhat more important for non-EC exports, whereas the relative importance of the EFTA countries declined slightly.

MARKET FORCES

Demand

Besides the chemical industry, the chemical plant equipment industry has a number of clients, all of which are processing industries. Among the outlets are: the chemical industry, the petrochemical industry, the pharmaceutical industry, the biochemical industry, food processing industry, water purification utilities, oil and gas exploration and production companies, refineries, power generation plants, environmental application companies, engineering contracting companies and government institutions. Most industries mentioned here follow cyclical business patterns: they are vulnerable to swings of the business cycle.

The development of capital spending in the chemical industries is of major importance for the processing machinery manufacturers. During the upswing of the second half of the 1980s, much of the spending in the chemical industry was directed towards de-bottlenecking, energy-efficiency, and environmental and safety measures, but real expansion investments were not common. The industry managed to maintain high growth rates for a long time.

Demand for chemicals began to decline in the middle of 1989, putting the chemical industry under pressure. With decreased capacity use, increased input prices, and output growing at barely the rate of inflation, the chemical industry does not have the resources to spend on capacity increases.

Factors which had a negative effect on the industry in 1991 included the Gulf war, recession in some major export markets, depreciation of the US dollar and the Japanese Yen. Only the increased demand in former East Germany had a ameliorating effect, which was not strong enough to counter the negative factors. Currently, the prevailing downswing of the business cycle, the cheap US dollar and the slow and uncertain restructuring process in eastern European countries are causing restricted demand for chemical plant machinery.

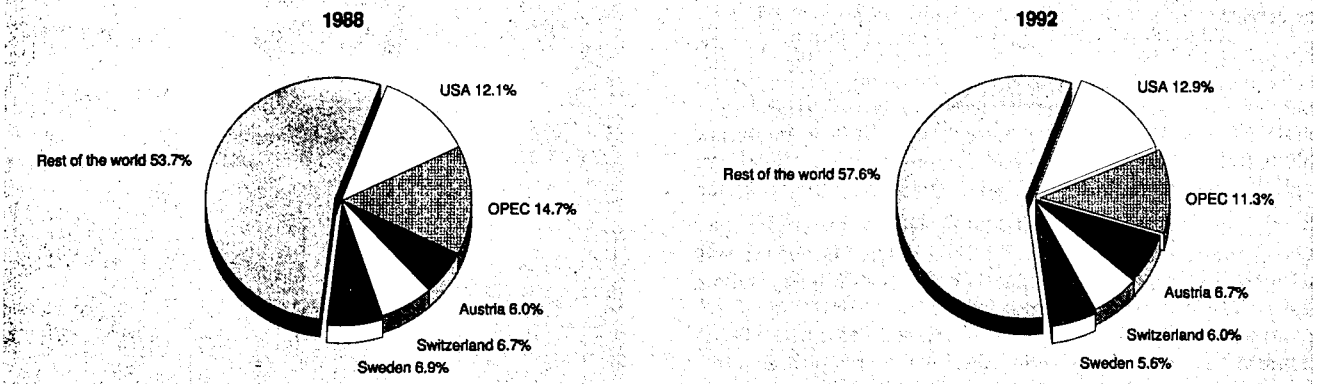
Supply and competition

Chemical machinery manufacturers operate on the world market. This applies not only to large firms, but also to small companies. Reasons behind this are the highly internationalised chemical and related markets, as well as the existence of large petrochemical multinationals. Since most of the machinery is designed for single-piece work, chemical machinery manufacturers from all over the world can bid for the specialised product needs of a multinational client. The competitiveness generated by this practice keeps prices low, and slow to respond to a booming market. On the other hand, in a recessive market prices will tumble quickly.

The dollar exchange rate and the oil price are important determinants of the demand for EC chemical machinery. The prevailing cheap US dollar does not only affect EC exports to the USA. In a more indirect way, a depreciating dollar also affects competition in the EC market, with competitors from abroad. In the past years, several orders have been lost due to high-valued EC currencies and the volatility of the US dollar. The price of oil is especially important for the production of heat exchangers. The relative low oil prices since the end of 1985 has had a significant impact on production.

Chemical machinery manufacturers can deliver their products directly to the end-user, or indirectly through an engineering

Figure 2: Chemical machinery
Destination of EC exports



Source: Eurostat

services firm, for which they act as a subcontractor. In recent, years there has been a trend towards outsourcing of several engineering services by the chemical industry, which has led to a more important role of engineering firms as an outlet for the chemical machinery industry.

Production process

Quality control has been a major concern of the chemical process industries, which has extended to machinery suppliers. Certification under the ISO 9000 series of quality-assurance standards gives companies a competitive advantage. It is fast becoming a prerequisite for competing in business worldwide. Several companies already comply with ISO 9000/9001/9002 quality standards, and others are working to reach these standards. Most of the companies comply already with some national standards, which is necessary to serve different customers in a competitive market.

Interesting technological developments are: size-reduction technology, energy-savings, new materials, new fibre finishes, computer aided manufacturing and engineering, and environmental engineering.

Pollution control is one of the issues that will influence investments of the chemical industry in the near and distant futures. The Chemical Industries Association of the United Kingdom found through a survey that in 1989 spending on environmental protection represented 11% of total capital spending and was expected to double in 1990-1992.

Growing activity in the field of biotechnical research and production will generate growing demand for laboratory and production equipment. Demand will also be of a different nature; nowadays new plants are specifying vessels of 40 000 to 200 000 litres, as compared to vessels of 500 to 4 000 litres previously. These growing and changing needs will cause machinery and equipment for the biotechnical sector to become increasingly important for the chemical machinery industry.

The increasing complexity of the machines as well as the higher quality standards with which they must comply, make it necessary to have more and better skilled labour. It is in this area that shortages are common. In-house training is a possible, but costly solution.

INDUSTRY STRUCTURE

Companies

In the chemical machinery industry there are no large multinational enterprises, although most of the companies engage in exports. Two types of firms can be distinguished: product specialists and jobbers or activity specialists.

Product specialists are firms which design and develop equipment by themselves and can successfully export specific products due to low unit cost. The enterprises normally are medium-sized and export more than half of production. They will usually have technical knowledge of the process in which the machinery will be involved after production.

Jobbers, or activity specialists are firms which manufacture items from the client's blueprint and which are the most common type of firm. They are less export oriented than the product specialists; exports account normally for less than 50% of production. They mostly have a very small knowledge of the processes in which the machinery will be involved.

Source: Eurostat

Strategies

The strong dependency on the chemical industry makes the chemical machinery industry not only vulnerable to cyclical swings, but also in a more structural way. One-sidedness can lead to a product-oriented attitude, which can be detrimental in a market in which competition is growing.

Knowledge of the chemical processes can be profitable for an enterprise, because it gives the company the ability to discuss with the customer not only the apparatus, but also the whole process in which it is a part. This is important because optimisation of the process cannot be achieved through optimisation of the individual units. An overall plan must be made.

Companies are diversifying in several ways. One of these is to engage in other markets than the chemical industry. Given the process oriented products, logical markets are the food, pharmaceutical, power and environmental industries. Other companies are applying knowledge of the chemical industry to develop new products for that industry. These companies tend to become niche players. While there are not too many real niches in the world, those companies which find one are much less affected by cyclical downswings.

ENVIRONMENT

It is estimated that in 1991 a world total of 4.4 billion ECU was spent for the prevention, containment, treatment and disposal of air, liquid and solid wastes in the petrochemical industry. A major focus of environmental control in the chemical industry will be waste minimisation.

Environmental concern has and will continue to have a large impact on the chemical machinery industry. The market for environmental products for cleaning industrial waste water, for example, is increasingly important, opening new opportunities to the chemical machinery industry. In countries where environmental regulation is already very strict, such as Germany and the Netherlands, enterprises are likely to have a competitive edge in this area.

There is however a caveat, the introduction of different environmental regulations can distort the market. Competitive positions can be altered by the strictness of regulations in different countries. Imports from countries with a less stringent policy than the EC could become a serious threat.

REGULATIONS

As in other sectors of mechanical engineering, the EC directive on machine safety is of primary importance. Provisions concern the design, the materials used, the way in which machine operations should be illuminated, machine operations itself, safety against mechanical risks, the application of screens and other safeguarding components, maintenance and machine indications and identifications. The directive is applicable as of January 1, 1993. Until January 1, 1995 however, manufacturers have the option to comply with either the old regulations used in the Member State where the products are sold, or the new EC regulations. Those complying with the EC regulations have the advantage of being labelled with the CE mark, which provides free access to the markets of the EC countries.

The EC directive on simple pressure vessels (87/404/EEC) is also of importance for this sector. The directive concerns simple compressed gases vessels, especially for oxygen and nitrogen. Pressure vessels have to fulfil several requirements regarding safety. After positive testing the manufacturer receives a certificate and can add the CE mark to his product. The directive does not apply to pressure vessels for nuclear installations, to pressure vessels for the propulsion of ships and aeroplanes and to fire extinguishers.

Source : CEFIC

OUTLOOK

Due to the prevailing worldwide recession and a cheap US dollar, project activity in the petrochemical industry is expected to grow slowly in the near future, with important stimuli from the environmental and health and safety regulations. Prospects for the chemical industry in the Western world are indicating low growth rates in the short-term. Moreover, the slow economic restructuring process and the shortage of foreign exchange, will restrict short-term demand from eastern European countries, although the needs for restructuring, as well as the environmental need for upgrading plants, will create opportunities for the chemical equipment industry. Further opportunities exist in environmental engineering.

In the medium-term, however, when more of the opportunities can be seized, growth will accelerate, but it is still expected to be modest.

Packaging machinery
NACE 324.2

The EC is the world's largest manufacturer of products belonging to this NACE with Germany and Italy as the major producing Member States. While Japanese and American firms benefit from large domestic markets, European firms have turned to export markets making the EC a net exporter. EC competitiveness will increasingly depend on enhanced engineering quality meeting the need for more versatile and 'environmentally friendly' products. This requires much R&D effort and a highly qualified labour force.
Over the 1989-1991 period the EC packaging machinery industry recorded double digit growth rates. In 1992, the growth declined significantly, due to the ongoing recession, the breakdown of East European markets, and the ending of the reunification boom in Germany. As this situation is expected to prevail in 1993, in the short run EC production growth will slow down. In the medium term, when an upswing in the trade cycle is expected, the prospects will improve. The new EC Packaging Waste Directive, will encourage the need for new packaging materials which will be a challenge for the manufacturers of packaging machinery.

INDUSTRY PROFILE

Description of the sector

The machinery classified under this NACE varies widely in use. The industry includes: form, fill and seal machines; combined filling and closing machines, group packaging and filling; accessories, parts and spares. These four groups account for around 60% of total production of the packaging machinery industry; "other machinery" is accounting for the remaining 40%. These products are used in a few main downstream industries.

Recent trends

The packaging machinery industry has been facing quite a favourable development in recent years.

EC production totalled an estimated ECU 6 billion in 1992. Germany and Italy allow together for almost three quarters of this figure. About 64% of EC production is exported, of which 55% has an extra-EC destination. Germany and Italy show an even higher export orientation than the EC on average, namely around 70%. Conversely, these countries have the lowest import penetration. Germany and Italy are both net exporters; all the remaining Member States recorded trade deficits in 1992. Total EC employment for this NACE is estimated at about 55 000 employees.

The breakdown of production stresses the importance of form, fill and seal machinery and the combined filling and closing machinery. Both types of machinery find their applications mainly in the food, beverage and tobacco processing industry.

In 1992, however, the situation deteriorated due to ongoing recession in the major industrial countries, having an adverse impact on domestic and foreign demand. Moreover, the EC packaging machinery industry is suffering from the breakdown of East European markets caused by lack of foreign currency. Finally, the reunification boom in Germany came to an end in 1992. These adverse developments caused a significant drop in growth rates; in Germany, the 1992 growth rate was 5% as against 13% to 15% per year from 1989 to 1991.

International comparison

The Triad's total production amounted ECU 11 billion in 1992. With 54% the EC held the greater share; Japan accounted for 26% and the USA for 20%. While Japanese and American firms benefit from large domestic markets European firms have turned to exports markets. German and Italy allow together for two thirds of the Triad's exports. Germany is the worlds' largest exporter. For Japan foreign trade is rather insignificant; only 6% of production is exported, whereas only 4% of Japanese demand is covered by imports. For the USA both rates are 25%. The EC is a net exporter and so is Japan, despite its low export orientation; the USA recorded a trade deficit in 1992.

Foreign trade

The EC has a surplus on its trade balance that nearly doubled during 1983-1992 period. Almost 70% of the extra-EC exports are destined for less developed countries or NICs. Within the industrialised world the USA is the most important destination, but its share has declined significantly since 1988. Especially, wrapping machines for candy, tobacco products and sundries were the main EC-products. The lack of a Japanese export orientation, thus far, enhances the market opportunities of

EC-manufacturers in Far East countries. Market demand for European packaging machinery for instance in countries like China and Singapore recorded high increases in recent years.

The extra-EC imports have their origin virtually only in the industrialised world (93%). The EFTA countries and the USA together allow for 85%; the EFTA countries are by far the larger trade partner. However, regarding the relative small extra-EC import flow they meet only 10% to 15% of the EC needs. Japan supplies are only 7.5%, which was lower than in 1988.

MARKET FORCES

Demand

Demand for packaging machinery comes mainly from the food, beverage and tobacco industry; these industries account for an estimated 60-70% of total demand. They are followed by the pharmaceutics, chemicals and related industries. These downstream industries each have their own specific needs. The fact that these industries meet primary consumer needs causes demand for packaging machinery to be less cyclical than demand for other machinery and equipment. The downstream industries require increasingly more efficient, reliable, flexible and versatile machinery, enabling the manufacturers to respond to the further diversification of consumer demand. This causes product life cycles to shorten. More flexible and versatile machinery imply quick change-overs for packaging different products, package sizes and variable quantity production runs.

Supply and competition

Many Italian manufacturers have invested heavily in research and development, and production equipment in recent years. The resulting improvement of the engineering quality of their products is more in compliance with current market requirements, which especially concentrate on flexibility, production speeds and fast change-over times.

The minor Japanese share on the world market and low export ratio can be explained by the industry's comparatively small business scales and the custom-tailored products which require far-reaching after delivery service. For this reason the Japanese have been focusing on the nearby and large domestic market. Once the industrial trend is moving towards more standardised machinery and equipment, Japan will be able to develop similar advantages as they have in the automotive and other industries. However, for the coming years when much attention will still be focused on engineering and tailor-made solutions not much threat can be expected from the Japanese. For example, the export share of Japan in the Extra-EC imports declined during the 1988 and 1992 period from 12% to 7.5%.

In contrast with other US machinery manufacturing industries, the packaging machinery industry seems to have been able to benefit from the lower dollar exchange rate. The US-exports increased by 4% in 1991, and by nearly 10% in 1992, but the export share remains relatively low (around a quarter) if compared to Italy and Germany. The US packaging machinery is noted for its robust construction and sophisticated electronics.

The high degree of concentration in downstream industries such as in the food industry, might result in price cuts and lower margins in the long run. The packaging machinery industry itself, however, is responding with a similar trend towards more concentration and a further internationalisation.

Production process

Like in other mechanical engineering industries, especially where custom-tailored products are being produced, the labour force is an important asset when the engineering quality together with research and development are taken into consid-

eration. As a consequence, the quality of the labour force and thus the quality of the training programs is a major factor influencing the success of EC-industry in the long run. Therefore, the quantity and quality of education and training should be maintained, otherwise the technological advantage of the industry could fall behind. Furthermore, when demand for well-trained employees exceeds the supply of labour, productivity losses are likely to occur.

Keeping the quality of the labour force, however, should not lead to excessive wage increases. Sharp rises in input prices of materials and labour wages, as happened during the last couple of years, will have a negative impact on the industry's profitability and will cause reduction in investments weakening EC-competitiveness.

Beside the quality of the labour force, the extent to which a manufacturer of packaging machinery is able to meet the customer requirements is also determined by the quality and precision of the own production equipment. The increasing demand for versatile machinery for instance requires advanced production equipment together with high labour skills and large investments in R&D.

INDUSTRY STRUCTURE

Companies

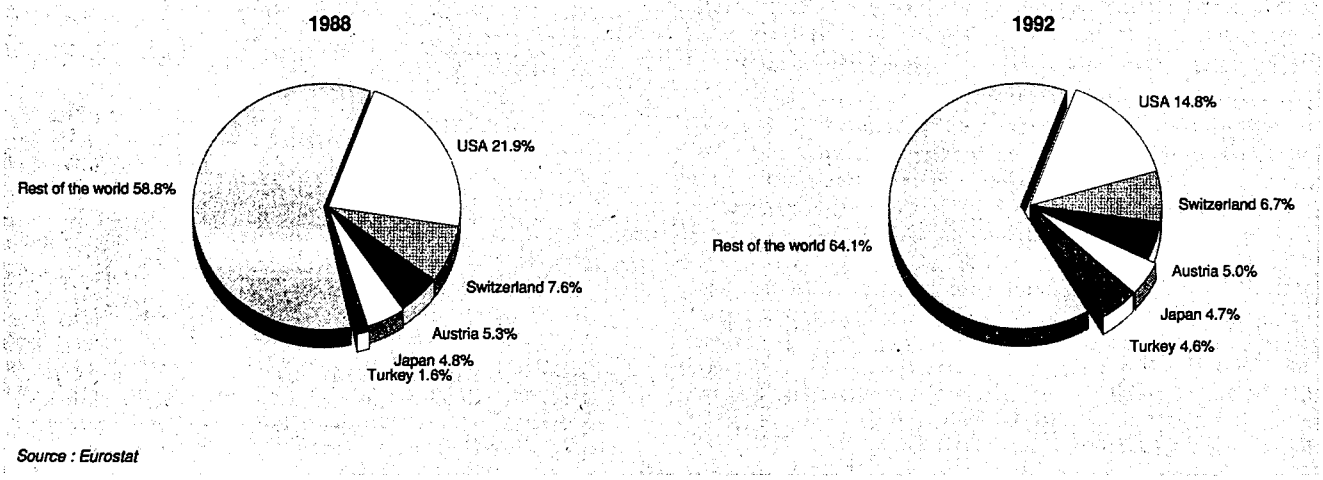
The total number of enterprises in the EC belonging to this NACE is estimated at 1 100. They are mostly medium-sized: on average they employ 50 employees with a turnover of some ECU 6 million. However, these figures vary significantly from one Member State to another. Employment by company ranges from less than 25-30 employees in France and Spain to 90-100 in Germany and the Netherlands; turnover per company varies from ECU 2.5 million in Spain and the United Kingdom to ECU 8.0-8.5 million in Germany, Italy and the Netherlands.

Strategies

In general the enterprises focus on one market niche (e.g. mostly one machine function for a specific industry). Larger firms such as Bosch (D) and AMCA/GD (I), which offer packaging machines for a wide range of industries, are still rare. A trend towards vertical integration might have been set by the two Swedish multinational companies Tetra Pak (milk and juice packaging group) and Alfa-Laval (manufacturer of food and other industrial equipment). Tetra Pak took over Alfa-Laval, thereby creating the possibility of 'one-stop shopping' as packaging and processing machinery can be bought at the same address.

The enterprises, in general, do not only react to market extensions coming from the single market, the German unification and the political changes in the former East bloc countries. Although, developments in specific markets force them to review their company strategies. The general trend towards more concentration by specialised companies merging or cooperating can also be explained by such developments. Cooperation enables them to offer tailor-made machinery and equipment to meet customer needs. A further explanation for the concentration of activities can be the threat of increasing market power of some large multinationals which dominate the downstream markets. This might lead to lower margins for the manufacturers of packaging machinery.

Figure 2: Packaging machinery
Destination of EC exports



Source : Eurostat

On the other hand, the same multinationals, by their expansions in the former East bloc countries, also offer market opportunities for the EC-manufacturers of packaging machinery. This trend of medium-sized companies penetrating more and more into these countries can be observed within the single market. A further internationalisation will also increase the strength of current market positions and will enhance opportunities to benefit from the European unification.

To maintain competitiveness EC manufacturers should invest in new, more efficient and precise production equipment in order to enhance the engineering quality and to reduce costs. An example of successful investments have been the Italian efforts to upgrade the own industry. The increasing demand for more versatile machinery, however, will also require new investments by machinery manufacturers.

ENVIRONMENT

The growing consciousness among consumers regarding environmental issues together with the growing influence of the downstream industries and retail networks on packaging decisions are becoming increasingly determinant factors within the industrial chain. The ever increasing restrictive legislation, particularly in the West and North European countries are controlling the nature of the package and packaging material. There is a growing demand for recyclable packaging material and 'environmentally friendly' packaging. Domestic government or EC legislation can best control the environmental problem. When environmental measures are in line with commercial and financial objectives, more support and initiative can be expected from retailers.

There is evidence of an increase in the use of recyclable packaging materials and 'environmentally friendly' packaging. For the near future a growing use is expected for form, fill and seal machinery caused by the rising demand for snacks and food in thermoform-packages. Further, growth is expected for combined filling and closing machinery and for group packaging.

REGULATIONS

Until now, environmental law and regulations have been limited to national levels. Germany and the Netherlands are in the lead if it comes to actual measures, although other EC-countries - especially those situated in the North part of the EC, have also made progress with governmental legislation. In contrast with the German Ordinance, the Dutch follow the path of mutual agreement. This consensus attitude between Dutch government food industry and retailers in the Netherlands has led to voluntary agreements to retain the deposited glass bottle and move out of PVC packaging. The German Packaging Ordinance, on the other hand, is said to constitute a barrier to free trade within the Community. In order to protect the single market principle, the European Commission has been urged to come to an EC Directive in order to prevent the occurrence of differing national regulations.

In the beginning of 1992, a fourth draft of the EC Packaging Waste Directive has been published. The stated objectives of the directive are: to reduce the amount of packaging waste produced; to require the recovery of packaging waste; and to minimise the amount of packaging waste which goes into final disposal. Practical implementation, however, can take until the mid-1990s. In any case, the packaging industry will be confronted in the near future with discouragement policies which will affect growth in demand for packaging materials. Limitations on raw material usage, less weight of packages and more recycling need not necessarily imply a threat to the manufacturers of packaging machinery. Products need to be packed and delivered to the consumer anyhow, but only the type of packaging material may change.

Only if current excessive packaging is forbidden the industry might be affected. Also, substitution of certain raw materials, induced by environmental concerns, by less polluting materials, might have consequences for the applied machinery. Some currently applied machinery is able to process different types of material and/or reduce the quantity of materials used.

Enforcement of the development and production of new packaging materials could even imply a stimulus for the manufacturers of packaging machinery. Demand for new and innovated machinery would rise and the extra expenses caused by the high development costs would probably be passed on to the end users.

The CEN/TC 146 EC safety standards also apply to the packaging machinery. In each member country, the packaging machinery manufacturers are cooperating with their national standardisation organisation to develop European standards.

OUTLOOK

Throughout 1989 and 1991, the EC industry developed very favourably: double digit growth rates of 13% to 15% per year were achieved. The situation deteriorated in 1992, although the sector's production still increased by 5%. However, since autumn 1992 production has fallen. The adverse development was due to various factors, such as the downswing of the trade cycle in major industrial countries, the breakdown of East European markets and the ending of the reunification boom in Germany.

Although the production is expected to recover by the end of 1993, this is not considered to compensate for the production loss suffered in the rest of the year. On the other hand the decline is expected to be less than in other machinery industries; client industries are less subject to swings in the business cycle, as they are meeting primary consumer needs. After 1993, production growth will pick at a level comparable with that prevailing before the booming years 1989-1991.

A shift in demand to more versatile machinery will stimulate and require further technological development at the supply side. The EC industry already has strong footholds on the world market. However, in order to retain its competitiveness much effort and means have to be put into research and development and maintaining the quality of the labour force.

The new EC Packaging Waste Directive need not necessarily harm the manufacturers of packaging machinery. While measures focus on recycling, less packaging quantities, and less waste of raw materials, the greater part of packages is non-excessive and current applied machinery is often able to process different materials and packaging sizes. Enforcement of the development and production of new packaging materials could even imply a stimulus for the manufacturers of packaging machinery.

Plastics and rubber machinery

NACE 324.3

The growth of the plastics and rubber machinery sector in the European Community has in recent years been well above the average of the manufacturing sector. This was due to high growth rates in the plastics processing industry and in the automotive sector, the latter being the main application for rubber products. Technologically there are two objectives: the continuation of the development towards automation, and the consideration of ecological issues. Against this background the medium term prospects of the sector are reasonable and competitiveness against American and Japanese products appears to be guaranteed.

INDUSTRY PROFILE

Description of the sector

The plastics and rubber machinery industry manufactures a wide range of equipment including: extruders, injection moulding and blow moulding machines, compression presses, foam manufacturing and thermoforming machines. It also manufactures other equipment not separately classified such as granulators, calendars, mills and a variety of spare parts.

Most of these machines can be adapted for processing plastics or rubbers and cover a range of sizes from small bench-top machines for making very small components to very big machines capable of moulding for example, large storage tanks. The variety of products that can be produced from these machines include expanded polystyrene burger cartons to large building insulation slabs, and medical catheter tubing to large diameter sewer pipes.

The variety of plastics materials that may need to be processed requires that machine specifications can be modified to suit particular processing characteristics. Specialised machinery, such as tyre forming, vulcanisation and associated equipment are particular to rubber processing.

In the European Community, the principal producer countries are Germany, Italy, France and United Kingdom. Switzerland, Austria, Spain, Netherlands and Luxembourg are also active in this field, but can not provide regular statistics. Germany and Italy are the main producers having shares of nearly one half and one third respectively of the EC total. The other countries together account for just one fifth.

The breakdown of the production and consumption figures by type of machinery shows the leading role that injection moulding machines and extruders play in the processing sector.

Recent trends

The plastics and rubber machinery manufacturing industry in Europe has a turnover of 7.2 billion ECU, comprises about 500 companies and employs about 70.000 people.

The apparent consumption in the four principal EC Member States rose by an annual average of 21% between 1983 and 1988, making this sector one of the fastest growing in the EC during the last decade. However, between 1988 and 1992 the equivalent figure was only 4%, due to a decrease in consumption of 21% between 1991 and 1992.

The production of machinery in these countries in 1992 totalled around 5.5 billion ECU, a decrease of about 14% compared with the previous year, reflecting the downturn in the world economy. This situation is only a temporary interruption in the continuing growth of the sector. The industry has solid competitive strengths and its demand is boosted by the continuing investment by the plastics processing sector, which must upgrade in response to both growing demand and intensifying competition on world markets.

International comparison

European manufacturers have always been the technological leaders in the sector and have established a commanding position with around three quarters of the world market.

Competition from the USA, Canada and Japan has intensified, but prospects remain good for European manufacturers, whose knowledge and experience still give them an overall advantage.

Foreign trade

Germany and Italy rank first and second respectively in world exports. Japan comes on the third place with only a quarter of the value of German exports of plastics and rubber machinery in 1992.

Following the high growth rates in foreign trade during the 1980s, the slowdown of the world economy has affected both imports and exports from the EC. Most of the trade in the early 1990s has been within the EC, with the United Kingdom and France being the main destinations.

Source : Eurostat

The single European market already exists in the plastics and rubber machinery sector. Little direct impact can be expected from the completion of the single market programme.

The potential markets expected in Eastern Europe have so far failed to show significant growth.

MARKET FORCES

Production process

The machinery industry is devoting a great deal of its technological resources to the development of computerised control systems and the standardisation of protocols for the links between machinery, ancillaries and central computer systems.

Automation and robotics are now often integral features of modern processing machinery. This has become an essential element of modern manufacturing plants in the drive to improve product quality and output, and to reduce costs and environmental impact.

New plastics materials emerging in recent years, together with new products and applications in almost every field, often require new processes and manufacturing techniques to be developed. The machinery manufacturers therefore are constantly researching, designing and developing equipment to meet new challenges. It is in these areas of expertise that the EC industry is still the world leader.

INDUSTRY STRUCTURE

Companies

The major machinery manufacturing companies in the EC include Krupp (D), Battenfeld (D), Klockner (D), Mannesmann (D), (including DEMAG and Krauss-Maffei) Sandretto (I), Reifenhauser (D), Engel (A), Stork (NL), Billion (F), Negri Bossi (I), Francis Shaw (UK), Netstal (CH) and Bucher Guyer (CH).

OUTLOOK

There are indications of an upswing in the UK economy in 1993 which in turn has been reflected in the plastics and rubber processing sector. In addition, increasing competition in consumer products markets, particularly in packaging, electrical goods and motor vehicles, has encouraged investment in modern new machinery to improve productivity. The same competitive pressures have also encouraged more extra-EC sourcing of goods from Asia, which has in turn opened up new opportunities for machinery sales in that region.

Japanese competition is slowly growing in Europe and has inevitably some impact on EC production.

Machinery for lifting and handling

NACE 325.5

The industries in NACE 325 basically produce investment goods. Demand, therefore, depends largely on investment decisions in downstream industries. Manufacturing of lifting and handling equipment allows for some 40% of the sector's total production.
The cyclical pattern of investments gave rise to highly variable growth rates for the industry. EC manufacturers largely cover EC demand, but the share of non-EC suppliers has increased in the past.
R&D and highly qualified labour are essential for the industry. Most companies tend to specialise in certain kinds of machinery, which resulted in a high dependency on specific markets. Recognition of this dependency together with the expected increase in competition in the Internal Market gave rise to merger and acquisition activities.

INDUSTRY PROFILE

Description of the sector

Among the products of the manufacture of lifting and handling equipment "industrial trucks" are an important category. These are defined as any wheeled vehicles, not running on rails, which are designed to carry, tow, push, or lift any kind of load. Other examples of handling equipments are: elevators, escalators, ropeways, cranes pneumatic handling equipment, hoists (electric and pneumatic) elevating work platform, storage and retrieval machines, etc.

Recent trends

In 1991 production of lifting and handling equipment accounted for some ECU 17.5 billion, and consumption totalled ECU 16.5 billion, which was 40% and 42% of the sector's total production and consumption respectively. The export rate was 16%, the import rate some 10%. Allowing for intra-EC trade, these rates were 37% and 33% respectively. The main producing countries of lifting and handling equipment are Germany, France, the United Kingdom and Italy. With a joint share of 95% they accounted for nearly the entire EC production. Germany held the greater share (42%), France and the United Kingdom allowed for 20% each and Italy for 13%.

Production rose by 6.5% (in current prices) between 1989 and 1991. In particular Germany and France contributed to this growth; Italy's production grew only slightly, whereas the United Kingdom recorded a small production fall. The remaining Member States revealed also a decline in their production.

International comparison

Considering the whole NACE 325 category, the EC is the largest manufacturer with an estimated share of over 50% in the Triad's total production in 1992. Around 30% of Japanese production, 23% of the EC production and some 10% of the US production is sold outside the domestic market.

In constant terms EC production declined in 1992 for the second consecutive year. Although data are lacking, the global recession together with declining EC imports from Japan and the USA (in nominal terms) indicate that production of these countries might also have dropped in 1992.

Foreign trade

Extra-EC exports increased in current prices at an average rate of 5.1% per year between 1988 and 1992. However, the growth took mainly place in 1989 when it was 12%. Since 1990 the export level remained unchanged. The annual growth of the extra-EC imports was 8.7% on average between 1988 and 1992. The importance of intra-EC trade is quite considerable: about two thirds of the total imports and some 55% of total exports. Between 1988 and 1992 it grew by 7.5% per year.

Throughout the period 1988-1992 the EC was a net exporter of lifting and handling equipment; the trade surplus fluctuated at around ECU 1.1-1.2 billion. The four main producing countries (Germany, France, the United Kingdom and Italy) are all net exporters. Minor producing countries like Denmark and Ireland recorded trade surpluses too, whereas for Spain the in- and outgoing foreign trade flows balanced; the remaining Member States are net importers of lifting and handling equipment.

Source : FEM

In 1992 the EFTA countries allowed jointly for 22% of the extra-EC exports, against some 28% in 1988. The share of the USA declined too: from 15% to 10%. The importance of some Asian countries (Iran, Saudi Arabia, South-Korea and Hong Kong) as export destinations increased between 1988 and 1992.

As regards extra-EC imports of lifting and handling equipment, the EFTA countries, Japan and the USA are the main origins. In 1992, they accounted together for 87% of extra-EC imports, which is virtually the same as in 1988. Remarkably, Japan's share declined (from 24.5% to 20%), whereas the shares of the EFTA countries and the USA increased; from 49% to 50% and from 14% to 16% respectively.

MARKET FORCES

Demand

The products of this sector are basically capital goods. Demand for these products is therefore highly dependent on investment decisions of downstream industries. The client industries differ by type of machinery.

Car manufacturing, building construction and companies in the transport and warehousing sectors are of particular interest to the demand for lifting and handling equipment. Moreover, companies which operate their own warehouses for materials or finished products are buyers of lifting and handling equipment. Investments in handling and storage equipment have become decisive factors influencing the operating profitability of manufacturing and processing industries.

Supply and competition

Despite the high volatility in demand, profit rates have remained fairly stable and even improved at the end of the eighties. In years with a declining market one would have expected a tendency to lower prices in order to fill existing capacities with new orders for machinery. However, this has not been the case in the industry: this implies that price competition must be fairly limited. An explanation can be found in factors like quality and technological level of products. Customers are prepared to pay more for high quality products, when efficiency improvements by these products enable a better return.

Production process

CAD/CAM systems are used to design and manufacture machines. Computerisation and application of advanced electronics have also become a basic feature in new machinery, not only to improve the efficiency of the machine itself, but also for machine safety, pollution control, precision in operations and the like. Hence, innovation has become top priority in maintaining competitive advantages.

The industry requires highly qualified employees, which have knowledge about modern technologies in machinery and equipment. Some companies have education facilities for its employees to keep them up to date with these technologies.

Source : Eurostat

Considering the NACE 325 category as a whole, developments since 1983 in labour productivity, unit labour cost and total labour cost indicate that the efficiency of the production processes has increased; labour productivity in current prices increased at a faster rate per year than unit labour cost: 6.8% versus 6.2% per year. Secondly, capital intensity of the production processes has increased; total unit cost increased more than unit labour cost: 6.7% versus 6.2%.

Enabled by a modular production process, using standardised parts and components, lifting and handling equipment has become only customised, rather than standard products. By combining different modules customisation becomes possible. The required increased production flexibility has been obtained by applying modern technology in the production process. Technological development is also proceeding in lifting and handling material itself. For example, as a result of factory automation and automated warehousing, industrial trucks have to be equipped with electronic devices for advanced handling systems. An example of a modern industrial truck is the automated straddle carrier able to locate and move containers without human interference.

INDUSTRY STRUCTURE

Companies

The lifting and handling sector consists of many small companies and a few large groups. The average number of employees per company is estimated at some 125. Large multinationals dominate the industrial truck market. European suppliers like Linde/Still (D), Lansing (UK), Jungheinrich (D), Lancer-Boss (UK), and Manitou (F) compete with leading suppliers from Japan, such as Toyota and Komatsu, and from the USA, such as Hyster and Clark. An important non-EC supplier from Scandinavia is Valmet, which has 60% of the world market in straddle carriers.

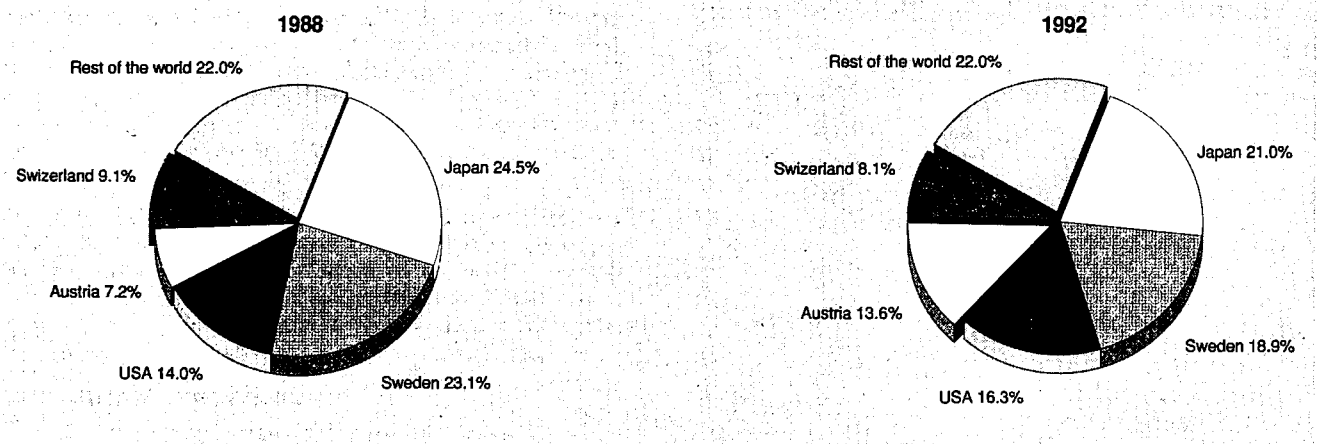
Strategies

In order to cope with increased competition on the EC market after 1992, EC companies are extending their involvement in mergers, acquisitions and strategic alliances with other companies. This process has also involved non-EC companies, aiming at maintaining or extending their position on the EC Market.

Japanese manufacturers have responded to the forthcoming establishment of the Internal Market by building production facilities in EC Member States. Nissan set up a production line for industrial trucks in Spain in 1989. Toyota, Komatsu and Mitsubishi have concluded cooperative agreements with EC sited companies. JCB (UK) linked with Sumitomo; Fiat (I), Hitachi (J) and John Deere (USA) considered a joint venture. Moreover, Krupp (D) concluded an agreement with Komatsu for selling Krupp's mobile cranes in Japan. US manufacturers have also expanded their activities to Europe: Clark and Caterpillar relocated factories to Europe during 1986.

Another reason for concentration is that companies want to centre around the core activities in which they have acquired strong positions. By merging and entering into strategic alliances, the risk of the dependency on specific markets is minimised.

Figure 2: Machinery for lifting and handling
Origin of EC imports



Source : Eurostat

ENVIRONMENT

Energy efficient and less polluting machinery and equipment are increasingly being demanded by the customers of this industry. The customers themselves want their production processes to be as clean as possible, not only as a result of consumer demands, but also to anticipate on restrictive government measures. R&D therefore focuses on these environmental issues.

Industrial trucks for outdoor use fuel-powered equipment have become more common, and restrictions on pollution from exhaust fumes have become more important. Industries are trying to improve on energy efficiency and exhaust pollutants. For battery-powered trucks, mainly for indoor use, battery obsolescence is given more and more attention.

REGULATIONS

The EC Directive on machine safety is of particular relevance to the industries in this NACE, as it is to the other mechanical engineering industries. This Directive, already adopted in 1989, envisages the application of safety standards for EC-produced machinery by January 1st, 1993. However, until January 1st, 1995, manufacturers have to comply with either the old standards prevailing in the Member State where products are sold, or with the Directive standards. The latter has the advantage of the products being labelled with the CE-mark, giving it free access to the markets of all EC countries.

In 1991 the coverage of the Directive was extended to apply also to cranes and other lifting installations and mobile machines. This extension is especially relevant for machinery in the construction industry and industrial trucks in mining and warehousing.

Another important issue is the harmonisation of technical norms and standards throughout the EC. Two normalisation institutes, CEN and CENELEC are currently working on proposals for European standards. There is also a preference to develop standards which meet those on a world level.

Regulations influencing the customers in downstream industries could effect the sector indirectly. For example, the opening up of the Internal Market for public procurement will influence activities in infrastructure construction and public works projects. Companies active in this field will need modern quality machinery in order to challenge the increased competition.

OUTLOOK

Investment in handling and storage equipment is increasingly important. Materials handling is the key ingredient in today's modern production processes where goods are to be conveyed, lifted, stacked on pallets and retrieved. Investments in handling and storage equipment, therefore, are decisive determinants of the profitability of manufacturing and processing industries.

The short term prospects for the sector are rather gloomy, because a recovery of the business cycle is not expected soon. Demand from downstream industries will remain depressed both within and outside the EC. Further, the positive impact of German unification on demand has virtually disappeared. Demand is expected to pick up in the course of 1994. After 1994 the economy will gradually recover, orders will pick up and growth rates may gain momentum again.

Transmission equipment
NACE 326.1, 326.2

Due to a further drop in EC demand, in 1992 the EC industry for transmission equipment was coping with the second consecutive fall in production; exports remained stable.
The EC industry's competitiveness depends largely on a high level of technological knowledge. To maintain or improve competitiveness, R&D activities and training programmes are essential. Moreover, competitiveness can be improved by internationalisation. Most of the mainly small companies currently have only local or regional coverage. As regards future development of production and consumption, the situation in the medium term is considered to be better than on the short run.

INDUSTRY PROFILE

Description of the sector

This industry encompasses two subsectors:

- manufacture of transmission equipment for motive power (NACE 326.1);
- manufacture of ball, roller and similar bearings (NACE 326.2).

The manufacture of transmission equipment includes the manufacture of gears, gear assemblies (gearboxes, variable speed gears, industrial gearboxes, high-speed gears and differentials), transmission chains (including bicycle chains) and other transmission equipment. Not included is transmission equipment manufactured for the automotive industry nor hydraulic or pneumatic transmission equipment. Some of the companies in the industry deliver to both the automotive industry and other manufacturing industries, or offer a wide product range thereby covering other products than transmission equipment, gears and bearings.

Germany is by far the largest producer in the industry accounting for 53% of total EC production, in value added. Italy, France and the United Kingdom follow with shares ranging from 11% to 17%. Except for Italy, where the 1992 production was almost 3% higher than in 1991, the major producer countries reached in 1992 lower production levels than in 1991.

Recent trends

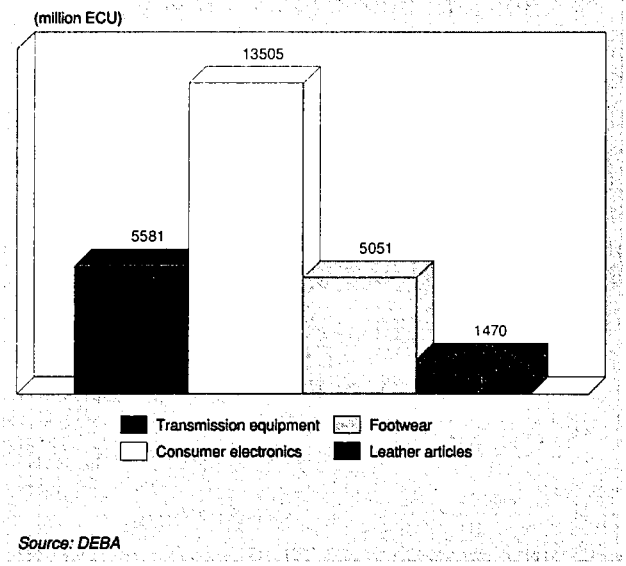
The industry went through a period of growth throughout the 1983-1990 period. In current prices consumption, production and exports increased at an average rate of about 9% per year. High growth rates were particularly obtained in 1984, 1985 and 1989. The positive trade balance grew too; it reached its peak in 1989. Employment peaked in 1990. In the beginning of the 1990s the situation deteriorated. EC demand fell and so did the extra-EC exports. As a result production and employment declined too.

In 1992, production in nominal terms declined by 2.9%. Employment dropped by more than 7%. The fall in production was entirely due to reduced demand in the internal market; non EC-exports remained unchanged. The export share is about a quarter of production; import penetration is about 18%. The EC is a net exporter of transmission equipment.

International comparison

The EC is the world's largest producer of transmission equipment. In nominal terms the EC production level is some 55% higher than that of the USA and about 39% higher than that of the Japanese. In constant prices both EC and US production declined by 4% to 4.5% in 1992. For the EC this was the second, for the USA the third consecutive fall in production. The USA had in 1990 the most significant decline (18%); EC production dropped most in 1991 (12%).

Figure 1: Transmission equipment
Value added in comparison with other industries, 1992



Source: DEBA

Foreign trade

The EC is in general a net exporter of transmission equipment. Moreover, the trade surplus increased on average by some 6% per year over the 1983 and 1992 period. The growth rate was highest (8%) during the period 1983-1990; the trade surplus reached its highest level in 1989 and has fluctuated since.

The export and penetration rates changed only little during the 1983 and 1992 period, although a slightly increasing tendency can be observed for both rates. The export rate was 25% to 26%, and the penetration rate 16% to 18%. Allowing for intra-EC trade these rates were 56% and 52% respectively in 1992, reflecting the importance of this trade. It reflects also the international, but not particularly global character of the sector.

As regards exports, the EFTA countries are the EC's principal trade partner; the USA ranks second. In 1992, they allowed together for 51% of the total EC exports. In 1987, this share was slightly different (53%). Japan is only of marginal importance to the EC exports of transmission equipment.

The EFTA countries and the USA play also a major role in the EC imports of transmission equipment, but Japan is important too. These three (blocks of) countries accounted together for 80% of total EC imports in 1992; in 1987 this was 86%. The decline is particularly due to the fall in the share of the EFTA countries, which remained however the most important origin of the EC imports of transmission equipment. The USA lost their second position to Japan.

MARKET FORCES

Demand

Customers of this industry are a variety of manufacturing industries. Demand for transmission equipment, therefore, depends largely on investments in capital goods made by these downstream industries. After a period of booming investments in the second half of the 1980s by some major EC and non-EC client industries, both EC and foreign demand fell as a result of disappointing growth rates on the downstream markets within and outside the EC. Profits dropped accordingly, which together with high capital cost was not encouraging for investments in capital goods.

The product range of the industry consists of rather conventional equipment like bearings, cranks and chains. Electronics and miniaturisation are becoming increasingly more important. This may give rise to increased demand for competing transmission techniques like electrical, hydraulic and pneumatic means of transmission. If, and then to what extent, substitution is threatening the manufacture of mechanical transmission equipment depends on the possible applications of other technique-based machinery and equipment. The increasing use and combination of different techniques by the manufacturers of transmission equipment makes it difficult to specify possible substitution effects.

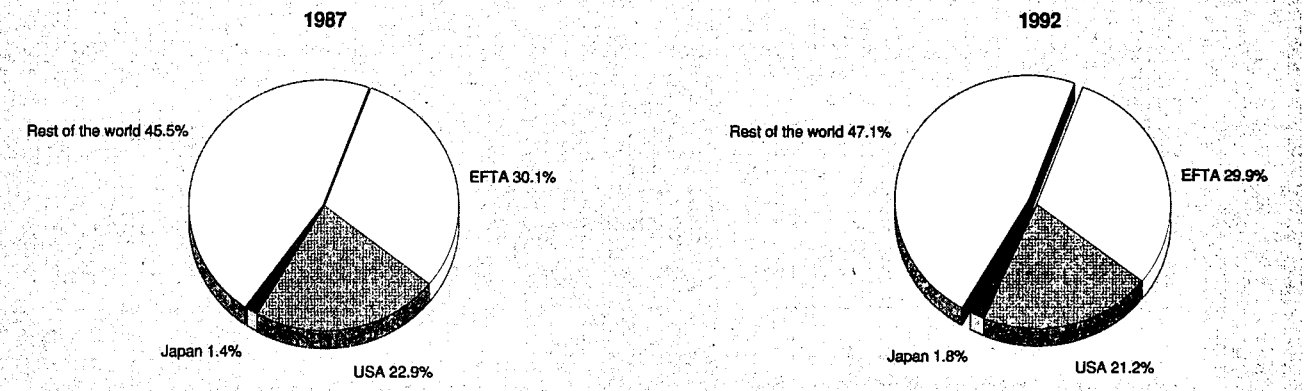
Figure 6: Transmission equipment
Destination of EC exports



Source: Eurostat

Supply and competition

Transmission equipment, gears and bearings constitute approximately 3 to 4% of total production of the mechanical engineering industry. The enterprises in the industry offer a wide range of products. A particular feature of the industry is that the manufacturers of transmission equipment supply other investment goods. This is a major reason why the industrial production of transmission equipment has concentrated in countries with an emphasis on investment goods production: Germany, France, Italy and the United Kingdom. Remarkably, Germany recovered slightly from the decline in 1991, whereas the other major producing countries were facing another decline in 1992.

The production fall in 1991 caused lower aggregated productivity rates, but productivity rose again in 1992. If the development of import penetration is considered, the competitiveness of the EC-industry does not seem to have been affected seriously. Nevertheless, the weakness of demand will continue to put pressure on margins as competition will intensify.

Production process

The EC industry's competitiveness depends largely on a high level of technological knowledge. Advanced technological machinery and a well trained labour force are important inputs in the production processes of the industry. Investments in R&D, therefore, are essential. At the same time training programmes must be implemented to keep the labour force informed on the latest technological developments, so that optimal use can be made of R&D results.

Developments since 1983 in labour productivity, unit labour cost and total labour cost indicate firstly, that the efficiency of the production processes has increased. Labour productivity in current prices increased at a faster rate than unit labour cost, namely by 6.7% and by 6.1% respectively. In constant prices the increase was only 1.7% per year. Secondly, the figures demonstrate that the capital intensity of the production processes has increased, as total unit cost increased more than unit labour cost: 7.2% versus 6.1%.

INDUSTRY STRUCTURE

Companies

German companies such as FAG Kugelfischer and ZF Friedrichshafen dominate the market. On the market for speed changers, industrial high speed drives and gears, the A.F. Flender Aktiengesellschaft is an important manufacturer.

Most enterprises are medium-sized and often do not operate plants in other countries than the mother country. Only a few EC enterprises are present in several EC countries. Of the non-EC manufacturers the Swedish enterprise SKF already has a strong foothold in the EC with production facilities in the major EC-countries. Like its main competitor FAG Kugelfischer, SKF has also invested in former East Germany. Also, Japanese companies have established some production plants in the EC. With the help of low cost production, low and even dumped prices and a worldwide distribution network, the Japanese have increasingly penetrated into the EC. In 1992, the USA lost its second position in the extra-EC imports to Japan.

Strategies

The European companies still concentrate their efforts in R&D to retain and extend their market position. However, in order to prevent foreign companies from easily penetrating the EC-market, the EC companies should expand operations to a European scale in order to benefit from the opportunities of the EC Internal Market.

ENVIRONMENT

The industry does not seriously threaten the environment. The hardening and galvanising stages of the production process could cause serious harm to the environment, but measures have already been taken to prevent this. As far as products in mechanical power transmission is concerned, noise might be a problem. However, noise levels have been largely reduced as a result of improvements in production techniques. Costs arising from environmental protection in this industry are relatively low.

REGULATIONS

The EC Machinery Directive applies to the industry's products only to a limited extent. The greater part of the output is absorbed by the production of bearings, which does not have a direct impact on the safety of work conditions in the industry. Furthermore, the industry's products are generally used as a component of machinery products. It is at this latter level that safety provisions have to met. For the production processes within the industry itself, however, improved safety conditions of the capital goods, will be favourably received.

Companies will have to invest in quality improvement to meet the ISO 9000 quality standards. In the long run, the industry's competitiveness could be harmed if these quality standards would not be met.

OUTLOOK

Given an export rate of around a quarter the production of transmission equipment depends largely on developments within the EC. The prevailing recessive EC economy is not expected to recover before 1994. In the short run, therefore, EC demand will continue to decline. Production will also decline further, since the short term prospects for the export markets are dim.

In the medium term the economies of the major Western industrialised countries are expected to recover. At the same time competition on the EC Internal Market from non-EC suppliers, particularly from Japan, will increase. This is also true for competition in the export markets. Further, a possible shift in demand as a result of the fast growth of alternative transmission systems, electronic and other, could be a threat to the industry. It is not clear, however, to what extent manufacturers will be hit by the adverse substitution effects.

To cope with increased competition and possible changes in demand, the industry will continue to invest in process and product innovation. Further, the industry will focus on training programmes, whereas, particularly the larger firms will internationalise. It is expected that these measures will enable the industry to benefit from the medium term economic recovery.

Woodworking machinery
NACE 327.1

In 1992, the sector revealed a strong fall in demand and production, caused by the economic downswing of the trade cycle and increased foreign competition. Increased competition and more restrictive environmental legislation are major challenges to the industry, urging innovation.
The prospects for the short run will remain gloomy. Demand will continue to decline and so will production. In the medium term the economic situation will improve and innovation will enhance the competitiveness of the EC industry. This will have a favourable impact on demand and production.

INDUSTRY PROFILE

Description of the sector

NACE 327 includes the manufacture of machinery and equipment for use in specific branches of industry. The following industries are categorised under this chapter:

- manufacture of machinery for working wood and similar materials (NACE 327.1);
- manufacture of paper, paper goods making, printing and bookbinding machinery (NACE 327.2);
- manufacture of laundry and dry cleaning machinery (NACE 327.3);
- manufacture of plant for the leather industry, including boot and shoe machinery (NACE 327.4).

More than 60% of total EC-production of this NACE is accounted for by printing machinery. The production share of machinery for working wood is estimated at 20% to 25%, followed by much lower shares for plant for the leather industry and for the manufacture of laundry and dry cleaning machinery. The present monograph will focus mainly on woodworking machinery.

Recent trends

In nominal terms, EC demand for the entire NACE 327 fell significantly (16%) in 1992. At the same time non-EC suppliers succeeded in extending their market share in the EC. As a result EC production dropped seriously too (production fell by 14% in volume terms). The demand fall was partly compensated by a 2% rise in exports. Employment also declined (6%), but less than production. The sector is a net exporter.

After the economic crisis of the early 1980s, the period 1983-1990 featured a strong growth in production and consumption for the whole NACE 327; in nominal terms double digit annual growth rates were achieved (12% and 14% respectively). The trade surplus rose by 7.5% per year. The penetration rate remained virtually unchanged between 1983 and 1990, indicating that EC producers could well cope with increased EC demand. Further, in 1990 total employment was 18% higher than in 1983.

Foreign trade

Extra-EC exports of woodworking machinery reached their peak in 1990, when they attained a value of 942 million ECU. Starting from 1991, the effects of recession have considerably reduced extra-EC exports, which accounted for 760 million ECU in 1992. On the other hand, extra-EC imports remain quite low (188 million ECU in 1992), and the trade balance in the sector is always largely positive. Interestingly, intra-EC trade in the woodworking machinery sector has been constantly lower than extra-EC exports during the 1988-92 period, thus revealing the strong export-oriented nature of the sector.

The developing countries represent the major destination of EC exports of woodworking machinery, and their share has increased substantially during the 1988-92 period to reach 30.7% in 1992. This increase has taken place mainly at the expense of EC exports to the EFTA and the USA, which both decreased from 1988 to 1992.

The EFTA countries account alone for more than two-thirds of total extra-EC imports of woodworking machinery. Austria holds the lion's share with 42.1% in 1992. The effects of the deep recession which affects Sweden is highlighted by the fact that Swedish exports to the EC have more than halved during the 1988-92 period.

MARKET FORCES

Demand

The woodworking industry mainly produces investment goods. In the large manufacturing countries like Germany, Italy, USA and Japan there is a strong domestic demand. In some countries the export shares in total production are high, which implies a considerable importance of foreign markets.

Wood-processing industries are relevant to the demand for woodworking machinery. Hence, the final demand for wood and products of wood is vital. Data for three Member States, Germany, Italy and France indicate a considerable increase (15% to 16%) in demand for woodworking machinery in 1991, mainly due to a 36% rise in German demand, as a result of the reunification. Italy revealed a moderate increase in demand of 2% to 3%; French demand decreased by 9%. In Germany some 30% of demand was covered by foreign supplies in 1991; in Italy this was a quarter, whereas French requirements are for over 80% covered by imports. Germany and Italy are net exporters of wood processing machinery. In 1991 their export rates totalled some 60% and 70% respectively; in 1990 this was 70% in Germany, but due to decreased foreign demand it declined significantly. At the same time imports increased, entailing a decrease in the trade surplus by 32%.

Data for Germany and Spain further revealed a drop in market volume in 1992. On the other hand, consumption remained stable in Italy and declined in France (in value terms). Although domestic orders continued to grow substantially, the cyclical downswing in Europe and the USA caused export orders to decline such, that the overall order position deteriorated.

In the demand for woodworking machinery a trend can be recognised towards further automation in order to save on the use of raw materials, to cut energy cost and to increase productivity and competitiveness. Furthermore, automation is aimed for in order to improve safety conditions in the woodworking industry.

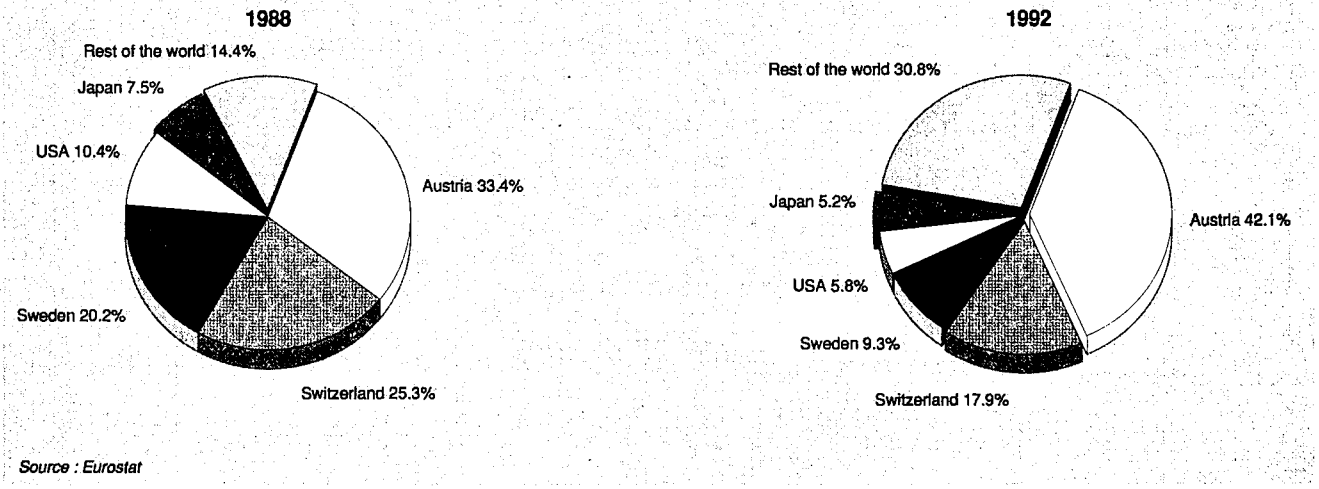
Supply and competition

The decrease of sales in the market caused an excess capacity, and will inevitably further reduce profit margins as price competition will intensify to some extent. However, the composition of the industrial customers are heterogeneous, which leaves room for extra margins especially if customer specific solutions are asked for. In this area, the EC industry is ahead of the competition from Japan and Taiwan. Within the EC, only Germany and Italy are important suppliers of machinery for specific branches.

Aggregate labour productivity (for NACE 327 as a whole) increased on average by 6.6% per year between 1983 and 1992; unit labour cost increased at about the same rate: 6.8% per year. Hence, efficiency in the industry has not improved over the years. This is particularly due to the developments after 1990. In 1991 and 1992 labour productivity fell by 3% and 5% respectively, whereas unit labour cost rose by some 7% in both years. In contrast, between 1983 and 1990 labour productivity increased at a much faster rate than unit labour cost: 9.9% versus 6.8%.

Over the years unit labour cost increased less than the growth of total unit cost (6.8% versus 7.4%), reflecting the growing capital intensity of the sector.

Figure 2: Woodworking machinery
Origin of EC imports



Source : Eurostat

The European woodworking machinery industry, which concentrates on labour intensive custom-made solutions, is negatively influenced by high wage costs due to increasing wages and decreasing effective working hours. On the US-market competition is fierce and the low dollar exchange rate has a negative impact on German and Italian sales. The quality of the European machinery and its after-sales service however, are at a high level and constitute an important competitive edge. In contrast with the European manufacturers Japanese and Taiwanese firms tend to focus on the building and delivery of standard and low-cost machinery.

The European woodworking machinery manufacturers concentrate on specialisation and innovation. Moreover, the industry is considering the EC increasingly as a suppliers market, where besides the traditional suppliers France and Italy, Spain and Portugal are becoming more and more important. Further, manufacturers are aiming at expanding their sales network, particularly through acquisitions. Examples are the Homag Group, encompassing 12 producing affiliates, the IMA group with five producing partners and the Wehrmann group, including, besides traders, six producing companies. Clients in commerce and industry are meant to benefit from the synergy effects of such cooperations.

INDUSTRY STRUCTURE

Companies

Some 780 companies in the manufacture of woodworking machinery employed 43 000 people (i.e., on average 55 employees per enterprise) in 1992, compared to a number of 42000 in 1988. The German industry encompassed around 242 companies in 1992: employment totalled 23 500 employees or almost 100 workers per company. The United Kingdom recorded an average company size of 72. Conversely, in Italy with 298 enterprises employing 11 100 workers, the average company size is much smaller, namely 37. Moreover, only 10% of the companies has more than 100 employees in Italy.

The EC industry is more labour intensive. Production per employee within the EC amounted to ECU 100 000 in 1990, while the same figure for the rest of the world was ECU 115 000. This is partly due to its higher degree of specialisation.

Strategies

Especially on the US market where competition is fierce for EC manufacturers, it will become more and more important to meet the specific market demands in order to retain market positions. In the Eastern European countries companies from the Western industrialised countries (including EC countries) are looking for cooperation (joint ventures) in order to create a strong strategic position, anticipating economic growth in the future. Other manufacturers seem to focus on direct trade with these countries.

REGULATIONS

Relevant to the sector is Directive 89/392, covering all types of machinery. It defines essential requirements concerning machine safety and health provisions. Provisions relate to the design, the materials used, the way in which machine operations should be illuminated, machine operations itself, safety against mechanical risks, the application of screens and other safeguarding components, maintenance and machine indications and identifications. Machines complying with the EC regulations will obtain the CE mark. Machine safety is of particular relevance to woodworking machinery. For specific types of this machinery compliance with the standards may be difficult.

In anticipation of EC regulations for a safer working environment the European manufacturers, therefore, already put much effort in R&D for the improvement of safety conditions of their machinery. In the manufacture of wood-working machinery the trend towards more automation also implies less dangerous working conditions. Although the safety regulations have officially been introduced as of January 1, 1993, there is a transition period until January 1, 1995, in which manufacturers have to comply with either the old regulation prevailing in the Member State where products are sold, or with the Directive standards. The latter has the advantage of the products being labelled with the CE-mark, giving it free access to the markets of all EC countries, provided that the complexity of interpretation of the directive, the increase in environmental regulations to which machinery must comply and the increase in controls will not end up to replace the old technical barriers with new ones and therefore reduce the competitiveness of European producers. The European industry would like to see the CEN standards also adopted by the International Standards Organisation (ISO) in order to safeguard the use of the same safety standards worldwide.

If ISO recognition does not happen, this legislation will probably result in European manufacturers having a two-tier production. Expensive machines with high safety standards will be built for the European market and cheaper versions will be assembled for other markets where safety standards are lower. This may allow European manufacturers to compete with emerging Asian manufacturers on a more equal footing.

OUTLOOK

In the greater part of 1993 the economic recession will prevail. At the end of that year the trade cycle will start to recover and this will continue into 1994. Demand for all product groups in the described industries is therefore expected to grow at a low rate. Further, the trend towards increased competition from non-EC suppliers on the Internal Market and on export markets, which EC manufacturers have been facing in recent years, will continue in the future. Hence, in the short run also production is expected to grow at a very modest pace.

The medium term prospects are considered to be better. This will particularly be due to economic recovery in the EC and on the major export markets. Moreover, the innovative activities of the manufacturers will affect their competitiveness favourably.

Liquid pumps
NACE 328.3

The EC is the world's largest producer of liquid pumps with Germany as the leading producing country. The EC is a net exporter. Due to the downswing of the trade cycle, and increased competition from outside the EC, production declined in 1992. However, EC manufacturers succeeded in maintaining their export rate. In order to cope with increasing competition within the EC companies tend to internationalise. Demand is expanding from the traditional applications of pumps to others, such as the use of pumps to make production processes less polluting.
The short term prospects for liquid pumps are not very favourable. The business cycle in the EC will not recover soon. The same applies to the current recessive export markets. For the medium term the prospects will improve, when the business cycle will recover. Additional demand can be expected from the rising interest for environmental protection.

INDUSTRY PROFILE

Description of the sector

This NACE includes the manufacture of compressors, pumps and equipment for operating machinery by hydraulic or pneumatic means. Besides liquid pumps the sector also covers compressors and vacuum pumps. However, for these latter product groups little statistical information is available. As a consequence, the description of the sector will mainly cover liquid pumps.

The liquid pumps can be divided into six classes: hand pumps; reciprocating pumps; rotary displacement pumps; centrifugal pumps; other pumps (not elsewhere specified); and parts for pumps.

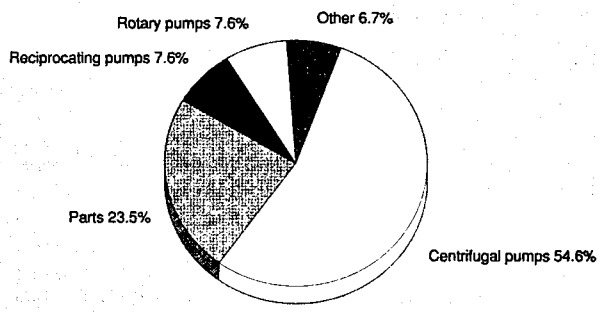
Recent trends

In 1992, both production and consumption of liquid pumps declined. Due to an increase of the extra-EC exports of 7%, however, EC production declined less than EC demand: 1.6% versus 3.2%. The EC is a net exporter of liquid pumps. In 1992 some 30% of production was exported; import penetration is modest: about 15% of EC demand is covered by imports. With a joint share of 78%, centrifugal pumps and parts allow for the bulk of the sector's production.

Germany, Italy, the United Kingdom and France accounted together for almost 90% of total EC liquid pump production. With over 40% Germany is by far the largest producing country. The other three followed at a distance: France has a share of 13%, the United Kingdom covers 16% and Italy's share amounts to 17.5%. Germany's leading position holds for all types of pumps, but it is strongest in hand pumps and reciprocating pumps. Remarkably, all the major producing countries recorded a production decline in 1992, whereas in the other Member States production grew.

Over the period 1987-1992 EC production, at current prices, increased at a slightly lower annual rate than demand: 7.4% versus 7.7%, indicating that the coverage of EC demand by EC producers, although still overwhelming, has fallen: from 86.6% in 1987 to 84.5% in 1992. Although the average increase of production was over 7% per year over the 1987-1992 period, production declined in 1992. Reduced demand on the Internal EC market, due to the prevailing cyclical downswing, and increased non-EC competition on this market, accounted for the production fall. Despite low exchange rates for the US dollar and the Japanese yen and recessive export markets, the export rate remained about stable.

Figure 1: Liquid pumps
Breakdown by major product line in the EC, 1992



Source: Europump

International comparison

The EC is the world's largest producer of liquid pumps. In 1991, US and Japanese production were respectively 60% and 36% of EC production. US production was 2.4% lower than in 1989. Conversely, Japan's 1991 production level exceeded that of 1989 by 5.4%. These developments comply with the general trend in mechanical engineering showing a weakening position of the USA and a growing Japanese share on the EC and world market.

Both EC and US production are more diversified than Japanese production.

Foreign trade

Both intra-EC exports and imports increased over the 1987-1992 period. Imports increased at a faster annual rate than exports: 10% versus 8%, entailing a decline in the exports to imports ratio from 2.67 to 2.38. Throughout the 1987-1992 period, the EC was a net exporter of liquid pumps. The trade surplus increased at a rate of 6.3% per year.

Extra-EC imports grew faster than demand, showing that foreign suppliers have become more important on the EC market. Their penetration rate increased from 13.5% to 15.5%. The export rate was in 1992 about the same as in 1989, namely some 30%.

With a growth rate of 12% per year during the 1987-1992 period, caused by strong demand in some major industries, intra-EC trade has been a major stimulus for production during that period. The share of intra-EC trade in EC production increased from a quarter to 30%. In 1992, extra-EC exports and intra-EC trade were virtually similar.

Germany has the highest export value; in 1992, Germany's total exports were 57%; non-EC exports accounted for some 48%. Within Europe, France and Italy are the most important export markets for Germany. In the same year the most important German export markets outside the EC were the EFTA countries and the USA.

MARKET FORCES

Demand

Market demand can be divided into two categories of liquid pumps: standardised pumps and engineered pumps. Both groups encompass a wide range of products and applications. Major markets for standardised pumps are the chemical industry, process industry, construction industry, food industry,

Source: Europump

shipping, horticulture, civil engineering and the original equipment manufacture (OEM) sectors. Engineered pumps are used in oil and gas industry, the petrochemical and chemical industries, power stations, irrigation and water supply. Both markets require custom solutions, for which an efficient production is needed.

Demand is expanding from the traditional applications into others. An important aspect is the use of liquid pumps for environmental protection purposes. In practically all end-use sectors, such as in the construction and chemical sectors, and the energy sector, pumps contribute to making production processes less polluting.

Supply and competition

The sharp increases in intra-EC trade during the last years in contrast with lower growth rates in extra-EC imports, could be an indication of the strong competitiveness of the EC-industry. In contrast with Japan for instance, the EC-industry - in general - seems to be more diversified into the various segments of the market for liquid pumps and has been able to benefit from growing segments.

Increased import penetration together with the weak global market, however, intensify price competition, causing a fall in profit margins. Most companies in the pump industry serve more than one end-use sector and, although not immune from the general economic cycle, do take advantage of the differing cycles of economic activity for each end-use industry.

Production process

Both capital goods and labour force are important inputs in the production processes of the various pump and compressor industries. The labour force is particularly important in view of technological research and development. As a consequence, the quality of the labour force and training programs is a major factor influencing the success of EC-industry in the long run. Keeping the quality of the labour force at a high level should not lead to excessive wage increases. Sharp rises in wages next to increases in input prices of materials (as happened in recent years) would have a negative impact on the industry's profitability and cause reductions in investments. This will weaken EC competitiveness.

INDUSTRY STRUCTURE

Companies

In general, most of the EC manufacturers of pumps are medium-sized. Most of them have specialised in a certain kind of pump or concentrated on one or more branches of industry.

In order to compete more aggressively on the EC Internal Market, the industry is trying to internationalise. This will bring changes in the structure of the pump sector. In recent years, a number of mergers and acquisitions have resulted in some big pan-European companies such as KSB (D), SIHI (D), Wilo Salmson (D), Grundfos (DK), GEC Alsthom Ber-

Source: Europump

geron (F) and Weir (UK). In addition, a number of non-EC companies have production facilities in the EC such as ABS (S), Ingersoll-Dresser Pumps (USA), Sulzer (CH) and ITT Flygt (S/USA). For the majority of the enterprises, specialised in smaller market niches, joint ventures with similar companies in other EC Member States should be a better means to benefit from the advantages of the European unification process.

Strategies

Weak markets have already forced many companies to capacity and cost reductions to retain competitiveness. The wide deployment of CAD/CAM/CIM (computer-aided design, computer-aided manufacturing, computer-integrated manufacturing) has resulted in productivity improvements and consequently to labour cost savings. This trend is likely to continue. In the standardised pump sector widespread and efficient distribution networks on key markets are becoming increasingly important. Most of the specialised companies will have to put more effort in product innovation and product modifications, both to retain competitive advantage and to comply with the general trend towards products which offer better environmental protection. The latter trend provides the industry with extra demand for pumps for water purification, for example. On the other hand, the same trend has induced the industry to produce less polluting pumps (i.e. without leakages).

REGULATIONS

The European Technical Committee for machinery safety and health regulations (CEN TC/197) has recently introduced safety standards, which also apply to the manufacture of liquid pumps. The central issue of these regulations (self certification by the industry) will give the final responsibility for setting standards to the various industries. CEN has the final task of providing detailed European standards.

Control on the use of the new standards has been given to the national governments. In the Member States with a long industrial tradition (such as Germany), safety and health standards are already established at a high level. For these countries the new EC standards will not have a negative impact on the domestic industries. Other EC countries, however, like Greece and Portugal which currently have much lower standards, could have some difficulty in achieving the European CEN-norms. European industry would like to see the CEN standards adopted by the International Standards Organisation (ISO) in order to avoid unfair competition on foreign markets.

ENVIRONMENT

Besides the quality and safety standards, more environmental regulations can be expected in the years to come. In the European Act of 1987 guidelines are set for the governments of the Member States to work on their own environmental laws. The industry fears unfair competition if these regulations are not applied on a European scale. The manufacturers of liquid pumps, however, are not expected to suffer from growing environmental pressures. Demand has risen for waste water pumps, partly due to the guideline (March 1991) addressing the management and processing of urban waste water.

Noise pollution has been considered a major problem for the industry, but thanks to steady improvements in production techniques and processes, noise has been and will be further reduced. Furthermore, due to growing environmental pressures, reflected in demand, the industry has been induced to manufacture less polluting pumps, with less leakage. Technologically developed manufacturers could take advantage of the environmental pressures, if their products can meet the environmental requirements.

OUTLOOK

The greater part (70%) of EC production is sold in the EC Market where it covers some 85% of demand. Hence, developments within the EC are of primary concern to EC liquid pump manufacturers. In the recent past the downswing of the business cycle together with increasing non-EC competition affected EC production adversely. Increasing exports compensated these negative effects partly.

In the short run the recession will largely subsist. A recovery is expected in the course of 1994. Further, non-EC competition will intensify. Although imports may develop favourably, like in the past, this will only alleviate the problem of declining production. However, it is not unlikely that the low exchange rates for the US dollar and the Japanese yen together with recessive export markets will have an adverse impact on exports. Furthermore, since the economic restructuring process in East European countries proceeds very slowly, a significant upswing of demand is not expected, in these countries, in the short run.

Medium term prospects for the EC liquid pump sector will improve. Firstly, because the business cycle in the EC, by

far the sector's major market, will recover. Secondly, major export markets will recover too. These developments will have a positive impact on demand for liquid pumps. Additional demand can be expected from the rising interest for environmental protection.

Overview
NACE 34

With a production volume of more than 260 billion ECU and a workforce of nearly 2.6 million, the electrical/electronic industry was one of the largest industrial sectors in Europe in 1992. On the one hand, the sector profits from the strong growth of the market for high-tech producer and consumer goods, of which itself is one of the major buyers. On the other hand, the sector's companies, with their innovative technologies and products, help to enrich the European market for electrical and electronic applications in other sectors of industry and further their technological development.

INDUSTRY PROFILE

Description of the sector

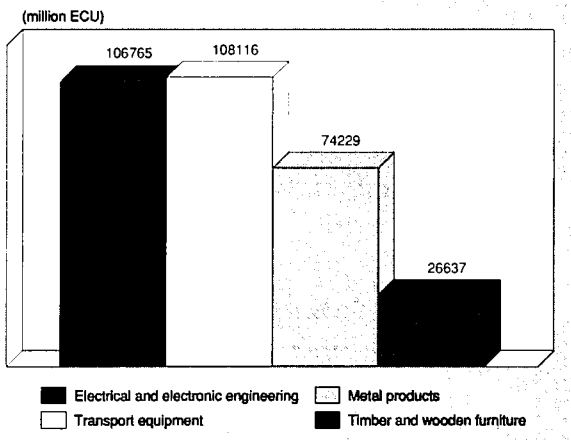
The electrical/electronics industry contributes a share of more than 10% to the total output of the EC industry. With its wide product spectrum, it directly shapes the complex pattern of the modern world and determines the quality of life. Given the importance of microelectronics as a key sector for technological progress, the competitiveness of industry and of whole economies widely depends on the electrical and electronics sector which is one of the main suppliers of infrastructure (power supply, traffic, information and telecommunications) of a country's economy. In statistics, the electrical/electronics sector is covered by the NACE group 34 which contains the following heterogeneous sub-groups:

- insulated wires and cables (NACE 341);
- electrical machinery including electric motors, generators, transformers and switch gear etc. (NACE 342);
- electrical equipment for industrial use and batteries and accumulators (NACE 343);
- telecommunications equipment, electrical and electronic measuring and recording equipment and electro-medical equipment (NACE 344);
- radio and television sets, sound producing and recording equipment (NACE 345);
- electric domestic appliances (NACE 346);
- electric lamps and other electric lighting equipment (NACE 347);
- assembly and installation of electrical equipment (NACE 348).

This statistical classification mostly does not follow the industry's actual market activities and in many cases does not provide conclusive information since the subsectors comprise extremely heterogeneous product groups. Therefore only the most prominent sectoral aspects are covered in detail in the following overview.

It is interesting to note that electronics, - i.e. telecommunications, electromedicine, measurement, control and automation, motor vehicle electronics, consumer electronics, and electronic components -, has registered the strongest growth and won a share of more than 50% in the sector as a whole. The other product groups, too, are increasingly permeated by electronic components. This 'electronification' is accompanied by a vigorous growth of industrial services which deeply change the structure of the net output. This primarily concerns project planning and engineering as well as the development of software which together have attained an estimated share of just under one fourth of the sector's total output. Some segments, as e.g. telecommunications, partly realise up to 50% of their turnover with such custom-specific solutions. The statistics with their underlying hardware production concept misrepresent both the reference quantities and the development because services are covered only inadequately.

Figure 1: Electrical and electronic engineering Value added in comparison with other industries, 1992



Source: DEBA

Recent trends

In the period from 1983 to 1992, production rose from 146.8 billion ECU to 257.5 billion ECU, in current prices. This is a nominal average growth rate of about 6% a year. In real terms, this amounts to an average annual growth rate of 4%, which is visibly above the remaining industries' development. In terms of net output, the German electrical/electronics sector achieved a share of 43% of the Community total. France accounted for 18%, Italy for 14% and the United Kingdom for 13%.

Source: DEBA

In the 1983-92 period, the major producer countries of electrotechnical and electronic goods recorded an accelerated real growth in production. Only in 1991 did this trend come to a halt in some countries. Among the countries reviewed here, Germany, in terms of production growth, came second after Japan and thus topped the average of the EC countries.

The worldwide slump in 1992 and especially in 1993 brought a shrinkage of the production and market volumes also for the electrical/electronic sector. The electrical/electronic trade cycle thus showed the typical pattern, following the other producer goods sectors with a certain time lag. By contrast, the prospects for 1994 signal that the recovery will come earlier since the worldwide demand for infrastructure investments generates autonomous demand impulses. The workforce was quickly adjusted to the lowered production. Already in 1992, it dropped by nearly a hundred thousand, which means a cutback of 3.4%. In 1993, this shedding of labour force continued at an accelerated rate of 7%. The slight rise in production achieved in 1992 was not sufficiently high to avoid a further heavy rise of 7% in unit labour costs. While Germany, as a result of unification, but also Ireland and Spain, had still growth rates to report, half of all EC Member States already registered declines in their electrical and electronic outputs. The bad business climate in 1992 and 1993 then led the sector as a whole into recession from which it is likely to recover hesitantly in the course of 1994.

International comparison

In 1983, the world market for electrical and electronic products had reached a volume of about 700 billion ECU. By 1992, it had almost doubled to just under 1.4 billion ECU.

The biggest shares in the world electricals market are held by the United States, Japan and the European Community. These three economic blocs together account for 75% of the world market (including the Eastern bloc). The European Community, with a share of nearly 25%, is the second largest bloc after the United States (27%). Besides the European Community, it was especially Japan whose electrical/electronics

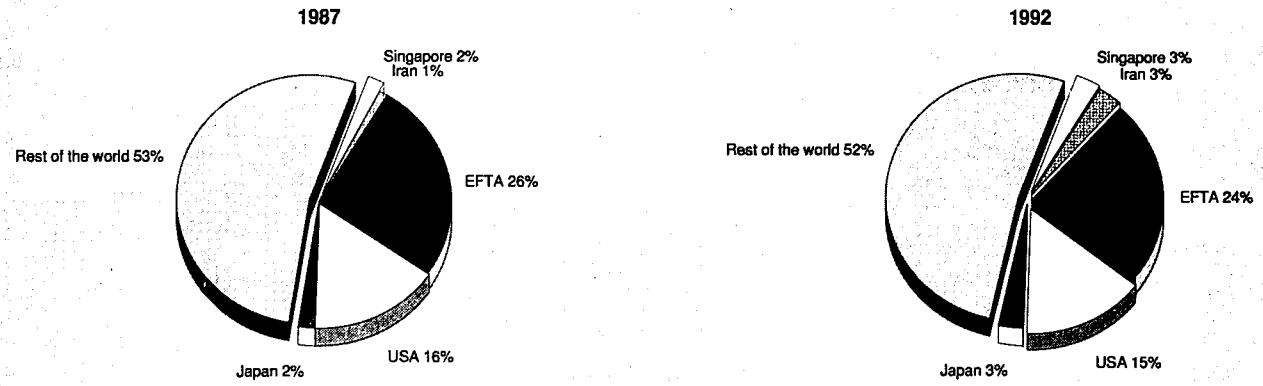
Destination of EC exports



Source: Eurostat

industry was afflicted by a deep recession while the US industry, in 1993, is already on the way of recovery.

In 1992, the EC electricals market reached a volume of 263 billion ECU. A production value of 258 billion ECU compared with Community exports of 46 billion ECU and imports of 51 billion ECU. This means an import surplus of 5.2 billion ECU in the trade with third countries. 77% of the Community's demand for electrical and electronic products was met from its own production, 23% originated from non-Community countries. Here, the United States led the league with a market share of 8%, followed by Japan (6%) and Taiwan (1%)

Foreign trade

The electrical industry has always been an export-intensive sector. The period from 1983 to 1992 witnessed a strong expansion in world exports (up 150 billion ECU). The three largest exporters Japan, the United States and Germany together accounted for around three fifths of all electrical and electronic exports. Other major exporters are the United Kingdom, France, Italy and the Netherlands.

The European electrical and electronics industry is the third largest exporter of electrotechnical products after Japan and the United States.

In the 1980s, the export growth rate for electronic components was distinctly above the average electrical/electronic growth rate while in other segments such as electronic measurement & control, power engineering, telecommunications and consumer electronics, growth was below average.

Producer goods make up nearly two thirds of electrical/electronic exports, consumer goods and primary materials account for less than one fifth each. The individual product groups vary in their export orientation. Also, their dependence on external markets is decidedly higher than indicated by the export ratio, i.e. the level of goods exported as a proportion of manufacturers' sales. If account were taken of indirect exports, i.e. of equipment which as intermediate products are absorbed by other products, the export ratio would be even higher. Besides motor vehicle construction, indirect exports are primarily found in mechanical engineering. The main end markets for EC exports of electrical and electronic equipment are the EFTA countries and the United States. The main buyers in the rest of the world are the developing countries though their import volumes levelled off in the last few years. The convergence of the international markets which involves stiffer competition has not been without effect on electrical imports. Back in the 1970s, electrical imports already rose faster than

100 or more	3 210	4.5	78.5	79.7

(1) Provisional estimates.
Source: Eurostat

exports. This trend continued in the years 1983 to 1992. Imports from third countries rose nearly threefold over this period, the average growth rate amounting to about 8% a year. As in the case of exports, producer goods also dominate imports and make up more than three fifths of the Community total. The remaining two fifths are taken by consumer goods and primary materials.

The import ratio which is the ratio of imports to the total supplies of the internal market, rose steadily in the period under review and reached 19.4% for electrotechnical products in 1992.

The regional structure of electrical imports shows that the main suppliers as well as the main buyers come from European countries. Other important sources of supply are Japan and the United States which each account for about one fourth of imports from third countries. Though an absolute rise in imports was noted for nearly all countries , there have been shifts in the import structure. Especially the Japanese suppliers could expand their share, almost exclusively by consumer electronics sales.

The marked revival of external trade in the 1980s in all areas of electrical and electronic engineering reflects the deepening international division of labour. The balance of trade for electrical goods, however, has seriously tended downwards into deficit. While in 1983, the surplus totalled 4.2 billion ECU, the balance was nearly even in 1987. After that, imports rose much faster than exports so that a trade deficit of nearly 5.3 billion ECU was recorded in 1992.

MARKET FORCES

Demand

About one third of electrical and electronic production are intermediate products, i.e. electrical and electronic supplies for further processing in the sector itself or in other industries, and two thirds are final products.

The electrical industry was the principal buyer of its own products, for further processing or for integration into other products. Other important areas of intermediate consumption are mechanical engineering, the services sector and motor vehicle construction.

If the producer goods in the electrical/electronics sector are taken separately, then the services sector is the most important buyer. Within this sector, traffic (including telecommunications) ranks first before public administration and road vehicle construction.

In 1991, more than 60% of all exports of EC countries went to other Member States (intra-Community trade), only about 40% were taken by third countries (extra-Community trade). More than 80 billion ECU of total Community exports, which amounted to 133 billion ECU, remained in other EC Member States. Of these, one third comes from Germany, 17% from the United Kingdom, 15% from France and 12% from Italy. With more than 21%, Germany is also the biggest buyer of electrotechnical and electronic products in the European Community, followed by France (17.5%), the United Kingdom (13.5%) and Italy (13%). In intra-Community trade, only Germany and the United Kingdom achieve trade surpluses, with

6 and 3 billion ECU, respectively. The other countries have to accept partly substantial deficits.

Supply and competition

Measured by its products and their applications, the electrical/electronic industry is a diversified sector with a product spectrum ranging from microcomponents through to nuclear power plants. Therefore the overall growth rate tells little about the very differentiated developments of the individual product groups. It appears that the rise in output, in terms of value, has been particularly high in the case of electronic components, motor vehicle equipment, and measurement, control and automation systems. Slow growth is registered in the areas of electricity supply and distribution, of domestic electrical appliances and in consumer electronics. As in the whole electrical and electronic sector, all product groups showed a nearly steady growth in output over the period under review. The different developments of the individual product groups also reflect the changes in demand that have occurred. Moreover, production growth is influenced by technological change, the very complex processes of electrical production ranging from heavy mechanical engineering outfits to miniaturisation in precision mechanics, and by the development of costs and prices and other factors as well.

The different growth rates of the individual product groups led to changes in the production structure. Declines were observed especially for investment goods in the areas of power engineering, domestic electrical appliances and consumer electronics. By contrast, growth was recorded for investment goods in the areas of electronic sector and for components.

On account of the very broad spectrum of electrotechnical and electronic products, close interdependencies have developed, both on the supply and on the demand side, between electrical/electronic engineering and other sectors of industry.

Intermediate supplies involve other sectors of the economy and imports. Intra-corporate supplies, i.e. companies' internal electrical supplies, make up nearly 50%. Extra-sectoral intermediate supplies are claimed especially in the services sector, with trade and traffic (including telecommunications) topping the list.

The major suppliers in the processing industries are the plastics and non-ferrous metal industries. As the iron and steel industry, they supply primarily raw materials and semi-manufactures whereas primary and intermediate products come from various other sectors (plastics processing, iron, sheet and metal working industries, mechanical engineering, paper and glass industry etc.).

The share of the services sector in intermediate supplies has risen steeply while the primary and producer goods industries have lost in importance. This is mostly attributable to material savings in the production process which were achieved through better utilisation of raw and other materials, and to smaller product dimensions. The share of imports in intermediate supplies has steadied at around 15%.

Among the sectors which supply the electrical and electronics industry with producer goods, mechanical engineering comes first. This sector accounts for half of the electrical industry's gross fixed investment. The second largest supplier is the electrical industry itself, followed by the construction industry.

Production process

Among the processing industries, the electrical/electronic industry is the largest employer besides mechanical engineering. Employment in the sector remained more or less stable up to 1991. The sector had a workforce of 2.633 million in 1992. This is 100 000 less than in 1983.

The employment levels developed differently for the individual product groups. So areas with an above-average growth in production (e.g. measurement, control and automation) also reported above-average employment figures. As expected, employment tended downwards in areas with below-average growth (e.g. consumer electronics).

The electrical and electronic industry is one of the most research-intensive processing industries. With between 8 and 10 per cent of its turnover spent annually on research, it tops the research-intensive league (not including the aircraft and spacecraft industry).

INDUSTRY STRUCTURE

Companies

Concentration in the electrical and electronic industry is very high in the Community. About 4% of all firms employ nearly 80% of the sector's total workforce and account for about 80% of its total turnover. It is a remarkable fact that in all EC countries and also in the other industrial countries, the size pattern of the firms is very similar. In all these countries, there is a number of very big firms which cover nearly all product segments and operate on a worldwide basis and then there is a host of small and medium-sized businesses.

Table 7: Electrical and electronic engineering
Expected real annual growth rates

(%)	1993-94	1993-97
Apparent consumption	1.0	4.0
Production	2.0	4.0
Extra-EC exports	4.0	6.0

Source: ZVEI

In 1991, the three largest firms in the sector were: Siemens (D), Philips (NL) and Alcatel-Alsthom (F). It is interesting to note the strong presence of EFTA firms among the top 15 firms, the most important of them being Asea Brown Boveri (CH/S), Electrolux (S) and Ericsson (S).

Strategies

Besides expanding exports, the electrical and electronic industry continues to be strongly oriented towards investment activities abroad (establishment of production centres and marketing facilities). In combination with the extension of existing or opening up of new markets, these investments serve primarily the purpose of effecting sales. Attention is focused especially on the public procurement markets which are subject to the EC utilities directive, and on the South-East Asian area which is presently taken to be the strongest growth market for electronics. High growth potentials, too, are likely to result in the longer term from the dramatic political changes in Eastern Europe.

REGULATIONS

In the view of the electrical/electronic industry, public procurement plays a decisive role in the structuring of the internal market. In the European Community, the contracts awarded by the Government and state-owned companies such as public railways, posts and telecommunications and electricity supply companies account for a high proportion of the gross national product. The liberalisation of public procurement is, no doubt, necessary to take advantage of the benefits of enhanced competition offered by the big market, in the areas of supply covered by the utilities directive. Here, care must be taken to ensure that these EC regulations are really implemented and that the markets are opened up synchronously. But Europe-wide technical standards development, too, is an essential prerequisite for the expansion of trade.

ENVIRONMENT

The production of electrotechnical equipment is not normally harmful to the environment. A different matter, with the changed conditions of consumption, is the disposal of appliances no longer used by commercial and private consumers (e.g. refrigerators, TVs, measuring instruments etc.). As a result of the high supply of the market, a large number of appliances no longer needed becomes available each year. The electrical and electronic industry, especially in Germany and on lines similar to those of the packaging ordinance, developed early initiatives to solve the problems of waste disposal and recycling. It has also, for a while now, adjusted the design and construction of its appliances to a technology aimed at the maximum possible saving of energy. Beside these activities, it is an interesting fact that the electrical/electronic industry, with a variety of equipment, such as measuring instruments and controls, provides the necessary technological means without which no effective environmental improvement, of water, air or noise, is possible.

OUTLOOK

The structural environment of electrical/electronic engineering will continue to be marked by the liberalisation and harmonisation of the markets within the Community and by technological progress. Following the dramatic 8% decline in real production in 1993, a slight 2% growth is forecast for 1994 which is likely to bring a vigorous upturn in the following years. But this growth is not likely to make up for the cutbacks in employment made in 1993 and also expected for 1994. According to latest estimates, the world market for electrotechnical products will have nearly doubled its volume by the year 2000, compared with 1990. In this context, the future-oriented research and development work of the companies and their investment activity play a decisive role.

Insulated wires and cables
NACE 341

The insulated wires and cables industry manufactures three main products: energy cables, information cables and winding wires. With more than 100 companies and more than 250 manufacturing facilities, the EC is the world's largest producer of insulated wires and cables, followed by the US and Japan. Demand for insulated wires and cables is influenced by two fundamental factors: the development of the infrastructure for electricity and telecommunications, and the general health of the economy.

INDUSTRY PROFILE

Description of the sector

The markets for insulated wires and cables are extremely diverse with applications in virtually all areas of modern life, from the winding wire in the electrical shaver to the optical fibre which provides the basis for the telephone call and to the energy cables which are used in the basic infrastructure of energy generation, transmission and distribution.

Electrical energy cables are fundamental to domestic life and all industrial and commercial activities in all parts of the Community. Wires and cables supply energy from the electricity generation centres to the individual point of utilisation, and differ according to the voltage range.

Information cables have two important areas of application: telecommunications and electronic data control and broadcasting. Recent demand has been strong in the field of telecommunications cables reflecting the massive surge in the demand for new telephones associated with the increasing use of fax machines as well as the demand associated with investment in the telecommunications infrastructure, particularly in those Member States which are modernising and extending the optical fibre network. Demand for information cables is also strong in the multifaceted area of electronic data/control applications and broadcasting. For many of the latest developments in information technology, communications cables, ranging from simple wires to coaxial cables, armoured cables and glass fibres are an important element.

Winding wires are used in all forms of electrical equipment where a magnet is required. Thus every electric motor, transformer, generator, dynamo, etc. requires a magnet or winding wire that is enamelled or otherwise insulated.

Recent trends

The fastest growing segment of the insulated wires and cables is that of information cables. Between 1986 and 1992, the share of communications cables in total production rose from 23% to 37%, while the share of energy cables declined from 70% to 56%. Winding wires accounted for the remaining 7% of total production value in 1992.

After five years of steady increase of the EC's consumption and production of insulated wires and cables, growth started to tail off in 1990. A sharp downturn in activity occurred in 1991, with apparent consumption plummeting as a consequence of the depression the sector's end-markets were experiencing. In 1992 and 1993, the recession converted into a considerably weaker demand in all EC countries. Demand in Spain and the United Kingdom remained flat, while France and Italy managed positive growth. Germany also reported positive growth of production. This performance should be analysed with caution, however. The German market only managed to retain its previous western level, and the overall growth figure largely benefited from the inclusion, from 1992 on, of activity originating in the eastern Länder. Production in western Germany was in fact actually down.

Between 1991 and 1992, employment in the insulated wires and cables industry fell sharply, reflecting recent restructuring and the adoption of less labour-intensive production techniques, but also reflecting the downturn in activity. In 1992, the number of people employed in the sector shrank by as much as 27% to 78 300, with a particularly sharp drop in the United Kingdom, Spain and Germany. As rationalisation of production facilities is bound to continue, employment is expected to drop further, though at a slower pace.

International comparison

The EC is currently the largest producer of insulated wires and cables in the world. Proximity to the market is very important, particularly for heavy industrial cable, and investment in Europe's infrastructure has thus been a strong source of demand for EC producers. Furthermore, healthy growth in export markets combined to boost annual production growth to more than 5% per year which is similar to rates achieved in Japan over the same period.

Foreign trade

EC cable-makers have always been an important source of cables worldwide with average exports over the past decade topping 1 billion ECU per year. The industry's trade balance, however, has declined sharply over the last several years. Traditionally strong net exporters such as Germany and the United Kingdom both became net importers in 1991. Trade data evidenced a continuing decline of EC's trade surplus in 1992.

The source of the weakness in EC exports can be explained in part by the fact that many former principal export markets have established their own production facilities. Sluggish markets in the Middle East oil-producing countries have been exacerbated by a tendency to greater home production. Opportunities still exist for EC cable makers, however, in countries where the level of technology is still beyond domestic production capacity. In order to benefit from these opportunities, EC companies are involved in joint ventures with local companies. This is particularly the case in countries of Eastern Europe where companies such as Alcatel or Siemens are engaging in ventures with local companies to build telecommunications infrastructure.

In terms of exports markets, the EFTA and OPEC countries are the single most important trading regions. The EFTA countries are not only the largest customers of insulated wires and cables, but they are also important suppliers, accounting for 31% of total extra-EC imports in 1992. Although the US was as important a supplier as the EFTA countries in 1986, its share of total EC imports fell to 19.9% in 1992.

MARKET FORCES

Demand

The three main categories of insulated wires and cables, that is, winding wires, information cables and energy cables, are subject to very different forces of demand.

The demand for energy cables is not only dependent on increases in electricity consumption but also on the demand for new generation and transmission facilities as well as on replacement demand. In the long-term, demand for energy cables will keep pace with the growth of GDP and the associated growth in electricity consumption. The customer structure of the energy cable industry shows the overwhelming share of power utility companies, which in many cases are publicly owned. As a result, the demand for wires and cables can be severely affected by energy policy; privatisation of the United Kingdom energy market was accompanied by a 35% fall in sales of insulated wires and cables.

The demand for information cables is linked to both the development of a country's telecommunications market and the level of advancement of its telecommunications infrastructure. The overwhelming portion of the market is accounted for by the public telephone network operators. The strongest growth is in trunk (long-distance) traffic, where technological developments have substantially reduced cable-costs. The demand for electronic data control cables is expected to continue its steady rise.

The demand for winding wires is naturally linked to trends in end markets such as electric tools and electro-medical devices.

Supply and competition

The production capacity of the EC cable and wire industry has traditionally exceeded demand. Technological improvements, an increase in capital intensity which has changed production techniques and shrinking home demand are the key forces which have combined to change the environment in which manufacturers operate.

The EC cable and wire industry has achieved a world lead in numerous technologies which are important for cable production: non-ferrous metallurgy, insulation physics, rubber chemistry, hightech materials, superconductivity, electrical engineering for power cables and opticalfibre technology for telecommunications cables. The industry's investment in R&D has also translated into new production techniques which have generated higher turnover and a steady decrease in employment, which has brought about a steady increase in productivity.

Production process

Two raw materials are of particular importance to insulated wires and cables production: copper and aluminium. In the EC cable and wire industry, more than 1.4 million tons of copper and about 196 000 tonnes of aluminium were used in 1992. The use of these two main inputs, however, varies according to their price, which fluctuates widely, taking into account the fact that about twice as much aluminium as copper is needed in electrical applications (copper is a better conductor of electricity than aluminium).

The trend in copper prices provides an example of the degree of this price variability; the price per tonne of copper doubled from 1 592 ECU per tonne in January 1986 to 2 986 ECU in January 1989. The average price per tonne of copper in 1991 was 1 772 ECU. Given these wide price fluctuations,

not to mention currency fluctuations, the trends in consumption, production and foreign trade in insulated wires and cables which appear in this report must be viewed in light of the price trends of its main raw materials.

During the last ten years, optical fibre has become another strategic input in the production of telecommunications cables. Optical fibre cables are particularly designed for transmitting data and sound impulses and signals. Perfect substitutes to copper cables in this type of applications, optical fibre cables also provide higher transmission capacity and are much cheaper than metal cables. The industry performed a major substitution from copper to optical fibre in the production of telecommunication cables. This shift accelerated in the last five years leading to a dramatic overcapacity. Although there are similarities between the manufacturing and production technologies applied, the production of optical fibre cables requires a clean, laboratory-type atmosphere, by contrast with the production of copper cables, which basically remains a metallurgical process. As a result, cable manufacturers tended to construct new plants dedicated to the manufacture of optical fibre cables instead of converting copper cable production facilities towards optical fibre processing. Today, as it is experiencing plummeting demand for copper cable, the EC industry faces a gross over capacity, and is actually operating close to break-even.

A painful restructuring is thus on the agenda even after the previous rationalisation of production facilities that led to a dramatic fall in employment levels.

INDUSTRY STRUCTURE

Companies

There are more than 100 firms that produce cables and insulated wires in the EC with 250 production facilities and almost 90 000 employees. Production sites are located in all Member States, with the exception of Luxembourg. The major manufacturers of insulated wires and cables are Alcatel (F), BICC (UK), Pirelli (I) and Siemens (D). If all of Europe is considered, ABB (S/CH) should be added to the list. These large companies produce both energy and telecommunications cables as well as winding wires. Small enterprises tend to specialise in one product, often in energy cables, although this varies according to country. In the smaller countries, small companies often manufacture the whole spectrum of products. In the France, Germany and Italy, however, apart from four of the top five large producers, there are many small specialist producers.

Source: DEBA

As a matter of fact, about 10% of production volume is accounted for by small and medium-sized companies in the EC.

The increasing share of glass fibre cables in telecommunication cables has led to the fusion of small and mid-sized firms in order to provide the necessary capital foundation for the technologically demanding production process. There are now only about a dozen manufacturers of optical fibre in the EC.

In the past few years, there have been several mergers and acquisitions. Examples are Alcatel's acquisition of the German AEG Kabel AG, BICC's purchase of KWO (D), and Pirelli's purchase of STC (UK). In 1993, further restructuring took place in the EC, with several mergers and acquisitions carried out by large companies, like the purchase of the German communications cables business of Philips by the joint venture between Nokia (SF) and NKF Kabel (NL); Draka (NL) purchased the Dutch communications cables business of Philips. This wave of mergers and acquisitions is not over, as evidenced by the ongoing purchasing process by Alcatel Cable (F) of the undersea communications cables business of Northern Telecom through its subsidiary STC (UK).

The EC insulated wires and cables industry is also characterised by its complete independence from its downstream industries, in spite of the close commercial links they have developed in terms of supply. The industry's activities do not evidence any vertical integration in Europe. The only example of such integration can be found in the USA, with AT&T, the leading telecommunications network operator, also active in cable and telecommunications equipment.

Strategies

To meet the challenges of increased competition, there are three main strategies: investment, research and development and cooperation and concentration. Investment activities have shown an upward trend, at least in the five EC countries for which figures are available. The main motive for investment is an increase in productivity and reduction in costs, especially labour costs. In the years when the cable business was booming, expansion was an additional objective.

Innovation in new products or new processes and production methods are other strategies for keeping up with the competitors.

Mergers, acquisitions, alliances and joint ventures are organisational methods for increasing or at least maintaining competitiveness on the international market. Several large cable manufacturers have made cross-border investments within the EC, either for reasons of cost or for closer proximity to markets. Investments outside of the EC have been made, above all, by French, Italian, British and German cable producers; these have been primarily in North America (USA, Canada), Latin America (Mexico, Argentina, Brazil and Peru) and Africa (Lebanon, Morocco, Nigeria and South Africa). The EC cable manufacturers currently show increasing interest in the emerging and promising East European and Chinese markets. Such investments outside of the EC have been primarily made in order to benefit from growing markets, and also aimed at diversifying into new markets to reduce companies' vulnerability to business cycles and over dependence on mature and declining markets.

REGIONAL DISTRIBUTION

The hub of EC insulated wires and cables is undoubtedly Germany, which accounts for 28% of total EC production and 33% of EC employment in the sector in 1992. The other large producing countries were Italy, France and the UK in decreasing order of importance in production terms. A glance at the regional distribution gives evidence of the gravitation of production of insulated wires and cables towards the industrial heartlands. Relatively limited by high transportation costs, particularly for heavy industrial cable, producers have made near their main customers who are predominantly located in central and western regions of the EC. The latter area accounted for more than 72% of EC production in 1992 and occupied greater than 76% of total EC employment in the sector.

ENVIRONMENT

Generally speaking, cable manufacturing is not a burden on the environment. The manufacturing process is clean and the materials used are normally non-toxic; those posing potential risks are strictly regulated. The cable industry has been very responsive to environmental concerns. In 1993, the manufacturers actually expressed this environmental consciousness by producing a voluntary code of practice.

The industry puts particular attention in its use of raw materials and its design of products minimising the potential hazards of their installation and use. Specially designed cables with reduced flammability are available and there are already acceptable alternatives to PVC and other compounds in areas with fire risks. Cable makers no longer use materials containing dioxin and are investigating the possibilities of substituting materials containing halogens. Cable insulation without halogens emits little in the way of toxic fumes. This is particularly important in public areas, in transport and warehouses as well as any place frequented by people or housing combustible goods.

REGULATIONS

Regulations that relate to technical standards, the use of dangerous preparations and health and safety all have implications for cable makers although there are no specific directives which are directed to the industry. The directive on harmonising national provisions on electromagnetic disturbance levels (89/336/EEC), for example, lays down the rules to which

cable and other electrical equipment manufactures must adhere.

On another front are the public procurement directives which liberalise the awarding of public contracts. The market for insulated wires and cables has been dominated in the past by the public utilities (both in energy and telecommunications) which often favour national suppliers. With the liberalisation of the tender procedure and procurement, competition within the EC will intensify. Harmonised standards will also allow EC manufacturers and their foreign competitors to penetrate other markets than their own.

OUTLOOK

The outlook for the EC insulated wires and cables sector is rather diverse across the three main categories, as they are subject to very different forces of demand. The development of the information technology market and the expected increase in personal communications will dramatically increase demand for information cables. There is a tremendous scope for the development of this market, which will further benefit from the ongoing market deregulation. Prospects are rather promising for optical fibre cables, the demand of which will increase steadily while demand for copper cables will drop sharply. Equally, if not more important, will be the impact of privatisation and the liberalisation of public procurement on the energy and telecommunications sectors.

The market for energy cable is now fairly limited as the energy infrastructure is virtually complete in the EC (with the notable exception of the east German federal states which represents a significant outlet for the industry in the EC). As for telecommunications and energy cables, sales possibilities in Third World markets will increase only slightly; despite great needs, improvement in the infrastructure is making no or only very little progress due to limited financial leeway.

The demand for winding wires, influenced by overall trends in the manufacturing industry in the EC, will face a further decline in demand as its main client industries (such as the automotive and domestic appliances industries) remain in the doldrums in the short term. In contrast, demand for data and control cables will remain buoyant. EC's industry will face fierce competition in this market segment, however, from computer-producing countries such as Japan or the USA.

In the long-term, demand for energy cables will strongly depend on the growth in GDP and the associated increase in electricity consumption. The demand for data and control cables as well as for winding wires will be primarily influenced by overall trends in the manufacturing industry in the EC. Telecommunications cables will remain the fastest growing segment, and will benefit from increased deregulation and the associated development of individual applications.

The industry is represented at the EC level by: European Confederation of Associations of Manufacturers of Insulated Wires and Cables (EUROPACABLE). Address: rue du Luxembourg 19-21, B-1040 Brussels; tel: (32 2) 513 0612; fax: (32 2) 502 2169.

Electrical machinery
NACE 342

After demand for products of the electrical machinery industry boomed during the second half of the eighties, production growth rates flagged down in the recent past. Indeed, overcapacity in the electricity generating sector and the decline in investment activity dampened demand for the industry's products.
Competition from outside the EC increased as well, particularly in the field of mass production of standard types of equipment.
During the course of the nineties, demand for the industry's products is expected to grow, mainly boosted by demand from the developing countries (South East Asia, China and East Europe). Domestic demand is expected to increase at a slower pace, in line with market saturation due to the investment boom in the recent past.
Competition from countries outside the EC is expected to rise during the next several years, as common technical standards within the EC are likely to ease the grip on this market for foreign competitors. Thus, EC firms have to increase their cooperation efforts, to streamline production and improve cost competitiveness.

INDUSTRY PROFILE

Description of the sector

The electrical machinery industry comprises two main sectors: the manufacture of machines, apparatus and instruments for the production and conversion of electricity; and the manufacture of equipment for the distribution of electric power.

The first subsector covers the production of electric motors, electricity generators and rotary converters, transformers, current rectifiers, electromagnets and electromagnetic apparatus.

The second subsector covers the production of apparatus for closing, opening, and protecting electric circuits of 1 KV or more (high-voltage switch gear), installation equipment up to 1 KV (low-voltage switch gear), and fixed and variable resistors, including potentiometers.

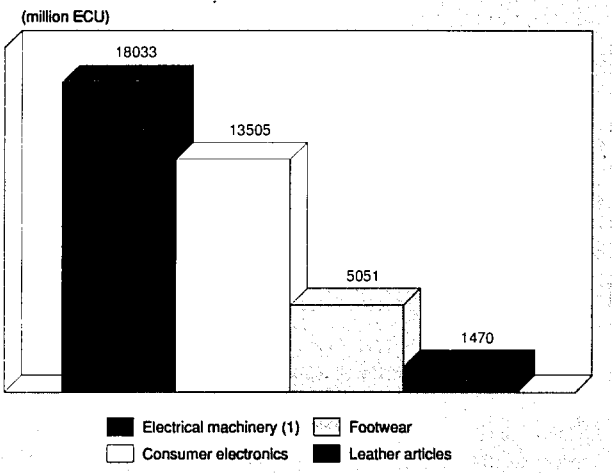
Germany is the most important producing country in the EC, with about 41% of total EC production, measured in terms of value added, followed by France (33%), the United Kingdom (14%) and Italy (10%).

Among manufacturing industries, the electrical machinery industry is of important economic weight. Measured in terms of value added in 1992, its output was about 30% higher than that of consumer electronics.

Recent trends

The electrical machinery industry in the EC enjoyed favourable development conditions over the last years. Production increased by 2.4% per year in volume from 1983 to 1992, a rate slightly below the overall growth of the manufacturing sector (2.8% per year over the same period). Demand for the products of the industry grew at a faster rate, of some 3% per year in volume. During the last few years, however, the industry was confronted with strong competition from outside the EC. Extra-EC imports grew by nearly 9% per year in volume from 1983 on, to reach some 8 500 million ECU in 1992 (i.e. some 20% of apparent consumption). After slow growth from 1983 to 1988, exports to countries without the EC grew briskly, at some 5% per year in real terms from 1988 to 1992.

Figure 1: Electrical machinery
Value added in comparison with other industries, 1992



(1) BAK estimate
Source: DEBA

The industry is highly export oriented, with sales outside the community of about 22% of production in 1991. The trade balance has been positive throughout the last decade, but has deteriorated considerably over time.

International comparison

The EC is the most important producer of electrical machinery within the triad. In 1992, Japanese production represented about 82% of EC production, while US production represented about 68%. Japanese production increased fastest, by roughly 41% from 1987 to 1991, an annual average growth rate of some 9% in volume. EC production developed more moderately, at roughly 3% growth per year in volume from 1985 to 1992. US production increased by only 1% per year over the same period and has actually been declining since 1989.

Foreign trade

The most important feature of the last decade was the fast growth of imports, which gained by more than 13% per year in value from 1982 to 1991. The EFTA countries were and remain the most important exporter to the EC, providing about

Source: DEBA

29% of total extra-EC imports. Switzerland, in particular, is an important competitor for EC producers. The United States and Japan both hold a market share in EC countries of slightly above 20%. During the last years, however, all the traditional competitors (with the exception of Japan), have been losing market share in the EC, mainly to the benefit of the developing countries, whose market share increased from 20% in 1987 to 28% in 1992.

Extra-EC exports grew by 5.8% per year in value from 1983 to 1992. The most important market for EC producers is the developing countries' group (including the East Asian NICs) which received about 60% of total extra-EC exports in 1992. EFTA countries receive about 26% and the United States about 13%. The main feature here is the increasing importance of the fast growing markets in South East Asia for EC producers.

The EC trade balance has remained positive, with exports about one third higher than imports. The surplus in the trade balance, however, has declined.

Trade within the EC has been growing fast, by some 13% per year, over the period 1983 to 1992. The share of intra-EC trade, out of total EC imports, has remained more or less constant, over the same period. The most important intra-EC exporter in the EC is Germany, with about 42% of the total, followed by France (19%), the United Kingdom (10%) and Italy (9%).

MARKET FORCES

Demand

In the field of the electrical machinery's industry as a whole, demand for the products increased considerably over the last several years. Considering the heterogeneity of the industry, demand analysis must be done separately for the different subsectors.

Demand for products closely related to manufacturing processes benefited mostly from the investment boom that started in the second half of the eighties. The EC manufacturing sector made efforts to expand production capacities and to improve production efficiency in expectation of the Common Market. These increased efforts provided producers of electric motors, electromagnetic apparatus, low- voltage switch gear (opening, closing and protecting electric circuits of less than 1 KV), installation equipment and fixed and variable resistors with robust and fast growing demand. Product innovation contributed to the demand performance as well: one example is the switch from DC converters to three phase converters. In the last few years, however, following the decline in investment activity, demand for the industry grew more moderately.

Subsectors, more closely related to the production and conversion of electricity, went through a quite different development pattern over the last decade. Fast growing demand for electric power during the second half of the eighties resulted in the expansion of electrical energy supply, as well as of distribution networks. Producers of equipment such as electricity generators, transformers and high-voltage switch gear (opening, closing and protecting electrical circuits with more than 1 KV), benefited from this demand boom during this period.

In the last few years, however, the demand picture has changed. With the slowdown of electricity demand growth, as a consequence saturated markets, along with the fall in prices of fossil fuels and energy saving measures, demand for products

Figure 4: Electrical machinery

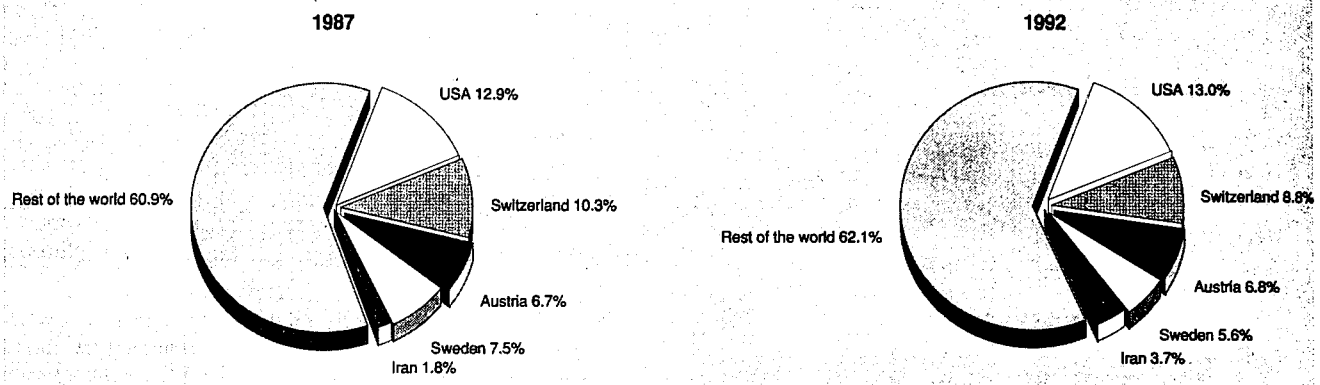
Figure 6: Electrical machinery
Destination of EC exports



Source: Eurostat

related to the generation and distribution of electricity has been declining. Electricity distribution companies have now completed very substantial investments in most of the EC countries, with the result that the industry now has significant excess capacities. Investments in these areas will therefore be oriented towards replacement, rather than towards capacity increase, at least for a number of years.

In addition, the recent downturn in general economic activity has affected demand for the industry's products, as decisions to invest in power stations are closely tied to expected growth of GDP. Another hampering factor for demand on international markets, which could partly compensate for losses on the domestic market, is protectionist measures, which limit the opportunities for EC producers, as the production of electric energy is regarded often as "strategic".

Supply and competition

In line with the increased in demand, production of electrical machinery in the EC production grew briskly over the last decade. In high-voltage switch gear, the EC is the most important producer, with a world production share of 35% in 1990. The share of the United States reaches roughly 28%, slightly above Japan's (26%). In the field of low-tension switch gear, the situation is nearly the same, with the EC in the leading position (35% in 1990), followed by the US (24%) and Japan (20%). Both, the United States and the EC, have lost production share, while Japan has increased its share over the last decade.

The sharp increase in imports from outside the EC, resulted in a decrease of the EC trade balance. Consequently, the import- consumption ratio increased from some 10% in 1983 to about 20% in 1992.

In the field of transformers, imports increased sharply during the last years, so that the ratio of exports to imports dropped from over 6 in 1982 to around 2 in 1991. The most important competitors are the United States and Japan, as well as South Korea and the EFTA countries (mainly Switzerland and Sweden).

In the field of low-tension switch gear, competition from outside the EC increased as well, mainly from Japan and the East Asian NICs. The latter are highly competitive in terms of prices, as a consequence of lower production costs, subsidised input prices and dumping policies. As to the Japanese,

Source: Eurostat

who dominate the market in South East Asia, they tend to specialise in mass production of standard type of equipment, which allows them to benefit from economies of scale.

Regarding high-voltage switch gear, on the other hand, world trade amounts to only about 23% of world production; this relatively low share is explained by the protected character of public markets.

Intra-EC trade in the electrical machinery industry increased considerably as well. This development is mainly the result of the opening of electricity markets to competition, in line with the advent of the Common market in 1993, stimulating efforts by producers to get a foothold in other EC member countries.

INDUSTRY STRUCTURE

Companies

The larger companies in the industry usually operate in a wide range of fields, while smaller firms are usually active only in a few subsectors; some firms work in niche markets, producing only one or two types of products.

The industry is dominated by a small number of very large companies, which operate in a wide range of electrical engineering activities. The most important are ABB (CH/S), the largest producer in the EC, Siemens (D), AEG (D), and GEC-Alsthom (UK/F).

In addition, there is a large number of more specialised small to medium-sized companies, as for example Transfo (F) and Pauwels (B), which specialise in the production of transformers.

Around 35 000 people are employed in the high-voltage switch gear industry in the EC; in the field of low-voltage switch gear, Germany alone, the largest EC producer, employs 48 000 people.

The larger firms in the EC operate on global markets, where they face strong competition from the United States and Japan. The smaller companies, on the other hand, are oriented towards niche markets, where they produce client-oriented equipment. Consequently, these firms often operate on the national market only, or even in regional markets.

In the United States, an important company is the Westinghouse Electric Corporation, which is a premier producer of transformers, besides its other varied activities. In Japan, the most important companies are Mitsubishi Electric Corp. and Kawasaki Heavy Industries Ltd, both in the field of electric power generation equipment.

Strategies

The EC electrical machinery industry has a relatively strong position in its own market. Nevertheless, competition from outside the EC has been growing over the last few years, often due to cost advantages, in particular regarding the East Asian NICs. Efforts of EC producers, therefore, need to be oriented towards cost reduction. On the other hand, EC firms also need to increase their R&D expenditures as well, to improve the performance of their products. To meet these and other challenges, companies are investing efforts to streamline production, through mergers and acquisitions.

In the field of transformers, the weakness of demand, in the face of excess production capacity, has brought about numerous structural changes, as many of the Community's producers were forced to close production units and to rethink their product range.

Another strategy would be for EC companies to increase their export efforts towards growth markets such as East Europe and the developing countries. China in particular is one of the most important promising potential outlets as the fast developing economy requires ever-growing sources of power. However, to succeed in these countries, EC firms will need to gain a foothold there, through joint ventures, cooperation agreements, subcontracting and the like. Thus, to facilitate its penetration in East Europe's markets, Siemens (D) has formed a capital tie-up with Skoda, a Czech maker of heavy electrical equipment; these two companies plan to set up a joint venture in Czechoslovakia to manufacture equipment for nuclear, thermal and hydroelectric power generation plants, as well as anti-pollution devices. Other similar agreements are the tie-up of Hitachi with General Electric of the US, for collaboration in the area of heavy electrical equipment; one result of the agreement has been the two firms' take-over of the Georgia based High Voltage Breakers Inc.. Another important tie up is the agreement between Mitsubishi Electric Corp. and Westinghouse, in the field of electric power generation, to seek enhanced competitiveness in advanced technology. These trends to increased co-operation between companies are expected to continue in the future.

REGIONAL DISTRIBUTION

Regarding the various subsectors of the electrical machinery industry, Germany is the largest producer in the transformer industry, as well as in high-tension and low-tension switch gear. Germany leads also in exports of transformers into the EC member countries (20% of intra-EC trade), as well as extra-EC exports (29% of total EC exports).

In the field of high tension switch gear, the production share of the German firms has been declining during the last decade from 42% of total EC production in 1980 to 36% in 1990, mainly to the benefit of Italy, which increased its production share from 14% to 17% during the same period. In the same subsector, the share of exports by the German firms out of total EC exports declined during the last decade from 36% in 1980 to 30% in 1990. French firms, in contrast increased their market share from 30% in 1980 to 44% in 1990.

ENVIRONMENT

Ecological concerns regarding the production process are not of major importance for this industry. In the past, the use of PCB (polychlorinated bi-phenyls) to isolate the wires in the body of transformers did represent an environmental danger, but this has since been discontinued.

On the other hand, it is likely that the industry will benefit indirectly from increased concerns about emissions damaging to the environment. Coal fired power plants, for example, may have to be substituted for by cleaner electrical energy generating methods.

REGULATIONS

The Directive 89/392, dealing with the standardisation of health and safety requirements of machines, is of particular importance to this industry. Machinery must conform to these regulations in order to be eligible for the EC label.

Two other important directives for this industry are the Low Voltage Directive (73/23/EEC) and the Electromagnetic Compatibility Directive (EMC; 89/339/EEC)

OUTLOOK

In the short term, prospects for the electrical machinery industry in the EC are somewhat pessimistic, as demand will grow only moderately. Those subsectors closely related to industrial investment activity will continue to suffer from the low propensity of companies to increase their production capacities. With the expected economic recovery in one to two years time, demand for this group of products is expected to start growing again. New markets in developing countries (in the short- to medium-term), and in East Europe (in the medium-term), will provide stable sources of demand growth in the future. In developed countries, on the other hand, demand is expected to grow only moderately, if at all. Competition from outside the Community is expected to stiffen, particularly from the East Asian NICs and Japan.

Subsectors related to the construction and expansion of power plants and distribution systems will experience moderate demand growth as well. Recent investments in the expansion of electricity networks, mostly of them completed by now, have led to overcapacities, at least in EC countries; demand for new equipment there is expected therefore to decline. Demand for replacement equipment, on the other hand is expected to be stable. The trend towards more efficient use of energy is an additional factor for a slower future growth. Within the EC, new demand can be expected in South Europe and in Ireland, where additional infrastructure and high-tension links are planned. New demand may also come from the East Asian NICs, East Europe and China. However, stiffening competition on these markets is to be expected. In East Europe, competition stems from the Polish, Bulgarian and the CSFR electrical machinery industries, which are important manufacturers in the field of high-voltage transformers. In China and South East Asian markets, Japanese companies as well as home grown producers will be the strongest competitors.

Within the EC, competition is also expected to increase, as common technical standards and trade liberalisation foster cross-border competition among EC member countries, besides easing also penetration by extra-EC competitors.

Electrical equipment for industrial use

NACE 343.1

Demand for electrical equipment for industrial use is highly sensitive to the general economic situation. The industry covers indeed a variety of subsectors producing investment goods, as well as intermediate goods used for the subsequent treatment in the industrial production process.
The decline in investment activities in the beginning of the nineties resulted therefore in a decrease in demand for the industry's products. Prospects for the short term are somewhat pessimistic, as the poor economic situation is not expected to change significantly before the middle of 1994. After this turning point, the industry should benefit from investment-led growth during the course of the nineties.
The competitive position of EC producers in the industry is quite good and the trade balance is positive, though deteriorating. Mainly in the field of mass-production products, competition from low cost producers is becoming potentially dangerous.

INDUSTRY PROFILE

Description of the sector

The electrical equipment for industrial use sector comprises a number of little related subsectors:

- electrical equipment related to internal combustion engines, to motor vehicles and other means of transport, and to traffic;
- electrical industrial and laboratory furnaces, ovens and other types of heating equipment;
- equipment, machinery and materials for electric welding and cutting of metals;
- hand held electrical tools;
- other electrical apparatus, appliances and equipment for industrial use.

Activities in this sector are spread among a large number of producers who are either narrowly specialised or active in a number of subsectors. Given the sector's heterogeneity, its analysis must be done by subsectors, rather than on the sector as a whole.

Recent trends

Over the last five years, total extraEC exports of the industry as a whole have remained more or less constant, but with significant year by year fluctuations. ExtraEC imports, on the other hand, increased by some 8% per year in value, during the same period. As a result the trade surplus, some 800 million ECU in 1988, fell by half over the period. Trade among EC member countries has been growing considerably as well, at an annual rate of about 8% per year, similar to that of extraEC imports. Consequently, the share of intraEC imports out of total EC imports has remained unchanged. In 1992, the value of intraEC trade was more than two times larger that of extraEC imports.

In 1988, total consumption of welding equipment in Germany, France, Italy, the UK, Spain and the Netherlands was about 870 million ECU. About half of the total represented arc welding equipment, 40% resistance welding equipment, and a little over 10% other types of equipment, such as laser and electron beam machines. Within these six countries, Germany was the largest consumer with some 44% of the total, France followed with 22% and Italy with 16%.

International comparison

For power tools, EC producers are faced with strong competition from abroad as well. The most important competitors for EC producers are the EFTA countries, with more than half of extra-EC imports. Japan is also a strong competitor and supplied with about 23% of import demand from outside the Community. Both areas, however, lost market share in the EC, mainly to the benefit of producers from China, which could increase their EC market share from close to nil in 1988 to about 6% in 1992.

The EFTA countries are an important trade outlet for EC producers as well; in 1992, about 35% of extra-EC exports were delivered to this area. Exports to the United States are far behind with about 13%.

For welding equipment, the most important competitors for the EC are the EFTA countries with some 63% of extra-EC imports in 1992. The share of Japan is about 15% and that of the United States about 13%. The share of the EFTA countries slightly increased over the last few years, mainly to the detriment of the USA's and Japan's.

Foreign trade

The tendency towards increasing import penetration, observed in the sector of electrical equipment for industrial use as a whole is felt particularly in the welding equipment subsector, while exports to countries outside the EC increased by about 2% per year in value from 1983 to 1992, extraEC imports increased by nearly 9% per year in value, more than doubling during the same period. In 1983, the value of imports was about half that of exports; in 1992, the value of imports was slightly higher than that of exports, leading to a negative trade balance.

On the export side, the most important clients for EC producers of welding equipment are developing countries (including the East Asian NICs), with some 39% of extraEC exports in 1992, followed by the EFTA countries (26%). Most interesting in this context is the sharp decline of the aggregate "rest of the world" from 45% in 1988 to only 10% in 1992. This results presumably from the collapse of demand in East Europe. The strong growth of intraEC trade, by about 9% per year over 1983 to 1992, resulted in a nearly stable share of extra EC imports out of total imports (about 40%), over the same period. The most important intraEC exporters are Spain (17% of total intraEC exports) and France (16%).

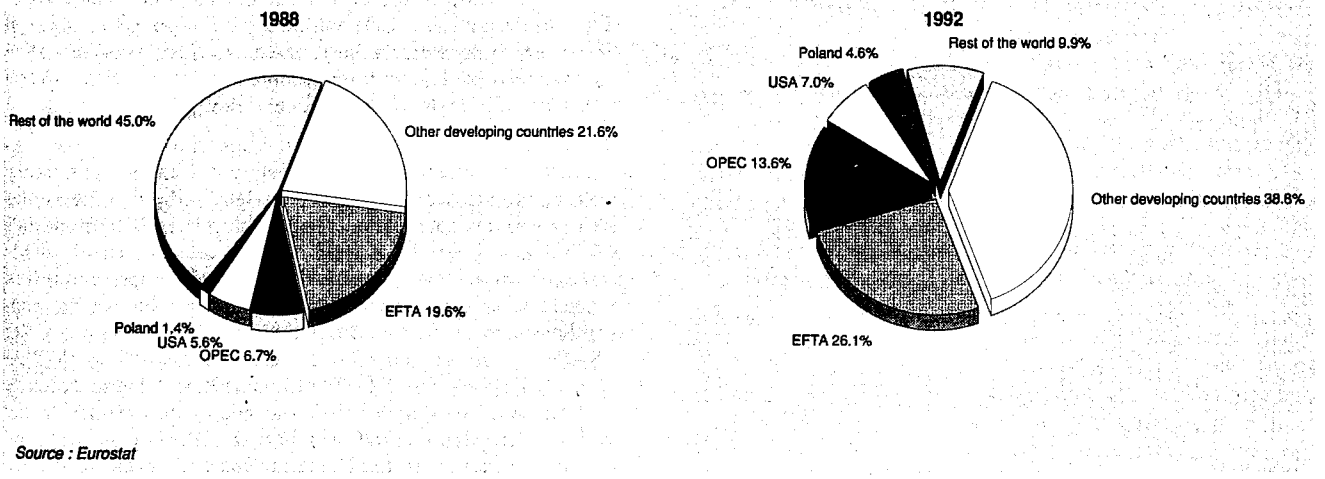
For power tools, the EC trade balance was negative throughout the period 1983 to 1992. ExtraEC exports increased by roughly 6% per year in value over the same period, but imports from outside the EC increased by more than 10% per year. The result was a sharp deterioration of the trade balance, from slightly negative in 1988 to a deficit of over 260 million ECU in 1992. IntraEC trade in power tools developed quite favourably during the last ten years, growing by nearly 10% per year from 1983 to 1992. The most important intraEC exporter is France, with some 23% of total intraEC exports, followed by Germany with about 16% and Italy (15%).

MARKET FORCES

Demand

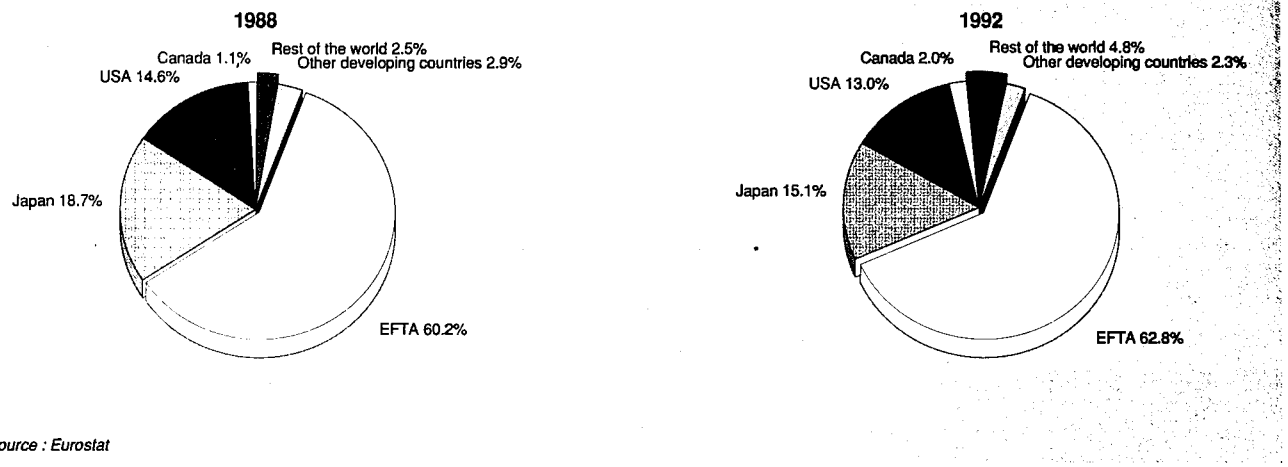
Apart from power tools, whose demand is determined to a large extent by private household expenditure, the industry's products are either intermediate goods used as inputs in other industries, or investment goods used to increase production capacities or production efficiency. Even welding consumables (filler materials) are not actually consumed as such but are used in connection with the production of durable investment or consumer goods such as cars and ships. Demand for the

Figure 3 : Welding equipment
Destination of EC exports



Source : Eurostat

Figure 4: Welding equipment
Origin of EC imports



Source : Eurostat

industry's products, therefore, is determined mainly by the evolution of production in a large number of client sectors, most of them of the investment goods category are:

- electrical equipment related to internal combustion engines, motor vehicles and other means of transport, and traffic where demand is determined by the level of production of transport equipment, and by replacement needs;
- furnaces and ovens, where demand depends mostly on construction activities or replacement for certain types of manufacturing plants, as well as of levels of R&D activity;
- welding equipment and materials, where demand depends mainly on activities in the transport industry, which includes the construction of cars, ships and aircraft's, but also on a wide range of other activities such as the production of cans, crosswire products, steel constructions, pipelines;
- electrical tools, where demand is mainly driven by small scale manufacturing, maintenance, arts and craft, hobbies and doityourself activities.

For most products of the sector, swings in the general level of economic activity will cause even wider swings in demand. Thus the fast pace of economic growth, which has characterised most of the developed world during the second half of the eighties, has also brought fast growth in demand for the products of the sector; on the other hand, the worldwide slowdown in economic activity, which started in 1990 and is widely expected to last at least until the end of 1993, has caused sharp drops in demand for all the industry's goods.

Supply and competition

The EC is leading in most types of electrical equipment for industrial use, with a large number of firms, providing the various needs of their client industries. Competition among EC member countries is very intense, but less so from outside the EC, as many of the products and types of equipment are custommade to a certain extent, according to the specific needs of the client industry. The strong cooperation between supplier and user is more important than pricing issues. For more massproduction products, however, such as power tools, completion from low cost producers is potentially dangerous.

In the case of welding equipment, especially so equipment for car assembly lines, nearby producers, or at least ECbased producers, have usually the edge over potential suppliers from other countries. On the other hand, "transplant" production facilities are almost always equipped by inhouse suppliers of the mothercompany. A good example is found in the case of Japanese car transplants in the UK, which have bought virtually all of their equipment in their own country.

Price and profit in the industry follow the vagaries of the business cycle. During the period of fast demand growth, prices and profits were high, as production was running into capacity constraints. Lately, however heightened competition over shrinking markets has caused prices and turnover to drop and profits to plunge.

Production process

For most of the sector's products, raw materials and energy represent a small portion of production costs. R&D is a very important input, as products must adjust to changes in production processes in the client industries. A major part of the labour force is skilled. Technological change is rapid, as already mentioned, but evolutionary rather than revolutionary. In particular the adoption of major innovations, such as laser cutting/welding technologies or electronbeam welding, may be held back by reluctance on the part of client industries to master new, untested, production processes. This happens too when other problems appear such as the high cost of the certification process. It is the case, e.g. whenever a new technology is being introduced in the aerospace industry.

INDUSTRY STRUCTURE

Companies

The industry is undergoing a wide ranging process of restructuring, with smaller firms merging into larger ones, both within each country and across borders. In each subsector and sometimes in specialised fields within a given subsector, one can find a small number of large integrated firms, often active in other sectors also, and small, more specialised, firms strong in a particular field or in a nichemarket.

Regarding the welding equipment subsector, one should distinguish between at least two fields: arc welding and resistance welding. In the arc welding field, where individual machines are of relatively small value, but consumption of fillermaterials represents a large part of welding cost, sales are usually made through a network of distributors. One finds there about half a dozen of major companies that are the product of the consolidation process carried out over the last 10 years or so: ESAB of Sweden and the UK, MesserGriesheim/Norweld/Lincoln (D/I/USA) and SAF/Oerlikon (F/CH). These recently merged companies under their old and/or new names in the various European markets. Hobbart & Miller of the USA are also major players in the European market. In the resistance

(1) EC10; 1983
Source: Eurostat

welding field, the number of players is much larger. Some companies have grown out of the resistance welding field to become major automation companies, and are mainly involved in the production of transfer lines used for the assembly of automobiles. There, one finds a number of big players: Sciaky - the major independent in Europe (F), Renault Automation (F), KUKA (D), Comau a subsidiary of Fiat (I), LambTechnikon (UK) and Stadco (UK), and another half dozen or so of smaller firms in different countries. The Comau of Italy has also other fields of activities, in machining operations. Other companies in the resistance welding field make more standard machines such as: classic spot welders, projection seam welders or various types of specialised equipment. These comprise a number of very large companies (500 workers and more), such as Sciaky, Comau and Renault Automation, again, and smaller companies in the range of 150 workers who tend to subcontract more of their work. These are: British Federal (UK), SciakyUK (UK), Ideal (butt welders and transformers) (D), Elrex (transformers) (D), Dalex (D) and PRD (F). Sciaky produces also, under a different brand name and separately, conveyors and mechanical handling equipment. Most of the firms in the industry operate internationally, at least in a number of EC countries.

Strategies

Demand for electrical equipment for industrial uses is and will remain subject to the vagaries of economic cycles, rising in times of investmentled growth, and plunging in times of slow growth. Firms in the sector, therefore, must be organised in ways that enable them to respond fast to fluctuations in demand high levels of automation, a maximum of outsourcing for the production of components, highly skilled manpower and high flexibility in employment and wage costs. R&D is an important factor in maintaining competitiveness, as is close cooperation with client sectors to best adapt products to needs and to build up customer loyalty.

ENVIRONMENT

Production processes in the sector of electrical equipment for industrial uses are little concerned with ecological issues energy consumption is low, emission of noxious fumes or other pollutants is negligible.

Recycling for the industry is rarely a problem as the industry produces relatively low volume and high value added products, with a large share of recyclable metals in their materials composition. For the arc welding industry, fumes represent a problem at the user's end, due to the special composition of the different types of electrodes used in the welding process. The danger is not for the environment in its usual sense but for the workers; it is dealt with by the use of aeration systems, filters, masks and similar.

REGULATIONS

The only regulations concerning the industry are those concerned with norms and their homogenisation across the EC. Only standard components are concerned, such as transformers, electrodes' sizes, cables and similar. Most of the equipment produced by the industry is highly specialised, and built to satisfy specific requirements, and there is little scope there for exogenously imposed normalisation. Some types of equipment produce electromagnetic radiation and the EC commission is working on a regulation to reduce its possible negative effects on workers and the nearby environment.

Other important directives that affect this sector are the Machines Directive (89/392/EEC), the Low Voltage Directive (73/23/EEC) and the Electromagnetic Compatibility Directive (EMC; 89/336/EEC).

OUTLOOK

The outlook for the industry of electrical equipment for industrial use is closely related to the outlook for its client industries. The car industry has been in the doldrums for the last three years in the EC, and is not expected to recover significantly until mid 1994. Later on, however, prospects are rather good, particularly so in the longer run after the midnineties once the East European market reawakens. This in turn will foster growth in the subsectors related to the automobile's industry electrical components for motor vehicles and in the welding industry. Demand for traffic related equipment has remained strong in a number of EC countries, mainly France, Spain and Germany, thanks to wide ranging railroad development projects. This is expected to continue in future.

Demand for other types of equipment is expected to benefit from the general recovery of business investment in the EC, forecast for 1993 onwards.

In general, demand (and consumption) for the industry's products is expected to decrease in 1993, is expected to start growing at a slow pace in 1994 and begin a recovery to relatively high growth rates in later years. In the mid-term forecast, production is expected to grow at similar rates as both extraEC imports and exports should follow similar growth paths as demand. In the longer run, export growth should outstrip import growth, thanks to the development of demand in Eastern Europe.

Batteries and accumulators

NACE 343.2

Increased use of portable electrical and electronic equipment, coupled with booming sales of motor vehicles stimulated demand for the industry's products over the last few years.
In the recent past, however, EC producers are faced with flat to declining demand, coupled with overcapacities in the field of batteries and accumulators, resulting in a rapid decline in prices.
Stiffening competition from outside the EC, mainly in the field of accumulators, contributed to the pressure on prices. Imports from outside the EC rose by over 8% in value, from 1985 to 1992.
Short term prospects for the industry are unfavourable. A weakening demand for starter batteries (about 45% of the industry's total production), following the sharp declines in motor vehicles' production, is expected to cause a sharp plunge in production.
The medium-term outlook is somewhat more positive, but environmental concerns and stiffening competition from South East Asian producers will represent serious challenges for the industry in the course of the nineties.

INDUSTRY PROFILE

Description of the sector

The batteries and accumulators industry can be subdivided into two main subsectors: the production of primary batteries, which are not rechargeable, and that of rechargeable batteries, i.e. accumulators.

There are six types of primary (non-rechargeable) batteries: zinc carbon batteries, the first type of dry batteries but still in use; longer life alkaline manganese batterics; mercuric oxide batteries; silver oxide batteries; zinc air batteries; and lithium batteries.

Accumulators are of two main types: lead acid batteries and nickel cadmium batteries.

Depending on their use, they can be further subdivided into : drive batteries, stationary batteries and starter batteries. Drive batteries are employed to operate electric motors to propel vehicles, in particular handling equipment, but also, lately, electric cars. Stationary batteries are used mainly for the operation of emergency devices such as alarm and control systems and as back-up, in case of power-breaks. Starter batteries are utilised in motor vehicles to provide electric power until the internal combustion motor has been started.

The most important producers of batteries and accumulators in the EC are Germany, France, Italy, the United Kingdom and the Netherlands.

Recent trends

Over the last few years, EC demand for starter batteries did increase considerably, with total sales (including imports from outside the EC) rising by 1.8% per year in value from 1983 to 1992, to reach some 48 million units by the end of the period. Sales batteries of European origin (including Switzerland and Sweden) increased by 1.2% per year in value over the same period. Demand from the motor vehicles' industry increased also at about 1.2% in average per year in value, from 1983 to 1992. Demand from industrial customers, with a weight about two times larger than that of car manufacturers, grew at a slower rate of 1% per year in value during the same period.

On the other hand, imports of starter batteries from outside the EC grew rapidly by 3.4% per year in value, to reach some 28% of total sales in 1992.

In the recent past, however, EC demand for starter batteries has declined, as the recession dampened demand in general. In particular, sales to car manufacturers declined by some 5% from 1990 to 1992.

International comparison

The most important competitor from abroad for EC producers is Japan, with more than 35% of total extra-EC imports. The United States and the EFTA countries follow, with a market share of roughly 20%, each. Developing countries reach a market share of about 22%. On the export side, by the far most important markets for EC producers are the developing countries (roughly 40% of extra-EC exports) and the EFTA countries (33%).

Foreign trade

Over the last few years, the EC batteries and accumulators' industry has been facing stiffening competition from countries outside the EC. While exports grew by about 3% per year in value from 1985 to 1992, imports increased at an annual rate of more than 13% over the same period. Thus, the EC trade balance turned negative from 1987 on, with imports exceeding exports by about 40% in 1992.

The most important exporter to countries outside the EC is Germany, with about 30% of total extra-EC exports in 1992; France follows with about 24%. Regarding imports, the most important market in the EC is Germany, with roughly 33% of extra-EC imports, followed by the United Kingdom, with about 18%.

Competition among EC producers has been stiffening as well, with intra-EC trade growing at roughly 7% per year from 1985 to 1992. However, given the fact, that extra-EC imports increased even more, the share of intra-EC imports out of total imports declined from 69% in 1985 to 64% in 1992.

MARKET FORCES

Demand

Demand for the products of the industry as a whole increased considerably during the last decade. In the field of non-rechargeable (primary) batteries, market growth was roughly 2% per year in volume. Primary batteries are used in high fidelity equipment (50%), games (20%), lighting (11%), watches and alarms (11%) and photo equipment (8%). Demand for this product depends therefore mainly on private consumer expenditure. Increasing use of battery driven devices, spurred by product innovation, was the main factor for the favourable development of demand. The short-living zinc-carbon battery is being gradually substituted for by the longer-lasting alkaline battery, whose life is nearly three times longer; the latter accounts at present for roughly 40% of the market in the EC. Newer developments in this context are zinc-air and lithium batteries, which contain no mercury. On the other hand, however, the longer life of the batteries affects demand negatively, despite the increased use of battery driven devices.

Demand for rechargeable batteries (accumulators), which are increasingly used in portable types of equipment that require relatively large amounts of energy, has been booming during the last years, particularly since 1985, when nickel-cadmium rechargeable batteries went on sale to the general public. The annual growth in sales over the last few years is estimated to 15% to 20%. Accumulators based on the nickel-cadmium principle are not only lighter but also live longer (5 to 10 years) than conventional accumulators, which results similarly to the above mentioned effect regarding primary batteries, in a decrease of demand growth.

Among accumulators, the most important segment is that of starter batteries (mainly used for motor vehicles, construction machinery, agricultural machinery and aircraft), with some 55% of total production of rechargeable batteries; drive batteries follow with about 25% of the total and stationary batteries, with about 8%. In West Europe as a whole, the market for starter batteries represented some 48 million units in 1992. About one third goes into new motor vehicles, and most of the remaining two thirds represent replacement demand for older vehicles. Replacement demand depends mainly on the size of the motor vehicles fleet, while demand for new starter batteries is highly cyclical, and follows the fluctuations in motor vehicles' production. As the size of the motor vehicles fleet keeps increasing, replacement demand keeps increasing as well.

Supply and competition

Increased in competition from outside the EC is mainly concentrated on accumulators, since the most important producers of primary cell batteries have also production facilities in EC countries. Nevertheless, dry batteries producers are faced with a rapid decline in prices a consequence of over capacities, built up on the basis of overestimates of the market's growth potential.

As said, competition from outside the EC has been rising in the field of accumulators, particularly from Japanese, South Korean and Indonesian firms; as contended by EC producers, the price competitiveness of these products is not due only to lower production costs, but also to subsidies on raw materials and an export-dumping policy. The fact that the production process requires little skilled labour represents apparently an important comparative advantage for low labour cost countries. In particular EC producers of starter batteries have been faced with fast growing imports, of 3.4% per year from 1983 to 1992.

In the face of increasing competition from outside the EC, and overcapacities within the EC, the market suffers from strong downward pressures on prices.

Production process

In 1990, the subsector of primary batteries employed about 15000 people in West Europe, in a total of 10 factories. In the accumulator industry, about 40000 people were employed in some 80 factories. As a result of slowing production growth and the need to improve productivity in order to reduce costs, in a world of stiffening competition, employment levels are expected to keep falling over the next few years. This is made possible by the relatively low level of sophistication of the production process, which eases automation efforts.

INDUSTRY STRUCTURE

Companies

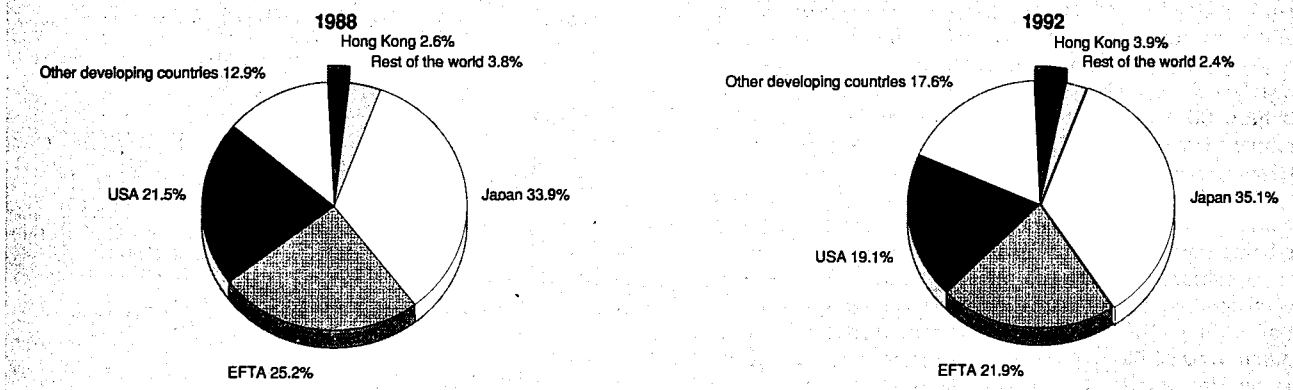
There are about 10 factories producing primary batteries in West Europe. This field of production is characterised by a high degree of concentration, with about 80% of the market being covered by the four largest manufacturers: the US based Duracell (UK), Varta (D), Philips (NL) and the US based Ralston Energy Systems (CH). Other important players in this field are the American Kodak, and the Japanese Sanyo and Matsushita.

In the field of accumulators, there are about 25 manufacturers in the EC. The most important are Varta (D), Bosch (D), the company Saft and CEAC (F), jointly owned by the Italian Fiat and the French Alcatel Alsthom, Hawker (UK) and the firm Tudor (E). The largest EC producer is Varta, active in both primary batteries and accumulators; this company has 35 subsidiaries spread over several regions in the world, among them Latin America and the Far East, in addition to its traditional markets in Germany and the EC. The group realises roughly 40% of its turnover in portable batteries, 27% in starter batteries and nearly 23% in storage batteries for industry. Regarding starter batteries, the number of manufacturers declined from 18 West European producers in 1988 to 10 producers in 1991. Following the increasing globalisation of their main clients, virtually all EC producers are operating at least on the European market at large and many of them, globally.

Strategies

The batteries and accumulators' industry in the EC is characterised by surplus in the production capacity, and by strong and growing competition from outside the Community. Together, these factors ensure that the downward trend in prices will continue over the next years.

Figure 2: Batteries and accumulators
Origin of EC imports



Source : Eurostat

To combat the squeeze on profits and to reduce costs, companies have had to rationalise production. In particular, efforts are oriented towards more concentration, in order to gain economies of scale. The American Ralston (based also in Switzerland) for example, has taken over in France the firms Wonder and Mazda. Since the beginning of 1992, Varta's and Bosch's battery activities have been consolidated, in the jointly owned VB Autobatterie GmbH (D).

The concentration process can be illustrated by the fact that in 1988, 18 producers existed in West Europe, while in 1991 10 producers were only active. Three companies, Varta/Bosch, CEAC, and Tudor hold together a market share of roughly 60% in West Europe.

Companies are also investing to penetrate new, expanding markets. Examples are the German firm Varta, that is establishing subsidiaries in countries as diverse as Finland, Argentina, Mexico, Brazil and Singapore, and the French Saft, that is doing the same in Korea and Finland, from where it hopes to penetrate markets in South East Asia and in East Europe. EC firms have to invest in R&D efforts to increase the quality of their products and to counteract competition from extra-EC firms that are highly competitive in terms of technology (USA & EFTA). Improvements can be made in the direction of longer-life for the products or in the context of environmental concerns.

Smaller companies are forced to operate in niche markets, which are very demanding in terms of technology and quality. The problem is, however, that these firms may face difficulties in financing R&D expenditures; cooperation in the development of new products could be the answer.

REGIONAL DISTRIBUTION

Within the EC, the main producers of primary batteries are Germany, France, Italy, the United Kingdom and the Netherlands. This is also where the most important firms are located. In primary dry cell batteries, the largest world producer is the American group Duracell.

In rechargeable batteries, the leading producer of the Community is France, with its company Saft; the biggest producers in the world, however, are the Japanese companies Sanyo and Matsushita.

ENVIRONMENT

Some of the most important product innovations in the industry over the last few years are related to concerns over the environment. Most important in this respect is the reduction in the heavy metals content of non-rechargeable batteries, namely of mercury, which has traditionally been used in both saline and alkaline batteries. Two directives of the European Commission in 1982 and 1984 require the reduction of mercury waste. Since 1985, the primary batteries industry in the Community has cut the amount of mercury discharged from batteries into the environment by half, and has undertaken to reduce this by a further 84%. The reduction in mercury waste has been the result of two developments: first, it has been possible to reduce by 97.5% the content of mercury in alkaline-manganese batteries, compared to 1985 levels, and to eliminate thus the need for them to be collected separately; second, mercuric-oxide batteries (containing 30% mercury) are being replaced by zinc-air batteries (around 1% mercury) and by lithium batteries (no mercury at all). Other environmental concerns are oriented towards recycling batteries. Some Member States of the Community have already introduced separate waste collection for primary batteries containing mercury. In 1991, the EC Commission proposed a directive about batteries containing harmful substances. This proposal had to be turned into national directives until September 1992. This directive requires for producers to take back used batteries, so that the materials can be recycled. The problem is, however, that the required low energy and low emissions recycling techniques are not available at the moment, except for lead recycling. In the field of lead-acid accumulators the recycling ratio is already close to 100%, in nickel-cadmium batteries it is about 60%. Besides the technological aspects of the problem, its economics are no less important as the use of recycled materials is likely to increase production costs. If international competition does not face the same requirements, EC producers could lose price competitiveness. Another factor liable to increase costs to customers is the decision of the EC Commission to impose a deposit on batteries, as an incentive to return them to the seller.

OUTLOOK

The prospects for the batteries and accumulators' industry are somewhat pessimistic for the short-term. The decline in motor vehicles production and in industrial investment in general is likely to affect demand for starter batteries, as well as for drive batteries and stationary batteries. Demand for dry batteries on the other hand, is less sensitive to cyclical fluctuations; production there should perform better than in accumulators.

In the medium term, the outlook for the industry as a whole is quite positive, as the expected economic recovery should stimulate demand for the products. In the field of primary batteries, demand growth will be stimulated by the development of better, longer lasting products, such as lithium batteries, which last about seven times longer than ordinary batteries and contain neither mercury nor cadmium. The trend towards the development of ever smaller appliances requiring ever smaller and ever more powerful batteries will further feed demand growth in the future. On the other hand, the decline in the quantity of energy needed in portable devices may dampen demand to a certain extent. In the field of accumulators, EC producers of starter batteries will be increasingly faced with strong competition from outside the EC, mainly in terms of prices. In addition, existing over capacities will strengthen pressures on prices in this area. Drive batteries and stationary batteries, on the other hand, will perform somewhat better, as the position of EC producers in this field is quite strong through the supply of services, a very important feature there. In addition, considerable demand for high energy drive batteries could possibly be created by the eventual development of electrically driven motor vehicles; the time horizon for actual use of such cars, however, is at the moment unpredictable. Finally, demand for stationary batteries will benefit from developments in the field of telecommunication, with ever more facilities requiring protection against power failure.

Domestic electrical appliances
NACE 346

The domestic electrical appliances' industry in the EC has been faced with changing in demand trends over the last few years. High saturation rates have dampened demand growth, when economic conditions were good in general; on the other hand, the effect of the economic downturn since the beginning of the nineties has been partly compensated for by the re-unification of the two German States.
Another important feature of the last decade has been the concentration process that took place in the industry during that period.
Prospects for the industry in the medium term are somewhat more optimistic as anticipated recovery of the housing sector and of consumer spending stimulates demand for the products of the industry. In addition, product innovation and the pressure to replace products using ecologically dangerous chemicals should keep demand growing in the course of the nineties.

Competition on the other hand is expected to keep increasing and will force companies to increase their mergers and acquisitions (M&A) efforts, as well as to streamline production in order to reduce costs.

INDUSTRY PROFILE

Description of the sector

The domestic electrical appliances' industry comprises the following products:

- domestic electric refrigerators and freezers;
- domestic electric washing machines and equipment;
- domestic electric dishwashers (including parts);
- other domestic equipment with electric motors (including vacuum cleaners, floor polishers, grinders and electric apparatus for treatment of hair and skin);
- boiling-plates, cookers and similar domestic electric heating appliances;
- other domestic electric heating appliances (including hair dryers, electric ironing appliances).

Compared to other manufacturing sectors, the domestic electrical appliances' industry is of relatively minor importance, as its output is about 58% of that of consumer electronics', measured in terms of value added in 1992.

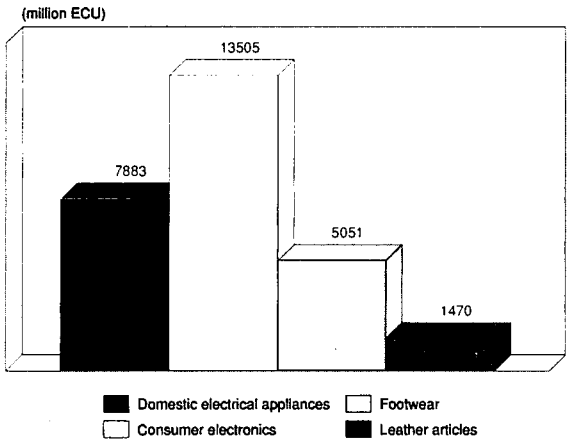
Within the EC, the largest producing country is by far Germany, with about 40% of the total in 1992. Italy follows with some 22%, France with roughly 14% and the United Kingdom with about 10%.

Recent trends

The domestic electrical appliances industry experienced a quite favourable development during the last few years, slightly above the average of manufacturing as a whole; while production in the manufacturing sector increased by 2.8% per year in volume from 1983 to 1992, production of domestic appliances grew by 3.3% over the same period, to reach some 23 700 million ECU in 1992.

Demand for domestic appliances, measured in terms of apparent consumption, increased by 3.5% per year in volume over the last few years. In the recent past, however, the EC industry has lost momentum. The decline in consumption

Figure 1: Domestic electrical appliances Value added in comparison with other industries, 1992



Source: DEBA

growth in the 1988-92 period caused a decrease in production growth as well, in spite of the sharp rise in export growth to countries outside the EC (10.3% per year in volume).

Over the first half of the 1983-92 period, the industry has been faced with a fast growth of imports from outside the EC, particularly in small appliances and microwave ovens, causing the trade surplus fall by half. From then on, however, the decrease in demand growth led to a decline in import growth as well, resulting in a considerable improvement of the EC trade balance, from 2.3% of production in 1988 to 5.2% in 1992.

International comparison

The most important producer of domestic electrical appliances within the Triad is the EC. Production here was about one fifth larger than that of the United States in 1983 and more than the double, at current prices, in 1992. From 1985 to 1992 production in the EC increased by more than 4% per year in real terms, while that of the United States rose by an annual 1.7% only. On the other hand, in Japan, production increased at a faster rate of some 6% per year in volume

from 1985 to 1991. In 1992, however, Japanese production fell by a steep 15% in real terms due mainly to a sharp fall in domestic demand.

Foreign trade

The development of trade with countries outside the EC has been dynamic over the last few years. Trade among EC Member States increased as well over the last few years, at an average annual rate of about 11% from 1983 to 1992 to reach about 7800 million ECU in 1992.

From 1983 to 1992, extra-EC exports increased by some 10% per year in value. Important markets for EC producers are the EFTA countries, with some 35%, and the aggregate "rest of the world" including the developing countries and the East Asian NICs, with more than 50% of extra-EC exports. The United States and Japan are markets of relatively minor importance for EC producers. The main feature of EC exports over the last few years has been the decline in importance of the traditional markets: while about 49% of total extra-EC exports had been delivered to the EFTA countries in 1987, the latter's had declined to 35% in 1992. The most important exporting countries within the EC are Italy (32% of total intra-EC exports), Germany (30%) and France (14 %). Germany is presently the largest importer of white goods within the EC, with about 22% of intra-EC imports, a result mainly of the unification of the two German states.

Competition from outside the EC has grown fast over the last few years. Extra-EC imports have increased by roughly 11% from 1983 to 1992. Thus, the share of imports out of apparent consumption increased from 6% in 1983 to 11% in 1992. The aggregate "rest of the world" (including the developing countries and the East Asian NICs) increased its market share in EC countries during the last years from about 42% in 1987 to roughly 53% in 1992. EFTA countries are important suppliers as well, with some 31% of extra-EC imports. Remarkably, Japan's market share has been declining over the last few years: in 1987, about 22% of imports from outside the EC came from Japanese suppliers; in 1992, their

Figure 4: Domestic electrical appliances

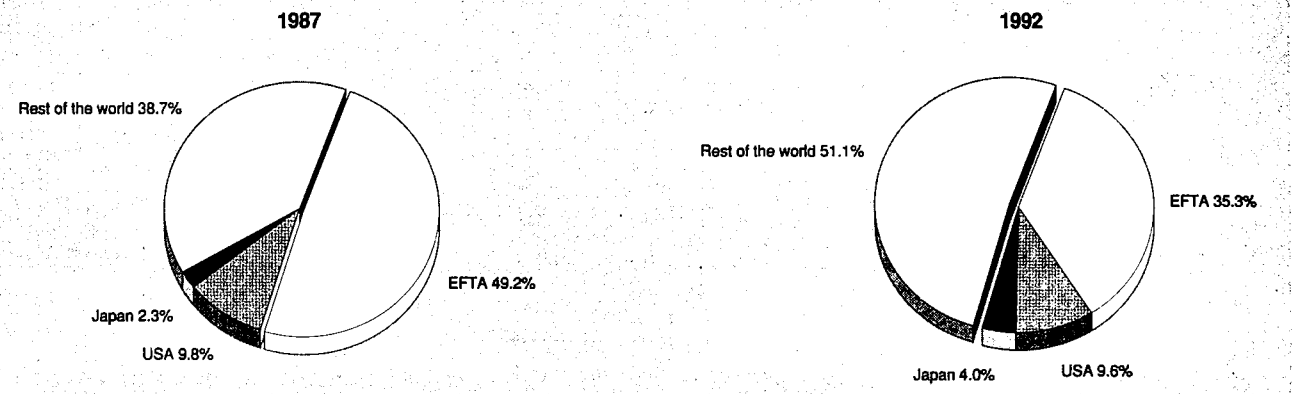
Figure 6: Domestic electrical appliances
Destination of EC exports



Source: Eurostat

share had declined to only 6%. A decline of competitiveness against other fast-growing economies and increased efforts of Japanese producers to build up production facilities in the EC are the main explanatory factors in this context.

During the 1989-92 period, total German imports increased at a rate of 17% per year in value, to the benefit mainly of other EC Member States, who increased their exports to Germany by 20% per year over the same period. German imports from countries outside the EC increased somewhat more slowly, at some 14% per year.

As a result of the strong competition from outside the EC, the share of intra-EC imports out of total imports has declined from 79% in 1983, to 76% in 1992.

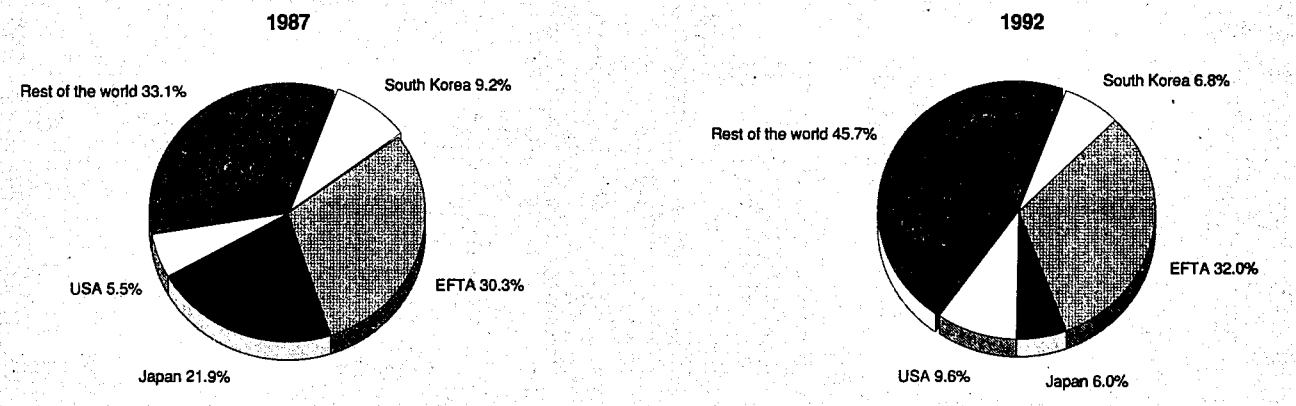
MARKET FORCES

Demand

Demand for domestic electrical appliances depends mainly on consumer expenditure and residential construction. In line with the economic upswing during the eighties, the industry experienced favourable demand growth, with apparent consumption increasing by 5.4% per year in value from 1983 to 1992. Since the end of 1988, however, demand growth has flagged, following the slowdown of economic activity. In addition, demand has been affected by the high degree of market saturation in most of the subsectors of the industry: in refrigerators, ownership rates had reached nearly 100% by 1989, and nearly 90% in both washing machines and vacuum cleaners. Ownership rates of freezers (41%) and dishwashers (23%) were considerably lower, but grew as well during the last decade. Once saturation is reached demand for the product is bound to weaken considerably, as they are then bought mainly for replacement purposes.

On the other hand, there are several factors that may compensate, at least partially, for the decline in demand for domestic electrical appliances. One factor is the role of product innovation: the introduction of electronic components in order to improve efficiency and to simplify use may boost demand to a certain extent; changes in the social structure of the population over the last few years, have stimulated demand as well: an increase in single person households kept growing the number of households making first purchases. Another important factor in the recent past, has been the unification of the two German states resulting in sharp increases in demand for German manufacturers as well as for other EC producers.

Figure 7: Domestic electrical appliances
Origin of EC imports



Source: Eurostat

As a result of the structural problems in the former East Germany, however, the demand boost lost recently its momentum and production growth has returned to pre-unification levels.

Supply and competition

EC producers of domestic electrical appliances are confronted with strong competition from abroad. The largest source of extra-EC imports is from the EFTA countries, representing more than 30% of the total. One of the world's largest and Europe's number one manufacturer is Swedish Electrolux (with most of its production facilities in the EC), with a market share of some 17% in West Europe.

As a consequence of relatively high transportation costs, extra-EC exports and imports represent only small parts of production and consumption. In particular, competition in large domestic electrical appliances is concentrated mainly among producers on the West European market. In some fields, however, competitors from East Europe are gaining market shares as well. The most important competitor in the dishwasher sector is again Swedish Electrolux, with a share of about 86% of total extra-EC imports. For washing machines, the picture is similar to EFTA countries supplying some 54% of extra-EC imports. Recently, Slovenia managed to build up its market share from nil in 1988 to some 18% in 1992. For vacuum cleaners, competition comes mainly from the United States (22% of extra-EC imports) and the EFTA countries with some 19%; China follows with some 18% in 1992. Poland tripled exports to the EC from 1988 to 1992, reaching some 20 million ECU, corresponding to a market share of roughly 13%. For refrigerators, the picture is similar to the EFTA countries and the United States as the most important competitors. Competition from East Europe, however, has increased considerably over the last few years: in 1988, Slovenia, Russia and Poland exported goods worth some 6 million ECU to the EC; in 1992, the export value was eight times higher and reached a market share of about 10%. In the field of small appliances, competition also comes from developing countries and the South East Asian NICs. For irons, for example, Singapore is a major competitor for EC producers, supplying nearly 50% of demand from outside the EC. The share of Chinese producers is about 32% at present.

Competition among EC producers has increased as well over the last few years. This development was stimulated by increasing concentration in the industry, as well as by the efforts of EC firms to increase their market share in order to compete in the single market.

Recently, producers in Germany and France have been hit by a loss in competitiveness following the appreciation of the French Franc and the Deutschmark against other European currencies.

INDUSTRY STRUCTURE

Companies

Compared to other industries in the manufacturing sector, the industry of domestic electrical appliances is highly concentrated. The manufacturing process is characterised by mass production, to benefit from economies of scale. The world's largest producer of large domestic appliances is the firm Whirlpool (USA). Europe's largest producer of household appliances is located outside the EC: Electrolux (S), with a market share of some 17% in the EC. As already mentioned, however, most of its production facilities are located within the EC. Other important producers in the field of large appliances are AEG Hausgeräte (D) and Bosch-Siemens Hausgeräte (D). An important producer of washing machines and dishwashers is Thomson Electroménager (a subsidiary of the state owned Thomson S.A.), recently acquired by the Italian firm Elfi (Elettrofinanziaria); the name of the new company will be Brandt Electroménager, and employ some 10 000 workers. In the field of small appliances, the most important firms are Philips (NL), Moulinex (F), and SEB (F). Other important producers of white goods are Candy (I), Merloni (I), Miele (D) and G.E./Hotpoint (UK).

Strategies

As already mentioned, the industry of domestic electrical appliances is highly concentrated. Important M&A activity took place during the eighties: in 1980, some 810 producers of domestic appliances were active in the EC; by 1989, the figure had declined to 430. Overcapacity, a feature of the recent past, is expected to lead to continuing consolidation efforts during the nineties as well. In the recent past, some important regrouping took place: Bosch (D) and Siemens (D) merged their appliances divisions together, Whirlpool (US) now owns the appliances' division of Philips (NL), Elfi (I) bought the Thomson Electroménager from France, Rosières (F) was taken over by Candy (I) and Scholtes (F) was taken over by Merloni

Source: BAK

(I). Nowadays, France has no production of washing machines, refrigerators and dishwashers under domestic ownership. The only production of white goods under French ownership takes place in the companies Moulinex and SEB in the field of small domestic appliances. Another important consolidation in the field of washing machines took place in the beginning of 1993: AEG and Electrolux started to produce washing machines together, to benefit from the effects of mass production. Further cooperation between these two companies is expected.

Another strategy aiming at reducing costs is the placement of production facilities in low cost countries to improve competitiveness on the world market. Beside this, a hollowing out production to reduce production costs, could take place, by producing components in low cost countries.

Beside cost reduction measures, new markets have to be found, mainly in the fast growing regions of South East Asia and in potential markets in East Europe. Electrolux for example, bought Lehel in Hungary in 1991, a producer of refrigerators. Such measures could serve as a springboard to other countries in the region.

ENVIRONMENT

Regarding ecological issues, the industry of domestic electrical appliances is faced with a number of problems. The most important is the use of CFCs in refrigerators, which has to be eliminated by 1995, even though the industry is not a heavy user of CFCs (4.3% of the "Montreal Protocol" base figure). Some firms have already introduced refrigerators without CFCs. Another impact on the environment stems from the use of water and energy in appliances. The industry's efforts, in order to reduce the environmental strain, are oriented towards the manufacture of products that use less water and less energy. Another problem, in particular for German producers, resides in scrap disposal regulations, that are planned to come into force in 1994. Companies expect these to increase their costs by some 15%.

REGULATIONS

There are two Commission directives that are particularly important for the free movement of domestic electrical appliances within the EC: these are the Low Voltage Directive 73/23/EEC of 19 February 1973 (JO no. L77 of 26 March 1973) and the Electromagnetic Compatibility Directive 89/336/EEC of 3 May 1989 (JO no. L139 of 23 May 1989).

OUTLOOK

Prospects for the domestic electrical appliances' industry are somewhat pessimistic for the short term. Demand is expected to drop in 1993 and to remain flat in 1994. In particular, producers from Germany and France will be affected by weak foreign demand in 1993, following the appreciation of their currencies, on top of weak domestic demand. In 1994 as well, both consumer expenditure and residential construction activity will remain weak, causing demand to recover only slowly. High ownership levels will further affect demand for the industry's products negatively.

In the medium term, an improvement in consumption and production can be expected, as the economic recovery boosts demand for the products of the industry. Product innovation, to save energy and water, should create demand for a new generation of appliances. Environmental concerns will also boost demand for refrigerators and freezers, with the phasing out of CFCs in these products until 1995. Dishwashers and freezers are expected to boost the growth rate of the industry in the nineties, as these products have considerably lower ownership rates up to-date.

Competition from outside the EC is expected to increase as well during the nineties, particularly in the field of small appliances. EC producers will thus have to increase their efforts to reduce production costs. Rationalisation efforts will result in a further decline of employment figures in the industry in the course of the nineties.

Written by: BAK
The sector is represented at the EC level by: European Committee of Manufacturers of Electrical Domestic Equipment / Conseil Européen de la Construction Electrodomestique (CECED). Address: c/o ANIE, 2 Via Alessandro Algardi, I-20148 Milano; tel: (39) 232 64299; fax: (39) 232 64212.

Electric lighting
NACE 347

The electric lighting industry in the EC experienced fast growth in the period 1983 to 1992. Robust growth in both business and dwelling construction was the main driving forces over that period. In addition, product innovation contributed to the favourable development of demand during the course of the eighties.
Competition from producers of the East Asian NIC's has been increasing during the last few years, leading to a gain in EC market share, mainly to the detriment of traditional suppliers from the EFTA countries and the United States.
Prospects for EC producers of lamps and lighting equipment in the medium term are quite favourable, as the expected economic recovery increases demand in the course of the nineties. Product innovation, particularly in the field of energy saving lamps and lighting equipment, will provide an additional boost to demand over the next few years.

INDUSTRY PROFILE

Description of the sector

The electric lighting industry can be divided into two main subsectors:

- electric lamps, which include incandescent lamps, discharge lamps and dual lamps for lighting purposes;
- electric lighting equipment, which comprises indoor electric lighting equipment, special purpose electric lights, portable lights, outdoor lights, spotlights (excluding lights for motor vehicles) and parts for electric lights.

In the EC, the sector is of minor economic weight within the larger aggregate of electrical engineering. The value added in 1992 was equivalent to 28% of consumer electronics. The most important EC producer country of electric lamps and lighting equipment is Germany with some 50% of the total; France follows with 15%, the United Kingdom with 14%, Italy with 9% and Belgium with 6%.

Recent trends

During the recent past, the industry in the EC enjoyed a favourable growth climate: while production of the manufacturing sector as a whole grew by roughly 3% per year in volume from 1983 to 1992, production of electric lighting equipment increased by about 5.2% in volume during the same period. Employment in the lighting equipment sector increased slowly by about 1% in average per year, to reach some 101 000 employees in the industry by the end of the period.

The fast rate of growth over the period analysed was mainly concentrated in the second half of the last decade, thanks to a healthy economic climate that boosted demand. From the beginning of the nineties, however, EC production more or less stagnated in real terms.

Demand, as measured in apparent consumption, grew at a rate well above production growth, of about 6.0% per year in volume from 1983 to 1992. During the same period, imports exhibited dynamic growth, of some 10% per year in volume. Exports grew considerably as well, but less dynamically than imports, at some 4% per year. The EC trade balance, however, remained positive over the whole period.

International comparison

The most important producer country in the field of electric lamps and lighting equipment is the United States, with an output nearly two times as large as that of the EC. The development of the US industry, however, was not as dynamic as that of their competitors from the EC. From 1985 to 1990, EC production increased by about 7% per year in real terms, while production in the United States was more or less stagnated. Consequently, their respective shares of world production changed over the last decade, to the benefit of EC producers.

Foreign trade

The lighting equipment industry was characterised by a fast increase of imports over the last decade. In nominal terms, imports increased by an annual average rate of about 12% over the last 10 years. Thus, some 13% of demand were satisfied by imports in 1992, against a 1983 figure of 11%. Important competitors are the EFTA countries, with about 25% of total extra-EC imports. More than half of extra-EC imports, however, stem from the aggregate "Rest of the world", mainly from developing countries, which are included in this aggregate. In this context, it is important to notice that traditional suppliers lost market share in the EC to the benefit

of developing countries. Extra-EC exports grew dynamically as well, though at a much slower pace than imports and increased by 7% per year in value over the last 10 years. For EC producers, the United States and Japan are markets of secondary importance, with about 15% of extra-EC exports delivered to these areas. More important are the EFTA countries with an export share of more than 30%.

Trade between EC member countries increased by 10% per year from 1983 to 1992; its volume is more than two times as large as imports from outside the Community. The most important intra-EC exporters are Germany and Italy, each with some 23% of the total in 1992, followed by the Netherlands (18%), France (11%) and the United Kingdom with about 5%.

Over the last decade, the share of intra-EC imports out of total imports declined slightly to the benefit of extra-EC imports, from about 74% of total imports in 1983 to 72% in 1992.

MARKET FORCES

Demand

Demand for products of the electric lighting industry is driven mainly by replacement demand (for lamps) and needs for the equipment of new buildings, dwellings and development projects (for lighting equipment). Much of replacement demand is insensitive to cyclical fluctuations, but the pace of growth of disposable income, as well as technological innovations and fashion trends, can affect replacement rates.

Demand for the equipment of new buildings, on the other hand, is highly cyclical, depending as it does on the level of construction activity. Electric lamps, one of the two main subsectors of the industry, are used mainly in private dwellings, industrial and offices buildings and for street lighting. A smaller part of demand for electric lamps stems from the motor vehicles' industry and from the photographic industry. For electric lighting equipment, the second of the two main

Figure 4: Electric lighting

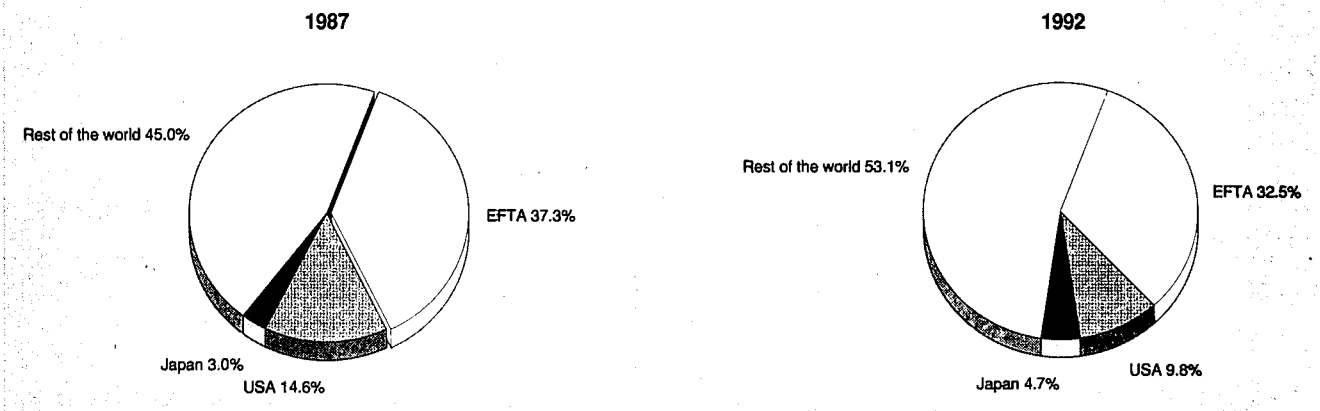
Figure 6: Electric lighting
Destination of EC exports



Source: Eurostat

subsectors of the industry, business and public construction activity are the more important sources of demand Thus, the industry did benefit considerably from the boom in EC construction activity in the second half of the last decade. The recent downturn in private and public construction activity, on the other hand, coupled with the plunge, taken lately by the production of motor vehicles, have considerably affected demand for the products of the industry.

Product innovation has been an important driving force for demand as well over the last years. New products, such as halogen lamps, discharge lamps and compact fluorescent lamps, which live longer and use less energy, have increasingly gained acceptance, causing a gradual shift in demand from cheaper lamps to high-grade equipment.

Supply and competition

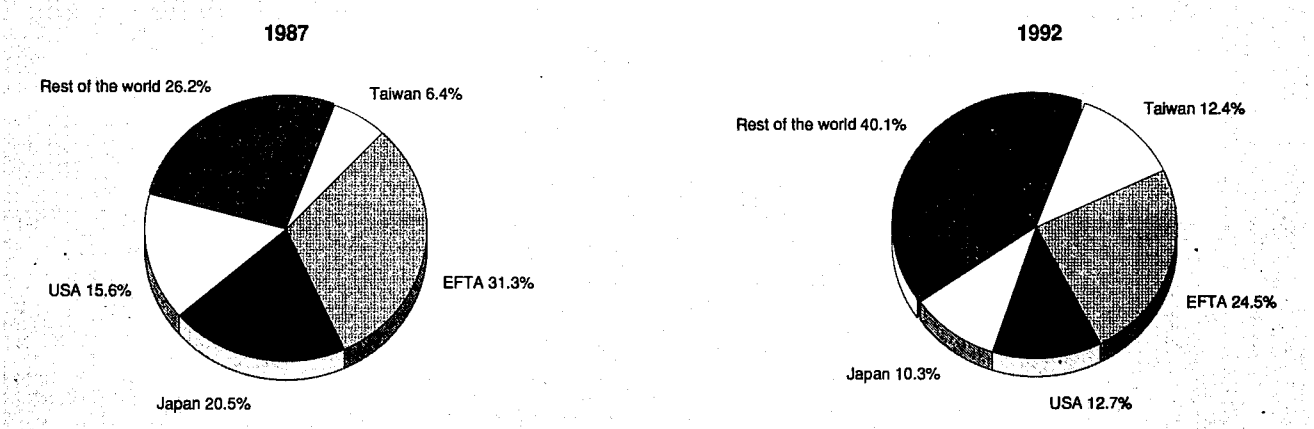
In 1983, among the Triad (the United States, Japan and West Europe), the US were the most important producers of electric lighting equipment and lamps, with about 50% of the total, followed by the EC, with some 30%; Japan was in the third position, with roughly 20%. Competition for EC producers increased considerably during the last few years, as the share of imports from outside the EC increased from some 11% in 1983 to 13% in 1992. In particular, imports from Taiwan increased from 2.5% of total extra-EC imports to roughly 12% recently; China managed to increase its market share in the EC as well. Imports from Japan, China and other Eastern countries increased particularly in the field of halogen lamps.

Trade among EC member countries enjoyed fast growth as well during the last decade, at a rate of roughly 10% per year in value. The increase in international trade in general is partly the result of the concentration process that took place in the industry during the last years.

Production process

The considerable increase in production was accompanied by meagre growth in employment figures, of roughly 0.4% per year from 1983 to 1992. The electric lighting industry employed roughly 101 000 employees in 1992, down from a peak of 111 000 in 1989. Productivity, measured in value added in constant prices per person employed, increased significantly, by 3.2% per year for the same period. Regarding individual EC countries, the fall in Spain's workforce was the steepest: from 1983 to 1992, it fell by some 66%.

Figure 7: Electric lighting
Origin of EC imports



Source: Eurostat

INDUSTRY STRUCTURE

Companies

In electric lamps, EC production is dominated by a small number of large firms. The tendency in that subsector of the industry is to concentrate activity in a few large firms, to profit from economies of scale, and to make it possible to muster the huge resources necessary for intensive R&D activities. All of the firms there are operating internationally, in most cases worldwide. The most important firm in the EC is Philips (NL), the multinational electrical goods producer, which plays a central role in assuring the dominant position of the Netherlands as Europe's number one in electric lamps. The market share of Philips is about 40% in Europe and 20% in the United States. Another important firm is the German Osram (a division of Siemens), who bought the American part of Sylvania from GTE. Osram is now one of the world's three largest producers of lamps, along with Philips and General Electric (US). The latter bought in 1990 the producer of lamps Tungsram (Hungary) and in 1991 the lamp division of the European firm Thorn EMI (UK).

In the subsector of electrical lighting equipment, production is much more fragmented. Many of the firms operate only regionally, or even locally. The most important firms are Siemens (D), Trilux (D), AEG (D), Philips (NL) and Thorn Lighting (UK). Important firms in other countries are Zumtobel in Austria and Lithonia, Cooper and GTE in the United States.

Strategies

EC firms in the electrical lighting industry are faced with stiff competition in the field of technologically advanced products, by traditional competitors from the United States and the EFTA countries; in the field of less technologically advanced products, the main competitors are the East Asian NIC's and China, benefiting from lower costs of labour, raw materials and energy. As a result, EC producers have to increase their efforts to improve production efficiency, to compensate for unit cost advantages in lower value added products, presumably through increased substitution of labour by capital, i.e. more automation of production. In the field of technologically advanced products, on the other hand, EC firms have to increase R&D expenditures, to maintain competitiveness with other industrialised countries. Efforts in this field are already apparent, as shown by the increase in inward investment, that was nearly four times as high in 1989, compared to 1983. This means also that the above mentioned trend towards increased concentration is likely to continue in the next few years. The concentration process is likely to be accompanied by further reductions in the industry's labour force.

REGULATIONS

The most important European Commision regulations concern the harmonisation of legislation applicable to electrical equipment. These should stimulate trade between EC Member States and are likely to facilitate competition from abroad as foreign competitors will no longer have to adapt their products to different national systems.

The penetration of the EC market by halogen lamp imports from Japan, China and other Eastern countries, has stimulated the Commission of the EC to impose for 1990 provisional anti-dumping duties, as high as 85.4% on halogen lamps imports from Japan.

ENVIRONMENT

Compared to other industries, environmental issues are of minor importance in the electric lighting industry. Gas-discharge lamps contain some toxic materials such as mercury, antimony and lead. Another problem in this context is the use of packaging materials, given the fragile nature of the products. Industry efforts are oriented towards the reduction of eco-toxic materials, the reduction of packaging materials and the development of re-usable or recyclable materials for packaging.

OUTLOOK

Prospects for the EC electric lighting industry are somewhat pessimistic in the short term, as the downturn in construction activities will dampen demand for the industry's products. The decline in demand, however, is dampened by ongoing replacement demand, little affected by cyclical fluctuations.

In the medium-term, demand and production are foreseen to gain momentum, stimulated by the expected general economic upswing, to reach again their past high growth rates. Product

innovation is expected to keep boosting demand, as recent research and development efforts of EC firms are oriented towards electronically regulated lighting devices, improvements in light emitting efficiency and in colour rendering and further reducing the size of electric lamps. These developments will presumably entail declines in the EC production of incandescent lamps, which will be displaced by top-of-the-range products. Competition from without the EC, particularly in the field of low end technology, can be expected to increase in the nineties.

Written by: BAK
The sector is represented at the EC level by: The European Lighting Council (ELC). Address: 31, rue Montoyer B-1040 Brussels; tel: (32 2) 513 6085 fax: (32 2) 514 3386

Overview
NACE 33, 344, 345

The development of a strong electronic sector -that includes subsectors like computers and office equipment, telecommunications equipment, electronic components and consumer electronics- is strategic for the development of the overall EC economy. Since 1991, the EC electronic industry has entered a phase of deep crisis caused, on one hand, by the economic recession, and, on the other hand, due to problems very specific to all the electronic sectors linked to the increased global competition and the dramatic drop of prices and profit margins. For EC companies, the crisis is particularly deep in comparison with US and Japanese companies which are more internationalised.
The EC has points of strength in the electronic market reflected in the fact that at least two or three EC companies rank among the world's top fifteen. All of them are well diversified in complementary sectors. However most of the major EC electronic companies suffered losses in 1992 and the first half of 1993 with the exception of the telecom equipment suppliers. The role of the EC is indispensable in supporting co-operative R&D and promoting the European integrated market.

INDUSTRY PROFILE

Description of the sector

The electronics industry includes: computers and office equipment (NACE 33), telecommunications equipment (NACE 344), electronic components (NACE 345) and consumer electronics (NACE 345.1 and 345.2).

The products manufactured by the computing and office equipment are:

- hardware: portables, notebooks, microcomputers, minicomputers, workstations, mainframes and network equipment;
- peripherals: printers, disks, monitors, keyboards and CD-ROM players;
- office equipment: electronic typewriters, electronic calculators, electronic cash registers, electronic accounting machines, dictation equipment.

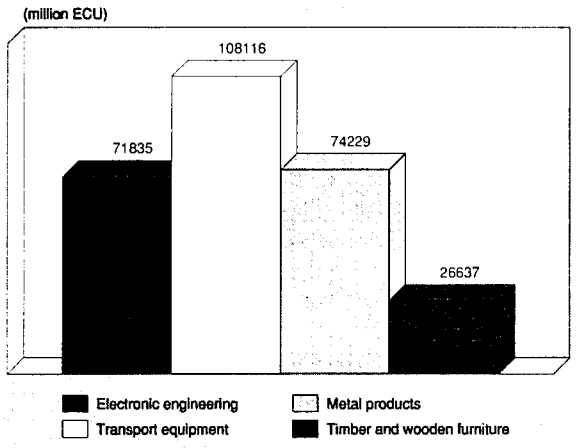
Telecommunications equipment main product categories are public switching, transmission, terminals, private switching, data communications and mobile communications.

Consumer electronics comprises: audio-visual products for domestic use and its accessories, such as colour and monochrome televisions, video recorders, video cameras and camcorders and audio equipment in general. The electronic components sector includes active, passive and electromechanical components.

All the electronic goods, either directed to consumers or to business, are based on microelectronics: and the dynamics of all electronic sectors is directly determined by technological developments in the microelectronics field. Increased intelligence and functionality, downsizing and downpricing characterise the production of every electronic sector.

The EC electronic sector is very important in economic terms: its value added is 70% of the transport equipment industry, almost as large as the metal industry's and 10 times as much as the value added of the timber & wood furniture sector. Because of its central role in the advanced information economies, the electronic sector is strategic for the development of the overall EC economy. Moreover, the sector is expected to grow more than any other large economic sector, automotive and transports included.

Figure 1: Electronic engineering
Value added in comparison with other industries, 1992



Source: DEBA

EC production is located primarily in Germany followed by France, the United Kingdom and Italy. These four countries account for about 90% of the total value generated by the electronic sector.

Recent trends

Both apparent consumption and production decreased in 1992 due to the recession and the continuous fall in prices. In particular, the slow down was very harsh in consumer electronics, in computer and office equipment and in components, whereas the telecommunications equipment market still increased.

In the EC, apparent consumption of electronic goods has consistently increased over the period 1983 to 1992 at a compound annual growth rate of 6.5%, whereas production has increased at an average rate of 6.2% and extra-EC exports at a rate of 6.9%. On the contrary, employment has decreased, reaching in 1992 its level of ten years ago.

International comparison

Broadly speaking, EC companies compete worldwide in all market segments. However, the consumer electronics market is dominated by Japanese companies and, to a lesser extent, by newly industrialised countries (NICs) (Korea, Taiwan, Honk Kong, Singapore) in the low value added consumer products segment. American and Japanese companies dominate the computer and office equipment market, but American companies set the worldwide standard in the sector, i.e. they control the guidelines of information technology developments. American and Japanese companies also control the microelectronics market. US companies, like Intel and Motorola, control the microprocessor segment where they impose worldwide standards, while Japanese companies are strong especially in the electronic memories market (particularly, dynamic random memory or DRAM).

EC companies are very competitive in the telecom equipment market where North American companies (like AT&T, Northern Telecom and Motorola) and Japanese companies (like Fujitsu and NEC) are also very strong. Above all, Europe has a growing importance as a huge market for global suppliers. In fact, Europe is the world's most important market for telecom, computer and office equipment and it is the second largest market in the world (after the USA) regarding consumer electronics.

Foreign trade

From 1987 to 1992, the percentage of exports to the USA (22% of total exports), Japan (which absorbed just 3-4% of the total) and lesser developed countries (42-45%) remained more or less stable. Exports to EFTA decreased from 30% to 24% in favour of rising exports to the OPEC countries that, in 1992, came to account for 8% of the total.

Extra EC imports have grown more than extra EC exports over the period 1983 to 1992: in fact while imports grew at a compound annual growth rate of 7.6%, export grew by 6.9%. The trend partially reversed from 1988-1992: in that period exports grew at a rate of 6.3% while imports grew

Source: Eurostat

just 4.2%. The EC trade deficit with the rest of the world has more than doubled in ten years and in 1992, it nearly reached 25 000 million ECU. It's very likely that the negative trend will continue.

The only sector where the trade balance is positive is telecom equipment. Computer and office equipment and consumer electronics show the widest trade deficit. Infra-EC trade grew very fast and more than doubled in the last ten years.

From 1987 to 1992, the percentage of imports from the USA, EFTA and Japan decreased, whereas imports from Taiwan and other NICs increased consistently.

MARKET FORCES

Demand

Business customers constitute the principal market for electronic goods. Computer and office equipment products, telecommunications equipment (especially regarding private data and voice networks) and electronic components (which enter as basic components in every manufactured electronic product or system) all target business customers.

The public sector market is quite important considering that national public operators constitute the main market for telecommunications equipment. The consumer market is important for consumer electronics producers, and increasingly so for telecom terminals (like wireless telephones) and home computer suppliers.

Demand depends heavily on the economic cycle: the recession of the past two years has significantly reduced consumer demand and to a lesser extent, demand by businesses' given that expenses in information and communications technology are strategic for business customers. Budget restraints in Member States also had an impact on telecom expenditure, despite the fact that Member States are implementing important modernisation plans for their networks.

Despite recession, electronic markets have expanded in volume due to large prices decreases. Demand is also becoming more differentiated and sophisticated and competition is spreading also in the most protected (and more profitable) public sector markets.

Supply and competition

In the electronic sector, competition is global: it is acknowledged that no important producer could survive until the

year 2000 without gaining world leadership at least in one, even small, niche of the world market.

Many American and Japanese electronic companies have R&D and production units in Europe, especially in the United Kingdom, Germany and France, even if new installations are decreasing because of the current crisis and overproduction. Other competitors preferred to acquire European firms (like Fujitsu with ICL (UK) and Nokia computer (SF) or to set up joint ventures such as Northern Telecom with Matra (F).

Broadly speaking, non-EC competitors are less present in the European telecom equipment than in other electronic sectors. Many European companies are also global, especially in the telecom equipment and consumer electronics sectors. In the computer and office equipment sector, however, EC companies suffer for not being internationalised to the extent that their American and Japanese counterparts are.

It is acknowledged that EC companies have a high degree of scientific and technological expertise, but they also have large disadvantages because of the high cost of labour (in comparison to South East Asia) and a high cost of capital (in comparison to USA and Japan).

Production process

The supply of electronic goods is characterised by high levels of R&D expenses: for instance R&D expenses could account for 15-20% of the electronic component suppliers revenues. In microelectronics and in telecom equipment sectors, R&D expenses are often higher than the production expenses. Moreover, supply is affected by a dramatic reduction in product life cycles because of rapid innovation in microelectronics. Therefore, economies of scale and rapid return on investment are needed. In the latter respects, it is becoming increasingly important for major electronic companies to be vertically integrated or to have strong links with the components suppliers and be suitably diversified.

Innovation is a key to success via control of world standards and the opening up of new business opportunities that allow for early exploitation of large profit margins before prices fall due to competition. Major innovation in electronic fields will be pocket computers, Personal Digital Assistant (PDA), High Definition TV, Integrated Services Digital Network (ISDN), broadband high speed networks to communicate voice, data and images, and GSM (Group Special Mobile) networks for mobile communications.

INDUSTRY STRUCTURE

Companies

In each electronic sector there are at least two or three European companies in the top fifteen world ranking. These are Philips (NL), SGS-Thomson (F) and Siemens (D) in the components industry; Siemens, Olivetti (I) and Bull (F) in the computer industry; Alcatel (F), Siemens, Ericsson (S) and Bosch (D) in the telecom equipment industry; and Philips and Thomson

in consumer electronics. All of them are diversified in complementary sectors.

Many EC companies suffered losses in 1992 and the first half of 1993 with the exception of the telecom equipment suppliers who, in any case had to face smaller profit margins. Broadly speaking the EC industry has its point of strength in the telecom equipment sector while it is weaker (in comparison with global competitors) in other sectors like computer and office equipment and consumer electronics.

Strategies

Every EC electronics company is engaged in big efforts to restructure, to cut costs, become leaner and reduce marketing time. Technological and commercial partnership agreements have become commonplace in the industry; joint ventures, alliances and take-overs between EC and extra EC companies are also very frequent in order to reach the right dimension to compete in the global market and to share technological know-how and market power.

In the future, the trend towards setting up networks of alliances for specific products/markets will intensify: in fact, the convergence between telecommunications, computer, software and media industries is limiting the ability of companies to face alone the new and more complex electronics markets.

ENVIRONMENT

The EC electronics industry is in a good position to play a positive role because it does not have a very relevant impact on environment - wastes or chemical emissions are secondary output in most of the production processes, at least in comparison with most other industries. Furthermore, the electronic industry is very innovative and often renews its production processes also with the aim of reducing polluting emissions. CFC (chlorofluorocarbons) waste (one of the main causes for the reduction of the ozone layer) has been reduced before the legislation that will completely forbid its use has came into force. An important goal is to minimise the residual waste and re-cycling hardware. Some of the main problems to be solved concern re-cycling cathode ray tubes, that contain toxic materials, and plastic components.

Environment-sensitive policy is often a successful strategy for the electronic companies: in fact consumers are becoming more and more sensitive to environmental problems and prefer to purchase products with a low environmental impact, while employees are becoming increasingly conscious about working for an environmentally friendly company.

REGULATIONS

The EC plays a central role in the industry's development by promoting European market integration and fair competition among EC and extra-EC players (for example through anti-trust legislation and directives concerning public contracts). One of the main goals of the EC is to open the EC market on the assumption of a mutual response from non-EC countries.

The EC is also funding strategic and pre-competitive co-operative research programs (like Jessi in microelectronics and Race in telecommunications) and it is promoting new advanced applications (like Trans European digital Networks) that benefit all the EC electronics industries. The EC also promotes financial aid for less developed and disadvantaged EC regions that aim to upgrade the technological content of their capital stocks.

OUTLOOK

Although the electronic market is very likely to remain flat over the next few years, there are few doubts that in the medium and long term it will grow more than any other traditional industry. Unfortunately, it's also very likely that the EC trade deficit in electronic goods will widen in the coming years. Competition from American and Japanese companies will increase and EC companies will have to sustain large efforts in R&D expenses and in industrial investment to win the competitive challenge. Alliances between companies are expected and the industry will surely concentrate more and more.

Despite present financial difficulties, East European countries present attractive market opportunities because of their proximity and untapped potential. Innovative markets and products - created by the convergence between consumer electronics, telecommunications, computer and media technologies - are foreseen as presenting opportunities in the next years. However, multimedia systems and networks constitute the major opportunity for the future.

Electronic components
NACE 345

The electronic components market has experienced moderate, and more recently, declining growth, in comparison to most of the 1980s. The effects of recession, combined with the European industry's difficulties to cover the competition gap with respect to North American and Japanese companies, have caused a turnaround in industrial strategies that have become more global market oriented. Industry players continue to form alliances as a means of imposing their standards, particularly in the areas of microprocessors and Digital Signal Processors (DSPs).
Mergers and acquisitions, international joint ventures and the setting up of USA and Japanese manufacturing facilities in Europe will probably characterise the coming years. In the medium to long term, as the consumer markets for computers, communications and automotives develop further, Europe is likely to recover market share.

INDUSTRY PROFILE

Description of the sector

The electronic components sector includes three main categories of products.

- Active components: semiconductors (typically integrated circuits and discrete semiconductors), microcircuits, valves, tubes and optoelectronics components;
- Passive components: all types of capacitors and resistors, inductors and other magnetic and ceramic components;
- Electro-mechanical components: printed circuit boards, connectors, relays, switches, keyboards and other functional devices.

The electronic components are mainly directed as inputs to the following sectors: telecommunications, computers, consumer electronics, military, automotive, automation systems, controls and instrumentation for industrial and non industrial applications (building, security, environment, etc.) and medical equipment.

Recent trends

The negative trend concerning the production of electronic components began in 1991 by declining from 12 845 million ECU in 1991 to 12 300 in 1992 and 11 200 in 1993, with some exceptions for a few segments of product. Extra-EC export trends follow those of apparent consumption, dropping from 5 237 million ECU in 1991 to 5 070 in 1993. As consumption dropped more harshly than production, the trade balance reduced its negative spread, from -9 473 million ECU in 1991 to -9 073 in 1992.

Since 1984, the employment trend has been discontinuous, depending on economic and technological factors, out of which the continuous process innovation in components manufacturing and the increasing location of new manufacturing facilities in low labour cost countries are the most important ones. Total employment fell from 233 000 in 1991 to 197 000 in 1993 with the trend likely to intensify.

The trend in apparent consumption has been on the decline, falling from 22 318 million ECU in 1991 to 21 373 in 1992. Estimates for 1993 show a stagnation to 21 500 million ECU. In the period 1988-1992, the average real annual growth rate of apparent consumption was low, extra-EC imports were increasing, while production and extra-EC exports were decreasing. So far, the European firms are both losing market share in the domestic market and unable to succeed in the foreign markets.

International comparison

Europe is the third largest market for semiconductors (19% of the world market share in 1992), after Japan (33%) and North America (30%). The European market share has been decreasing over 1991-1993 because of recession and globalisation of the electronic equipment manufacturing industry. Despite the strong effort to develop a competitive European components industry - by supporting pan-European R&D projects (like JESSI) and by favouring intra-European joint ventures and mergers - the results are still not satisfactory.

Foreign trade

The exports/imports ratio concerning the passive components (0.74) did not vary in the period 1991-1992. The exports/im-

Source: EECA

ports ratio of the electro-mechanical components was more than 1, whereas in the other segments extra-EC exports were lower than extra-EC imports. Overall, the higher decrease of extra-EC imports improved the trade balance as measured by the exports/imports ratio, that fell from 0.36 in 1991 to 0.33 in 1992.

Most European exports are absorbed by smaller markets, while only a minor share of export is destined for the USA and Japan. On the contrary, EC imports of active components come primarily from the USA (28%) and from Japan (22.4%). As for passive components, Japan accounts for 29% of import and it overtook the USA (25%). The increasing importance of the South-East Asian countries is underlined by a global EC-imports share of about 22%.

Regarding the active components segment, extra-EC exports decreased from 4 767 million ECU in 1991 to 4 369 million ECU in 1992. Extra-EC imports also followed a downward trend. The exports/imports ratio in 1992 (0.61) recorded a slight decrease from the previous year (0.65). The EC trade balance concerning the different categories of semiconductors was negative in the period 1990-1992, displaying a strong and increasing dependence on extra-EC imports.

MARKET FORCES

Demand

The demand for electronic components comes from the OEMs, (Original Equipment Manufacturers) of electronic equipment in a wide range of industry sectors ranging from telecommunications to automotives. The passive and electromechanical components are relatively mature, whereas the active components, the integrated circuits above all, have great possibilities of further development and innovation. Particularly, the semiconductor sector displays high innovation rates boosting demand of many new final products. The spread out of the C-MOS technologies, the IGBT (Insulated Gate Bipolar Transistor), the Smart Power-IC and the ASIC (Application Specific Integrated Circuit) are some examples. In recent years fast innovation rates have been generating sophisticated components leading to the partial replacement of some categories of products, like passive devices in general.

The computer sector is still the main market for electronic components, accounting for about 40% of total semiconductor demand and 30-35% of other components demand world-wide: the development of the individual and social applications of I.T. can be mentioned among the driving applications.

Figure 3: Semiconductors

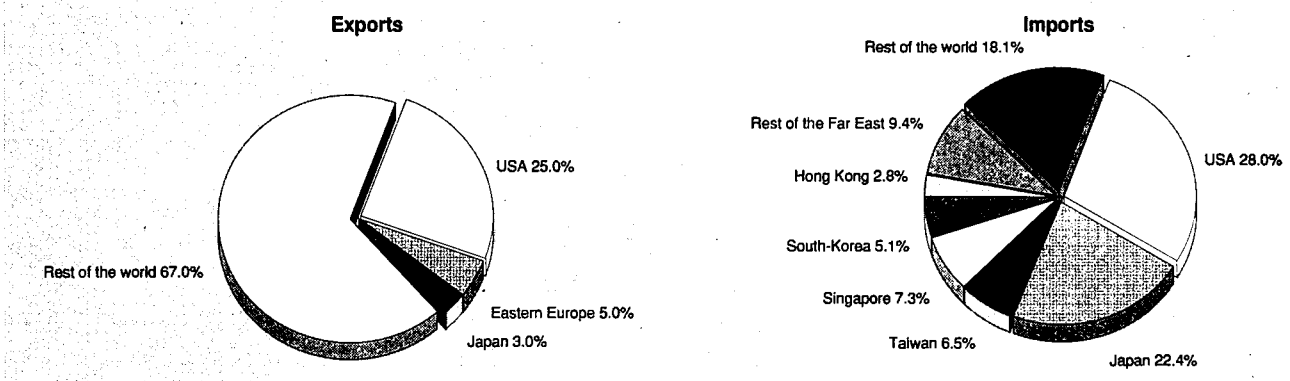
Source: Eurostat

Figure 4: Active components (1)
Destination of EC exports and origin of EC imports, 1992



(1) TV & monitor tubes, other tubes, integrated circuits and discrete semiconductors.
Source: EECA

The telecommunications sector is second in importance, requiring innovative components based on Digital Signal Processors. The development of the GSM (Group Special Mobile), of ISDN (Integrated Services Digital Network) and ATM (Asynchronous Transfer Mode) switching technologies are amongst the leading applications.

Consumer electronics requires sophisticated electronic components, as its range of products is widening and becoming increasingly high-tech intensive, but in general its share of total components consumption is decreasing. Innovative products concerning this area are HDTV (High Definition Television) and digital radio.

Automotives absorb a lot of electronic components for sophisticated devices, advanced diagnostics, engine management and - in the future - on-board computers. The present strong recession in automotive production, however, is seriously limiting the development of this important market.

Military and defence, which have traditionally been important user sectors for electronic components, are rapidly losing market share and they now represent less than 3% of total consumption, even though they are still important for some of the advanced and high value-added components.

Industrial and medical equipment are losing in overall importance, but they continue to constitute a major area of application for electronic tubes, optoelectronics and electromechanical components.

Among geographic market segments, East European countries are likely to represent a very important outlet in the coming years, as they are embarking on industrial modernisation and are still very far from the market saturation level. Components distribution channels constitute an important part of the supply chain, particularly for the supply of passive and electro-mechanical products to industrial equipment sectors, which generally consist of a large number of small and medium manufacturers.

Supply and competition

The European microelectronics industry has three main categories of problems affecting its local and global competitiveness. Firstly, as far as some components like printed circuit boards are concerned, the size of the individual producers is too small to reach economies of scale and to generate margins to be invested in technological development and manufacturing investments, which are the necessary conditions to keep up with the speed of technological innovation. Secondly, although

Source: Eurostat

Europe as a whole has strong capabilities in the different layers of the microelectronics industry it is weak in exploitation. The traditional strength of the European industry in machine tools and precision mechanics could be, for instance, a healthy basis for the semiconductor manufacturing equipment. In addition, the excellent capabilities in basic research could be adapted to the industrial world to become more effective.

The trend towards further concentration is likely to result in strong polarisation: on one side there will be the technological leaders, about ten large global companies; on the other side there will be a lot of small companies specialised in products/markets niches.

Passive and electromechanical components are more mature products, still evolving but at lower rates. In these segments, prices are the main competitive weapon. The supply is very fragmented, as many players are small local ones having their own market niches.

Production process

The components sector is typically science based, linked with the scientific research and discoveries, such as those in micro physic, material science, optics, mathematics, modelling, etc. combined with manufacturing innovations like micro-fabrication, photolithography and etching technology, packaging technology, etc. The processes are more and more capital intensive and the process know-how becomes a strategic factor of success in order to reduce costs and to guarantee the highest level of product quality and reliability.

Besides innovation and dependency on R&D, the production process is linked to upwards and downwards integration issues and location choices. Regarding the upwards integration, the proximity to special equipment manufacturers and to manufacturing/engineering services suppliers is a key factor of success that accounts for the manufacturing facilities concentrating in a few regions and "valleys". When components are produced by downwards integrated companies, the geographical proximity of the plants can provide logistic advantages. Finally, there is a need to achieve good communication between branches or affiliated companies, to be kept aware of changes in the final markets.

INDUSTRY STRUCTURE

Companies

Regarding semiconductors, there is a strong presence in Europe of USA and Japanese companies. Some European companies, such as Philips (NL), Siemens (D), SGS Thomson (F/I), are worldwide leaders, too. The passive and electro-mechanical components supply is more fragmented, with many small local operators having low market share. Here too the market is dominated by international companies, mainly USA and Japanese, as well as the above mentioned European ones. Some categories of products - i.e. most of the printed circuits - are delivered by small to medium sized enterprises or large companies active in captive markets.

Overall, for semiconductors Philips is the leader on the European market with a share of 9.3%, closely followed by Intel (USA), whose microprocessors are inset into about 80% of the personal computers produced worldwide. Another American company, Motorola, is in third place. Two European companies, Siemens and SGS-Thomson Microelectronics, and a long list of American, Japanese and South East Asian players follow.

Strategies

The manufacturing of semiconductors is a capital intensive industry, where it is necessary to produce large volumes for the global market to achieve economies of scale. About 40% of the revenues are directed to feed R&D and production investments. The required amount of these investments will grow even more by the mid 1990s as the new generation of 0.3 micron chip components will be on development contributing towards further concentration on the supply side.

The strategy of European companies is dramatically changing as a consequence of both the recession and evidence of the unsatisfactory results of the 1980s policy that was based on strong competition with American and Japanese companies to gain independence and to protect the domestic market. Companies now look for joint ventures (for instance Siemens with IBM (US) and Toshiba (JPN) for a joint R&D effort in memories) and pay attention to small but high value added product/application niches. SGS-Thomson's strategy concerns a few specific components addressed to the faster growing applications in the EC market (cellular telephone, broad band communications, satellite communications, high definition television, automotive controls, etc.).

There is also an attempt to achieve economies of scale and synergism between European manufacturers: the agreement between SGS-Thomson and Philips for ASIC manufacturing is a clear example of this trend. As a consequence of the European competitive strategy turnaround, some important European R&D projects - like JESSI (Eureka) - have been reduced in size and importance, and some other R&D programmes, like OMI (Esprit) have been narrowed down to more specific and application oriented objectives.

Another established trend is towards vertical integration to supply functional devices, equipment and systems based on proprietary components. Japanese companies, NEC, Matsushita and Fujitsu for instance, are the most integrated. Among the American ones, Motorola and Texas Instruments have the highest vertical integration. The European companies are less integrated, with the exception of Siemens and Philips. SGS Thomson is now developing a downwards integration in specific niches with some of its customers, such as Thomson, Alcatel (F) and Bosch (D).

REGIONAL DISTRIBUTION

The main companies manufacturing both active and passive components, come from Japan and USA. Newcomers are companies from South East Asia (i.e. South Korea, Taiwan, Hong Kong and Singapore), having the competitive advantage of lower labour costs. Many USA and Japanese players have manufacturing facilities in Europe in order to strengthen their

direct presence in local markets, to be closer to the end-users requirements, to spare distribution costs, to take advantage of their image and to accede to local governments by giving employment possibilities to the local labour forces.

ENVIRONMENT

The impact of the electronic components sector on the environment is linked with problems concerning the industrial end users sectors, particularly the electronic data processing sector. One of the main problems is the power consumption of the computers used in offices. For this reason, plans are being made to reduce the power waste of both computers and peripherals.

Electronic components producers are involved, Intel above all, within the 'Energy Star' program, proposed by the United States Environmental Protection Agency (EPA). The purpose of this plan, joined also by the European partners of Intel, is to solve the problem starting from the microprocessors, giving to the SL series the capability to stop the power consumption when the CPU is not actually used, even if the computer has not been switched off.

Other problems concern the use of polluting substances. According to the Montreal Protocol, the product processes have been modified in order to avoid CFC (chlorofluorocarbons) waste, the main cause of the reduction of the ozone layer. Waste recycling is another key point, hence components are being made more and more of recyclable substances.

OUTLOOK

In the coming years, the trend of the electronic components sector will depend on user industries development (capital investment trend and location), but also on factors like components technology innovation and industry competition (product pricing trends, import restrictions and taxation, mergers and acquisitions, etc.).

Table 9: Electronic components
Expected real annual growth rates

(%)	1993-94	1993-97
Apparent consumption	-5.9	1.4
Production	-7.5	1.2

Source: Databank

Some sectors, such as telecommunications and some consumer electronics segments (video games for instance), are expected to sustain their recent growth trends supporting the demand for specific components. As for other sectors, like computer, automotive and defence, the crisis is not yet over and may impact on the components production, too. Even if car sales may stagnate in the short term, sales of electronic components to the automotive sector will continue to grow because of the increasing share of electronic components in car manufacturing. The demand for more innovative and high price components is not guaranteed as it depends -case by case - on factors like software availability, market acceptance, public policies, and so on.

In conclusion, the European market will grow less than the world market average in the period 1992-1995, while in the long-term the development of new computer and communication systems for the European mass market will probably have a strong and positive impact.

Computer and office equipment
NACE 33

The computer sector is going through a deep restructuring phase. Prices are falling dramatically, consumption and production are slowing and the market is getting fragmented into many niches. Downsizing and standardisation have intensified competition and squeezed margins. The major European manufacturers suffered losses during 1992, and are trying to shift their activities from manufacturing to software and services that still display high growth rates.
The major EC companies have been signing cooperative agreements with US and Japanese companies to acquire technology in exchange for links to the European distribution channels and customers; in some cases, though, the technology flow has been reversed (e.g. Bull with IBM). Top EC manufacturers are further pursuing strategic alliances on common European research programs. Despite hard times in recent years, Europe could still become one of the fastest growing markets in the world over the medium-term.

INDUSTRY PROFILE

Description of the sector

The products manufactured by the computer industry are :

- hardware: portables, notebooks, microcomputers, minicomputers, workstations, mainframes, network equipment;
- peripherals: printers, disks, monitors, keyboards, CD-ROM players;
- office equipment: electronic typewriters, electronic calculators, electronic cash registers, electronic accounting machines, dictation equipment.

The business is integrated with Information Technology (I.T.) software and services, as the largest global competitors are oriented to supply more complete solutions to the end users. The data provided by Eurostat in the figures and tables correspond to hardware only. Employment data also include software and related services.

Recent trends

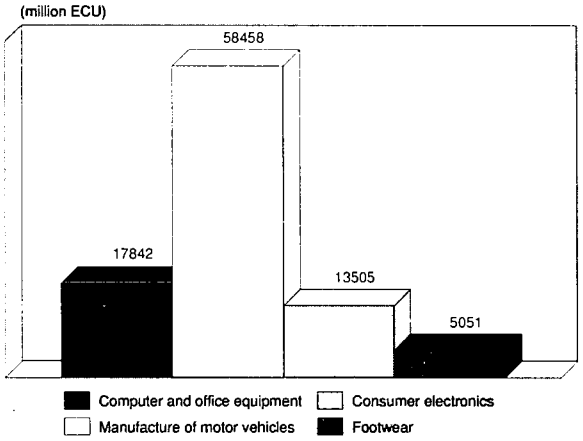
In 1992 all main indicators show a slight decrease in current prices, the only exception being extra-EC exports. However the trade balance deficit has been widening, from -13 920 ECU in 1991 to -14 500 ECU in 1992.

The general crisis of the main manufacturing sectors has a major impact on the computer sector, which is more sensitive to changes in the macro-economic trends because of the high level of investments already undertaken by the companies in I.T. systems and services, associated with their present attitude to rationalise I.T. architecture and usage. The trend of the market, associated with the fast technological innovations in basic components (which have incorporated most of the value added formerly due to computer equipment) and in manufacturing process (which are highly automated and/or decentralised to low labour cost countries) caused a decrease of more than 8 000 units in employment, that declined from 251 100 employees in 1992 to 242 300 in 1992.

International comparison

Production is rather concentrated in four Member States that are, in this ranking, Germany, France, Italy and the UK. In 1992 , Western Europe (including EFTA countries) accounted

Figure 1: Computer and office equipment Value added in comparison with other industries, 1992



Source: DEBA

for 36% (the EC 31%) of total I.T. consumption, compared with 35% for the US and 17% for Japan.

From a production point of view, Europe is less important than the USA and Japan, but European based production rose notably in the '80s, thanks to the localisation of new manufacturing facilities belonging to non European companies: in 1983 EC production in current prices was 50% of the correspondent USA production, compared with 80% in 1992.

The EC industry is weak in integrating research, technological development, innovation and standardisation into marketing practice. The strength of Europe lies in its continuing ability to identify new I.T. applications and to adapt I.T. technologies to support applications as well as in the relative flexibility of its industrial structure. Of the ten leading firms in the world, five are American, three Japanese and two European.

Foreign trade

Since 1983 extra EC exports have been growing strong, averaging at 9 984 million ECU in 1992, but they add up to less than half the extra EC imports. The trade balance has been worsening since 1988. From 1987 to 1992 EC computer and office equipment exports to the USA and Japan had a small increase, while EC exports to the EFTA countries de-

Source: DEBA

creased. Intra-EC trade has more than tripled over the last ten years experiencing higher growth than that of extra-EC exports and production

From 1987 to 1992, EC imports of computers from the USA decreased sharply, partly due to the emergence of US manufacturing facilities in Europe. Among new supplying countries, East Asia (South Korea, Taiwan, Hong Kong and Singapore) is the emerging player in personal computers, office equipment, printers and related devices manufacturing.

Traditional European manufacturing companies like Olivetti (I) and Bull (F) have been obliged to set up production in East Asia for PCs subsystems and peripherals: they found lower labour cost, associated with good technological standards and skilled work force. In fact nearly 40% of extra EC imports are peripherals, mainly coming from East Asia. Nevertheless, still 21% of EC exports are peripherals (very often re-exported), while 33% consists of data processing systems and parts. Only 18% of exports are finished products like office machines and data processing systems.

MARKET FORCES

Demand

The impact of economic recession on I.T. expenditure is only one of the factors affecting the recent trend of computer and office equipment demand. Other factors relate to downsizing (i.e. different mix of products sold) and the increasing importance of customer satisfaction. Additionally, the growth of open systems is making many hardware items increasingly "commodity" with a consequent reduction in unit price.

Investment in computers and - to some extent - in office equipment has to adapt to the growing requirement by customers for business solutions, rather than for technology tools only. As a consequence the economic trend of each market segment and, moreover, the business and organisational changes occurring in each industry (like, for instance, in banking, public administration, health, etc.) are demand-driving factors. The ability of vendors to really understand the user organisation and business needs and to provide customer oriented solutions - by integrating the right hardware, with the appropriate software and with the required quality of services - will be key factors of success. The lack of easy to use,

Table 3: Computer and office equipment
Breakdown by size of enterprise, 1990 (1)

number of employees	number of enterprises	% of enterprises	% of employment	% of turnover
Less than 20	6 800	88.8	7.5	5.3

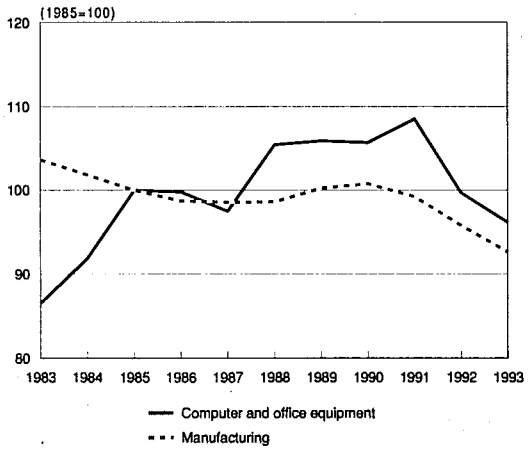
Figure 3: Computer and office equipment Employment compared to EC manufacturing



1993 are Eurostat estimates.
Source: DEBA

vertical software and the lack of human resources skilled to analyse customer needs and to supply vertical solutions will be market braking forces in the short term.

Factors related to the above mentioned trend that will have an accelerating effect on the market, once the current recession is over, are the following:

- the first is the opening of new applications and new markets due to innovation in technologies and infrastructures, like on line multimedia, broad band communication (ISDN), electronic highways, very high performance computers, etc.;
- the second is the increasing penetration of low-end market segments by low cost computers - like PC in retail, tourism, etc., Personal Digital Assistants and personal electronic equipment for family and individual use.

"Downsizing" is a major factor: users are buying fewer large and intermediate systems and are adopting networks of PCs and workstations to develop most of the new applications, because of the best price/performance ratio. Continuous hardware innovations, increased performance, falling prices for Personal Computers together with the emerging importance and penetration of hardware and software standards have forced this trend.

In the medium term, although shrinking, the role of large and intermediate systems will remain significant, operating as platforms for specific applications (high performance computing, on line transaction processing, etc.) and as servers of company-wide client-servers architecture. Portable computers are expected to maintain high growth; in fact by 1995 one out of four PCs purchased could be portable.

Supply and competition

Technology and production are becoming globalized and the major companies operate with multinational strategies, looking for economies of scales. On the other hand, demand is becoming more and more segmented and companies are reorganising in smaller and independent business units, that are in principle more agile and capable to address changing business requirements.

It is gradually becoming harder to be a market leader in more than a segment. Producers tend to become less and less vertically integrated. Large hardware manufacturers in Europe, like the EC subsidiaries of IBM and DEC, Siemens Nixdorf, Olivetti and Bull suffered big losses during 1992. The winners, in this new scenario, are companies able to impose standards or to get large scale economies or, on the contrary, to gain market niches.

Production process

European production accounts for 76% of apparent consumption, but taking into account the amount of EC exports, less than 60% of the apparent consumption is satisfied with European products. Most systems incorporating high-tech devices and basic innovations are imported from the US and Japan. Personal computers, peripherals, monitors and other low value added products are increasingly imported from East Asia.

Large European groups are decentralising their production activities over many countries. While R&D and innovative systems are located in Europe (generally in the country of origin) and in USA (especially for R&D), products with low value added are produced in the NIC's countries where labour costs are lower than Europe.

In Europe vertical integration is fairly limited compared to the US and Japan. Some companies have attempted to integrate upstream activities by producing components for their own needs. However, the lack of a sufficiently large internal market did not allow them to reach the critical thresholds of production and sustained investment levels.

INDUSTRY STRUCTURE

Companies

The European computer industry, that had traditionally been an oligopoly, is becoming a very competitive market, fragmented in many niches. About 5 200 companies are active in the sector (while 50 000 firms operate in the Information Technologies sector as a whole). 87.4% of them have less than 20 employees while only 3.6% of companies accounts for 86.4% of the total labour force. Many new players have entered the PC segment(clone manufacturers, PC assemblers), as the entry barriers have been lowered due to the standardisation in production and the availability of basic technologies and skills on the market.

Despite increasing integration the EC is still divided into different national markets led by national manufacturers, like Siemens Nixdorf and Vobis in Germany, ICL in UK, Bull in France and Olivetti in Italy. Nevertheless, in all the largest EC markets USA vendors and namely IBM in the business sector and Commodore in the consumer market - are the better positioned firms.

Strategies

In order to balance the dramatic erosion in profit margins, companies have been reducing expenses, particularly via redundancies. They are also trying to focus their activities on more profitable market segments and to change the organisational structure by decentralising activities to be closer to customers.

Hardware manufacturers are trying to shift their offering towards software and services. Software and professional services already account between 20% and 50% of the turnover of the largest world manufacturers. Many European companies also try to sign technological and commercial agreements with services firms, for gaining competence in the service sector and for getting closer to the customers.

European companies also try to develop new and cheaper sales channels compared with the traditional (and expensive) direct sales, still maintained for serving the largest customers. Software houses are vital channels for sale to small and medium user companies, while distributors are becoming more important to sell personal computers and other commodities products to the smallest business and to residential users.

European firms are trying to become stronger outside their national market, particularly in the rest of Europe via mergers & acquisitions but primarily through "growth by external networks", where cooperative agreements, both equity and non-equity, are taking place. Most of the agreements are between European and non-European companies; particularly Japanese and American. National and even local requirements are also emerging, as a further differentiating factor that encourages cooperative agreements between European, US and Japanese companies. Non-European manufacturers offer their technological and financial strength while European companies have commercial networks and knowledge of the customer's needs. The agreements signed in the last few years between Olivetti and Digital (USA), Bull, IBM and NEC (JPN), Fujitsu (JPN) and ICL are examples of this strategy. However American and Japanese companies, like IBM, Digital, Hewlett Packard (USA), Toshiba (JPN), Hitachi (JPN) are already well established in the European market, most of them with R&D and production facilities.

European companies decisions in technological and strategic alliances are neither coordinated nor convergent. Olivetti, for instance, has adopted DEC's RISC technology (Alpha), while Bull has preferred IBM's Power PC and ICL Sun for their future developments in the RISC/UNIX environment. Further strategic alliances are expected in the coming years, namely from Siemens Nixdorf and Olivetti. The most significant efforts to coordinate a European strategy for the computer industry are in Research and Development and the creation of a pan-European data communication network between Siemens Nixdorf, Olivetti and Bull.

REGIONAL DISTRIBUTION

Regional distribution of production is technology and price driven. As basic components, like microprocessors, require high investments in R&D and large scale production, most of the manufacturing is settled in the US and Japan. The Four dragons, headed by Taiwan, thanks to low labour costs and a sound technology level, are increasing production and becoming the emerging area for the production of peripherals and assembly of PCs.

Production of PCs and peripherals has became a low value added sector and large volumes associated with economies of scale (in marketing, logistics, etc.) are becoming a must. For all these reasons, manufacturing is shifting towards countries with a low cost work force. For instance, Taiwan has become the world's top manufacturer of colour monitors and of other components and systems. Component construction however is still strong in Ireland and Scotland as companies benefit from lower taxes and local government incentives.

ENVIRONMENT

The computer and office equipment industry does not impact the environment strongly. Nevertheless, there are some fundamental issues related to electrical power waste by computers. Global energy consumption is expected to grow 10% within the year 2 000. In order to reduce this amount, different agencies launched programs: Recommendations by DG XVII, the "Jeida" program of MITI, the "Energy Star" of EPA (Environment Protection Agency), all target to optimise the consumption of energy. Olivetti and Intel are part of "Energy Star". Energy saving protocols are incorporated in the i486 SI enhanced processor and in M26 Suprema Olivetti computer.

REGULATIONS

The standardisation of computer and office equipment at the European level is mainly represented by organisations such as the CEN (Committee of European Standardisation) and the Committee of European Electrotechnical Standardisation (CENELEC).

The influence of the official sources of "de jure" standards on the computer industry development has traditionally been weak with respect to the importance of proprietary technologies and "de facto" standards. This situation is changing as far as the market of Open Systems and the user orientation to standard technologies are increasing.

The attitude of hardware vendors to co-operate to identify and assess common standard at the different levels of computer and software architectures is now positive, but still posing some problems to the European computer industry:

- most of the standardisation committees are in the US; consequently, the influence of European manufacturers is weak (with the notable exception of Open Systems) and proportional to their world market share;
- on the same subject of standardisation (Operating Systems, User Interfaces, Communication Protocols, etc.) two or more standardisation committees have been set up, consisting of groups of vendors having common interests and striving to impose their technologies: the choice whether to co-operate within this framework becomes part of one's strategy on alliances and mergers, rather than a pure technological consideration;
- user companies participation in standardisation committees is traditionally very weak, particularly with reference to European users.

The EC is taking an active role to support and sometime directly represent the European computer industry and the European user community in the standardisation committees. Further, it is also actively promoting standardisation through R&D programmes which are actually conceived and focused on standard technologies. Apart from standardisation, problems like industrial concentration, price and protection policies and strategic technologies exports are under EC observation.

While limitations on strategic technologies exports and the protection of national/continental markets are loosing importance, the concentration process and national government supports to local manufacturers (Bull, Olivetti, etc.) are closely monitored and regulated at EC level.

OUTLOOK

The sector is going through deep restructuring : the general crisis of the computer industry and, on the other hand, the growth of lan/wan networks combined with the expected rise of the multimedia systems are among the most important developments. Computer, office equipment and telecommunications are merging with the TV networks and media sectors. Thanks to the convergence between these sectors, the consumer

will play a growing role. Bottlenecks are in fact at user level: in order to sell new products incorporating technological innovations, it is necessary to conceive in advance appealing and user friendly applications for the new systems.

The industry is represented at the EC level by: European Association of Manufacturers of Business Machines and Information Technology (EUROBIT). Address: c/o VDMA, Lyoner Strasse 18, D-60528 Frankfurt/Main; tel: (49 69) 660 3530; fax: (49 69) 660 3510.

Telecommunications equipment
NACE 344

In 1991 the EC European market for telecommunications equipment was the second largest in the world accounting for 28% of the total while the US market accounts for 35% and the Asian for 15%. Telecom equipment constitutes one of the few high technology sectors where the EC has a trade surplus. The EC public telecommunications markets - the biggest market segment for telecom equipment vendors - have developed as closed markets driven by public operators with strong links with domestic manufacturers. However, the global trend for deregulation is rapidly bringing down national barriers. Data and voice equipment for the business and consumers markets represent the fastest growing and most competitive segment.
European vendors of telecom equipment have a sound position in the world market: four European companies stand alongside four North American and two Japanese companies amongst the top ten. However, European suppliers are increasingly threatened by Japanese and South East Asian producers (for consumer products) and by US producers (with regard to private data networks).

INDUSTRY PROFILE

Description of the sector

The main product categories manufactured by this industry are: public and private switching, transmission systems, terminals, radio, data communications and mobile communications equipment. In addition to the manufacture of telecommunications equipment, NACE 344 includes the electrical and electronic measuring equipment, recording equipment and medical equipment. The data in this monograph refer only to telecommunications equipment.

Telecom equipment manufacturing is a strategic industry as it is becoming more and more interconnected with other technologies and industries, like electronic components, computers, aerospace (satellites), software, consumer electronics and, more recently, with broadcasting both video and audio, media and publishing industries. Some years ago most of the equipment was sold to domestic public carriers and the offer of equipment and terminals for the private sector was very limited.

In the last few years, the great diversification of telecom services -both in the public and private sectors- and the digitalisation of the networks and terminals had a big impact on the industry. Actually, this has become a multi-product industry, with the scope of equipment ranging from the traditional wire telephone sets to mobile telephone hand sets, video conference equipment and multimedia workstations. Business and consumer markets are becoming more important and the market as a whole is getting global and very competitive. Moreover, because of the rapid changes of digital technologies, and because of the different services increasingly requested by customers, the life cycle of the products has shortened dramatically.

Recent trends

European production of telecom equipment has increased slightly from 1991 to 1992 and reached the value of 25,378 million ECU. Premise telecom and radio equipment account each for 25% of the total market; public switching for 40,6%, mobile communications equipment for 6,7% and broadcast and studio equipment for almost 3%. A slight increase is expected for 1993, with the market reaching the level of 25,500 million ECU. In 1992 extra-EC exports and trade balance also increased and reached the value of, respectively, 5 850 million ECU and 718 million ECU. From 1985 to 1992 the productivity index increased by one third.

International comparison

European vendors of telecommunications have a sound position in the world market: four European companies Alcatel (F), Ericsson (S), Siemens (D) and Bosch (D) stand alongside four North American (AT&T, Motorola, Northern Telecom and IBM) and two Japanese companies (NEC and Fujitsu) in the top ten positions in the world ranking.

Regarding technology, the European telecom industry has a strong position with respect to other competitors in the world market. This is reflected in major developments such as Integrated Services Digital Network (ISDN) to communicate both voice, data and images on just one digital network, GSM (Groupe Special Mobile) and Digital Europea Cordless Telecommunications (DECT) for wireless communications, which originated in Europe. The European telecom industry is therefore competitive in international terms and is holding its ground world-wide.

Source: Eurostat, Dataquest 1993 - European Semiconductor Application Services

In 1991 the Western European telecom equipment market was the second largest in the world accounting for 28% of the total following the North America market with 35% and followed by the Asian/Pacific with 15%, while the rest of the world accounted for 22%.

Broadly speaking, the US leads in the deployment of new services and technologies, assisted by the long standing homogeneity and prosperous level of its market, compared with the hitherto fragmented European market. The US telecoms market claims to be very open to foreign competitors. In the consumer sector of the market, the Japanese have achieved a good level of penetration. In main network equipment, switching and transmission, however, the market is heavily dominated by two suppliers AT&T and Northern Telecom; the latter Canadian based firm like AT&T itself being well integrated as they both supply telecom services as well as equipment. Companies like Siemens, Ericsson and GPT do compete in this sector.

The Japanese market, where NEC and Fujitsu are the main suppliers, is closed to foreign competition although increasing trends towards liberalisation in the Japanese telecom services arena are resulting in growing imports from the USA and the EC. Currently the standing of the Japanese industry is problematic: out of the 15 top companies that in 1992 posted declines in their communications equipment revenues, 11 were Japanese (NEC, Hitachi, Sumitomo, Oki, Mitsubishi, Sony, Ricoh, Sharp, Sanyo, Canon).

Foreign trade

Even though in recent years European imports have been growing faster than exports, the trade balance in telecom equipment is positive, this being quite an exception among the high technology sectors. In 1992, the trade surplus was standing at 718 million ECU (+87% than the previous year). However trade surpluses were much higher in the early '80s: in 1983 the exports/imports ratio was 1.95 compared to 1.14 in 1992.

EFTA accounts for 19% of extra-EC exports and the USA (10%). Japan accounts just for 1% of the total EC exports and the rest of the world (mainly East Europe, Asia and developing countries) absorbs the rest of the EC exports. Japan (25%), USA (24%) and EFTA countries (23%) are the main exporters to the EC, together with South East Asia countries (10%). A weakness in EC external trade structure is that EC exports are mainly directed towards less developed countries while imports mainly come from the most advanced industrial countries (Japan and USA). EC countries mainly export network systems (that is switching, transmission and radio related equipment) and then terminals; while they import mostly facsimile machines and other terminals (62% of total EC imports).

MARKET FORCES

Demand

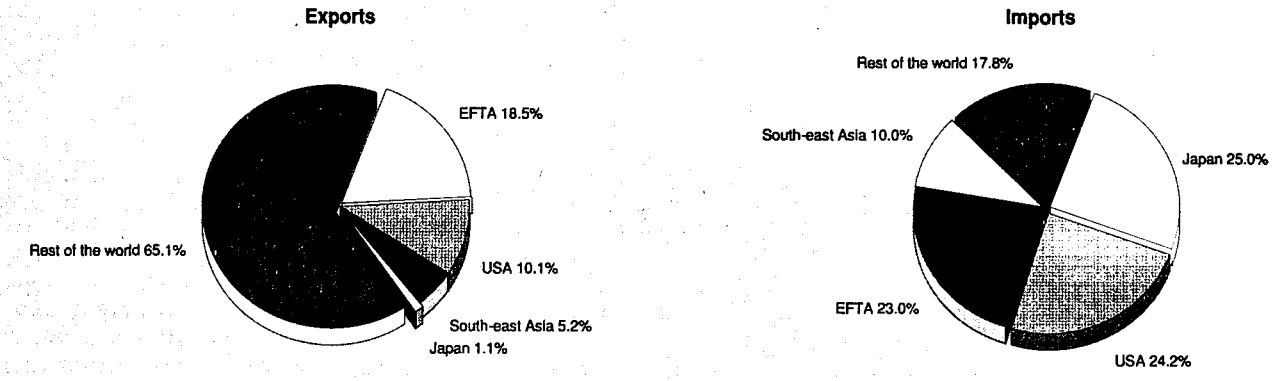
The telecommunications equipment market can be divided into three overlapping categories: the first -and by far the largest- is public switching and transmission systems for traditional telephone networks. The EC major telecommunications markets (but also USA and Japan) have historically developed as closed markets driven by public operators with strong links with the domestic manufacturers. Thanks to the world-wide deregulation trend, national markets are now opening up. In Europe this process is being mandated through EC directives and the process of products standardisation. This has turned out to be a very gradual and uneven process.

Demand for new high speed services provided by the public networks is evolving and becoming more sophisticated; therefore manufacturers have to provide software and data bases - integrated in the hardware systems (like in switching) and in the network - that are able to supply services like, for example, identification caller and personal number. New and more advanced equipment for high speed and mobile networks area also requested. The other subsectors, business and consumers markets, are quite competitive and faster growing. Demand is driven by two main categories of services: customer premises data and voice services directed towards the business sector and mobile communication targeting the consumer.

The field of private data and voice communication network is very dynamic, because of the increasing need by EC companies to integrate their activities and react rapidly to the changes in the market. While some segments of the communication equipment market have already or are in the process of becoming saturated, (modem, facsimile machines, electromechanical private exchanges) new markets are emerging, like terminal adapters for digital networks, digital PABX (Private Automatic Branch Exchange) for connecting both computers and telephones, multiplexer TDM (Time Division Multiplexing) and ATM (Asynchronous Transfer Mode) switching equipment for high speed and optical fibres networks.

Regarding the consumer market, the need for mobile, customised and cheap services has implied added attraction for products like cordless, cellular telephones and multifrequency telephoné sets that are able to give many added services, like repeat dialling and memory systems. Moreover, sophisticated residential customers increasingly demand communications

Figure 3: Telecommunications equipment
Destination of EC exports and origin of EC imports, 1992



Source: Eurostat

and information services for professional use: for this reason, the demand for equipment like facsimile, videotex, modem (connected with personal computer to get electronic mail or data bank services) is spreading also in the home segment.

Supply and competition

Conventional wisdom has it that there will be no more than five or six suppliers of public telecommunications systems by the year 2000. However, telecoms are expanding so quickly and in so many directions that this opinion is starting to be regarded as misleading, as it would be inconceivable for a handful of suppliers to control the whole market.

Broadly speaking, the domestic manufacturers traditionally have strong links with the national telephone carrier i.e. the main buyer of telecom systems and products. In the EC, like in the US and Japan, public operators supplying basic telecom services have long-standing relations with their suppliers, hence limiting opportunities for newcomers. Market accessibility is associated with the share of the national telecom market held by the largest domestic vendor. The share of the main domestic vendor varies from 80% in France and Sweden to 40% in Italy.

The fragmentation of the EC market acts as a major constraint for innovation and a hindrance in adapting to global competition. One of the negative side-effects is higher prices for the end user. New EC regulations and liberalisation of almost all telecom carriers imply that the link between domestic carriers and manufacturing companies will loosen. So protectionist (or quasi protectionist) national barriers shall fall in the next years and competition will spread to include also provisioning equipment to national carriers.

Competition has already got stronger, especially in the business and consumer arenas. In the dynamic field of data communications, the arrival of US networking companies is threatening to marginalise European leading equipment suppliers. Systems are increasingly based on sophisticated computer software and networking companies like Novell (USA), Cisco Systems (USA) and Synoptics (USA) are bringing products to the data equipment market faster than European companies.

In the consumer market, the competition of Japanese and South East Asian companies is very strong. Many low value added products, e.g. telephone hand sets, are being manufactured in East Asia at lower prices due to cheaper labour. With regard to the highest value added products, like cellular telephones, Ericsson and Motorola (USA) are the leading suppliers. Anyway, as consumer electronics companies (like Sony for example) diversify into mobile telephones, they will increasingly compete with telecommunications companies.

The prices of telecom equipment are falling very fast -resembling trends with computer products- because of the rapid innovation in basic fields like micro-electronics and optics; but the fall in prices is more pronounced in the consumer market than in the business one.

Production process

Product costs are increasingly being dictated by high R&D costs for hardware and software. R&D costs -depending on production volume- already exceed value added generated by manufacturing. It is estimated that investment in R&D for the last digital generation of public switching was about 700 million ECU. R&D subsidies, such as development agreement or cost free technology transfers from government organisations or network operators represent a very important factor in competition.

The most innovative and sophisticated telecom technologies today are SDH and ATM. SDH (Synchronous Digital Hierarchy); a high speed transmission technology recently installed by public operators in order to replace or supplement existing transmission systems. Moreover, in the next few years, public carriers will adopt ATM (Asynchronous Transfer Mode); a switching technology for broad band multimedia communications. Companies are now starting to use ATM systems to increase the speed and widen the range of services of their private networks. A most promising product for the next years is the Personal Digital Assistant (PDA), a pocket personal computer that will also be able to communicate data and voice as a very intelligent mobile telephone.

INDUSTRY STRUCTURE

Companies

European companies are very well positioned in the global market of telecom equipment. Alcatel is the first company in the world ranking of telecom industries. However, the telecom business of Alcatel is hardly growing because of pricing pressures on the current generation of equipment and systems.

Siemens (the German group diversified in energy, industrial equipment, computers and semiconductors) contends with AT&T the second position in the world ranking. In 1992 it posted a 13% growth in communications equipment sales and a 17% growth at its public telecom unit. In fact Siemens is leveraging its position in East Germany to get the biggest share of orders for Deutsche Bundespost Telekom's massive public network upgrade in that region. Siemens also got important contracts in newly industrialised countries.

Ericsson, the sixth supplier of telecom equipment in the world, counts on Sweden for less than 20% of total revenue and has operations in 100 countries all over the world. In 1992 it increased its revenues by 3% and offset a drop in sales of public and private telecoms equipment and cables by substantial growth at the company's radio communications unit. Ericsson and Motorola (USA) are firmly established as the leading suppliers of world cellular telephone networks.

The Bosch Group (D) increased its revenue by 5% in 1992. The Italian company Italtel also increased its revenue (6%), thanks mainly to the big investment made by Stet-SIP for modernising Italian public fixed and mobile networks. The major EC companies show declining profits, while Philips (NL) even suffered a loss in 1992.

Regarding extra-EC companies, Nokia (SF) registered the most notable increase in its telecom revenue by 52% in 1992 and was the fastest growing public network manufacturer, thanks to its strength in the mobile segment.

In order to expand, EC companies will have to take advantage of opportunities in East Europe and Asia. Alcatel, Siemens and Ericsson are already well positioned in China and India, while Siemens and Alcatel are well positioned in Eastern Europe.

Strategies

The telecommunications equipment sector is evolving fast and alternative scenarios are emerging. The major trends are globalisation and concentration of the market through mergers and acquisitions, mainly directed to break into foreign markets, which have traditionally been dominated by domestic companies.

Broadly speaking, for winning orders in foreign markets a supplier has to form a joint venture or buy a stake in one of the established suppliers. Mainly for this reason, a lot of joint ventures, mergers and acquisitions have been concluded in the last few years. The examples of Siemens and GPT (UK), Northern Telecom and STC (UK), AT&T and Italtel (I), are the most recent but suppliers rationalisation is far from over. Another big push towards concentration arises from the need to find partners for lessening the burdens of high R&D expenses. Alcatel and Sprint for example made a joint venture to develop a new switching system. Some telecom companies try to share the expenses of R&D in new products and systems (like ATM) with computer companies. Moreover many medium sized companies (like the Italian Italtel) are looking for foreign partnerships to enter the international market and secure the most sophisticated and expensive technologies.

The major European companies have to balance the goals of expand in new markets, like mobile communications and data services, and securing existing customers. The speed of technology innovation and the creation of international commercial and production units are the most important challenges for telecoms companies.

REGULATIONS

The single European market helps promote economies of scale through standardisation of network systems and their terminal interfaces. However this is unlikely to be completely accomplished in less than 10 years. The European Telecommunications Standard Institute (ETSI) works intensively for fixing common European standards but full European standardisation will be possible only when new systems, such as narrow band ISDN, broadband ISDN, GSM and the like will be introduced and widely diffused in Member States.

Table 4: Telecommunications equipment Trade breakdown by sector, 1992

Source: DEBA

According to EC procurement guidelines for public contractors, all contracts exceeding 600 000 ECU should have been opened to international bids as of January 1993. This guideline leaves a lot of leeway with regard to the type of allocation, e.g. open or restricted invitation to bid, negotiation and prequalification procedures and so on. It's generally acknowledged that until now it has not been possible to create all the conditions for an effective open market within the EC. Generally speaking, the basic principle of mutual opening of markets under fair and not discriminatory conditions must apply not only within the EC, but also in other markets of the world.

Among its many other initiatives aimed at speeding the process of the introduction of harmonised advanced networks and services across Europe, the EC is continuing to support the RACE R&D programme into advanced communications and secure the early and wide diffusion of its results.

OUTLOOK

The telecommunications equipment industry will surely grow in the next few years: in fact advanced telecom services will become strategic for the economic development of the nations and will drive demand for telecom products and systems. Massive investment projects in new intelligent and high speed digital networks, in mobile communications by public and also private (in the case of GSM) carriers for modernising their services, will be essential to the development of the equipment sector.

For the rapid growth of the sector, the execution of pan European pilot projects will prove important. Two prime examples are the Trans European Network (TEN) and the European Pilot ATM network (EPAN). The former will connect integrated broad band communication islands; and the latter will be used to test innovative technologies, like ATM.

The importance of supporting common European standardisation is shown by the success of the GSM digital mobile system; in addition to 22 European countries, 40 non European countries are in the process or have already introduced the European standard (and European equipment).

In the next few years the major trends towards more globalisation, more competition, more concentration of the suppliers, and less employment in the sector, will increase. European public Telecom operators (that will be almost all privatised) will behave more and more like private sector customers vis-a-vis manufacturers. Finally, it is likely that US and Japanese companies will increase their share in some of the EC's fast growing market segments affecting negatively the EC trade balance with these two countries.

The compound annual growth rate of the world market is forecast to be 3.7% over 1992-97 with its Western European counterpart growing by 1.4%, the US by 3.5% and Japan by 3.8%. The market in the rest of the world is expected to grow by almost 8% per annum with China and the rest of Asia being the leaders. Prospects in East Europe are promising despite current financial difficulties.

The industry is represented at the EC level by: The European Telecommunications and Professional Electronics Industry (ECTEL). Address: c/o FEI, Russell Square House, 10-12 Russell Square, London WC1B 5AE, United Kingdom; tel: (44 71) 331 2020; fax: (44 71) 331 2042.

Consumer electronics
NACE 345.1, 345.2

Demand saturation, further price erosion, increasing concentration of the purchasing power in the distribution, congestion of locally manufactured and imported brands and economic recession in Europe have characterised developments in the industry over the last few years. Direct employment has exhibited a negative trend as automation has dominated the production processes. Japanese companies, also facing serious profitability losses, have the largest market share in the sector world-wide, especially for products like VCRs and camcorders. The two biggest EC companies Philips and Thomson rank well in the world top 10 with particular strength in the CTV segment. However, as have others in the last few years, both of them suffered serious profitability drawbacks in the consumer electronics sector. Nokia is the third largest European-owned EC manufacturer. Technology innovation, user friendliness, price, quality service and distribution are the key factors for success in the consumer market.
In the short term, the recovery of the EC consumer electronics industry hinges upon the successful completion of the vigorous restructuring programs undertaken by the leading companies for cutting costs and returning to structural profitability. In the long term, awaiting the new era of multimedia, success will depend more on the ability of EC companies to increase their global market share and produce both new standards and innovative products (like Digital Compact Cassette, Compact Disc Interactive, Improved Definition and Widescreen receivers, HDTV, Digital Audio Broadcasting and Digital Personal Electronics).

INDUSTRY PROFILE

Description of the sector

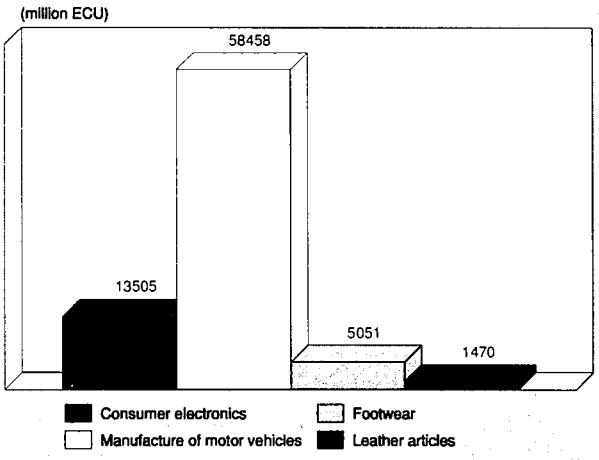
The consumer electronics sector includes all audio-visual products for domestic and portable use and their accessories, such as colour and monochrome televisions, video recorders, video cameras and camcorders, CD readers and audio equipment in general (NACE 345.1); other 'brown goods' are classified in this sector (NACE 345.2) including cable terminals and pay TV decoders. Other products are: antennas and satellite dishes, in-car entertainment and traffic guidance systems, mobile phones, home computing and telecom terminals. Video games, although no quantitative data are provided in the present chapter, are another category of increasing importance that can be included in the consumer electronics sector.

Among audio-products, Digital Compact Cassette (DCC) by Philips and MiniDisc by Sony, released in Europe in 1993, are very new and innovative: both of them are miniaturised products for digitally recording and playback of high fidelity sound and they are going to be the next generation of products (in substitution for traditional Compact Cassettes and, partially, for Compact Disc), but they are still far from achieving the market success of Compact Disc. CD-I (Compact Disc Interactive), a new interactive multimedia system, is in the initial stages of market penetration. Widescreen (16:9) and improved definition television receivers are starting on their market entry curve.

Recent trends

The consumer electronics sector generated a value added of 13 505 million ECU in 1992. Most of value added comes from France (5 336 million ECU in 1992), followed by Germany, Italy and UK, respectively contributing 2 214, 2 043 and 1 760 million ECU.

Figure 1: Consumer electronics
Value added in comparison with other industries, 1992



Source: DEBA

The EC consumption and production (in value terms), after years of strong growth over 1983-88 - with growth at a compound annual rate of 8.3% and 6.8% respectively - have been experiencing hard times since, as growth rates fell respectively to 0.9% and 1.1%. Finally, in 1992 both the EC consumption and production recorded a decline. Apparent EC consumption fell from 55.4 billion ECU in 1991 to 51.4 billion ECU in 1992, and the EC production from 42.2 billion ECU to 39.7 billion ECU.

EC employment was 356 000 in 1992, that is about 20 000 less than in the previous year. Since 1987 employment has been falling more dramatically than in the manufacturing industry as a whole and is expected to maintain its downward trend over the next few years. In the period 1985-92, the EC productivity index increased by nearly one third, while unit labour costs increased by 44%.

International comparison

Japanese companies are the main producers of consumer electronics good for the world market, with an estimated 43% of total production. Japanese manufacturers control over 99%

of their domestic production and account for 50% of production in the USA and 27% of production in Europe. The EC manufactures produce 15% of consumer electronics goods in the world and the USA 13%. Europe is the second largest market for consumer electronics in the world, after the USA. Growth in Japanese consumption slowed in recent years as the market for audio and video products saturated, forcing manufacturers to place more emphasis on the USA and Europe for sales. Japan exports over 50% of its consumer electronics production. Both the USA and the EC are very significant net importers of consumer electronics, showing a strong negative trade balance in this field.

Foreign trade

In 1992 extra-EC exports increased in comparison with the previous year while extra-EC imports decreased. Thus the trade balance deficit declined from 13 155 million ECU in 1991 to 11 768 million ECU in 1992. Since 1988 exports, (10.2% of compound annual growth rate) have been growing faster than imports (4.4%).

Over 1987-1992, extra-EC exports have registered a shift in destination. The percentage directed to EFTA countries and the USA has declined in favour of exports towards the rest of the world, primarily less developed countries. The latter accounted for 58% of the total in 1992 compared to 50% in 1987. Very few EC products are exported to Japan which accounts for just 3% of total EC exports. Parts and accessories (54% of total exports), TV sets (17%) and blank tapes and discs (11%) are the main categories of exported products.

Most extra-EC imports comes from Japan (33%) and South East Asia countries, such as Korea, Taiwan, Hong Kong, Singapore, Malaysia and Thailand. The latter as a group have steadily increased their share in EC imports in the last few years. In 1992, 17% and 7% of EC imports came from the US and EFTA respectively. Parts & accessories (23% of total imports), home audio (16%), TV sets (14%), camcorders (13%) and blank tapes & discs (11%) are the main products imported.

MARKET FORCES

Demand

Recession in the EC accounts for slow market growth, fierce competition and falling prices. However, falling prices have favoured a wider diffusion of consumer electronics and the range of products sold in the market has increased.

Broadly speaking, consumer demand can be divided into two main segments. High end users ask for better quality products and service (for example high specification and 16:9 format screen TV sets, VCRs, or premium audio products with state-of-the-art sound), while low end users ask for cheaper and easier to use products. It is also acknowledged that many functions of volume products (like VCRs and camcorders) are not actually used because of their complexity.

Product user friendliness, price and service and distribution quality are the main factors of success in the consumer electronics market, and the suppliers try to balance these features to get the right mix for the different segments of the market. Another key factor concerns brand image and the expansion of distribution channels, such as discount stores for the mass market, or specialised retail channels for high quality and sophisticated products.

Supply and competition

Japanese companies have the largest market share in the sector world-wide, especially for products like VCRs and camcorders. EC companies are strong above all in the CTV segment. Korean manufacturers are becoming better positioned in the world ranking of consumer electronics companies, favoured by their lower prices for high volume production. They are strong in the most mature and low end products, and improving in the VCR and camcorder markets. Hardly any US company can be found in the world ranking of consumer electronics companies, because of Japanese and EC companies dominance of the US market itself. The Japanese owe their strength in the sector to the benefit of large economies of scale, lower capital access costs and their traditional strength in manufacturing. Japanese companies are also favoured by better cash resources for R&D which were accumulated thanks to high profit margins in their domestic market. Japanese companies are generally able to take more profit from their vertical integration and diversification: in fact, many big Japanese producers are also big players in the electronic components market, and many of them are well diversified in other electronic fields, such as computing, professional equipment and telecommunications. Therefore they are able to cross-subsidise

the high investment in R&D required for electronics among the different divisions. Recently though, a strong movement towards delocalisation of production outside Japan has started taking place in order to maintain margins and cost competitiveness.

European-owned manufacturers, though to a lesser extent than the Japanese, are also vertically integrated and diversified: Philips is the main EC producer of electronic components and Thomson is one of the main shareholder of the semiconductor producer company SGS-Thomson.

Traditionally, Japanese companies gained global market share by selling high volumes at low price and modest profit in their export markets. The Yen revaluation, the current price war and the dramatic reduction of gross margins are deeply affecting Japanese companies, which are also hit, for the first time, by a reduction of their domestic consumer market which traditionally represented the platform for their strong profitability. Most of the Japanese consumer electronics companies are experiencing a dramatic reduction of profits and, in some cases, losses. Both Japanese and European companies are trying to rationalise their production facilities and to move low value added production to South-East Asian countries, where labour is cheaper.

Production process

The consumer electronic sector is characterised by the coexistence of relatively mature products, like CTVs and VCRs, alongside new products. In fact, suppliers try to revitalise the market by introducing new sophisticated products and by imposing enhanced standards and features. In the last months of 1992, Philips launched the Digital Compact Cassette (DCC) for recording digital sound. Sony launched the MiniDisc, another optical device for recording digital sound. Both are trying to emulate the success of compact disc, replacing traditional analogue cassettes. They are also trying to establish their standards with alliances with hardware suppliers (for example DCC of Philips is produced also by Matsushita, the largest Japanese

consumer electronics company). For both contenders, the partnership with the "software" industry, i.e. the music recording industry, is vital for their new products' success.

Philips also introduced CD-I, an interactive multimedia optical device connected with traditional television sets and compatible with compact disc. Also in this case partnership with the "software" industry, that is movies industry, is the key to success.

The biggest attempt to revitalise the mature TV market has been made through enormous investment in R&D to supply High Definition TV, i.e. a new TV standard set providing high definition images (comparable to the level of image definition of the movie screen).

Over recent years, the EC supported a strong effort in R&D to promote a mixed analogue/digital standard of HDTV: HD-MAC. This would have been compatible with D2-MAC receivers, offering improved definition television pictures and downward compatibility between 16:9 and the existing 4:3 aspect ration pictures and standards.

Unfortunately, before these technologies could become established, the prospect of fully digital solutions became apparent, particularly in the USA, where electronic companies, including Philips and Thomson, promoted the principle of a new advanced digital TV standard. It is likely that fundamental features of this standard will be incorporated in the satellite and terrestrial digital TV standards, which will be adopted in Europe. Digital television standards can be used to promote either HDTV or a substantially increased number of standard definition channels, or a mixture of both. It is expected that these new developments will revitalise the US and EC consumer electronics industries.

For the new generation HDTV sets, large flat screens will be needed. Although the Japanese are more advanced than US and EC companies in R&D concerning such development, a significant and important amount of research work is going on in Europe on this and other technologies through the Eureka, Race and Esprit programmes.

An important development in Europe is likely to be the introduction of enhanced definition TV sets employing the D2-MAC standard and, in the immediate future, the PAL PLUS standard, both with a 16:9 format picture. This will be particularly important for terrestrial broadcasters as a measure to compete with satellite digital TV in 16:9.

The EC Commission has put in place an action plan to provide financial support to broadcasters to update to 16:9 studio equipment, and to foster providers and producers to convert to and make 16:9 programmes. There will be no direct funding to the consumer electronics industry in this plan.

In the long term, innovation is linked to the trend of convergence with telecommunications, computer and media technologies. Traditional industrial boundaries are disappearing and competition will stronger between companies originating from different sectors. Video telephone and personal communication electronics are examples of technological convergence that promises increasing competition and alliances between consumer electronic and telecommunications companies; multimedia PCs are a further example of technological convergence between TV and computer industries. Another sector of likely competition and/or partnership will be cable TV and pay-TV where media, telecommunications and consumer electronics companies will compete or set up new alliances.

INDUSTRY STRUCTURE

Companies

The only EC companies ranked in the top 10 of consumer electronics world-wide are Philips and Thomson. Nokia is the third largest European-owned manufacturer. 1992 and 1993 have been very tough years for the European industry. Many analysts claim that very few companies have been making profits in Europe in the last five years. Although consumer electronics is a mature market, - where usually established companies can consolidate good profits - fierce global competition and overcapacity seem to have forced the industry to give away all productivity gains to the customer.

Strategies

The strategies of the consumer electronics companies are directed towards controlling costs, rationalising production, improving the quality and user interface of existing products, expanding commercial networks and launching innovative products. On one hand, companies are likely to concentrate on their core competence and on the other to co-operate and set up new joint ventures with companies that might even originate from other sectors, like music records, computers and telecommunications.

Strong competition is generally forcing companies to seek networks of alliances and partnerships. After a wave of mergers and acquisitions over the 1980s, strategies have shifted towards agreements concerning a limited range of products or R&D on some technologies. Philips and Thomson for example were partners in developing HDTV and are jointly developing the flat TV screen and LCD (Liquid Crystal Display) technology. Digital Audio Broadcasting (DAB) is another area of R&D cooperation.

REGULATIONS

Regulations will be introduced by 1994 to limit interference when equipment is attached to the main supply. This will be mandatory for all suppliers of consumer equipment and may for example require the redesigning of the power supply stage.

Environment protection legislation is another key issue. Laws concerning waste disposal have already been introduced in Germany and France. EC and national laws will push the suppliers to adopt recyclable materials.

OUTLOOK

The future of the consumer electronic industry depends heavily on the developments of new technologies, such as in standard definition digital TV, improved definition TV, encryption systems and widescreen format TV, as well as on the successful marketing and adoption of new products, such as DCC, CD-I, DAB, in-car traffic guidance systems and personal electronics. However, hard times are likely to persist over the next few years, because of market saturation, fierce price competition, the concentration of purchasing power in distribution, congestion of locally manufactured and imported brands and economic recession in the EC.

Source: Databank

In the short term, the recovery of the electronics industry hinges upon the continuation of rationalisation programs being put forward by major companies in the sector. In the long term, the success of the EC consumer electronics industry depends also on its ability to increase its share in the global market and to create a wide range of technological and commercial alliances. The emergence of the new multi-media industry will present the major business opportunity, implying convergence of the consumer electronics, computer, telecommunications and software industries.

Boeing 747

Overview
NACE 35, 36

The transport equipment industry ranks among the major industries in the EC, and has a significant influence over important supplying sectors (ferrous metals, rubber and plastics). Consequently, the deep depression the EC industry has experienced over the past two years has had a dramatic impact on its suppliers. This recession shows signs of having reached a bottom now. Following a deep slump in activity in 1993, attention is now turning to the timing and strength of recovery from 1994 on. The restructuring the industry is engaged in will continue and further lay-offs are to be expected, particularly in the motor vehicle and aerospace industries.

INDUSTRY PROFILE

Description of the sector

According to the NACE classification, the transport equipment industry covers the following sub-sectors:

- motor vehicles (NACE 351 and 352);
- motor vehicle parts and accessories (NACE 353);
- shipbuilding (NACE 361);
- railway rolling stock (NACE 362);
- mopeds and motorcycles (NACE 363);
- aerospace equipment (NACE 364).

The major category of the transport equipment industry is by far motor vehicles, which is the largest producer and employer of the sector. Aerospace ranks second in terms of production and employment.

Recent trends

With value added at above 47.7 billion ECU in 1992, Germany is by far the largest transport equipment producer. France, the United Kingdom and Italy rank as the three largest producers after Germany. These four leading producers together account for 85.6% of EC transport equipment output.

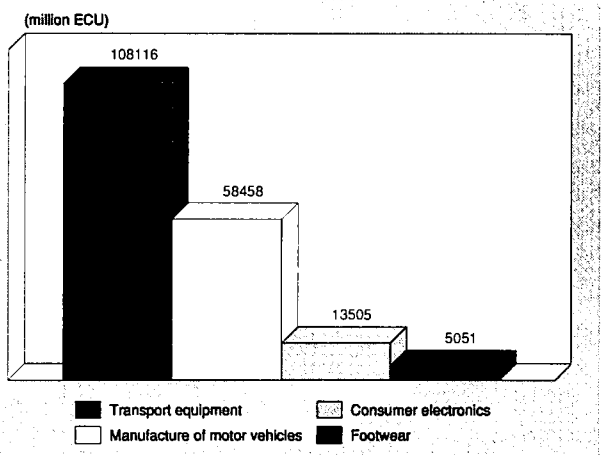
The transport equipment industry maintained sustained activity with an above 5% real annual growth rate between 1985 and 1989, thanks to the particular dynamism of the motor vehicle industry over the period. Motor vehicle parts and accessories was the fastest growing sector over the period, while shipbuilding and railway rolling stocks reported declining production.

After a slowdown reported in 1990, real production of transport equipment actually fell in 1991 and 1992. Since 1991, production of both motor vehicles and motor vehicle parts and accessories suffered declines, following a worldwide slump in both domestic and extra-EC demand. The downturn in extra-EC exports had a damaging effect on the sector's trade surplus which shrank by 43% in current terms in 1991. A strong increase of imports in the aerospace and motor vehicle industries contributed to dampen the sector's trade performance. 1992 proved to be a better year for the sector's trade balance. The trade surplus improved significantly thanks to stronger extra-EC exports, whose growth outstripped extra-EC import growth.

International comparison

Thanks to significant growth in the decade up to 1992, the EC has become the world's largest producer of transport equipment. The EC aerospace industry is largely responsible for this record, as it reported much stronger growth than the US, the unquestionable leader in the production of aerospace equipment.

Figure 1: Transport equipment
Value added in comparison with other industries, 1992



Source: DEBA

The US, which used to lead the market ten years ago, ranks second in the transport equipment industry, due to the poor growth rate reported throughout the decade. In contrast, Japanese production more than doubled between 1983 and 1992, reflecting Japan's ability to penetrate markets worldwide, particularly in the motor vehicle segment. Overall, Japan's transport equipment industry ranks among the top three producers in the world, with production value at 287.8 billion ECU in 1992 just 2% below that of the US.

Foreign trade

The EC transport equipment industry exports some 16% of its production outside the EC, while 13% of its consumption is produced outside the European Community. However, trade intensities differ significantly across subsectors. For example, the motor vehicle industry imports less than 10% of its do-

mestic apparent consumption, while only 12.5% of its production is exported. This peculiar aspect is the result of the strategy of internationalisation implemented by the major automotive producers, aimed at locating production plants near local consumer places, which leaves reduced space for extra-EC trade. In contrast, the aerospace industry ranks among the largest open to trade, with both export intensity and import penetration at about 35%.

Like for other industries largely open to trade, swings in currency values have made imported transport equipment cheaper than EC produced equipment. This was among the factors that tripled the value of extra-EC imports over the past decade and significantly reduced the EC's trade surplus.

Since 1986, the EC transport equipment sector has experienced a number of major shifts in both the destination of extra-EC exports and the origin of intra-EC imports. Japan accounted for an increasing share of EC exports in 1992 compared to 1987, while export shares to the EFTA and OPEC countries remained stable. A notable decline in the export share to the USA can be mainly attributed to a substantial depreciation of the dollar during that period. For the same reason, the US increased its share of extra-EC imports by six points to 27.5% in the five year period to 1992, mainly to the detriment of import shares for the EFTA countries and Japan.

MARKET FORCES

Demand

Demand for the different categories of transport equipment varies significantly. Consumers are the single most important component of demand for the mopeds and motorcycle industry, and for the motor vehicle industry (through demand for passenger cars). Consequently, overall economic activity, personal disposable income and demographic trends are overriding factors influencing demand for such equipment. It is no wonder, then, to observe that these sectors are characterised by a combination of short term cyclical fluctuations and long term

Figure 4: Transport equipment

growth. By contrast, the government sector is the aerospace industry's largest outlet through its military orders, followed by airline companies. Given the tough spending constraints its main clients are facing, along with changing defence policies and with increasing peace initiatives, the aerospace industry is currently experiencing its worst ever downturn in demand.

The shipbuilding and railway rolling stock industries have a relatively small number of customers, usually national or regional companies, which may be either private or public. These two industries are more sensitive to transportation and infrastructure policies, rather than to general income developments.

More generally, demand in the different subsectors can be attributed to a wide variety of factors as certain forms of transportation are close substitutes for each other (travelling by car versus rail or air travel, for example). Furthermore, an increased awareness of transportation's impact on the environment on the part of the general population may also affect demand as increased use of public transportation reduces emissions and traffic congestion.

Supply and competition

As a whole, the EC transport sector is fully capable of meeting the demand for transport among its Member States. In fact, the EC maintains a trade surplus, albeit declining, in transport equipment on an annual basis. In the motor vehicle industry, Japanese competition clearly constitutes the main challenge faced by European producers over the next two decades. In response to such competition, EC car manufacturers need to further implement the lean production techniques in order to at least maintain market shares. In the aerospace industry, the US remains the formidable competitor, but newcomers, such as Indonesia, might represent a serious threat over the next two decades.

The profits to turnover ratio shows the European transport industry improved its profitability between 1983 and 1992. The effects of the world-wide recession, however, have diminished a previously positive trend which peaked in 1989. The most notable rise and subsequent fall in this trend occurred in the aerospace subsector, which experienced a considerable drop in orders for both civil and military aircraft.

Production process

Confronted by a highly competitive market, the transport equipment industry is bound to produce faster, better and cheaper. New forms of organisation and management of production have been implemented, along with new production methods. Innovations in the production process are particularly noticeable in the automotive industry, and to a lesser extent in the aerospace industry, where new techniques such as just-in-time production and increased emphasis on quality control are reducing significantly production times and allowing for greater cost effectiveness. The latter is of major concern for the transport equipment industry, which has experienced a strong deterioration of its cost structure, simultaneous to the inflation of unit labour costs.

As rationalisation and innovations in automated production techniques continue to be applied to the production process, employment in the sector continues to dwindle. In spite of a brief period of relief in 1989 and 1990, the trend in employment is dramatically downward oriented. Since 1991, the employment decline has actually accelerated, with a cut by 3.3% decline in 1992 and a further slump by 11% expected for 1993.

INDUSTRY STRUCTURE

Companies

The transport equipment sector is well represented among the leading European companies. Daimler-Benz (D) is the leader in terms of turnover, and the third largest industrial company in Europe, and the eleventh in the world. The sector is highly concentrated as the top 6% of the companies (i.e. companies with more than 99 employees in 1990) accounted for 94% of the transport equipment industry's turnover.

Some of the leading corporations in this sector have interests in various industries. Many of the large volume car manufacturers, such as Renault (F), Fiat (I) and Daimler-Benz, also have interests in the truck industry. Peugeot SA (F) produces mopeds, motorcycles and bicycles, whereas both Fiat and Daimler-Benz are involved in both the motor and aerospace sectors. In addition, British Aerospace (UK) now holds a majority stake in Rover Group (UK). At the time of the Rover Group take-over by British Aerospace, much was made of the opportunity for the two companies to enjoy industrial synergy. Although there does not seem much evidence of this synergy in general, companies with dual interests are at least able to allocate risks across their diversified branches.

Strategies

Although the EC can still lay claim to some of the largest transportation companies in the world, a strong movement towards international cooperation between EC manufacturers and American and Japanese companies is quite prevalent.

In the motor vehicles industry, a number of mergers have occurred, in particular between the large mass producers and smaller luxury car makers. Some examples include Fiat's takeover of Alfa Romeo (I), Ford's (USA) purchase of Jaguar (UK) and General Motors' (USA) 50 % stake in Saab's (S) car division. Apart from outright mergers, a cooperative agreement between Volvo (S) and Renault through complex cross-share holdings has made Volvo/Renault the world's largest truck producer.

Collaboration has not taken place solely between EC producers, however. In recent years, there have been a number of collaborative ventures or cooperative agreements between EC companies and Japanese or American organisations. The aim of such ventures is to develop new models together, in order to share development costs. Usually, the products of this cooperation are marketed separately to maintain a clear distinction between brands.

The Japanese motor industry's superior standing in certain areas of the production process has led to a steady stream of joint manufacturing agreements. Examples of such collaboration include General Motors' arrangement with Isuzu (JPN) to jointly produce vans in the UK, the much publicised Rover-Honda (JPN) alliance which has now been existence for over ten years, and Piaggio's (I) agreement with Daihatsu (JPN) which led to their common development of a new microvan called Hijet, whose marketing started in March 1993.

In terms of cooperation between US and EC companies, the aerospace sector is the unquestionable leader. This cooperation is essentially taking place between aerospace engine manufacturers (MTU (D) and Pratt & Whitney (USA) or General Electric (USA) and Snecma (F), for example). It is also worth mentioning the contribution of out-sourcing, particularly between US companies to the Airbus programme as well as European companies to some of the Boeing (USA) and McDonnell-Douglas (USA) programmes.

Although cooperation among companies has occurred, outright mergers and acquisitions activity is still somewhat limited in industries such as aerospace where governments of respective Member States still have a controlling interest (particularly in the production of military equipment). Given the advantages of scale economies and large R&D expenses, however, some very important mergers and acquisitions have occurred in the aerospace industry. Such a development is quite pronounced in Germany, where much of the aerospace industry is performed by divisions under the wings of Daimler-Benz which were acquired through mergers and acquisitions.

REGIONAL DISTRIBUTION

In 1992, more than 85% of EC production was concentrated in four Member States: Germany, France, the UK and Italy. For motor vehicles, these four countries accounted for 91% of all value added within the EC. In the aerospace sector, EC's Big four countries produced about 94% of value added in Europe.

The opening of frontiers with Eastern Europe promises to have a significant impact on the distribution of European production facilities, particularly for the motor vehicle industry. For example, many major West European manufacturers have already entered into agreements with East European producers, in anticipation of future rewards. Opel (a subsidiary of General Motors), Volkswagen (D), and Mercedes-Benz have all set up production units in former East Germany. Fiat took over FSM in Poland at the end of 1992, and acquired a 30% stake in VAZ, the Russian car producer. Among the other deals which have been successfully finalised, it is worth mentioning the purchase by Volkswagen in 1991 of a 31% stake in Skoda, the Czech manufacturer.

In the aerospace sector, principles of cooperation have also been agreed upon in the space industry between CIS and the EC.

ENVIRONMENT

Transport has been one of the main targets of environmental regulations for several years. Transport services account for one-quarter of total carbon dioxide emissions (carbon dioxide is the main gas responsible for the "greenhouse effect"). Given the strong "technological" link between carbon dioxide emissions and energy consumption, heavy energy users such as the aerospace and motor vehicle industries are likely to be under attack over the course of this decade. This could be

Table 6: Transport equipment

Source: DABLE

to the benefit of some of the smaller transport subsectors like rail. In the area of personal transport, increasing congestion in most towns and cities, coupled with growing environmental awareness should benefit the bicycle, moped and motorcycle industry, as well as the public transport equipment sector. In the long term, the kind of solution adopted to solve the global warming problem is of major importance, given that it could lead to a significant shift in production between certain branches of the sector.

REGULATIONS

Increasing penetration of Japanese motor vehicles will have a substantial effect on the sector as a whole. An agreement made in 1991 between the EC and Japan called for a complete opening of the European market to Japanese vehicles by the year 2000. During the agreement's interim period through 1999, the share of Japanese car makers will be progressively raised. Japanese producers have promised to refrain from a rapid adjustment of their penetration rates in what are presently the most protected markets, France and Italy.

OUTLOOK

The European auto industry has experienced a deep recession during the past two years. This recession shows signs of having reached a bottom and attention is turning to the timing and strength of recovery in 1994 and 1995. During the 1990's, European producers will face a series of important challenges ranging from Japanese competition to environmental pressures and the development of the East European market. The re-structuring of the industry will continue and sizeable lay-offs are expected.

Following the current downturn in the aerospace subsector, growth is expected to be encouraged in the medium term by both a rapid growth in air traffic and the need for airlines to replace their ageing fleets. Such a forecast also assumes that airlines will be in a better position than they currently have to make such investments.

Table 8: Transport equipment

Prospects for the railway rolling stock industry are somewhat different, with problems stemming more from the demand than from the supply side as world demand remains sluggish. Sales in Europe will be somewhat spurred by investments in a European high speed rail network, the upgrading of the Italian and East German networks, and increased environmental concern which puts more emphasis on the development and expansion of efficient transport networks. In addition, an expected hike in oil prices will likely raise the cost of travelling (by car or by air, in particular), making rail travel a more affordable form of transportation.

Overall, production growth in the transport equipment sector is expected to average 2.5% per year up to 1997, slightly weaker than the above 3% annual rate of growth over the period 1983 to 1992.

Written by: DRI Europe

Motor vehicles
NACE 351

The European car and commercial vehicle markets are in midst of the worst decline since World War II. The industry is facing declines in sales greater than those which occurred after the first oil crisis in the early 1970s. Much of the industry is operating at a loss as car and commercial vehicle makers take drastic action to reduce production and cut jobs. 1993 has witnessed extensive short time working and new pressure on component suppliers to cut prices.
The current recession has highlighted the need for all vehicle manufacturers to accelerate restructuring programmes needed to achieve global levels of competitiveness. All vehicle manufacturers are meeting this challenge by restructuring their development and production processes, re-evaluating their sourcing policies and improving skill and productivity levels.

INDUSTRY PROFILE

Description of the sector

NACE 351 covers the manufacture and assembly of motor vehicles and manufacture of motor vehicle engines. Motor vehicles include passenger cars as well as commercial vehicles. All the volume car producers also operate in the commercial vehicle market, especially the light commercial vehicle market.

Vehicle manufacturers also produce motor vehicle components and accessories (NACE 353) and are engaged in the distribution and maintenance of vehicles.

Recent trends

World-wide sales of new cars increased only marginally from 33.9 million units in 1991 to 34.1 million in 1992. There was also hardly any growth in the EC market, with 1992 sales of 12.6m units being only marginally better than in 1991, when sales reached 12.55 million units.

Whilst the UK and the Italian markets were stable, growth in the French (up 4%) and Spanish (up 11%) markets in 1992 compensated for weakness in the German market which was down 6% from the 1991 post unification boom level.

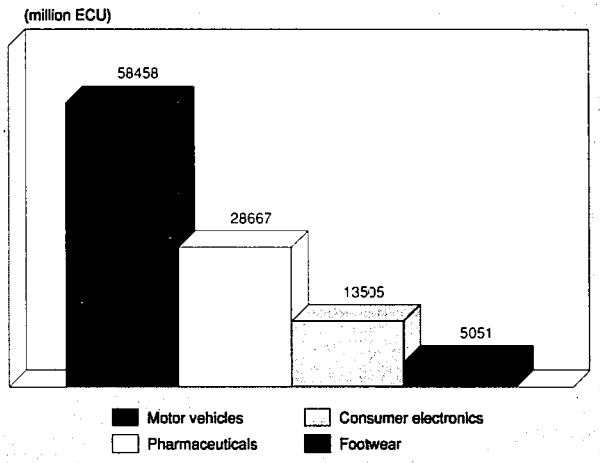
1993 has seen sales slump in almost all the EC markets and total 1993 sales were over 15% below the 1992 levels. Of the major European markets, Germany and France suffered declines in demand of over 18% and both Italy and Spain suffered declines of over 20%, with only the UK market showing growth (of over 10%) from the 1992 levels.

Sales of light commercial vehicles tonnes gvw rose by 7% from 1.24 million to 1.33 million between 1991 and 1992 but sales of trucks 6 tonnes gvw declined from 258 000 in 1991 to 233 000 in 1992 - a decline of over 10%. A sharp decline is being witnessed in 1993 with the light truck sales expected to be around 20% below 1992 levels and sales of trucks 6 tonnes gvw expected to be around 23% lower than in 1992.

Between 1991 and 1992, sales turnover of the EC motor vehicle industry rose by 4% to 210.5 billion ECU and production rose by 3% to 216 billion ECU.

According to Eurostat, the vehicle assembly industry employs 1.16 million people in the EC, representing some 3.7% of total EC manufacturing employment. Productivity improvements, restructuring, and rationalisation have all contributed to a steady decline in the level of employment in the industry. The current downturn is exacerbating this situation and 1993 has seen many of the vehicle manufacturers announce large reductions in their workforce.

Figure 1: Motor vehicles
Value added in comparison with other industries, 1992



Source: DEBA

Imports from outside the EC accounted for 9% of total consumption and exports to countries outside the EC accounted for 12% of production.

The industry is a net exporter and an important positive contributor to EC's trade balance; however the surplus has declined from 16.2 billion ECU in 1985 to 5.6 billion ECU in 1992. The main reason behind this decline is the loss by EC carmakers of third countries' market.

Vehicle manufacturers adopt Pan-European if not global strategies, while exploiting strengths of specific countries and expanding their presence in the major markets through new investments, joint ventures and alliances.

Germany retains its dominant influence on the EC industry, accounting for 38% of total EC consumption, 44% of production and 54% of value added (see Figure 2).

Between 1982 and 1993, production in nominal value terms doubled. In real terms it increased by 37% (see Figure 3) but changes in competitive dynamics have led to significant structural changes and implementation of new organisational and production processes and this has led to a reduction in employment levels.

Total employment in the EC vehicle assembly industry fell from over 1.3 million in 1983 to 1.05 million in 1993, a reduction of about 20%.

Employment or rather unemployment remains an important issue for the industry and the sharp downturn of vehicle production in 1993 is exacerbating this situation. Nearly 260 000 jobs have been lost between 1983 and 1993. 1993 has seen many of the vehicle manufacturers announce large reductions in their workforce. From vehicle manufacturers announcements which have already been made, indications are that the workforce will be reduced by a further 10% by 1995, equivalent to 110 000 jobs.

Figure 4 illustrates the employment trends in the five major EC countries. The German industry, which until 1991 witnessed increases in levels of employment, is expected to suffer the largest reduction in level of employment in 1993, as almost all manufacturers accelerate their rationalisation and productivity improvement programmes.

International comparison

In 1992, EC accounted for 37% of world-wide cars sales and 36% world-wide car production and Europe was both the

Source: DEBA

largest consumer of vehicles and the largest producing region for automobiles.

In 1993, sales of cars in EC countries amounted to 10.68 million compared to 8.8 million in the USA and 4.14 million in Japan. Production of cars in EC in 1993 was 11.17 million compared to 6.23 million in USA and 8.68 million in Japan.

Between 1988 and 1992, in a static world market, sales of cars in EC countries grew by 6.5%. North American sales dropped by around 20% and sales in Japan rose by 20%. By 1992, car sales in EC countries had exceeded sales in the North American market by 3.4 million units. However, in 1993, this gap was narrowed to 1.17 million units as EC sales declined and North American sales enjoyed a revival.

Trends in motor vehicle production (cars and commercial vehicles) growth in value terms in EC, USA and Japan are compared in Figure 7. Production in real terms has grown by 30% between 1985 and 1992. This contrasts with a decline of 3.6 % in USA and a growth of 43% in Japan.

Foreign trade

In the mid- eighties, North America was the most important export market for EC car manufacturers and the major outlet for the European car segment above 3 000 cc (the so-called luxury cars) output (see Figure 8). Unfavourable currency movements, recession in North America, increased competition from domestic car manufacturers and encroachment into the luxury sector by Japanese manufacturers have all contributed to decline in exports of EC produced cars to North America.

In recent years, some EC car manufacturers operating in the luxury cars segment have responded by announcing plans to invest in North American production facilities. As this capacity comes on stream, EC's trade surplus with North America could be reduced further. US owned car manufacturers have been well established in Europe and absence of direct imports from USA have contributed to EC's trade surplus with USA.

Figure 9 shows the trends in imports of passenger cars into the EC and Figure 10 illustrates the picture in value terms

for the whole industry including commercial vehicles. Japan continues to be the main source of imports, accounting for nearly 70% of all imported vehicles in unit terms and 54% in value terms. EFTA's share has declined in value terms, whilst imports from Korea increased sharply from 21 000 units in 1988 to 80 000 units in 1992. In 1992, Korea and USA accounted for 3% and 7% respectively of the total imports in value terms, compared to 1% and 2% respectively in 1987.

MARKET FORCES

Demand

Cars

Demand for cars is determined by a number of factors including trends in personal income and wealth and consumer confidence. These factors account for the cyclical nature of sales over the past two decades with economic downturns generally triggering slumps in new car registrations.

The Western European passenger car market has grown steadily over the last twenty years, punctuated by two periods of downturn. (see Figure 11) A further market weakness began to emerge in 1992 and 1993 has seen sharp downturns in most of the EC markets.

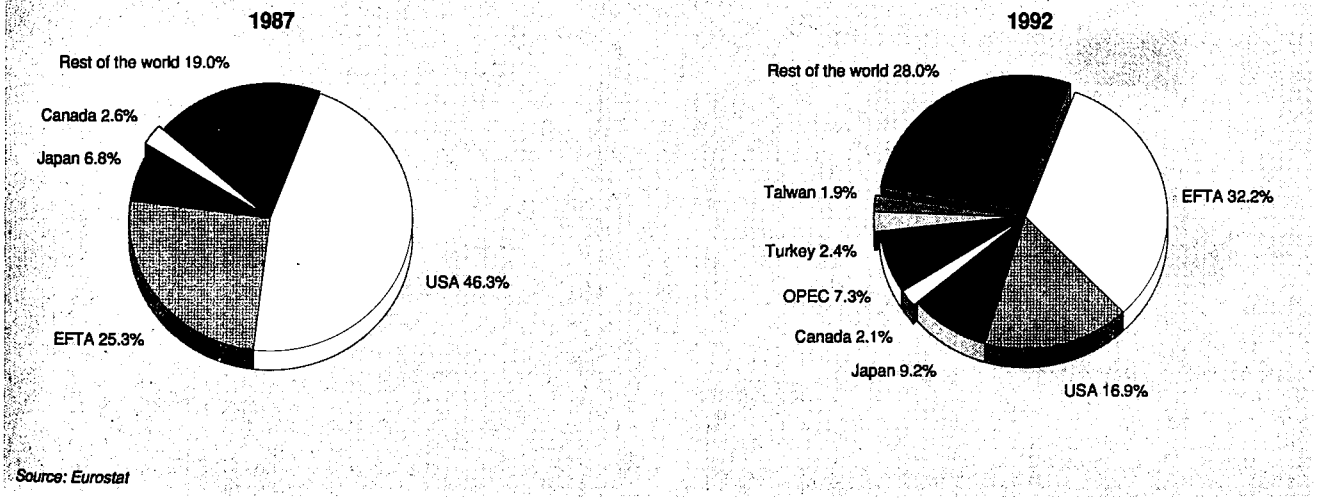
In the medium and long term, however, as motorisation rate continues to grow, demand for cars will continue to rise. Average car ownership figures vary widely across countries (as illustrated in Figure 12), it being nearly 600 units per 1 000 inhabitants in Western Germany, over 400 cars per 1 000 inhabitants in Italy, France and UK, but under 400 units per 1 000 inhabitants in Belgium, Netherlands and Spain. In countries such as Portugal, Greece and Ireland, penetration is considerably lower. There is further scope for increases in car ownership throughout the EC, especially in countries where car ownership per capita is currently low.

Trucks

Truck demand is highly correlated with trends in industrial output and in investment in plant and machinery.

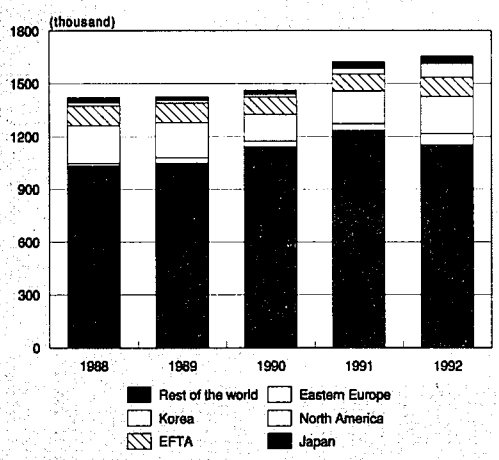
Long term truck demand is highly dependent on trends in the road haulage industry, which in turn is affected by the level of economic activity and by the competitiveness of road haulage with respect to other transport modes. Over the past two decades, the road haulage sector has consistently gained

Figure 7: Motor vehicles
Destination of EC exports



Source: Eurostat

Figure 8: Motor vehicles
Source of EC Imports (in unit terms)



Source: DRI Europe

market shares against rail and inland waterways; the trend is expected to continue.

Whilst demand for freight transport is expected to grow strongly in the future, harmonisation and deregulation of the road haulage industry is resulting in larger trucks being used much more efficiently. Whilst the EC truck fleet will continue to grow, it will be truck replacement patterns which will continue to be dominating factor in determining the overall levels of demand of new trucks.

The commercial vehicle market is highly cyclical. This market suffered dramatic downturns in the mid-1970s and the early 1980s but in the late 1980's, increased economic activity led to large growth in road freight transport demand, with a corresponding growth in the size of the EC fleet. This accompanied by high replacement demand (to replace the vehicles initially registered in the late 1970s) led to a boom in the truck market.

1990 saw the beginning of a cyclical downturn, and EC sales of trucks over 6 tonnes gvw declined by 6.7%. This trend continued in 1991 with EC sales declining by 2.3%. Post re-unification sales increase in Germany cushioned this decline but sales have dropped sharply in 1992 (down 11.3%) and in 1993 (down 25%), with only the UK showing signs of recovery.

Supply and competition

Cyclical under-utilisation of capacity is one of the key issues facing the European vehicle assembly industry at present. During the boom of the late 1980s, the industry was operating very close to full capacity. In this period the European assemblers enlarged total capacity, mostly through elimination of bottlenecks and new shift practices.

With the recent addition of new transplant capacity as well as capacity in Eastern Europe and a steep decline in sales, there are serious implications for vehicle manufacturers' profitability. Significant efforts are now being made to reduce break-even points with inevitable impact on employment.

The new challenge for European manufacturers is also from Japanese production in Europe, where Nissan, Toyota and Honda are already claiming state-of-the-art levels of quality and efficiency. Whilst Japanese imports are liable to remain broadly stable in market share terms, due the framework agreed by EC and Japanese negotiators, significant growth in Japanese manufacturers' market share will come from the output from these transplants.

Newly industrialised countries, for example from East Asia, and the East European automotive industries, are adding to the competition in EC. Although the volume of imports into the EC from these countries is still at a relatively low level, the EC market continues to be attractive to importers. Imports from Korea represent one recent growth area. In 1990 16 000 cars were imported into Europe from Korea; in 1992 this had risen to 80 000 cars. Plans for new models and distribution capacity indicate an ambition from Korean companies to raise European sales substantially. This would have a direct impact on European produced passenger car sales. Japanese car manufacturers played a key role in the development of the Korean and Malaysian automotive industries with Mitsubishi having close ties with Hyundai of Korea and Proton of Malaysia and Mazda having ties with Kia of Korea.

Several studies have shown that Europeans have a relatively high cost to productivity ratio. Figure 13 shows an international comparison of wages and social costs for 1992. The data shown in Figure 13 should be interpreted with caution, the high labour costs of the German industry in particular.

Employers in some countries of the EC have higher social costs and have less flexibility to make adjustments to the

Source: VDA 1992

labour force in response to changing commercial requirements than some of their global competitors.

Reduction in unit costs through productivity improvements in all parts of the supply chain, is the most important issue facing the industry.

1993 has seen vehicle manufacturers, workforce and unions in EC Member States responding to this challenge by taking steps to increase flexibility and improve competitiveness to internationally acceptable levels.

Production process

In recent years, changes in the production and operational philosophies in the motor vehicle industry have led to widespread adoption of the so called "lean production" techniques, resulting in lower levels of vertical integration and substantial changes in the nature of :

- relationship between vehicle manufacturers and its suppliers;
- co-ordination between product design and the production process;
- production and logistic operations;
- workforce responsibility, flexibility and skill levels.

Benefits have included reduction in the time from initial product concept to production, improvement in quality and productivity and increased flexibility and responsiveness.

Changes in the interaction between vehicle manufacturers and component suppliers are widely seen as instrumental to achieving global standards of competitiveness. These changes imply a restructuring of the automotive component supply chain with ramifications for the production and logistics processes (see section on Industry Structure). It is now common for the level of co-operation between vehicle manufacturers and suppliers to extend to joint development of complete subsystems and assemblies and their supply to the assembly plant on a Just-In-Time basis.

Shorter reporting lines, improved interfaces between management and workforce and better communication systems are all enabling concepts such as Total Quality Management, Quality Circles and Continuous Improvement programmes to be successfully implemented, with resulting improvements in productivity and quality. Flexible shift working is already leading to better utilisation of plant and equipment.

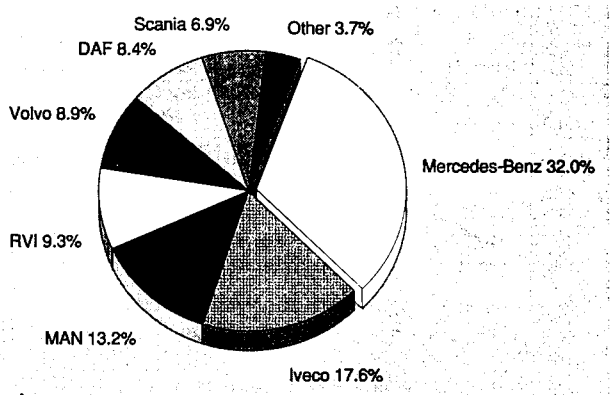
Major European vehicle manufacturers' EC market share for trucks > 6 tonnes gvw, 1992



Source: DRI Europe

Improvement in flexibility through reduction in machine set up time, optimisation of batch size and reduction in raw materials, work in progress and finished goods inventory are all part of common continuous improvement programmes; the current recession has placed additional emphasis on the need to reduce break-even volumes.

Simultaneous (or Concurrent) Engineering approach, involving the use of multi disciplinary teams to control a design project with the use of specific techniques such as QFD (Quality Function Deployment) and DFMA (Design for Manufacture and Assembly) and complemented by widespread use of tools such as Computer Aided Design (CAD) and Computer Aided Engineering (CAE) are widely implemented by car manufacturers.

New automated equipment has been introduced in those areas which represent the hardest and most repetitive working conditions. Widespread use of robotic painting and welding in the industry is improving quality, reducing labour costs as well as reducing the mundane and hazardous manual operations. Optimisation of capital to labour ratio is expected to continue to be a key instrument in improving competitiveness, and latest trends no longer feature ever-increasing robotisation of operations. Final assembly remains largely the domain of the manual employee, due to the variety and complexity of the operations. Whilst "state of art" work practices have been adopted in many of the newer vehicle assembly plants, EC manufacturers face the task of extending these practices to all their plants and all aspects of their activities.

INDUSTRY STRUCTURE

Companies

In the European passenger car market, five car manufacturers have market shares of between 10% and 12% and the top six manufacturers account for 75% of the market. The Volkswagen Group (including Audi and Seat) is the leader with market share of 17.5%. This is illustrated in Figure 14. The share of market accounted for by Japanese manufacturers has increased from 10.9% in 1989 to 12% in 1993.

Whilst several manufacturers have market shares of between 10% and 12% at European level, a different picture emerges at country level. The individual markets are still dominated by domestic manufacturers. Vehicle manufacturers tend to have larger distribution infrastructure in their respective domestic markets and nationalistic buying behaviour still plays a significant role in some markets.

In the market for trucks over 6 tonnes gvw, Mercedes-Benz is the clear leader; its market share rising from 23% in 1989 to 32% in 1992. Both Mercedes-Benz and MAN benefited from the reunification boom in Germany in 1992 and were

the only manufacturer to record higher levels of sales in 1992 than in 1989.

Strategies

Vehicle manufacturers' strategies are driven by the need to respond to long term trends affecting the industry. The current slump in motor vehicles sales is accelerating the implementation of certain elements of long term strategy and resulting in a re-examination of the more ambitious expansion programmes. Key long term trends which will continue to shape vehicle manufacturers' strategies include:

- Globalisation: the need to reduce traditional dependencies on domestic market and improving ability to compete initially at European level and subsequently on a global level. Whilst non-EC manufacturers have been investing in transplant production facilities in EC, EC manufacturers have been active in investing outside their home country as well in non-EC countries, particularly in Eastern Europe and North America. Asian markets are enjoying high growth rates and this region has already attracted a lot of attention. EC manufacturers are expected to increase their presence in this region, especially through joint ventures.
- Product Development : the rate at which new vehicle models are introduced into the market place has become one of the key basis for competition in the automotive industry. Car manufacturers are speeding up their innovation processes, restructuring their product and process activities (Simultaneous Engineering) to reduce the time from initial concept to production. Continuous improvements in the flexibility of designs and processes are needed to ensure maximum degree of customisation to consumer requirements. Evolution in manufacturers' market shares reflect the competitiveness of the manufacturers' rates of new model introductions.
- Improved competitiveness through improvements in organisational processes: cost structure, productivity, quality and flexibility have all become crucial elements of competitiveness.

The current recession in the industry has highlighted the need for all vehicle manufacturers to accelerate the restructuring programmes needed to achieve global levels of competitiveness. Manufacturers are

- restructuring their design and production processes (see section Production Process);
- re-evaluating the degree of vertical integration, outsourcing policies and supplier relationships;
- improving workforce skill levels.

In the short term, each EC manufacturer is faced with different priorities and this is reflected in their strategies.

The late 1980s and the early 1990s saw reduction in the number of independent motor vehicles manufacturers, as niche producers were acquired by volume manufacturers. As product and business development costs escalate, partnerships and alliances are increasingly be regarded as providing the most cost effective method of developing a competitive product portfolio and reducing dependence on domestic markets.

Alliances between Ford and Iveco in the light commercial vehicle market, between PSA and Fiat and Ford and VW for development and production of a multi-purpose vehicle and between Ford and Nissan for development of a four wheel drive vehicle are examples of product development and joint production alliances.

Rover and Honda worked together on a number of collaborative projects before taking a cross share holding of 20% in each others UK businesses in 1990. Both companies now produce versions of a jointly developed car and further collaborative projects are anticipated.

ENVIRONMENT

The reduction of emissions achieved by the EC motor vehicles in the past few years industry has been impressive. However, further technical improvements are already becoming harder to achieve and progress in the areas of driver education, more frequent and stringent vehicle inspection and the use of road telematics to reduce traffic congestion are more likely to prove to be more effective strategies for reducing emissions.

Since the early 1970s, EC legislation has controlled the emission of both unburned hydrocarbons and carbon monoxide. In 1978, oxides of nitrogen also became subject to control. The "Luxembourg Agreement" of 1985 marked a significant step for future emissions standards and effectively initiated developments which were to lead to directive 88/76/EEC and the requirement for 3 way catalyst system.

The EC has moved rapidly in introducing a series of further light duty vehicle directives, 89/458/EEC and the present newly consolidated Directive, 91/441/EEC. This directive added a high speed element to the standard test cycle to provide better reflection of emissions in suburban driving situations. In December 1992, the Commission issued a new draft directive aimed at tightening the car limits still further. This directive incorporates a totally new annex for conformity of production (COP) testing. These limits are expected to come into force in 1995/1997.

Emissions of light commercial vehicles have been reduced to the level of passenger cars emissions with Directive 93/59/EEC of June 1992. Following the introduction of the most recent emissions standards at the end of 1992, passenger car CO emissions will have been reduced by over 90% com-

pared to 1970 levels and HC plus NO_x emissions by 80% from 1970 levels.

During the last decade, the European automotive industry has invested heavily in improving the environmental performance of vehicles. For the manufacturers, the technical changes required to meet these regulations were substantial, with the consequence of higher costs which couldn't always be passed on to consumers. For gasoline engine passenger cars, the need to have closed loop catalytic converter systems also meant that fuel injection and management systems were required.

During the next decade, whilst vehicle ownership levels and traffic levels will continue to increase, older models will be replaced by models equipped with 3 way catalyst systems and the European car parc is expected to produce substantially less emissions of CO, HC and NO_x than today.

Legislation for heavy duty diesel vehicles followed along a similar path. Regulation No. 49 was introduced in 1982 and established limits for CO, HC and NO_x. Directive 88/77/EEC lowered the emissions limits but it was not until the introduction of 91/542/EEC that fundamental changes to technology were signalled.

Euro 1 regulations came into force in 1992-93 and Euro 2 limits will come into force in 1995-96. Complying with Euro 2 limits without increasing fuel consumption and without using expensive after-treatment equipment presents a major technical challenge for the European industry. A further tightening of emissions limits (Euro 3) can be expected before the end of the decade but this is still under discussion.

With the introduction of new limits for cars and trucks, a complete set of stringent standards, acknowledged to be as severe as the US 1994 requirements will be in force by 1996. These will set the EC on course for substantial improvements by the end of the century

Road transport is estimated to account for around 20% of total European carbon dioxide emissions and reducing fuel consumption is the only method of reducing these emissions. Vehicle manufacturers have made substantial progress improving fuel efficiency, (for example through reducing drag factors and improving the combustion process and weight reduction) but in order to contribute to the goal of stabilising carbon dioxide emissions at 1990 levels by the year 2000, improvement in both traffic efficiency and fuel consumption will be needed.

Disposal/scrappage of vehicles at the end of their lives, is another issue receiving attention, by the vehicle industry, regulators and environmental groups. Some of the manufacturers have already set up recycling plants and EC manufacturers appear to be leaders in this field.

MONITORING

Until the end of 1992, various EC countries imposed quotas on vehicle imports. Table 7 summarises the restrictions in force in 1992 and the market share of Japanese manufacturers (transplants and imports).

One consequence of the further opening of the borders to trade is that national restrictions on Japanese motor vehicles imports have to disappear. A transitional period for this process has been agreed.

The EC and Japan signed an "Understanding" in July 1991, aimed at establishing the ground-rules for Japanese access to the European Community markets. 1993 represents the first year of the new transitional arrangement for Japanese manufacturers to reach a fully open EC markets and under the agreement Japanese manufacturers will link their exports volumes to developments in the European market during the seven year transition period.

The agreement assumes an EC market for cars and light commercial vehicles up to 5 tonnes to be 15.1 million in 1999. Total sales in EC by Japanese manufacturers are projected to be 2.43 million units of which imports into the EC will be 1.23 million units. This implies Japanese market share of 16.1% in 1999.

The 1991 EC-Japan understanding is based on the principle of fair sharing of market increases as well as downturns and an understanding that the EC market will be fully open at the end of 1999.

OUTLOOK

The EC car market remains in deep recession and is expected to show a decline of 15% in 1993 compared to 1992. Of the major EC markets, Germany, Italy and Spain are all expected to show reductions in sales of over 20% and while the declines in France are only marginally lower, the UK market is recovering and expected to show increases of over 10% over 1992.

The recession in the EC shows signs of having reached a bottom and attention is turning to the timing and strength of recovery in 1994 and 1995. According to DRI, total EC sales are expected to increase in 1994 by around 3.4% but sales in Germany and Italy are expected to be flat with the French, UK and the Spanish markets showing small rates of growth.

Table 8: Motor vehicles

Source: DRI Europe

1995 should see higher rates of growth in all the major EC markets; total EC sales are expected to increase by 7.5% between 1994 and 1995. Sales are not expected to reach 1992 level of 12.6 million units until 1996.

1993 will be remembered for the sharpest downturn in European production since the 1974 oil price induced recession. Output is expected to fall by 15.8% or nearly 1.9 million units to 10.9 million units. Car production is expected to recover to 11.2 million units in 1994, with Japanese transplant production growth accounting for a significant part of this growth, increasing from 307 000 units in 1993 to 411 000 units in 1994.

After achieving a 5.1% growth in 1992 (re-unification boom), the light truck market is 20% decline in sales in 1993. An 8% recovery is expected in 1994 and sales will not reach 1992 levels until 1996.

EC's 4-year truck sales slowdown has taken a severe turn for the worse in 1993 and the market is set to decline by around 23%. Sales are down in markets with the exception of the UK. Germany, Spain and the Benelux countries, in particular, are now suffering major falls in demand. demand prospects for 1994 remain weak and the market is expected to remain flat. A slow revival of demand is not expected until 1995.

All EC vehicle manufacturers are expected to continue to streamline their operation to reduce costs and improve competitiveness. Introduction of Four wheel drive and Multi-purpose Vehicles dominate short term car product development programmes. Joint development and production, already used with success in such programmes is expected to continue as complexity increases, development costs escalate and manufacturers look for cost effective alternatives

Apart remaining financially viable in a difficult market, truck manufacturers resources will be focused on meeting 1995-96 emissions legislation (Euro 2).

Written by: DRI Europe
The industry is represented at the EC level by: Association des Constructeurs Européens d'Automobiles (ACEA). Address: Rue du Noyer 211, B-1040 Brussels; tel: (32 2) 732 5550; fax: (32 2) 732 6001.

Motor vehicle parts and accessories
NACE 353

The motor vehicle parts and accessories industry employs nearly the same number of people (approximately 1 million) as in the motor vehicle industry it supplies. Unlike the motor vehicle industry, the parts and accessories sector presently includes a sizeable number of small firms; however, greater industry concentration is expected as trends in vehicle production techniques increasingly demand a tighter integration with the parts and accessories industry.
The business climate for parts and accessories is strongly tied to the cyclical performance of the motor vehicle sector. While the supply of parts for new cars closely reflects the fluctuations in new car demand, there are superimposed on this several trends with longer term influence. On the positive side, there has been a steady upgrade in car model mix to larger and better equipped models. At the same time the equipment levels on all vehicles is continuously improving, thereby increasing the value to the components suppliers. Acting contrary to this however is the demand for improved durability and life expectancy of all vehicle components which has a significant effect on replacement demand.
While the European car parc will continue to grow through the 1990's, much of the new car sales growth will be taken by the Japanese transplants, and the opportunity and challenge for the European parts industry is to supply this demand and in doing so, raise its performance to best world standards.

INDUSTRY PROFILE

Description of the sector

The parts and accessories market is traditionally broken down into two main segments. The first is the market for original equipment manufacturers (OEM), that is the parts that car manufacturers buy from specialised producers for assembly into new vehicles. The second is the replacement market which comprises parts destined for repairs and automotive accessories.

The precise coverage of the component industry in terms of products is difficult to assess. Data which corresponds to NACE 353 (parts and accessories for motor vehicles) is too narrow in its coverage as its excludes for instance heavy construction vehicles, tire manufacturers who supply vehicle manufacturers and most of the electrical and electronic components that are so important in vehicle manufacturing today. Furthermore, existing statistics which are based on the production of companies of more than 20 employees slightly understate the value of production of the fragmented parts and accessories industry.

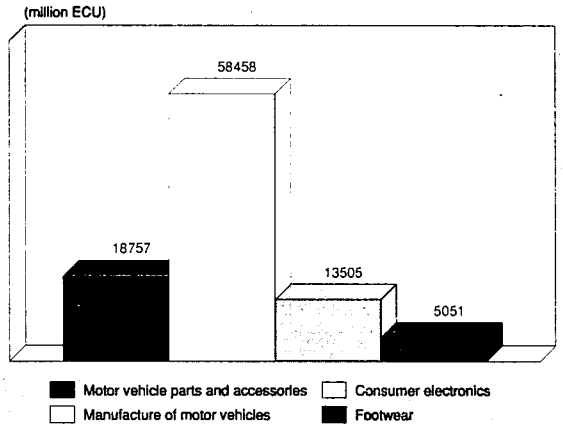
A study carried out for DGIII, also sourced in this monograph, covers a wider range of products than the strict NACE definition.

Recent trends

With a turnover estimated at almost 100 billion ECU, the EC parts industry represents about half of the size of the auto industry. In terms of employment, however, the parts and auto industries are much closer in size with each exceeding 1 million workers.

Within the parts and accessories sector, independent manufacturers account for nearly 90% of both production and employment, the remaining 10% stemming from subsidiaries of vehicle manufacturers.

Figure 1: Motor vehicle parts and accessories Value added in comparison with other industries, 1992



Source: DEBA

Turning to the breakdown of production by Member States, leading vehicle producing countries are also leading parts producers. Germany accounts for more than 45% of EC turnover. It is followed by France, Italy, the United Kingdom and Spain. Similar rankings can be observed in the auto and parts industries. This is explained by a frequent geographical clustering of parts manufacturers in proximity to vehicle production sites.

Over the 1980s, the industry has been expanding somewhat faster than its main industrial end-market, the auto industry. It has grown consistently between 1982 and 1990 but remained flat in 1991 and dipped during the second half of 1992, following the downturn in the car market.

Car makers are expecting new car demand to drop approximately 15% in 1993 from the previous year's 13.5 million vehicles sold. During the first five months of 1993, new car sales dropped by 20% in Germany alone and fell in 15 out of 17 car markets across Europe during the same period. This will directly affect demand of parts suppliers, although they have the replacement parts market to marginally help buffer the fall in original equipment demand.

Productivity improvements in the parts industry have been marginally faster than improvements for the vehicle manu-

Source: DEBA

facturing industry, on average. They have been achieved thanks to rapidly expanding production rather than lay-offs, and as a result, employment was still higher in 1991 than in 1982. A substantial proportion of productivity gains have been transferred, by negotiation and sometimes by imposition, to the OEMs so that inflationary price adjustments of parts and accessories have lagged far behind vehicle price increases. OEMs have not realised all their differential pricing gains as net cost savings in cash, but have partially reinvested them in enriched vehicle equipment, thus keeping their suppliers' level of activity buoyant well into 1992.

The sharp downturn in vehicle demand and production did not become visible until 1993 on a year-on-year basis and has clearly affected suppliers directly. The industry is now only beginning to suffer from the type of painful restructuring endured by car manufacturers during the first half of the 1980s.

International comparison

Once relatively sheltered from foreign competitors, EC component suppliers are now facing increased domestic, European and worldwide competition. This trend, which is tracing a new international division of component production, is fostered by several factors:

- The creation of the single market is forcing European suppliers to intensify cross-penetration of each others' markets.
- The increased internationalisation of EC car producers implies geographically enlarged supply bases, with a tougher competition prompting a constant search for lower cost purchasing alternatives.
- Japanese investments for car assembly plants within the EC are also drawing the attention of Japanese component makers on the European market.

The Japanese component industry has several serious competitive advantages over its European counterpart. Although smaller than the EC industry (280 000 people in the first tier suppliers compared with 1 million people), the Japanese component industry is much less fragmented and already benefits from the tiered structural shape which the EC industry is presently constructing. Aside from the 40 000 sub-contractors who form the second and third tiers of the pyramidal structure of the Japanese industry, there are 310 first tier component suppliers, compared to 3 200 companies in Europe. The average size of the first tier enterprises is 900 people each compared with the European average of 270. Including the sub-contractors, the per company average of employees would be just 5.5. Of the Japanese firms, 45% employ more than 500 people, compared with only 10% in Europe.

Japanese companies have close organisational and financial links with vehicle manufacturers, and most of them are attached to groups around a major manufacturer. For instance, Nippondenso (the largest Japanese component producer) is partly owned by Toyota. Many component producers are owned by more than one vehicle producer. This system has resulted in an industry which is more specialised and concentrated than the European industry.

According to a study undertaken for the EC Commission, the EC industry remains competitive with Japan in terms of technology, but suffers (in its first-tier segment) from several disadvantages such as lower labour productivity, lower product quality, lower stock turns, slower design and development cycles.

When the Japanese car manufacturers started building cars in North America, their inclination was to put pressure on their traditional suppliers to come with them and set up new plants. While they needed high local content, they did not think that existing US component companies would be willing or able to provide them with components and systems of the quality and price they were used to from their close knit keiretsu family suppliers. As a result, Japanese component companies set up over 300 plants in the USA during the 1980's to support the growing transplant production.

For several reasons this has not been repeated in Europe. One reason is that the projected volumes of car build in Europe are too small to justify setting up new plants solely for the transplants. The financial performance of the Japanese com-

ponent companies in the US to date has been a growing cause for concern, and with falling margins throughout the Japanese car industry, they are not looking to repeat this mistake. Another reason was the intense political concern in Europe over the arrival of the Japanese transplants. The Japanese car companies have taken pains to reassure Governments that they will be good Europeans and one way of doing this has been to choose European component suppliers. While there have been some 50 new components plants set up by Japanese companies to date, and a few notable acquisitions or joint ventures (such as Calsonic and Nippondenso), for the most part the Japanese car producers have selected existing European companies to supply their components. What is more, the Japanese car companies, particularly Nissan and Toyota, have set out to where necessary, to bring these companies up to Japanese standards, and in so doing they are making a real contribution to the European component industry. In Europe there has traditionally been an adversarial relationship between the OEMs and their suppliers with the OEMs continuously demanding lower prices and threatening to use alternative suppliers. While this is now beginning to change, the Japanese, while equally tough, have been much more concerned about their suppliers' costs, and helping them to improve their quality and efficiency, and in doing so have developed more constructive and certainly more long-term partnerships. The long-term result of the arrival of the Japanese transplants in Europe will be to accelerate the restructuring of the components industry and to help raise its standards to world class. The benefits of this will be available, not only to the transplants but to all European OEMs.

Foreign trade

The internationalisation of the industry has been a determining factor in the substantial increase in foreign trade experienced since 1980. The expansion of intra-EC trade has been particularly rapid in recent years as intra-EC trade reached the 14 billion ECU level in 1991, a threefold increase compared to 1980. The industry remains essentially intra-EC oriented

Figure 4: Motor vehicle parts and accessories

and intra-EC imports are more than 4.4 times higher than extra-EC imports, a ratio which is usually in the 2 to 2.5 region for most of the engineering and transport industries. Given the difficult nature of defining the industry, a word of caution regarding trade figures is in order. Statistics on trade are not necessarily related to the independent component industry's products but frequently include the movements of the OEM's own in-house products to and from assembly plants across national borders, thus causing significant distortions in the data.

The industry is a traditional balance of payment earner. After a peak in 1985 when it reached 6.5 billion ECU, the EC trade surplus decreased to almost 2.5 billion ECU in 1991. The second half of the 1980s were marked by a rapid increase in extra-EC imports and a relative stagnation in extra-EC exports. This situation is partly attributable to a change in the classification of trade statistics and, more importantly, to the rapid growth of car demand experienced in Europe between 1986 and 1990. During that period, European parts producers were predominantly busy trying to meet increased demand from the EC car manufacturers. As a result, their export effort remained limited, while imports were boosted by the buoyancy of the EC car market. Nevertheless, the trend was not really reversed in 1990 and 1991 when the European vehicle demand was somewhat weaker. The dwindling European trade surplus certainly signals some of the structural problems presently encountered by the European industry.

Extra-EC exports are relatively diversified in terms of destinations with the EFTA countries and North America respectively accounting for about 27% and 15% of total shipments as developing countries also remain an important end market with a share of more than 35%. In terms of extra-EC imports, flows are more concentrated with 50% of total non-EC supply originating from the EFTA countries, Sweden in particular. With a share of 20%, Japan is the second largest supplier to the EC. The share of trade with North America has dwindled considerably in recent years both in terms of imports and exports. With regard to the EC trade surplus, Germany continues to be the major contributor.

MARKET FORCES

Demand

Demand for OEM is, by definition, linked to the level of activity in the automotive production. Some segments of OEM, however, benefit from a faster growth than the auto market

in general. This situation corresponds to components whose rate of penetration in vehicles is still on the rise. Such is the case, for instance, of equipment which a few years ago was optional (primarily in the upper car segment) and are now increasingly fitted as standard equipment on most models. Some examples include: electronic fuel injection, anti-lock brakes and air conditioning systems. In addition, original equipment manufacturers have largely benefited from a trend towards increasing outsourcing by vehicle makers.

On the other hand, demand for replacement parts depends on the usage of automobiles and other motor vehicles, as opposed to new sales. Demand is likely to be more stable in this market than in the original equipment market. The replacement parts market differs greatly from country to country. Market features in the various EC countries depend largely on the annual mileage per vehicle, the age of the car parc and the existence of specific legislation with regard to obligatory inspection of vehicles when they reach a certain age.

Supply and competition

The supply of original equipment is undergoing fundamental structural change. Increasing internationalisation of vehicle manufacturers calls for the emergence of large international (sometimes worldwide) component manufacturers. In addition, the pattern of relationships between manufacturers and suppliers is being substantially modified and a rising share of the value added generated in the auto industry is transferred from vehicle to component manufacturers. To some extent, the balance of power is now shifting from the former to the latter.

A major reason behind such a change arises from the necessity for car manufacturers to limit investment and resources to essential activities which represent the core of their industry. One method is to increase outsourcing and to pass on the responsibility for product development, manufacturing and quality assurance functions to their suppliers (systems suppliers and/or specialised affiliated companies). Component producers contribute to the competitiveness of the industry, and the two sectors become increasingly interdependent.

Although conceiving, designing and producing in accordance with manufacturers' specifications, the component producer is increasingly technically autonomous. This is typically the case of systems suppliers who possess proprietary technology and product know-how. As a result of these transfers of value added, car manufacturers reduce the number of their suppliers to a smaller number of large producers which will in turn outsource part of their output to smaller companies, the whole supply chain thus posting a tiered structure.

The current pattern with regard to outsourcing practices within the EC automotive industry differs greatly from manufacturer to manufacturer. It is generally accepted, however, that the overall level of outside purchasing carried out by the European car manufacturers (60% to 70% of total component requirements) is more important than in the US industry (40% to 50%) but less than in Japan (around 80%).

Turning to the replacement equipment, it is generally estimated that about 70% of the market supplied by independent parts manufacturers, with the remaining 30% is controlled by the car manufacturers via their distribution and service networks. With regard to the industrial origin of such parts, however, car manufacturers comprise only a 10% share of the market.

Production process

The nature of the automotive products, together with shorter product life cycles, puts increased emphasis on the technological content of automotive parts. Increased use of electronics and new materials leads to increased collaboration with other leading high-tech industries and a sizeable investment in R&D organisations and equipment at all levels of the pyramidal structure of the sector. Once almost exclusively oriented towards applied engineering, the existing R&D resources of the sector are now taking greater initiative in terms of new technologies offering improved performance, fuel economy, emission control, safety and comfort. Black-box engineering is becoming an increasingly standard practice within the industry requiring enlarged R&D functions utilising up-to-date CAD (Computer-aided design) equipment and involvement at an early stage of the development process of new vehicles.

The competitive pressure on costs, prices, quality and delivery standards has led the industry to restructure in a parallel manner to the car manufacturers. Automotive parts suppliers compete on the basis of price as well as delivery and quality. Just-in-time, zero-defect, CAM (Computer-aided manufacturing), automation, and faster communication systems, are some of the features which have allowed substantial productivity gains while improving flexibility and allowing self quality assurance schemes to be put in place. This process (requiring sizeable investment and a recourse to skilled manpower) is far from being complete, especially among small to medium-sized producers.

INDUSTRY STRUCTURE

Companies

The industry is basically composed of three types of producers: the large diversified producer, whose output consists of many products in addition to auto parts (Bosch and Siemens in Germany); the larger producers specialising in auto parts (Valeo in France, Magneti-Marelli in Italy); and hundreds of SMEs producing auto parts on a smaller scale.

The trend towards more component outsourcing by car manufacturers combined with fundamental changes in the nature of the industry are having a dramatic result on the overall numbers of independent operators present in the industry. Vehicle manufacturers are cutting back on the number of suppliers and committing larger shares of their purchasing requirements to preferred systems suppliers. These systems suppliers outsource part of their work to second or third tier suppliers. Overall, during the past five years, it is estimated that the number of independent first tier companies supplying a single vehicle manufacturer has been reduced by less than 25%. A large part of this reduction has been achieved via mergers, takeovers and consolidations among previous competitors or companies having industrial synergies, such as Valeo/Neiman and Magneti-Marelli/Solex/Jaeger/Weber. However, the actual number of suppliers directly servicing the OEMs has decreased by approximately 50%. Supply relationships are, however, very difficult to estimate given the various numbers of models produced by the manufacturers and the underlying groups of parts suppliers supporting each model line. Various combinations of suppliers are possible leaving these figures on decreasing numbers of suppliers a rough estimate.

In spite of the increased presence of large international companies, the original equipment sector continues to be very fragmented. The average size for firms is about 270 people, but 64% of these enterprises employ less than 100 persons. Only 4% of the companies account for 50% of total employment (firms with more than 1 000 employees). This is essentially due to the nationally based nature of parts procurement. Although intra-EC trade has grown to extremely high levels during the past decade, most vehicle manufacturers continue to source largely from their domestic suppliers. For instance, Daimler-Benz procures approximately 90% of its needs from Germany, Renault, about 70% from France, and Fiat, about 85% from Italy.

The independent German industry dominates the European market with over 45% of the total European production (estimated at 79 billion ECU in 1988). This strength comes from the sheer size of the German motor vehicle industry, the importance of the upper market segment, and from strict legislation on car maintenance. The large German firms have played a major role in developing new products as illustrated by Bosch (the world's largest unaffiliated auto parts producer) which is a pioneer in the fields of fuel injection and anti-locking brake systems. Bosch alone is estimated to account for nearly

Table 5: Motor vehicle parts and accessories

Source: Boston Consulting Group

a quarter of German production. The leader's vitality aided many smaller firms and contributed (together with other large firms such as ZF, Fichtel and Sachs, Teves, and VDO) to the unchallenged leadership of Germany within the European ASI.

The French industry is the second largest in Europe, with about 23% of the European total. Its structure is still characterised by a large number of nationally oriented small to medium-sized producers. Major restructuring has taken place in recent years, led by the three international scale emerging groups: Valeo, Bertrand-Faure and ECIA (PAS group).

The Italian industry (which accounts for about 14% of the European production) is dominated by the Fiat group. The leading producer is Magneti-Marelli (a subsidiary of Fiat) which now has an increased presence in all major European markets. Widely dispersed in the early 1970s, the sector is being tightly restructured under the influence of Fiat.

The United Kingdom components industry (10% of the total sector) has been badly hit by the decline of British vehicle production and its excessive dependence on domestic manufacturers. The major British component producers (such as Lucas, T&N and GKN) have taken advantage of the existence of an important replacement market, together with the increased rate of (Japanese) investment in automotive production in the United Kingdom, to expand overseas through investment and acquisition and have strengthened their position in a home market with considerable potential.

The Spanish industry has emerged since the late 1970s as another important producer of automotive components, having now reached a size comparable with the United Kingdom. Originally developed to comply with local content requirements, the industry has grown considerably since the early 1980s, thanks to the increased importance of Spain as a car manufacturing country. However, most of the components producers present in Spain are subsidiaries of foreign companies.

Strategies

As the Japanese car industry has shown, the necessity for the car manufacturer to rely increasingly on a smaller supply base implies fundamental changes in the structure of the sector. This means an increase in the sharing of high-value added products, faster growth in R&D expenditure and a need for organisations to adapt to new constraints (excellence in quality, delivery and price, not to mention production flexibility). Finally, there is a need to share productivity gains on a continuous basis with car manufacturers and to finance a growing share of productive investments (tooling and specific equipment) necessary for tailor-made products.

In return, car manufacturers are offering longer term purchasing commitments and closer cooperation, both of which contribute to improved stability in mutual relationships.

As a result of this process, the component industry will increasingly be reshaped into a pyramidal structure. First tier suppliers with a worldwide presence, proprietary technology and scale economies will design and supply full systems rather than single components. They will outsource part of their work from smaller second or third tier suppliers. The observed past trend toward increased concentration will continue during the decade but a further radical reduction in the number of independent producers is unlikely since many will survive as second or third tier suppliers.

OUTLOOK

Automobile sales in 1993 are expected to remain depressed. A sales increase of 1.7% is forecast for 1994 and a healthier increase of 7% per year during 1995 and 1996 is expected. This also places a cloudy outlook for automobile OEM suppliers for the near-term. The medium term outlook is brighter with expected increase in demand for new vehicles. The main source of overall market growth will come from the Asia-Pacific region (excluding Japan), particularly China, Malaysia, Thailand, Taiwan and South Korea.

With regard to the original equipment market, most of the growth will result from: vehicles increasingly fitted with such standard equipment as automotive electronics, anti-pollution devices and more efficient safety restraint systems; the general "up-market" move in car demand with customers demanding more equipment, comfort and power; and the increase in component outsourcing by car manufacturers with high added value.

With regard to the replacement market, it should be remembered that this segment is governed by the number and the state of vehicles on the road, as well as changes in consumer behaviour. These changes can either come about spontaneously, or be spurred by legislation on vehicle testing or compulsory maintenance. The constitution of the single market makes it likely that such measures will spread to countries where they have been absent until now. This, combined with the consumer's desire for safer and more comfortable driving, and the expected growth of the total car park in Europe, implies that there will be promising demand growth in the replacement parts market. Technological advances should, however, result in more durable parts and slow replacement cycles. Increased opportunities in East European markets will also have a positive influence on demand for automotive components.

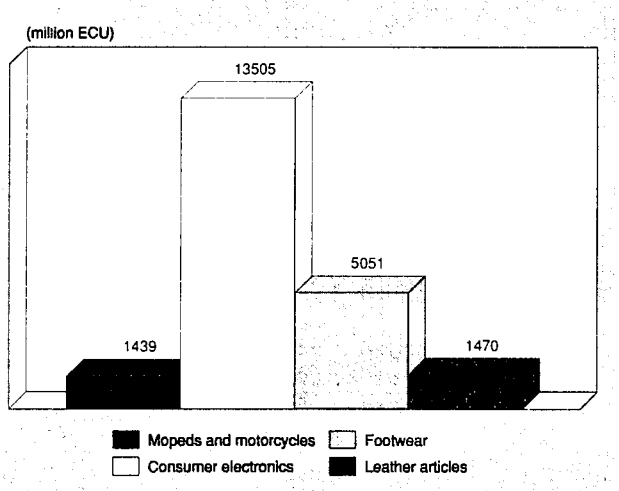
The overall outlook for growth in motor vehicle parts and accessories is good, but major adaptation and competitive efforts from the industry are still required.

Written by: DRI Europe
The industry is represented at the EC level by: Comité de Liaison de la Construction d'Equipments et de Pièces d'Automobiles (CLEPA). Address: 93 Rue de Stassart, B-1040 Brussels; tel: (32 2) 511 2919; fax: (32 2) 513 3802.

Mopeds and motorcycles
NACE 363

Apparent consumption of mopeds and motorcycles has steadily increased in the EC from 1986 to 1992, although from 1991 to 1992 the growth rate was less than 1%. Production of mopeds and motorcycles in the EC experienced two years of negative growth rates from 1990 to 1992. As a result, average real growth rates of extra-EC imports grew at a rate of nearly 18% from 1988 to 1992. External trade balance continues to pressure the EC moped and motorcycle industry to take measures to become more competitive (restructuring, mergers, licensing production to low-cost labour markets, investment in R&D, etc.) Intra-EC trade has steadily increased, aided partially by the presence of foreign manufacturer production and assembly plants in EC Member States. The outlook for this industry is not favourable in the short-term. A decrease in production and consumption rates from 1993 to 1994 is expected; there are prospects of a sluggish increase in demand for, and production, of EC produced mopeds and motorcycles beginning later in 1994

Figure 1: Mopeds and motorcycles
Value added in comparison with other industries, 1992



Source: DEBA

INDUSTRY PROFILE

Description of the sector

NACE 363 comprises the manufacture of mopeds, motorcycles, scooters, bicycles and their parts and accessories (bicycles are discussed in another monograph). The largest component of the industry is the production of mopeds and motorcycles where mopeds are defined as motor driven vehicles of two to three wheels with an engine displacement not exceeding 50 cc and a maximum design speed of 50 km/h. Motorcycles are motor driven vehicles with two to three wheels with an engine displacement greater than that of mopeds.

Recent trends

In volume terms, Italy, Spain and France were responsible for 90% of the EC production of mopeds and 86% of motorcycles: Italy, alone, was responsible for 43% and 68% of moped and motorcycle production, respectively. Italy exported 30% of its motorcycle production and 20% of its moped production to non-EC countries in 1992; their exports made up 83% and 51%, respectively, of the EC export totals for that year. Italy and Germany, together, were responsible for 97% of extra-EC exports of motorcycles and mopeds Although Belgium was responsible for only 2% of the 1992 EC total production of mopeds, it exported 85% of its production; this made up just over 10% of the extra-EC moped exports.

France regained second place with 25% of EC moped production and 6% of motorcycle production, while Spain decreased its share of EC motorcycle production from 23% to 12% and slightly increased its share of EC moped production from 18% to 20% from 1991 to 1992.

Production of mopeds and motorcycles stagnated during the first half of the 1980s, such that by 1987 EC output was approximately the same as that of 1982. Consumption began to increase in 1987 with production levels increasing the following year. Production in current prices increased 36% from 1987-1992 at an average rate of 4.6%, but has shown two consecutive years of decline from 1990-1992. All Member States listed as producers showed decreases in production volumes during the same period (with the exception of the United Kingdom whose figures remained the same).

Through all this, employment levels have steadily declined by a total of -35% over the past decade; a 6% decrease in numbers occurred from 1991-1992 alone. Employment in 1992 was less than half of what it was in 1980. The increase in EC demand, the recent decrease in production and a three-fold increase in the trade deficit more than partially explains the steady decline in the number of this industry's workers.

During the fourth quarter of 1993, the Piaggio Group (I) announced the closure of its Gilera subsidiary's Arcore plant. Gilera will now only manufacture one line, the Typhoon 50 cc scooter. Production of this will be shifted to Piaggio's Pontedera plant. This cut back will result in a 40% decrease in Piaggio's 125 cc product, reducing total 1993 production of that product class to 77 000 units, down from 100 000 in 1992.

International comparison

From 1983 to 1992, EC production in current prices experienced a 40% increase; EC production in constant 1985 prices increased by 11.6% from 1985 to 1992. Production in current prices in the USA decreased 3% from 1983 to 1992. From

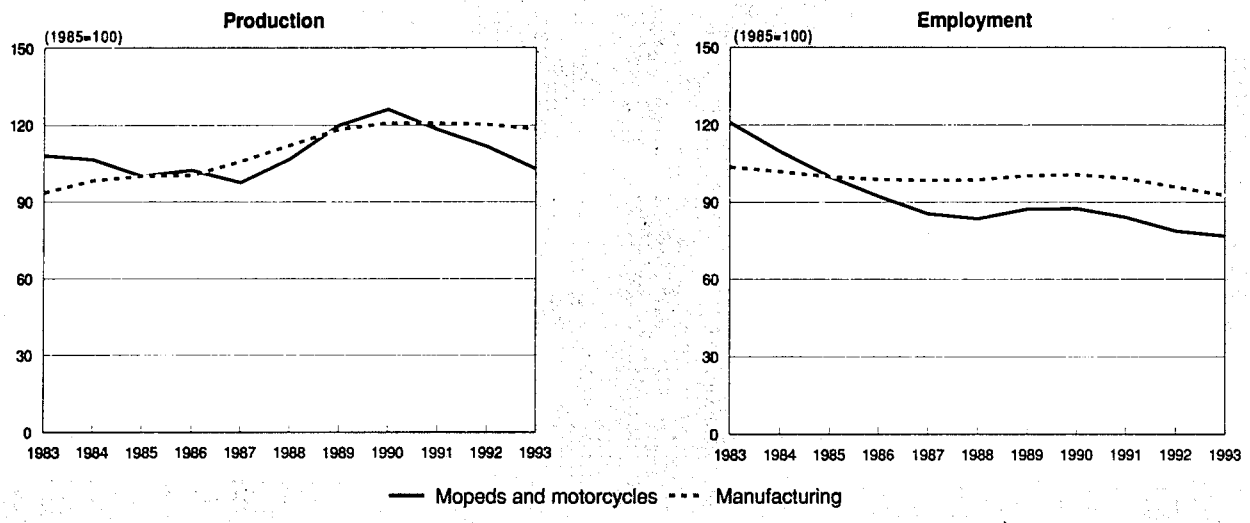
Figure 3: Mopeds and motorcycles
Production in constant prices and employment compared to EC manufacturing



1993 are DRI and Eurostat estimates.
Source: DEBA

1985 to 1992, however, production in constant prices increased by 47% with the help of strong years in 1989 and 1991. Japan's production in current prices jumped 152% from 1983 to 1992 and in constant prices, it rose by 86%, surpassing both EC and USA growth rates even though total numbers produced in Japan fell during the 1980s. Average annual production rates in constant prices from 1985 to 1992 for the EC, the USA and Japan were 1.8%, 6.9% and 9.8%, respectively.

Foreign trade

Extra-EC exports in terms of value (1992 prices) was 12% of the total value of 1992 production. In volume, EC Member States exported 20% of units produced (18% of mopeds and 29% of motorcycles left the EC as export). Italy was the EC leader in exported units with 60% of the total exported (51% of total mopeds and 83% of total motorcycles that left the EC were built in Italy). France was second with 27% of the 1992 EC exports, followed by Belgium with 10%. Spain, the EC's third largest producer of mopeds and motorcycles, was responsible for only 1.3% of EC exports. Extra-EC exports recently displayed slight increases in value terms (up 16% from 1988 to 1991 in current prices) only to fall again in 1992 by 7%. The destination of EC exports has remained constant from 1987 to 1992. The EFTA countries receive nearly 38% of extra-EC exports. The USA purchased 13%, followed by Japan who took 7%.

During the period 1988-1992, extra-EC imports increased by 130%. The export/import ratio has decreased during the past decade from a high of 0.77 in 1985 to the low of 0.19 in 1992. The majority of imports to the EC (59%) comes from Japan. This has changed since 1987 with the recent transfer of Japanese production to the East Asian NICs who now are major importers to the EC of Japanese (and EC Member State) brands licensed to these countries to take advantage of their low labour costs.

Intra-EC trade has experienced strong growth during the 1980s and into the 1990s. Internal trade increased 92% in current prices from 1988-1992, and demonstrated a 14% increase from 1991-1992 alone.

MARKET FORCES

Demand

Overall economic conditions, personal disposable income and trends in demographics are the main drivers in consumer demand for mopeds and motorcycles. The recent recession has only served to slow the increase in EC demand for these products. One possible explanation is that mopeds and motorcycles become a more attractive means of transportation when considering purchase, operating, maintenance and insurance costs. Also, European cities are now considering passing laws, as has been done in Rome and Milan, to limit automobile access to sections of city centres to reduce pollution and traffic congestion.

Increased traffic volume can have a negative effect on demand as safety concerns surface regarding the operation of mopeds and motorcycles in dense traffic. Also, increasing safety requirements for drivers of these vehicles (helmet requirements, training, testing and licensing) serve to distract from the attractiveness of purchasing a moped or motorcycle.

Of the approximately 7.2 million motorcycles in operation in the Member States during 1992, 78% were in the EC's major markets of Italy (34%), Germany (17%), the United Kingdom (14%) and France (13%). These countries experienced double digit growth rates in the numbers of motorcycles in use from 1987 to 1992 (Italy, 30%, Germany, 16% and France, 12%) with the exception of the United Kingdom which had just over a 2% growth for the same period. Italy has the highest density of motorcycles per capita in Europe with 43 in use per 1 000 inhabitants, followed by Switzerland with 40, Spain with 24 and Luxembourg with 21. Luxembourg experienced the highest European growth rate from 1987 to 1992 with an increase of 103% in the number of motorcycles in use. Similar statistics are not available for mopeds, alone. However, in 1990, the total number of motorised two-wheeled vehicles in use per 1 000 inhabitants was highest in the EC in Italy (142) followed by France (110), the Netherlands (64) and Belgium (52). Switzerland lead Europe with a density of 145 vehicles per 1 000 persons. Worldwide, Taiwan topped the list with 341 vehicles per 1 000 persons, followed by Japan with 180 per 1 000 persons. These figures must be treated with caution, however, since they include estimates of un-registered vehicles.

Source: DEBA, Census of Manufacturers, Nikkei

Although the stronger economic climate of the late 1980s led to a resurgence in demand for both mopeds and motorcycles (in terms of number of units), sales have not reached 1980 levels.

East Europe demand remained high during the late 1980s. Economic conditions and the prohibitive price of automobiles, compared to average salaries, drive consumer demand there. This is expected to continue in the near future.

Supply and competition

Within the EC, Italy has maintained (if not consolidated) its dominance as the most important producer of mopeds and motorcycles over the 1980s. About one third of Italy's total production of mopeds and motorcycles is bound for countries outside the EC. Extra-EC exports of motorcycles from all Member States declined 28% from 1991-1992, while foreign sales of EC produced mopeds increased 40% from 159 000 to 222 000 units during the same period. Foreign demand is the most important for Italy, whose exports of mopeds increased by nearly 60% from 1991-1992. The export/production ratio remained stagnant from 1988-1992 but the import/consumption ratio steadily increased over the last decade to the point where nearly 43% of EC consumption is met by extra-EC imports.

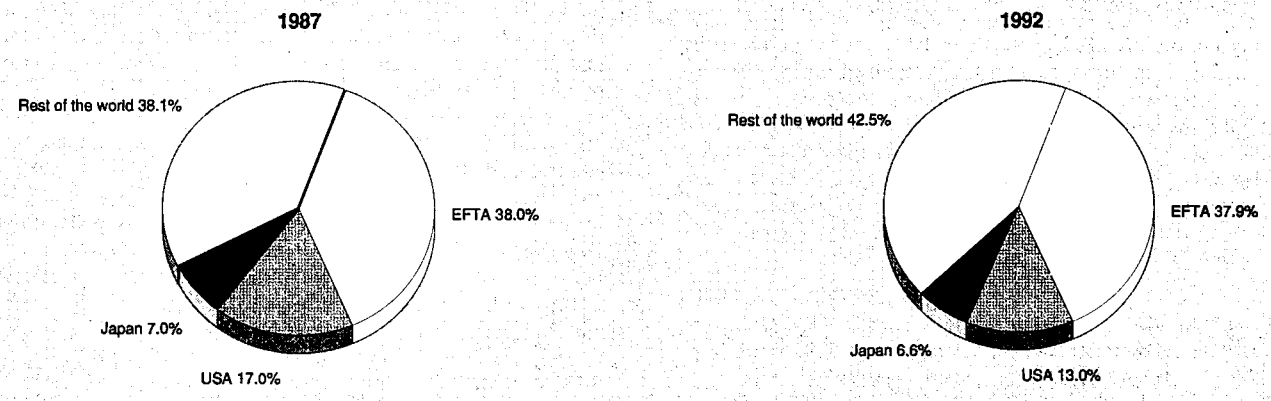
Although Japan's share of the EC market decreased from 77% in 1987 to 59% in 1992, the same has happened to the EC's share of the Japanese market, thus widening the trade deficit further.

With the fall in employment rates over the past decade and the increases in production experienced in the past several years, labour productivity has necessarily increased steadily since 1982 with a 33% gain in value added (in 1992 prices per person employed). Unit labour costs have increased 77% from 1983-1992; 40% occurring since 1987. This has helped spur the growth in production in the East Asian NICs as EC producers licence the manufacture of their products to the low labour cost countries there.

Production process

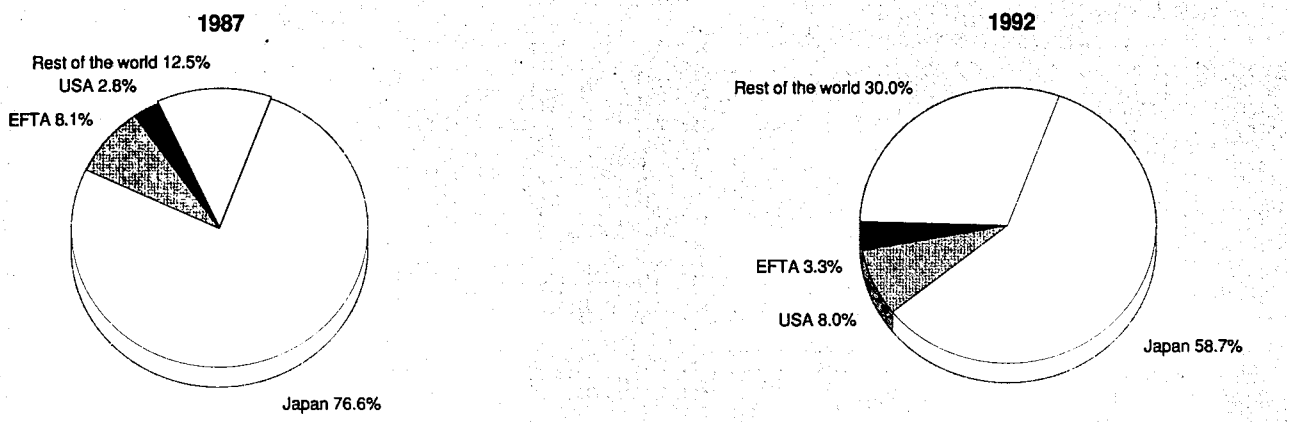
Falling levels of production as the 1980s progressed lead to plant closures and restructuring that resulted in lower employment levels in the industry. The associated improvements

Figure 6: Mopeds and motorcycles
Destination of EC exports



Source: Eurostat

Figure 7: Mopeds and motorcycles
Origin of EC imports



Source: Eurostat

in productivity have lead to an increase in the EC industry's competitiveness, however.

Impetus to improve competitiveness has also come from the single market as all major EC manufacturers are actively pursuing strategies to help them capitalise on opportunities offered by the new EC competitive environment. Common standards adopted by the Community will lead to further rationalisation and automation of the EC manufacturing process. Standards presently differ widely across the EC as illustrated by requirements on the gearing on mopeds. In Belgium, France and Portugal, automotive gears are required; in Denmark, the maximum number of gears is 2 and in Spain, 4. The opportunities arising from the single market will also depend on a common transport policy and the result of trade talks with Japan regarding the opening of its market and easier access to its distribution network.

The industry is developing new technologies both in terms of the design of the vehicles and their construction. The use of CAD/CAM has introduced the use of robotics, laser cutting machines, improved painting systems and more sophisticated quality control systems. These will help to increase productivity further as manufacturers begin to produce single models marketable across the entire EC.

Labour productivity varies, depending on the type of model produced by each company. Thus, in 1989, labour productivity ranged from 18 units per employee per year at BMW (D) to 102 at Honda (JPN), and 122 at Moto Vespa (E). On average, labour productivity is around 100 units per employee per year for the larger companies.

INDUSTRY STRUCTURE

Companies

Fifty-one manufacturers of mopeds and motorcycles in the EC account for about 85% of total EC production, with the remainder being produced by Japanese owned or controlled producers. More than half of the EC producers are located in Italy. Spain and Portugal are the next most important countries in terms of number of manufacturers, with seven and six, respectively.

The moped and motorcycle industry (excluding parts and accessories) is fairly concentrated with the ten largest producers accounting for about 68% of EC production. The size of the enterprises is larger than average in France, Spain, Italy and the Benelux region.

Japan controls 15% of EC production through licence agreements and financial holdings in local plants. Some Peugeot MTC (F) scooters are built under license from Honda (JPN) which owns a 25% share of Peugeot MTC. The second largest manufacturer in France, MBK Industrie, is fully controlled by Yamaha (JPN) and assembles Yamaha scooters and light motorcycles and manufactures mopeds under the Motobécane design. SIS (P) also assembles Yamaha trail bikes. Of Japan's direct investments in the EC, Yamaha, Suzuki and Honda are the three largest producers. These companies target the larger engine market (251 cc), of which they hold 82% share of the EC market.

Based on sales, the Italian Piaggio Group is the largest supplier of moped and motorcycles to the EC market, followed by Peugeot MTC, Moto Vespa (E) and Derbi (E). Piaggio is ranked third worldwide behind Honda and Yamaha of Japan.

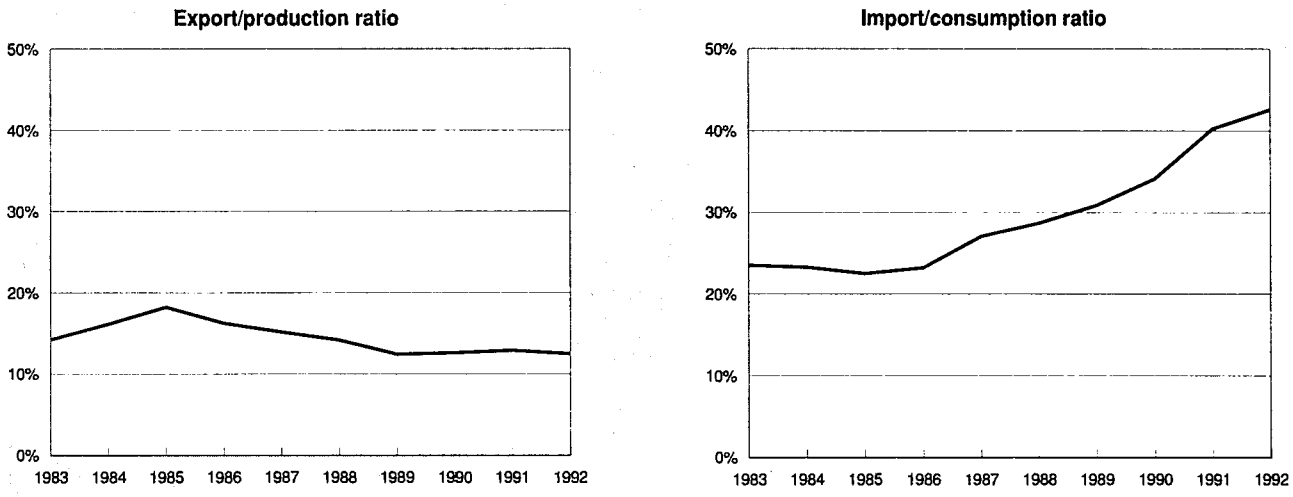
The Piaggio group includes Piaggio, Gilera, Puch (A) and Moto Vespa (Spain's largest producer). Other important Italian producers are the Cagiva Group (Cagiva, Ducati, Husqvarna and Moto Morini), Aprilia and the Moto Guzzi-Benelli Group. Italy has a large number of smaller producers, as well. France's largest is Peugeot MTC and is primarily engaged in the manufacture of mopeds and scooters (50-80 cc). Some Peugeot scooters and 50 cc engines are built under licence by Honda. In Spain, Moto Vespa and Derbi are the main manufacturers accounting for 59% of Spain's output of mopeds and motorcycles. The assembly operations of Honda, Yamaha and Suzuki account for one-third of local production in Spain.

Germany's largest producer is BMW; it strictly focuses on the manufacture of top of the line motorcycles with large capacity engines. In Portugal, SIS Vehiculos Motorizados LTDA is the largest manufacturer, producing mopeds equipped with engines either from Fichtel & Sachs (D) or Franco Morini (I). The second largest manufacturer in Portugal is Famel.

Honda Belgium is the largest producer in Belgium. Up to 75% of the parts used in its assemblies are of European origin. In the Netherlands, the most important manufacturer, Sparta BV, produces light mofas. The assembly of mofas and mopeds is also carried out by Tomos.

March 1991 saw the start of production by the new Triumph Motorcycle Company in the United Kingdom. In the subsequent 18 months to July 1993, this company produced some 9 000 motorcycles, and has successfully established distribution throughout the EC, Japan, Australia and New Zealand. Further sales have been made to a number of other markets including South America. It is anticipated that Triumph will

Figure 8: Mopeds and motorcycles
Trade intensities



Source: DEBA

enter the USA and Canadian markets in 1994. To supply these new markets, production is planned to increase substantially. In addition to Triumph, Norton Motors (UK) continue to manufacture rotary engine motorcycles, and BSA (UK) specialise in the supply of machines for the African market

Strategies

Since the early 1980s, many European manufacturers have carried out major investment projects to improve their competitiveness, yielding advances in the area of moped, scooter and low capacity motorcycle production. To capitalise on the improved demand outlook at the end of the 1980s, companies were undertaking further investment to improve production facilities and devoting resources to developing new models. Investment in R&D to develop new, more advanced, cleaner burning models is becoming increasingly important in the face of heightened competition. According to a sample of nine moped and sixteen motorcycle manufacturers, R&D spending was equivalent to 3.4% of turnover in 1989, while investment in new capacity reached almost 5% of turnover. BMW spent 8.1% of turnover on R&D in 1989.

In response to the poor economic situation of the early 1980s, a number of companies began to engage in merger and acquisition activities to buy market share and to take advantage of economies of scale in production. For example, the Italian Piaggio Group acquired Puch (A), and Cagiva-Ducati merged with Moto Morini and Husqvarna. However, merger and acquisition activity has been dominated by Japanese companies interested in acquiring a base in Europe. For example, Suzuki bought Avello-Puch of Spain in 1986, while the following year, Yamaha bought Babesto. The investments are now beginning to show positive returns. Although the Japanese have acquired about 15% of EC moped and motorcycle enterprises, they accounted for 36% of sales in 1989. Also, although the top 12 EC producers of mopeds and motorcycles accounted for 94% of total EC output in 1989, they accounted for only 64% of sales in the EC, reflecting the high degree of import penetration. Most of these Japanese producers, however, do perform assembly operations in Europe.

Consolidation within the larger industry groups will continue as companies fight to stay competitive during times of decreasing demand.

REGIONAL DISTRIBUTION

The distribution of production and consumption is clearly concentrated in the Southern EC region. Italy, Spain and France together contributed 67% of value added in 1992. This figure would be higher if data were available for Portugal. The same three Southern EC countries accounted for 82% and 57% of moped and motorcycle sales, respectively. Central Europe also had a significant share of EC motorcycle sales.

ENVIRONMENT

The main environmental considerations that may have an effect on the moped and motorcycle industry are the problems of urban traffic congestion and exhaust emissions. Should more governments introduce restrictions on traffic circulation in the larger cities, demand for mopeds and motorcycles may be stimulated. Manufacturers have also been concentrating on more fuel efficient, cleaner burning engines.

REGULATIONS

Legislation concerning the harmonisation of standards in the industry would allow manufacturers to standardise parts manufacture as mentioned previously. This could increase economies of scale by lengthening production runs and could instigate further rationalisation in the industry.

Increased use of mopeds and motorcycles has given birth to safety requirements that are sometimes unwanted by the consumer. There are suggestions that the Italian 1986 crash helmet requirement, speed limit introductions and the requirement for all mopeds to be registered in Germany have dampened demand for mopeds in these countries. These possible reactions are considered temporary and will diminish as consumers become more accustomed to the new regulations.

OUTLOOK

The length of the current worldwide recession resulted in a declining production growth rate from 1991 to 1992 in the EC. This was also exacerbated by the increase in demand for import models. Consumption growth rate slowed to a crawl (0.5%) from 1991-1992 further increasing market shares of imports. Short-term prospects for the EC moped and motor-

cycle industry do not look favourable as evidenced by the cutback announced by the Piaggio Group early in the fourth quarter of 1993 for their Gilera product line. The overall EC production growth rate from 1992-1993 will see its largest decrease of the decade and could be in the range of -8%. A further decrease from 1993 to 1994 is forecasted, however it should only be approximately 6%.

In the medium term, with world economies expected to grow at continued slow pace, particularly in Europe, internal demand in the EC is expected to grow only 1-2% faster than that of the 1991-1992 rate. Production could see a turnaround to positive growth if economies show moderate growth rates, particularly the economies of Italy, Germany, France and Spain. Future success will depend on the sector's ability to benefit from economies of scale in production and research and development. Standardised parts development could also help bring costs down and help encourage further restructuring of the sector. Continued environmental concerns may continue a push in many congested urban areas to limit automobile access, encouraging demand for mopeds and motorcycles. Growth in real consumption should continue its slow increase in the short-term. The medium-term prospects look slightly better as consumption should increase at a rate of approximately 1% to 2% per year from 1994 -1996 in line with expected consumer spending increases. The EC manufacturers short and medium-term prospects could actually be slightly better depending on how well they can tap into the expected higher growth rate markets in the East Asian NICs. The continued consolidation efforts will leave the remaining firms in a better growth position to take advantage of a future upturn in consumer spending.

Bicycles
NACE 363

Overall bicycle consumption in the EC has been increasing in the last decade. However, most of this increased consumption was accounted for by cheaper imports from non-EC countries, particularly from the Far East. Since 1992, the economic recession and changes in fashion have severely reduced consumption levels, and prospects for 1994 do not look very promising.
The importance of bicycles as an alternative and environmentally friendly means of transport has been recently recognised by the EC Commission in its White Paper on Transport Policy. It is widely recognised that action to promote the use of bicycles can make an useful contribution to the solution of traffic congestion problems in urban areas.

INDUSTRY PROFILE

Description of the sector

Bicycles are considered within the NACE 363 category, which also includes mopeds and motorcycles.

There are different types of bicycles, according to the end-user to whom they are destined: sports/touring bicycles (light weight), conventional adult bicycles, All Terrain Bicycles (ATB, or mountain bikes), hybrid bicycles (a cross between a mountain bike and a touring bicycle), small wheeled bicycles (for short distances, mainly aimed at the commuter) and children's bicycles.

Recent trends

In 1991, about 12.2 million bicycles were produced in the EC according to data published by the association EBMA. This figure was 10% lower than that of 1990, and about at the same level of production volume in 1989.

The strong growth in production which took place in 1990 is completely attributable to increased activity in the two main producers within the EC, namely Germany and Italy (see Table 1).

Consumption of bicycles in the EC has been constantly rising in the 1989-91 period. The strongest growth in consumption has taken place in Germany, where reunification has propped up bicycle sales from 4.6 million units in 1989 to 6.5 million units in 1991.

Preliminary figures for 1992 and 1993 indicate that consumption of bicycles in the EC has decreased: it is estimated that the drop in sales stands at around 8-10% per year.

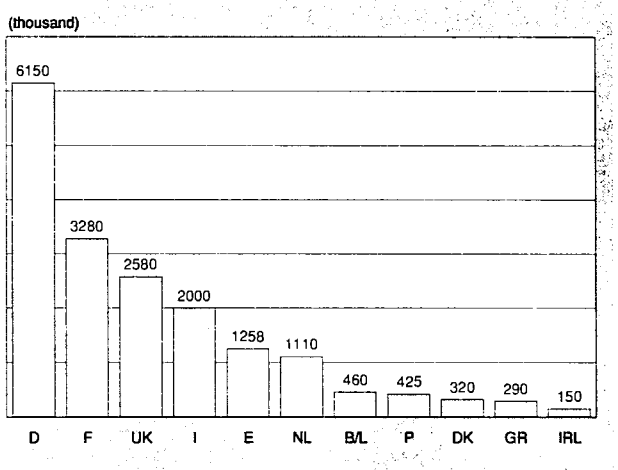
Foreign trade

In 1992, bicycle imports from non-EC countries stood at around 6.3 million units, down 5% from the level of 1991. Geographically speaking, most of EC imports come from the Far-East, and particularly from those countries which enjoy a preferential trade treatment under the Generalised System of Preferences (GSP) scheme.

Taiwan has the lion's share of bicycle imports to the EC (2.3 million units in 1992), followed by China (1.7 million units) Thailand (520 000 units), Indonesia (360 000 units) and Malaysia (345 000 units). These five countries account together for about 83% of total EC imports.

On the other hand, bicycle imports from Japan and the USA are quite low (46 000 and 128 000 units respectively in 1992). Among East European countries, the most important exporters to the EC are Poland (190 000 units) and the Czech and Slovak Republics (163 000 units altogether).

Figure 1: Bicycles
Breakdown of the EC bicycle consumption, 1991



Source: EBMA

As for intra-EC trade, in 1991 its volume reached about 3.4 million units. Italy is by far the largest intra-EC exporter with 1.8 million units, or 54% of the total. The main EC markets for Italian bicycles are France (875 000 units) and Germany (348 000 units).

MARKET FORCES

Demand

The surge in bicycles sales which has taken place in most recent years can be fully attributed to the success encountered by mountain bikes, particularly among youngsters of the 15-24 age group. At the same time, demand for traditional adult bicycles has been falling rapidly.

Since 1992, however, the boom in sales of mountain bikes seems to have levelled off. The main reason for this slowdown is doubtlessly the general economic recession that has rendered the price of ATBs quite prohibitive. Fashion considerations also play an important role in this respect.

Demand for bicycles is principally related to leisure and fun activities, and secondarily to the desire of consumers to keep fit. Other popular reasons to buy a bicycle are for recreational purposes, for local trips (i.e. shopping), or to commute to the workplace. Concerning this last reason, the use of bicycles as an alternative to private and/or public transport is increasing particularly in large cities, where traffic congestion is strong.

Supply and competition

Within the EC, the two largest bicycle producers are traditionally Italy and Germany. In terms of international competitors, Taiwan has become in the recent past the largest source of EC imports. Other competitors are also located in the Far East, namely China and Thailand.

These countries enjoy low labour costs, which allow them to undercut the prices offered by European producers. Moreover, Far East producers often make use of the so-called "screwdriver plants", i.e. they produce locally all the components which are later assembled in factories located in other countries. As a consequence of this unfair competition, several European manufacturers were thrown out of the market or nowadays design bicycles which are produced in the Far East and imported as finished products.

The component market has been practically taken over by two Japanese manufacturers, Shimano and Suntour. They specialise particularly in the gear and brake mechanisms, and

Source : EBMA

their entry in the market has seriously affected the level of activity of their European counterparts, which is now mostly confined to the most expensive models' segment (i.e. racing bikes). On the other hand, European manufacturers have increased their R&D efforts in order to obtain innovative product developments.

The bicycle sector in Europe has also witnessed a major change in distribution channels. Not a long time ago, bicycles were sold uniquely in specialised shops, while at present an increasing share of bikes is sold in large department stores, hypermarkets or by mail order.

INDUSTRY STRUCTURE

Companies

The industry is composed of a number of large, medium and small-sized companies, some specialising into some niche-markets such as children's bikes. At the same time, each European country has local producers which operate in all market segments and which take the biggest market share.

The following enterprises are the market leaders within their respective countries: Kynast, Derby Cycle Werke and Nurnberger Hercules (Germany); Bianchi, Rizzato and Carnielli (Italy); Peugeot, MBK and Gitane (France); Raleigh, Townsend and Dawes (UK); BH, Orbea and Rabasa (Spain); Gazelle and Batavus (Netherlands).

Strategies

In order to face the threat represented by import competition from Far East manufacturers, European companies have established alliances or cooperation agreements. The main aim of these alliances is to rationalise the production process and realise economies of scale in purchasing components.

In 1992, for example, the largest Spanish bicycle manufacturer BH announced the creation of a consortium with Peugeot and Gitane under the name of Cycleurope. Other major consortia are the Derby Group (formed by Raleigh, Gazelle and Derby) and the ATAG group (formed by Batavus and Dawes).

REGIONAL DISTRIBUTION

The largest market for bicycles in the EC is Germany. In 1991, one out of three bikes sold in the EC was sold in Germany (6.1 million). France comes second with 3.3 million bikes sold, and the United Kingdom third with 2.6 million units.

The Netherlands and Denmark are the two countries with the highest bike density in the EC. However, the highest growth rates in bicycle consumption in the last years come from Southern countries such as Spain (46% growth in 1991), France (13%) and Portugal (10%); on the other hand, consumption has been decreasing or stagnating in traditional bicycle markets such as the United Kingdom (-0.7% in 1991), the Netherlands (-2.1%) and particularly Denmark (-11.2%).

ENVIRONMENT

The bicycle is increasingly viewed as one of the most environmentally friendly means of transport. Its contribution to the solution of traffic congestion problems in large urban areas has been generally underestimated by local authorities within the EC.

In order to promote the use of bicycles in urban areas, it is necessary to provide facilities for cyclists such as bicycle lanes and specific parking areas. Unfortunately, this is more the exception than the rule in most large urban areas of the EC. In some European countries where the bicycle is traditionally a popular means of transport (i.e. the Netherlands, Germany and the Scandinavian countries), facilities are widespread. On the other hand, in the Southern European countries the absence of such infrastructures makes the use of bicycles in the city quite hazardous. Therefore in these countries the demand for traditional bicycles is mainly concentrated in the countryside.

REGULATIONS

The unfair competition and dumping practices which are commonly used by Far East producers have been recently sanctioned by the EC authorities.

Table 2: Bicycles
Significant bicycle imports to the EC, 1991-92

(thousand)	1991	1992

USA	130.8	127.9
India	29.0	121.3

Source : EBMA

In August 1993, the EC Commission proposed a council regulation which imposes a definitive anti-dumping duty on imports into the EC of bicycles originating in China. The EC Council subsequently adopted the regulation: the rate of the duty has been set at 30.6%.

OUTLOOK

The general economic recession which is affecting Europe has badly influenced sales of bicycles in the last couple of years: in fact, during recessionary periods, consumers tend to postpone the purchase of new bikes. Moreover, the lessening of the consumers' excitement for mountain bikes will further reduce consumption, at least until a new cycling fashion appears.

On the other hand, the action of the EC authorities to prevent unfair competition practices by Far East manufacturers is expected to help reducing the price gap which hampered the activity of EC producers.

Shipbuilding
NACE 361

Contrary to the widely-held belief that Japanese and South Korean shipbuilders dominate the shipbuilding industry, the EC continues to maintain its position as the world leader in the high value added segments of fully cellular container ships, refrigerated vessels, cruise ships and fishing vessels.
In sum, however, the EC shipbuilding industry continues to confront considerable challenges for the near future. Weaker than hoped for growth in sea-borne trade and the lingering overcapacity in the shipping industry in 1992 worked against the prospect for an immediate upturn in production volumes or employment. On top of that, exchange rate fluctuations (particularly vis-à-vis the US dollar) have helped weaken the competitiveness of EC shipbuilders.
The longer term outlook is potentially positive for the EC shipbuilding industry as the world fleet becomes increasingly aged, and legislative requirements for ship design favour some of the EC acquired expertise.

INDUSTRY PROFILE

Description of the sector

NACE 361 comprises the building and repair of seagoing vessels (NACE 361.1); building and repair of vessels for inland navigation (NACE 361.2); building and repair of boats and yachts (NACE 361.3); painting of ships (NACE 361.4); and ship breaking (NACE 361.5).

Most of the industry is accounted for by the construction of seagoing merchant vessels (i.e. NACE 361.1). Given the smaller economic significance of the other sub-sectors and the limited availability of data, this article refers predominately to trends in the manufacture and repair of seagoing merchant vessels.

Recent trends

In 1992 the growth of world trade accelerated in line with output growth; world sea-borne trade (measured in tonnes miles) followed the same pattern with growth of 2.3 % compared to 3.3% in 1991. Shipbuilding in the EC recorded strong growth in 1992 to exceed 2.8 million compensated gross tonnes (cgt), a 7.2% increase over 1991, that gave the EC a world production share of almost 24%. However, production had declined slightly in 1991 (compared to 1990) to 2.65 million cgt which was coupled with a marginal decline in its world production share (23%).

The principal product lines in 1992, and their corresponding share of aggregate EC production (including fishing and non cargo vessels, but excluding military vessels), are as follows: full container (19.1%); general cargo (15.2%); ferries and passenger ships (14.9%); fishing vessels (9.2%); oil and chemicals carriers (18%); LPG carriers (6.7%); and dedicated dry bulk vessels (3.6%).

After many years of decline, world ship production began to recover in 1989 and accelerated sharply in 1990. In the EC, production declined steadily from 1983 to 1988. For the first several years, EC production declined more rapidly than world production, so the EC share of total production that was 23.7% in 1980 had fallen to 19.7% in 1986 (former East Germany is included for both years). The EC's share improved significantly in 1987 and regained its 1980 comparable value in 1988, which it has maintained since then.

International freight rate performance, which is an important factor in scrapping and new-building decisions, varied according to ship-type in 1992, although total employment of the world fleet was very similar to 1990. The Gulf War in early 1991 partially prompted a surge in tanker oil movements and storage. Hence, rates during the first half of 1991 for various tanker sizes, notably VLCC's, Suezmax and Aframax tankers, were the best seen since the early 1970s. However, a significant amount of additional tanker tonnage came onto the market in 1991 approximately 11.5 million deadweight tons (dwt) was added. This addition of the largest increase in supply since 1977, coupled with high stocks, a reduction in tanker storage, minimal scrapping and a slowing of demand pushed rates down significantly in the second half of 1991. This depressed situation continued into of 1992, such that a significant number of tankers were withdrawn from the market (although not fully mothballed) and the number of tankers scrapped witnessed a dramatic rise. The two-tier rate structure that had emerged in 1991, where modern tonnage commanded a premium on some trades over older tonnage, died in 1992 and some of the owners of the more modern tonnage faced the greatest exposure to the weak rates due to their substantial capital costs.

Rates for product tankers followed a similar pattern as that for the crude carriers in 1991, albeit with a slight strengthening of rates at the end of the year, and 1992. The rates for bulk (and combination) carriers also declined further in 1992 following the deterioration in 1991, but managed to remain more stable than the declines in the tanker rates. This stability was due to the impact of rates on different sized ships, with smaller vessels commanding reasonable rates, whilst the larger ones were faced with declining rates.

Developments in other vessel type rates were rather muted. General cargo remained relatively flat, and gas carrier rates declined marginally as the increased supply of new-buildings exceeded demand.

Employment, after falling steadily throughout the eighties reached a trough in 1990, before growing strongly in 1991 and stabilising in 1992 (note that some eastern German employment is included from 1991).

In 1991 the tendency of rising prices for new ships, which started in 1985, reached its peak. In 1992, the weakening freight rates of 1991 and 1992 translated into weakening orders

for news ships, and coupled with shipyards nearing completion of a delivery programme that had the yards working to full capacity over 1990/1991 meant that surplus capacity in the yards was appearing and hence prices (in nominal US dollars) for all vessel types were forced down significantly in 1992. However, prices in European currencies adjusted for exchange rates and inflation are close to the 1990 level, although significantly lower than in 1991.

This weakening in prices due to the widening gap between freight rates obtainable and the price of new ships and financing difficulties are considerably dampening the threat of rising prices in the short term.

International comparison

The EC's major competitors in shipbuilding are Japan, with a world share of 36%, and South Korea. However, the EC marginally gained share in 1992, whilst Japan's share had declined by 2%. Most of the share gain in world production has been due to the very active South Korean yards, which have increased share from 11.5% in 1985 to the current 16.5%.

The 1992 EC share of its principal product lines in world production, are: fully container (33%); general cargo (35%); ferries and passenger ships (49%); fishing vessels (47%); oil and chemicals carriers (12%); LPG carriers (37%); and dedicated dry bulk vessels (8%). The EC is the leading producer of containerised and general cargo vessels, dedicated reefer vessels and cruise vessels.

Foreign trade

Within the EC, the most important exporting countries by value and cgt in 1991 were Germany, Spain and France in order of rank. All of the EC Member States continued to post a trade surplus with the exception of Greece, which imports more than it exports due to the concentration of large bulk and tanker shipping companies in that country. EC exports in new shipbuilding reached 3 038 million ECU in 1991 compared to 2 988 million ECU in 1990.

MARKET FORCES

Demand

In the last years, demand for EC manufactured vessels has accelerated from the early to mid-1980's decline, which reached a trough in 1986. However, the volume of new orders, which rose by close to 30% in 1989 in terms of cgt to its peak, stagnated in 1990 and declined in 1991 and 1992. The 1992 result of new orders of 1.8 million cgt is a substantial decline from the 3.2 million 1989 peak. Also, world new orders have declined substantially and the EC has also lost share of this declining market due to stiff competition: the EC share was 23% in 1989 and is now just under 20%.

In 1992, the largest ship producing Member State was Germany (958 thousand cgt for a share of 34%), followed by Spain (15%), Denmark (14.6%) and Italy (10.2%). The outstanding order book for the EC producers at the end of 1992 maintains Germany in pole position with 29%, but puts Italy in second place with 20.5%, and Denmark third with 13.3%.

Supply and competition

Three-quarters of world shipbuilding is carried out by industrialised countries. The EC dominates the high added value market of fully cellular container ships, reefer and non-cargo

There are several hundred shipyards in the EC that manufacture and/or repair vessels of varying sizes. However, of these, only about seventy are capable of producing and/or repairing ships over 5 000 cgt. The repair industry has been faced with declining business as owners and operators have tried to strike a balance between keeping down costs and the absolute minimum level of maintenance required to match the demands of

the various regulatory bodies. This is despite an ageing fleet, which should require more maintenance.

Scrapping

The scrapping of ships at the end of their usable life is decided not only by the age of the ship but by a combination several factors such as the vessel's operating profit margin, changes in environmental legislation and quality considerations and the existing market psychology (i.e. the expected return on a vessel). Given the aforementioned criteria, it is not surprising that many shipping firms have decided to scrap their vessels during the recent downturn in the shipping industry. The average age for vessels is presently around 12.5 years, which is higher than it was during the last period of intense scrapping activity during the mid-1980s; in addition, the share of the world fleet over 20 years old has increased substantially (now around some 35%). This is further indication that a considerable number of ships were retained during the favourable economic climate in the late 1980s and have served their useful service life. Scrapping in 1992, at 348 vessels of 18.5 million dwt more than doubled from the 1991 result of 5.3 million dwt in 1991. China currently dominates world scrapping followed by Pakistan and Bangladesh (and to a lesser degree India). Given the substantial increase in scrapping the prices paid for scrapping in 1992 declined for nearly all vessel types, the major exception being the vessel containing high quality stainless steel (such as chemical carriers).

Labour

Employment in the EC shipping industry has experienced a prolonged period of downsizing due to a number of factors. To begin, the world shipbuilding industry experienced an unprecedented period of expansion during the 1970s in which shipping tonnage was doubled within a ten-year period. The sudden influx of new tonnage resulted in an overcapacity of shipping tonnage which the shipping industry has yet to recover from, despite the fact that a number of ships were prematurely scrapped in the mid-1980s (some after less than 10 years of service). A secondary development was the shift in production centres away from Europe and the USA towards new shipyards in Japan and South Korea. For example, South Korea launched only 0.1% of new ships in 1972, by 1992 that share had blossomed to 16.5%.

The reduction in the EC shipbuilding workforce has continued and in 1992 stood at slightly more than only one-third of the 1975 total of employment for the present Member States. Employment is dominated by Germany, which employs 36.5% of the total, followed at a significant distance by Italy and Denmark with almost 11% each. The country that has seen the most substantial decrease in employment over the last two decade is the United Kingdom, with labour force one tenth of that in the mid seventies - which at that time was the largest individual workforce of the current Member States.

Production process

The industry has had to invest in automating the production process wherever possible, usually by introducing computerised sheet-cutter and automated welders. The changes in the production process have been similar to that in the automotive industry and is predominately a response to increasing competition from lower cost manufacture taking place outside the EC. Part of process of adjustment has included the adoption of Eastern style management techniques, multi-skilled work practises and purchases of complete systems and sub-systems from external suppliers.

INDUSTRY STRUCTURE

Strategies

The number of shipbuilding firms in the EC has been reduced by yards either going out of business or by mergers and acquisition activity, and many of the remaining shipyards have been forced to find niches in the shipbuilding market in order to survive. The EC shipbuilding industry in general seeks to differentiate itself from its main competitors in Asia by specialising in the construction of ships with relatively high value added rather than relatively simpler dry-bulk vessels or oil tankers. Examples of such ships include dedicated refrigerator vessels ("reefers"), dedicated container vessels, gas tankers, chemical tankers and cruise ships.

The major centre for mergers and acquisitions activity has been the privatisation of shipyards in former East Germany by the Treuhandanstalt, the German agency responsible for privatising former East German industries following unification. Most of the largest acquisitions have created Germany's largest shipbuilding group, Bremer Vulkan, however, other firms such as Norway's Kvaerner have also acquired facilities in the new Länder and other Member States.

ENVIRONMENT

Although oil spills are often considered as the greatest environmental threat posed by the shipping industry as a whole, as evidenced by the IMO regulations for new tankers to constructed with double hulls, prevention of oil spills is by no means the only major environmental issue confronting the shipbuilding industry. The shipbuilding industry is presently focused on the painting of ships where paint and coating substances and abrasive blasting done to prepare a painting surface are of particular concern.

A number of paint and coating (anti-fouling) substances have been brought under scrutiny. Paint components red lead (Pb3O4), zinc chromate (ZnCrO4) and tin compounds are

expected to be banned along with previously discontinued substances such as cadmium and other heavy metals. Meanwhile, other substances used such as carbonates, silicates, coal tar, organic chloride compounds and polyurethanes are all suspected to cause specific health hazards. Abrasive blasting is another source of concern because of the vast amounts of hazardous dust which results from the preparation of metal or concrete surfaces before painting.

REGULATIONS

The global shipbuilding industry is subject to competitive distortions due primarily to differing levels of subsidies by geographic region. EC level of subsidies to shipbuilding come under the auspices of the 7th directive on aid to shipbuilding (approved in November 1990) and must be reviewed each year. In December 1992, the Commission determined that the common ceiling for state aid, which is based on the difference in costs between the most efficient EC yards and their major competitors (typically form the Far East), should be the same for 1993 as for 1992. This means that ships contracted in 1993 for delivery in or before 1996 should have a subsidy ceiling of 9% of the contract value. The ceiling for ships with a contract value less than 10 million ECU was 4.5% of that value.

With regard to environmental regulations, the EC and the USA are leading the industry with the preparation of legislation designed to reduce solvent emissions resulting from particular paint substances. Such legislation is expected to be similar to the German TA Luft legislation. Member States such as Denmark and the Netherlands have already initiated programmes designed to reduce solvent emissions.

Increasing pressure on the shipping industry on maritime safety may act as a boon to the shipbuilding industry depending on the level and degree of legislation that is applied. This will be due to the potential for shipbuilder to incorporate additional,

high value added safety features in new vessels, as well as ship repairers having to outfit existing shipping with add-on equipment. Recent research on claims arising from major casualty reports indicates that equipment and mechanical failure account for 20% of these casualties, whilst structural failure accounts for 13%.

OUTLOOK

For the immediate future, the outlook for EC shipbuilding industry does not appear to offer obvious change from the persistent contraction of production and employment. The existing overcapacity in the shipping industry combined with a lingering global recession prevents the likelihood of any immediate boom in demand for new shipbuilding. However, as sub-standard tonnage becomes increasingly under pressure to improve and as the relevant authorities apply more stringent ship surveys, there should be a substantial pick-up in repair demand in the short-term in advance of the large influx of new orders.

On a more encouraging note, in the long-term over half of the current fleet will be over 25 years old by the year 2000, up to one-third will need to be replaced during the interim period; world trade will accelerate to use up much of the current excess capacity and with current trend for lower prices there should be an acceleration of orders.

From a long-term perspective, the EC shipbuilding industry will be keenly focused on the development of the next generation of shipping vessels which are predominantly being developed in Japan by Mitsubishi Heavy Industries. Although Mitsubishi is the primary developer of the super conductive electromagnetic propulsion (SEMP) vessels, certain EC firms are performing crucial roles in the development of the SEMP project. The most significant contributor is Germany's Motoren und Turbinen Union division of Daimler-Benz, which won a prestigious contract to develop two high-speed engines used to power the SEMP's innovative magnetohydrodynamic (MHD) propulsion system.

The industry is represented at the EC level by: Committee of EC Shipbuilders Associations (CESA). Address: Juan Hurtado de Mendoza, 13-7-9, E-28036 Madrid; tel: (34 1) 345 7078; fax: (34 1) 359 9336.

Railway rolling stock
NACE 362

In 1992, the EC railway rolling stock industry continued its growth. Production increased and trade balance went on its recovery started in 1991. Employment, however, remained low. The industry has few clients and is completely dependent on them. Products are tailored to these clients and continuous innovation is necessary to satisfy them and to ensure that EC firms stay competitive. Therefore, the EC railway rolling stock industry tends to be more concentrated. East European countries have become dangerous competitors on the basis of prices, although their technology needs very often to be updated.
Although the railway rolling stock industry is less polluting than the air or road transportation means, efforts are made to protect the environment. In addition, European integration will lead to a more competitive EC market as national governments open bidding procedures to all EC manufacturers to compete. The reorganisation of the railway operators can delay investments in several EC countries

INDUSTRY PROFILE

Description of the sector

The railway rolling stock industry includes the manufacture of standard large and narrow gauge railway and urban transport railway equipment. This includes:

- locomotives;
- heads of motor coaches and motor-coach trains;
- mainline passenger coaches, metro cars and tramways;
- goods wagons;
- rolling stock equipment;
- fixed track equipment;
- electric signalling, safety and control devices for railways..

Production of passenger coaches also includes material for regional traffic and medium distance e.g. coaches for the "interregional" service, and for additional services like: mail vans, restaurant cars, sleeping cars; even if these specific cases concern a restricted manufacture.

The performance of the industry is dependent on the transportation needs and on public policies regarding the development of the railroad lines and purchase of rolling stock.

At the EC level, results also depend on well running enterprises that use railway networks for their inter-subsidiaries transports, and on the innovation capacity linked to R&D works.

In 1992, according to the Verband der Deutschen Bahnindustrie, Germany exported a value of 435 million DM, towards France (414), Canada (314), USA (290) and the United Kingdom (37).

Recent trends

After the fall during the 1985-87 period, production began to recover and reached some 5 billion ECU in 1992. In constant prices, production fell continuously throughout the 1983-88 period. Apparent consumption was more variable throughout the 1980s because of the variability in extra-EC imports and exports. Employment continued to fall in 1992 despite an increase in production reflecting increasing productivity. Trade balance remained positive throughout the eighties but with a strong fall from the second half due to the decrease of the exports/imports ratio. Since 1991, trade balance recovered and surpassed, in 1992, its level of the beginning of the 1980s.

International comparison

In 1992, EC was the leader in the production of railway rolling stock, outpacing US production by 57% and being more than the double of the Japanese one. Nevertheless, measured at constant prices, Japanese production grew at the fastest average annual rate during the 1985-1992 period.

As a competitor on world markets, Japan railway industry has suffered in recent years from the high exchange rate of the yen and in high speed its technology appears less advanced than the ones of European leaders. As far as urban transport systems are concerned the existing Japanese production is not competitive and Japanese industries do not envisage any significant penetration of the market in the near future.

Threat for the European rail industry comes rather from South Korea: the technological transfers required for participating to projects in South Korea could be dangerous for Europe's suppliers in the long term. On extra EC markets, Japan may offer more attractive financial packages.

Foreign trade

In general, both extra-EC exports and imports exhibit large variations from year to year, due to the high value nature and irregular delivery of long term contracts. In 1991 and 1992, large exports to the former Soviet Union from Germany, and to some extent from France caused extra-EC exports to increase. Extra-EC exports consisted mainly of passenger coaches. Destination of extra-EC exports changed significantly as EC exports towards developing countries increased by 20%, while those towards USA decreased by 15.2% during the 1987-92 period.

EC suppliers changed also from 1987 to 1992 as the share of EC imports coming from the developing countries doubled when USA share in EC imports decreased from 10.6%. EFTA countries remained the largest exporters to EC though the opening of East Europe could provide the EC with important new sources such as Czechoslovakia.

Goods wagons represented the largest part of extra-EC imports while imports of passenger coaches and locomotives came from other EC Member States.

Intra-EC sales showed a steady increase since 1988, although its share of total sales varied between 60% and 70% throughout the eighties.

MARKET FORCES

Demand

The industry has a relatively small number of customers, in national and regional railroad companies, urban transport companies, private rental and lease companies and industries with their own railway rolling stock. Enterprises of UNIFE also produce for private clients exploiting their internal network and with their own material e.g. big petroleum industries or automobile industries.

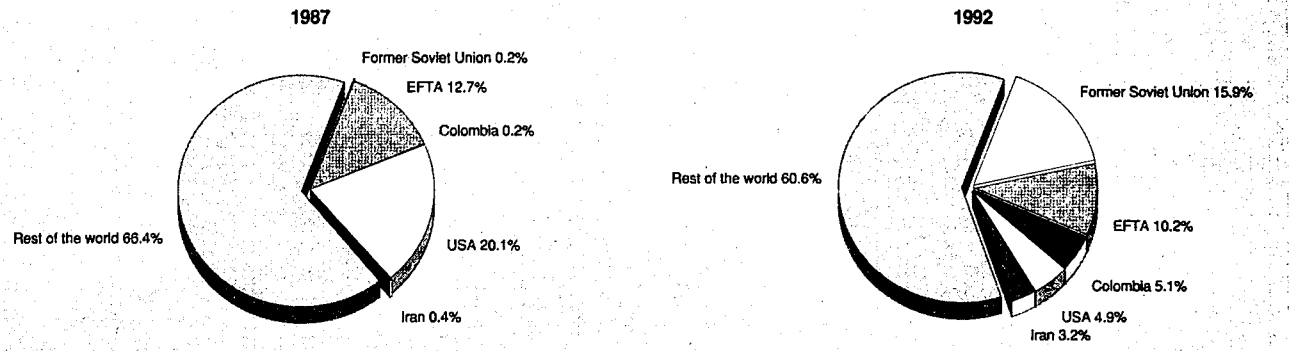
Figure 6: Railway rolling stock
Destination of EC exports



Source: Eurostat

The industry is less affected by general income developments than by transportation and infrastructure policies. Planning of new networks and increases in infrastructure tend to be long-term plans. Short-terms variations arise however from budgetary bottle-necks. Railway rolling stock has a long economic life. Product innovation does however involve the purchase of replacement of certain parts of rolling stock.

Product innovation has a significant effect on demand. Increased demand for fast transportation led to the development of the high-speed rail technology and resulted in plans by many countries for new high-speed networks. France is increasing the network of its TGV, and it is expected that by the end of the century, all west European countries will have high-speed rail connections. Beyond, France, Germany, Italy and Spain in particular are well started on their high-speed networks.

Supply and competition

For many years EC has been the world market leader. Since Spain has become an EC member, the European leadership has been reinforced towards competition from Japan, USA and Canada. East European countries might eventually become competitors for the EC, due to the lower labour costs and transfer of technologies from EC manufacturers. Competition thus is mainly on the technological side. Japanese manufacturers are looking for new international markets to boost flagging exports, including Europe and USA.

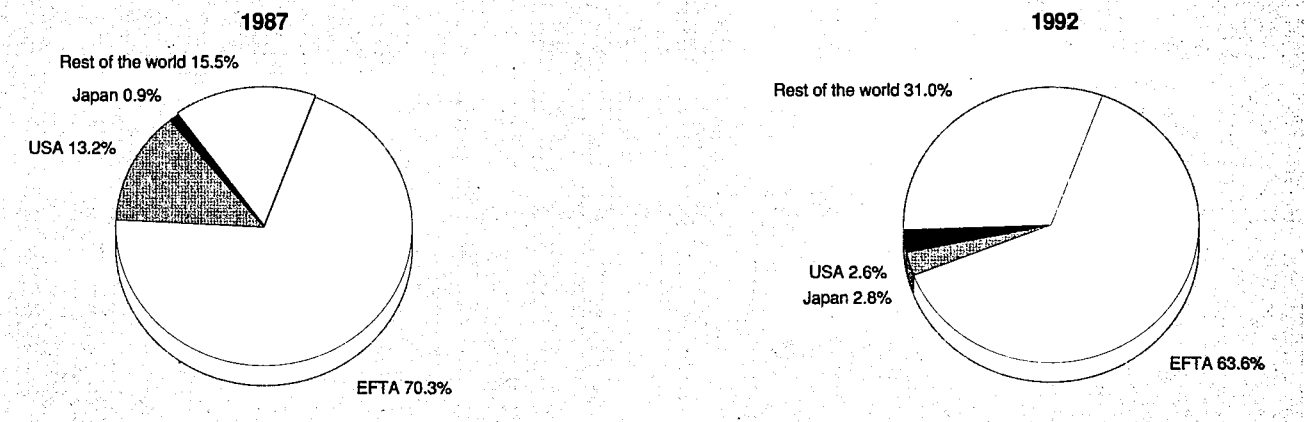
During the 1987-90 period, while US production continued its growth, EC production at constant prices fell as well as the other EC manufacturing industries did. This decrease led to a downsizing of the employment in the railway rolling stock while it was more variable in the other EC manufacturing sectors. Even after the recovering of the production in all EC manufactures, employment remained low in the 1990-92 period due to high unit and total labour costs index.

The result of this downsizing was growing productivity that should help the EC to maintain its competitiveness compared to producers with lower labour costs.

Production process

Since the industry has only a few clients, it works very closely with its customers. Producers can only develop new equipment in close collaboration with their clients. The Single European Market should make cooperation easier, as requirements will be harmonised through European standardisation.

Figure 7: Railway rolling stock
Origin of EC imports



Source: Eurostat

Innovations have been numerous in the industry. For example, high-speed and tilting car body technology allow higher medium speeds on curved tracks.

Multi-micro processor control equipment and three phase drives have become standard in various countries. The use of new materials like light alloys, composites, carbon fibres and the use of new propulsion systems with low weight transformer will decrease vehicle weight significantly and increase power efficiency.

Technological developments will also address information and telecommunication technologies regarding signalling and safety systems allowing trains to cross national borders; advanced telematics that will allow for example identification and localisation of vehicles; software applications, e.g. experts systems aiming at total predictive maintenance.

Additional technological innovations worth to mention are: bogies for locomotives and coaches with radial steering wheel sets to minimise lateral forces on track and wear of rail and wheel flange; satellite oriented control and communication systems; integrated transport systems for passengers and freight; innovative aerodynamic and silent proved trains and automotive train control systems for mass transit transport. Urban vehicles with low-floor and advanced propulsion systems are more and more used.

INDUSTRY STRUCTURE

Companies

The industry comprises about 100 locomotive, coach, and wagon builders, and about the same number of railway equipment manufacturers. Locomotives are mainly produced by divisions within large firms engaged above all in other industrial sectors, while passenger coaches and goods wagons are usually the primary product of the producing firm. The size of companies varies widely, from less than 100 employees to several thousand workers. The largest companies include GEC-Alsthom (UK-France), Asea Brown Boveri (Sweden-Switzerland and Germany), Siemens and AEG (Germany) and Ansaldo (Italy). All these companies produce in many fields other than transportation. Several of them are the result of mergers. There is a need for a concentrated industry structure to deal with the continuous expense of R&D and innovation, and with foreign competition.

Strategies

Major railway suppliers generally have significant presence in their main markets in the EC with production capacities in the main countries they serve. Today they are forced to rationalise their capacities and facilities across border to survive fierce competition. Indeed, East European railway industry can be seen as direct threat for EC industry as they benefit from low-wages conditions and generate a delocalization process adding pressure on existing overcapacity in Europe.

The primary strategies for the leading firms of the industry are increased innovation and technology and increased concentration. European firms must stay competitive on the basis of quality and modernisation.

Companies must also be large enough to withstand foreign firms. The specialised nature of products does not allow a large amount of economies of scale, but knowledge of different standards and requirements by different EC customers does give European firms an advantage over non-European firms on the world market. This advantage might well disappear after the introduction of European norms. Firms must therefore be prepared to face more direct foreign competition, as well as more intra-EC competition. However, the drawback of the creation of these European norms will only concern the diversity of the industrial supply. A technical harmonisation at the European level allows manufacturers to turn themselves to standardised rules and give them, as a result, the possibility to profit from economies of scale. Yet this allows also the railway industry to increase its competitiveness through more effective and more economic production methods so that the drawback of too much diversified production, i.e. in a very small scale, can be more than compensated. It is that objective that has led to the proposal of a directive for the high-speed trans-European network.

The railway industry is looking in three primary directions. Much of current investment is going into the high-speed railways, which are seen as one of the most important of near future developments. These high-speed systems will require some transformation of existing networks and infrastructure, as well as new infrastructure, and therefore provide the railway industry with new opportunities. Technical specifications on interoperability need to be prepared by industry and operators which would later on be transformed into mandatory standards.

Source: Eurostat

High-speed systems are limited in scope. However, another area which is receiving a lot of attention is the urban transit sector to which should be added the regional transport. Expanding cities and suburbs are making efforts for fast and easy public transportation, especially into the heart of cities. As urban transit systems cut down on both pollution and traffic, this is of primary importance to city planners. With the growth of cities, the transit systems will continue to grow to accommodate the increasing number of people and increased area. This sector is therefore considered by the industry to be at least of equal importance and some industrialists are even believing that it should be larger to the high-speed rail development, because of the almost unlimited room for expansion and demand. High speed, regional and urban transport systems need to be interconnected to create the "citizen networks" proposed by EC in its White Paper on Future Transport Policy.

Combined transport is another important field for the future activity of the industry. As it is not possible for railways to deliver goods to every location trucks can reach, the combined rail/road haulage offers a good solution, especially as it offers environment, energy saving, security and anticongestion advantages. Goods can be transported by rail for long distances and dispatched to their final destinations by trucks. Quick loading and unloading systems are essential for the success of combined rail/road traffic.

ENVIRONMENT

Rail transport is a less polluting mode of transportation than air or road. Nevertheless, efforts are made to protect the environment. A coordinated transport system for Europe has been identified as a prime objective of the EC policy in order to ensure sustainable mobility of freight and passenger under the best environmental and energy efficient conditions.

As environmental concerns are considered as a main issue in Europe, railway has to adapt to more and more strict environmental measures. In this way, weight-savings; more economical use of energy; cooling system increasingly designed with recyclable components and research for technologies to reduce environmental damages such as noise and air pollution are good examples.

REGULATIONS

The Single European Market will have a significant effect on intra-EC trade, especially due to the European standardisation efforts, and the enforced opening up of public procurement competition to all qualified EC companies regardless of nationality. The so-called "Utilities Directive" (Directive 90/531, in force since 1/1/93 excepted for Spain, Greece and Portugal) imposes four requirements to the public contracting entities: information, non discriminative specifications, transparency and fairness. It should lead to major changes in the old national practices and supremacy for the operators' requirements.

The "Remedies Directive" (Directive 92/13, in force since 1/1/93 excepted for Spain which will be in force on the 30th of June 1995 of, Greece and Portugal both in force on the 30th of June 1997) completes the system set by the above-mentioned Directive by giving the rights to suppliers to be assured that the obligations of the purchasers are fulfilled.

The "Service Directive" (Directive 93/38, in force on 1/7/94 excepted for Spain, Greece and Portugal) completes Directive 90/53 of which it contains a consolidated version in order to take into account the characteristics of service contracts. It will namely be applied to certain R&D services if they lead to contractual commitments. R&D contract which affects the competitive award of subsequent contracts has to be opened.

OUTLOOK

It is not easy to forecast economic indicators for the railway industry, because the industry is extremely dependent on factors beyond its control, and which are not always foreseeable. Changes in the political climate or the budgetary situation of a country can lead it to cancel long-standing contracts, for instance. However, by examining medium and long-term trends general forecasts can be made by industry.

Despite negative growth trends for railroad rolling stock in the 1980s, the outlook for the early to mid 1990s looks promising. Increased interest in high-speed lines as alternatives to air travel and road travel look good in the face of continuing worries about pollution from cars and overcrowded roadways, as well as the proximity of railroad stations to town centre compared to airports. Looking at the figures, consumption is expected to grow at about 0.5 to 1% and production at 2% during the period 1993-97.

Positive effects of European integration include increased freight and passenger traffic among Member States. The former Soviet Union countries can also offer EC manufacturers large new markets, as the need for technology in those countries creates business opportunities for western firms, provided that financing is available. Although the Single European Market may also involve risks for firms as well. The primary risk is that deregulation of airlines and road haulage firms will make them more competitive with rail. There is thus no guarantee that the Single European Market will increase the demand for railway equipment's.

An important factor affecting the market development will be the reorganisation and restructuring of European railway operators. Financing of transport infrastructures should also be promoted by EC and Member States in order to improve European global competitiveness and keep European railway industry technology ahead of international competition.

Aerospace equipment
NACE 364

Activity in the aerospace equipment industry is traditionally characterised by its cyclical nature. Since the beginning of the nineties however, the European aerospace manufacturers are experiencing their worst crisis, resulting this time from worrying structural problems. The slump in civilian demand for aircraft could have merely generated a cyclical downturn in the aerospace industry, but in fact, it translated into the largest depression ever through its coincidence with the dramatic reduction of military orders. Now, the European aerospace industry is facing problems of structural adjustment. The EC aerospace industry is increasingly operating in a global market, and its future will depend on its ability to surmount the current problems, in particular by increasing its export market share in spite of the emergence of newcomers and increasingly determined US competition.

INDUSTRY PROFILE

Description of the sector

Data available for the aerospace industry divides total turnover into four subsectors: complete systems (aircraft, missiles, etc.) engines, equipment, and space. Complete systems represent about 50% of the sector's turnover. Equipment represents some 26% of the turnover of EC aerospace industry, followed by engines with 18% and space with 6%. These products have both civilian and military applications. Civilian businesses cover several products: large commercial jets, regional aircraft (turboprops and small commercial jets), helicopters, space hardware (satellites and launchers).

Military operations comprise the manufacture of aircraft, missiles, helicopters and space hardware. The share of military activities in total aerospace manufacturing has been constantly decreasing since the early 1980s, as a result of political détente. However, the relative share of production for military purposes still represents more than half of the sector's activity in the EC.

Recent trends

Total EC production value amounted to 42 billion ECU in 1992, increasing by more than 5% per year (in real terms) over the eight year period to 1992. The four largest producing countries, France, the United Kingdom, Germany and Italy, together accounted for 94% of EC aerospace consolidated turnover in 1992.

The European aerospace industry achieved spectacular growth in productivity over the eighties, at above 5% on a yearly average between 1985 and 1990. Such performance accompanied an important increase in apparent consumption. Demand for large commercial aircraft and for space equipment had indeed expanded at a strong pace, which somewhat counterbalanced the cutback in the production of military aircraft. Consequently, the aerospace industry produced at a substantial rate throughout the eighties, a rate which actually jumped in 1989 and 1990.

1990 turned out to be a dramatic turning point. Hit by a sharp recession in both military and civil activities, EC's apparent consumption of aerospace equipment fell by as much as 14% (in current ECU) between 1990 and 1992. Meanwhile, production was cut by only 4.6% due to a strong EC performance on export markets. Employment, which had been regularly increasing over the second half the 1980s, fell by above 7% between 1990 and 1992.

International comparison

The EC emerged as a powerful competitor in the world's aerospace industry in the last decade. The founding of the Airbus Industrie consortium, composed with four companies: Aérospatiale (F), British Aerospace (UK), Deutsche Aerospace, also known as DASA, (D) and CASA (E) marked the return of Europe to the large civil aircraft market.

Competitive pressure to EC manufacturers still essentially stems from the US. The world aircraft industry has always been dominated by the United States, which posted 78.8 billion ECU of production value in 1992. Japan is also a sizeable aerospace manufacturer, with production value averaging 4.5 million ECU in 1992 (as such, Japanese turnover is more than five times smaller than EC's).

New players are emerging in other places. Far East Asian countries are endeavouring to build up an aerospace industry, often from scratch. To reach this objective, manufacturers in these countries are engaged in negotiations aimed at setting up joint ventures or alliances with western companies. The Indonesian industry has actually emerged as a respectable aerospace manufacturer, as this country managed to build up an industry in about one decade, which is now about to manufacture its own turboprop.

The former USSR is another potential entrant. The CIS, in particular, has one of the world's largest aerospace industries and holds an impressive technological know-how in aerospace manufacturing. This industry is nevertheless suffering from serious handicaps in terms of efficiency, organisation and overmanning. There is thus a long way before the east European aerospace industry becomes competitive and up-to-date. Meanwhile, principles of cooperation (in the space sector particularly) have already been agreed upon between CIS and the EC.

Foreign trade

It is no wonder, given the global nature of the aerospace industry, to find that exports are the sector's largest outlet. More than 39% of EC's production is exported, a share which exceeds 60% in France. Most of these exports are directed to extra-EC markets, North American being one of the major EC trading partners, with 35.6% of EC's exports and 67.5% of total imports to the EC.

Exports and imports to/from the EC broadly balance in terms of size. The very large fluctuations of the American dollar compared to European currencies have largely influenced EC's trade balance during the 1980s. In particular, the weakness of the dollar since 1986 has dampened EC's export competitiveness, which coupled with increased purchases of American aircraft by EC airlines, led to a deterioration of Europe's trade balance. In 1991, EC's trade deficit amounted to 1.8 billion ECU. In 1992, slackening apparent consumption in the EC translated into decreasing extra-EC imports. Consequently, EC's trade balance was positive by about 3 billion ECU. In 1993, EC's trade balance is expected to have deteriorated again, with extra-EC exports falling by 30% in value.

MARKET FORCES

Demand

Apart from export markets, the largest outlet for aerospace equipment is the government sector, through its military orders. The government sector actually represents more than half of the sector's domestic sales. It is then easy to understand how severely governments' drastic cuts in defence budgets have affected the aerospace industry as a whole. Under strong budgetary constraints, governments started cutting defence budgets in the middle of the eighties, that is far before the fall of the Berlin Wall. This trend has nevertheless accelerated over the recent past, in line with the end of the Cold War. The shrink in the defence market translated into cancellations or postponements of new or existing programmes.

Airline companies are the other major outlet for the aerospace industry, through their demand for new aircraft, replacement parts and maintenance services. Since 1990, airline companies have faced sluggish or negative traffic growth, fierce competition and rising costs, an occurrence of factors which translate into deep financial losses. Also enduring large over capacity due to the investment boom of the late eighties, most airline companies have severely revised their investment plans, often postponing or even cancelling orders for new aircraft.

Figure 3: Aerospace

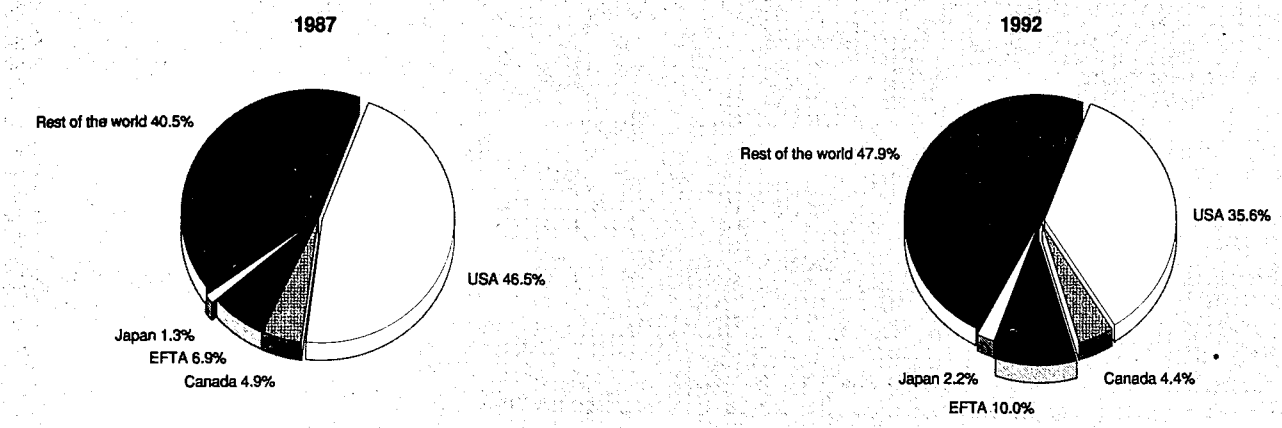
Figure 5: Aerospace
Destination of EC exports



Source: Eurostat

Regional airlines are suffering more from the recession than their larger counterparts, due to their difficult financial position, and their smaller market share. They have drastically cut orders. For example, new orders of EC produced turboprop aircraft dropped from 451 units in 1990 to 222 in 1992.

Civilian and military activities have traditionally posted asynchronous cycles. Since 1991, the deep recession in civil aviation, linked to the airline sector's difficulties, has coincided with sharp cuts in defence spending. Civil operations are therefore hardly not able to offset the dramatic decline of defence businesses for the aerospace industry.

Supply and competition

As indicated earlier, the world's aerospace industry is clearly dominated by US firms, which enjoy the advantage of a large domestic market, and lead in production volume, range of models and rate of production. In addition to these competitive advantages, the under valuation of the US dollar with respect to European currencies further handicaps the EC industry.

The relationship between the EC and the US is an outstanding mix of cooperation and competition. Collaboration exists, particularly in the case of engine manufacturers where strong links have been built up between EC and American manufacturers. Competition is, nevertheless, harsh between the major producers, and takes place both in civilian and military businesses.

Such intense competition led the EC aerospace industry to implement changes in the production process, which brought about significant changes in the organisation of work. Forced to shorten production cycles and to cut costs to remain competitive, the industry shifted towards increased automation. Simultaneously, new forms of organisation and management are being introduced, which aim at producing faster, cheaper and more efficiently. In particular, the aerospace industry is introducing just-in-time management. Airbus is also implementing simultaneous engineering, in order to efficiently manage the wide range of activities the group traditionally coordinates.

The development of such new forms of production (inherited from the Japanese automotive industry), is pushing the industry to a substantial reduction in the number of component suppliers, and contributing to the restructuring and consolidation of the aerospace supply sectors.

Production process

The aerospace industry is characterised by important synergies between the military and civilian segments of the market. Most of the synergies take place at the research and development stage. Generally, new technologies are first developed for military applications, and are in a second stage adapted for civil purposes, mainly in engines and avionics.

Another important feature of the aerospace industry is the importance of economies of scale in the production process. Research and development costs are the most important sources of economies of scale, although some scale economies may also be achieved at the production stage. The initial cost in R&D that is necessary to develop a new model is one of the largest of all industries. For example, the development of a large commercial aircraft requires up to 10 billion US dollars spread over four or five years, and the length of the product cycle is characterised by very long periods of time before reaching break-even. Economies of scale can also be achieved on the demand side, by enabling the costs of maintenance and training to be held in check.

Along with these economies of scale, the aerospace manufacturers can also benefit from "family economies". The existence of a learning curve and production overheads indeed provide manufacturers with a cost advantage when developing and producing new models. This actually gives manufacturers a strong incentive to produce a full range of models.

INDUSTRY STRUCTURE

Companies

Contrary to its American competitor, the European aerospace industry is largely segmented. Moreover, the main European aerospace manufacturers are smaller than their American competitors. Of the world's leading aerospace manufacturers in 1991, only four were European: British Aerospace, DASA, Rolls Royce (UK) and Aérospatiale.

The aeroengine industry is dominated by three players: Rolls Royce, General Electric (USA) and Pratt & Whitney (USA). The large jet aircraft industry is controlled by an oligopoly of similar size: Boeing (USA), Airbus and McDonnell Douglas (USA). The regional aircraft industry is dominated in the EC by few manufacturers including ATR (a joint venture between France's Aérospatiale and Italy's Alenia), British Aerospace, CASA, DASA, and Fokker (NL).

Apart from the leading European producers, a substantial amount of small and medium sized firms account for a significant share of the production. The production of an aircraft, which can be represented by a complex system of equipment, is indeed divided into parts which can be sub-contracted. Subcontracting activities are organised, like in the automotive assembly industry, in a hierarchical structure. The prime contractor, i.e. the aircraft manufacturer itself, delegates the production and sometimes even the conception, of complete systems to large suppliers which in turn out-source parts of

the operation to a third level of sub-contractors. Overall, France's Aérospatiale estimates that sub-contracting represents over 25% of the production of an aircraft.

In Germany and in the United Kingdom, the production is very concentrated under the wing of a single national company, respectively DASA and British Aerospace. This is not the case in France and in Italy where the industry remains particularly fragmented.

Strategies

The contraction of the defence industry led manufacturers to diversify increasingly into commercial activities. This has put greater pressure in the commercial business already suffering from over capacity caused by falling orders and deliveries.

To answer these challenges and difficulties in funding the development of new aircraft, the major aircraft manufacturers have been engaged in a deep restructuring. Besides the trend towards concentration, they have entered in a process of international cooperation which takes the form of mergers, acquisitions and strategic alliances. For example, Deutsche Aerospace received in May 1993 a go ahead from the European Commission to acquire 51% of Fokker of the Netherlands. This approval paved the way for the building of further links in the regional aircraft industry. DASA has actually proposed to Aérospatiale and Alenia to take a minority stake in Fokker. The French and Italian manufacturers already team up in the ATR regional aircraft venture.

International cooperation finds an interesting illustration with the negotiations held between Boeing of the US and Europe's four Airbus partners. Boeing and the partners of Airbus indeed forgot their recurrent disputes to reach an agreement upon a joint marketing study to develop the so called Super Jumbo, a civilian aircraft that should carry between 550 and 800 passengers. The size of the necessary initial outlay for the development of such a large project calls for a need to spread risks, a constraint largely understood by the potential partners in this operation.

REGIONAL DISTRIBUTION

In spite of efforts from both national and EC levels, the manufacture of aerospace equipment remains divided between numerous highly specialised production sites situated in different Member States, and France, the United Kingdom, Italy and Germany account for the bulk of aerospace production in the EC. With more than 30% of EC turnover each, France and the United Kingdom are the largest aerospace manufacturers in the EC. Recent trends in production and employment by country confirm the growing importance of Germany and Italy in aerospace manufacturing. The latter countries represent respectively 22% and 8% of EC manufacture of aerospace equipment. The Netherlands, Belgium and Spain provide the remainder of EC aerospace production.

ENVIRONMENT

Aircraft and engine manufacturers have long integrated environmental concerns in their production processes. Environmental performance has actually become an important criterion in an airline's aircraft and engine selection process. The oldest and least efficient aircraft have already been withdrawn pursuant to a number of international agreements, with major financial impact on the airline companies.

The aerospace industry is concerned with three different types of pollution. Noise created both on take-off and landing is one such problem. The aerospace industry has been dealing with this issue for a long time. However, the actual growth of air traffic, combined with the increased size of the aircraft, threatens substantially to reduce the benefit derived from the regulations that have come into force during the last decade. Unless aircraft noise is reduced still further, current international standards may face increasing challenges as individual airports seek to impose tougher controls.

Pollutant emissions, and in particular gaseous emissions in the high atmosphere, are another crucial environmental concern, often associated with the growing awareness of problems connected with the greenhouse effect. The industry has been handling this issue through several technical programmes, particularly through developments in advanced jet propulsion. The current environmental standards regarding gaseous emissions nevertheless appear to be inadequate in so far as they do not take into account the whole flight envelope: during a long distance flight more than 90% of the gaseous emissions are not covered by current standards.

Lastly, aerospace manufacturers are particularly concerned with the problem of energy conservation. This issue is all the more crucial as the industry is bound to produce increasingly powerful civil engines to match the growing size of aircraft. The engines of the future will have to be increasingly efficient in order to meet such requirements as energy conservation, thus requiring further research.

REGULATIONS

Owing to the intensification of international competition, all firms are operating under the same competitive conditions. In the context of progressive globalisation of the aerospace market, this principle applies just as much to competition within the EC as it does to external competitors. All the factors

that could affect competition must be taken into account, and this includes both direct and indirect public subsidies.

When the rules on competition, particularly Articles 85 and 86, are applied to the aerospace industry, the specific conditions of its viability such as the high level of investment needed, the necessary degree of cooperation and the comparatively small number of producers, are taken into account. Some sectors are confronted by difficult challenges of size and depth inherent in the industry: the worldwide dimension of the market, often national markets are too restricted to nourish the development of enterprises strong enough to be internationally competitive; industrial operations of such a size that no existing European enterprise can master all the technologies and acquire the production equipment needed to manage a complex programme in industrial and economic terms; financial requirements that have reached a level beyond the ability of any individual operator to accumulate; and the high degree of integration of the main competitors of the European aerospace industry.

Mergers are subject to Council Regulation (EEC) No. 4064/89 dated 21 December 1989. Their impact is generally evaluated on the world market. Consequently a merger bringing together most of the supply capacity of the EC in certain sectors of the aerospace industry does not necessarily amount to the creation of a dominant position incompatible with the Single Market.

Government subsidies for the aerospace industry are subject to articles 92-94 of the EEC Treaty. At the present time there is no sectoral aid framework laying down special directives for Member States in granting assistance to the aerospace industry. The distorting effects of subsidies on other competitors are also taken into account.

There are general regulations governing state assistance for R&D, but the special features of the sector are taken into account: the advanced technology content of the products, the fierce international competition and lastly the cooperative nature of research.

The sectoral agreement of GATT [General Agreement on Tariffs and Trade] on international trade in civil aircraft, which came into effect on 1 January 1980, lifted most of the tariff and non-tariff barriers to trade in commercial aircraft. In particular, it regulates the various forms of government subsidy to the aerospace industry. Because the situation of the US is fundamentally different from that of Europe and governed by different considerations, the signatories to the agreement do not agree on how it should be interpreted.

On 1 April 1992 the negotiators of the EC and of the USA concluded an agreement resolving their dispute about large commercial transport aircraft. In July 1992, a multilateral negotiation was opened within the GATT framework in order to reach an agreement covering all types of aircraft and all aircraft producer countries so as to arrive at multilateral rulings for this sector.

OUTLOOK

Given the reduction in the share of military work, which is not going to stop given the peace initiatives. the outlook of the EC aerospace equipment sector appears closely linked to the prospects for the airline industry.

Table 7: Aerospace

Production	-0.5	2.0
Extra-EC exports	-0.5	1.5

Source: DRI Europe

The combination of sluggish traffic and the large amount of new aircraft orders which peaked between 1990 and 1992 has resulted in a serious over capacity. Consequently, short term prospects call for a slackening of commercial aircraft deliveries, in spite of the improvement in air traffic. The markets for engines and equipment will grow in line with aircraft. The only way for the European aerospace manufacturers to secure growth will be through increased market shares. Airbus seems rather well positioned from this point of view, and the EC industry will continue to grow faster than its American counterpart.

After 1995, the growth in air traffic will be fully reflected in the world commercial aviation industry, translating into increased delivery rates. Economic recovery in the world and the need to replace old aircraft will keep activity going in business aircraft and helicopters, while the market for regional aircraft will grow more slowly. The space market will continue to grow apace, particularly in the commercial segment. Sales of military aircraft will continue to fall as programmes are either cancelled or postponed, and defence budgets are cut. Modernisation of aircraft might nevertheless partially check this decline.

Further rationalisation, increased concentration and an enhanced and more coordinated R&D effort appear necessary to enable the European aerospace manufacturers to remain competitive against the formidable US industry. Employment levels are in particular most likely to go on shrinking in the coming years.

The growth in air transport in the medium and long term will necessitate the development of higher capacity, more efficient aircraft, and the improvement of airport infrastructure. Research into environmental technologies to meet increasingly stringent standards will be essential to ensure that this predicted growth is sustainable.

Overview
NACE 37

The instrument engineering industry covers a wide range of diverse products. Demand for the industry's products stems from investment activities, mainly in the manufacturing sector, and from consumer expenditure on durables.
Thanks to the healthy economic climate of the last decade, EC production increased considerably. Product innovation was an important driving force as well, giving birth to new generations of devices. The increased use of electronic components and the integration with data processing systems brought about significant changes in the industry's relations with up-stream industries.
Competition from producers outside the EC increased rapidly over the last few years, causing a deteriorating trade balance throughout the eighties and into the beginning of the nineties. The outlook in the short term is somewhat pessimistic as the slowdown in the EC's economy dampens demand for investment goods and consumer durables.
In the medium term, however, the outlook for the instrument engineering industry is quite good, as the expected economic recovery will boost demand. Increased automation efforts in production processes, the development and use of new generations of devices, growing environmental concerns and the effects of the ageing of the population are all expected to stimulate demand for the industry's products.

INDUSTRY PROFILE

Description of the sector

The instrument engineering industry comprises the following sectors:

- measuring, checking and precision instruments and apparatus (NACE 371);
- medical and surgical equipment and orthopaedic appliances (NACE 372);
- optical instruments and photographic equipment (NACE 373); and
- clocks, watches and parts thereof (NACE 374).

The most important sub-sector is that of measuring, precision and control instruments, with about 38% of total 1992 industry output; the sub-sector of medical devices follows with about 32% of total output, optical instruments and photographic equipment represent approximately 25% and clocks and watches, around 5%. Within the EC, the most important producing countries are Germany with about 46% of the total, the United Kingdom (19%), France (14%) and Italy with some 9%. The smaller countries within the EC produce about 12% of the total. Compared to other sectors of the EC manufacturing industry, the instrument engineering industry is of minor economic weight, with output equivalent to only about 11% of that of the transport equipment industry, for example.

Recent trends

In the recent past, the EC's instrument engineering industry experienced a quite favourable development. Production increased by some 4% per year in volume from 1983 to 1992, well above production growth of the manufacturing sector as a whole, which grew by about 3% in real terms during the same period. Employment figures remained more or less stable with approximately 323 000 employees on the industry's payroll in 1992.

Demand for the industry's products, as measured by apparent consumption, increased at a faster pace than production during these last few years, about 5% per year, in real terms. The difference was made up by sharp increases in imports (7.5% per year in volume). Exports to countries outside the EC increased considerably as well, though at a slower pace than imports (4.6% per year). The result is a deteriorating EC trade balance over the last several years, with a deficit of nearly 3 billion ECU in 1992.

International comparison

The most important producing country in the field of instrument engineering in the Triad is the USA, with more than 50% out of the Triad's total in 1992. The performance of the three main producing areas within the Triad was similar over the last few years. Production growth in the USA and the EC was about 7% per year in value from 1983 to 1992. The most dynamic development for the industry was in Japan, with an average annual growth rate of more than 9% over

the same period. Consequently, the share of USA and EC production of the Triad's total declined slightly by two percentage points, each, from 1983 to 1992, benefiting mainly Japanese production, which increased its share in the Triad's total from about 27% in 1983 to 31% in 1992. This performance was mainly the result of fast growth in the sub-sectors of measuring, precision and control instruments and of clocks and watches, where Japanese firms tripled their production during the period.

Foreign trade

Trade in instrument engineering products grew at a highly dynamic pace over the last few years. Extra-EC exports grew by 6.0% per year in value from 1983 to 1992. The most important markets for EC producers are the developing countries (including the East Asian newly industrialised countries [NICs]), with some 32% of total extra-EC exports. The EFTA countries and the USA receive about 23% each of extra-EC exports. Developing countries' markets - mainly the East Asian NICs, but also China - have been gaining more importance over the last years. This has caused the share of the USA and the EFTA countries to decline significantly from 1987 to 1992, while that of the East Asian NICs increased considerably.

Imports from outside the EC increased even more dynamically, at roughly 9% per year in value from 1983 to 1992. Consequently, the EC trade balance has been deteriorating and its deficit suffered an eight-fold increase between 1983 and 1992. On the import side, the most important competitors for EC producers are Japan, the USA and the EFTA countries, representing together about 80% of total EC imports in 1992. Imports from developing countries (including the East Asian NICs), however, are likely to gain importance in the future, mainly to the detriment of Japan, which has lost 8.7 percentage points of market share over the last five years.

Most dynamic, however, was the development of trade among EC member countries. Intra-EC trade grew by some 11% per

year in value during the last few years. As a result, the share of intra-EC trade out of total EC imports increased from 45% in 1983 to 49% in 1992.

MARKET FORCES

Demand

Demand for products of the instrument engineering industry, as measured by apparent consumption, increased considerably over the last few years, at a rate of 5% in volume from 1983 to 1992. Goods of the industry are used in nearly all production processes, largely to monitor and regulate production. However, like the diversity of the industry's products, demand pattern for its goods varies as well. On the whole, the industry benefited from the strength of investment activity during the last few years, induced by high capacity utilisation levels in a healthy economic climate. Investment activity was also inspired by preparations for the establishment of the EC single market in 1993 and by the need to compete in global markets. In addition, tighter environmental regulations in some EC countries increased demand for products of the industry.

Product innovation was also an important driving force behind the development of demand. The use of electronic components and their integration with data processing systems is now a common feature of nearly all the sub-sectors of the industry. Efforts of the manufacturing sector to automate production processes to increase efficiency have required the ever wider use of precision instruments.

The sub-sector of measuring, precision and control instruments benefited most from these developments. Another beneficiary was the sub-sector of optical precision instruments, a subgroup within optical instruments and photographic equipment that is also increasingly used in manufacturing processes. In particular, the tendency to substitute optical methods for mechanical measuring methods has given fresh impetus to this sector since it permits measurements to be taken without having physical contact with the measured object, thus increasing speed and accuracy.

In the field of spectacles, lenses, frames and mountings, demand stems mainly from private households. Demand growth was supported by increases in the number of people wearing corrective glasses, as well as by dictates of fashion that induced the use of new products, or even the use of more than one pair of glasses.

Demand for products of photographic and cinematographic equipment has been stimulated by the development of new products through the introduction of electronic processes. This has overcome market saturation by simplifying camera usage thus broadening the market to consumers previously unwilling to use less automated models. Demand for the industry's products also benefited from monitoring needs in manufacturing processes.

In the field of medical and surgical equipment, the driving forces behind demand were the general ageing of the population, as well as increased health consciousness on the part of the population in general. In addition, the development of new materials (bio-compatibility) and the increased use of disposable and sterilised instruments strengthened demand for these kind of products.

In the sector of clocks, watches and components, demand depends mainly on consumer expenditure. Demand is driven mainly by fashion trends, and only to a lesser extent by technological innovations since the most important developments took place more than a decade ago. Increasing affluence among consumers resulted in a gradual shift from cheaper watches to the higher-end range.

Supply and competition

Increasing competition from producers outside the EC is one of the main features of the EC instrument engineering industry in the last few years. Extra-EC imports grew by about 7.5% per year in volume from 1983 to 1992, well above the growth of extra-EC exports (4.6% per year) during the same period. Considering instrument engineering as a whole, the market shares of the USA and EFTA countries increased slightly over the last few years. In 1987, about 47% of extra-EC imports stemmed from these two areas, but this increased to roughly 51% by 1992. The USA increased its market share considerably with assistance from the depreciation of the USD against European currencies. Japan's EC market share dropped from about 36% in 1987 to 28% in 1992; it still retains the highest single-country EC market share, however. In recent years, competition from developing countries, mainly from the East Asian NICs, increased as well. The success of these countries in the EC is mainly based on low-end products mass produced at highly competitive prices. In the last few years, however, these countries have also become active in technologically advanced products; competition from the East Asian NICs in advanced products can be expected to stiffen in the course of the nineties.

The position of EC producers varies considerably in the various sub-sectors. In measuring, precision and control instruments, EC producers have a relatively strong position in the production of technologically advanced products, resulting in a trade balance that is still positive. In the other instrument engineering sub-sectors, however, the EC trade balance has been negative over the whole period or has become negative during recent years. In medical and surgical equipment and orthopaedic appliances, EC producers are confronted with

Source: Eurostat

strong competition from the USA. EC production in the field of photographic equipment shrunk over the last few years to only a few niche manufacturers. For clocks and watches, the situation is characterised by the strong penetration of Japanese and the South East Asian NIC products in the lower price range, and of Swiss products in top-of-the-line and fashion watches. Switzerland is the major EFTA exporter to the EC with about 70% of imports coming from this trading block.

Production process

The introduction of electronic components has caused important changes within the instrument engineering industry. While manufacturers produced much of their products' components themselves in the past, the increased use of electronic components has forced them to hand over portions of their component production to subcontractors causing a shift in know-how to sub-contractors. As a result, some producers restrict themselves to the design and assembly of their products. This development has caused some professions to literally die out. One such example is in the field of watch movements where electronically regulated movements have largely displaced mechanically regulated ones in the low and middle quality watches. Another change in production processes has been increased automation efforts to reduce labour costs, or the displacement of labour intensive production processes to low cost countries. Increases in the value of production were not accompanied by similar increases in employment figures, the end result being productivity increases of 3.1% per year from 1983 to 1992. The strength of competition from the South East Asian NICs, Japan, and the USA guarantees that the trend for lower labour inputs will continue, whereas the importance of capital inputs will continue to increase in the next few years.

INDUSTRY STRUCTURE

Companies

The instrument engineering industry is largely organised in small and medium sized firms with about 32 000 firms in the EC. About 89% of the firms operating in the industry employ less than 20 workers; 9% have a size of 20 to 100 workers. Larger firms with more than 100 employees represent only 2% of the active firms in the industry; however they are responsible for about 63% of the industry's turnover.

Most of the firms are highly specialised in a particular area of activity and have a small number of competitors within the EC. The more important competition stems usually from firms outside the EC. Given the small size of demand for their specialised products, most of the firms operate at least on the national level, with some operating on the global market.

The larger firms, in general, offer a broad range of products usually in a single sub-sector. A few of the large firms do operate in several sectors of instrument manufacturing. For example, the company Zeiss (D) is active in measuring, checking and control machines as well as in the optical instruments field. For some of the larger companies, instrument engineering is only one of a number of branches. Siemens (D), for example, deals in optics, medical and surgical equipment and metrology along with its involvement in a large number of fields such as computers, household appliances, consumer electronics, electrical industrial equipment and many others.

Strategies

Competition from outside the EC can be divided into two categories: competition in technologically advanced products, mainly from EFTA countries, USA and Japan; and competition in the field of less technologically advanced, standard, instruments, mainly from the East Asian NICs.

In the field of technologically advanced products, EC producers have a relatively strong position. To remain competitive, however, they will have to increase R&D expenditure. In looking at the structure of the industry it is apparent that firms are often too small to finance the necessary R&D efforts: an industry restructure towards larger firms could bring advantages in this context. Cooperation in the field of research and development, as well as in production, could also help the industry to survive the challenges of competition from abroad.

To compete in the field of standard instruments, efforts have to concentrate on cost reduction and increased production efficiency. Another strategy is the relocation of labour intensive production processes to low cost countries: a trend already apparent in the production of clocks and watches.

REGIONAL DISTRIBUTION

The most important producer in the EC's instrument engineering industry as a whole is Germany, with some 46% out of the EC total. The picture is similar in nearly all the subsectors of the industry: in measuring, precision and control instruments, in medical and surgical equipment and orthopaedic appliances and in optical instruments and photographic equipment, Germany is by far the largest producer with more than 50% of the EC total. Within the latter sub-sector, Germany produces mainly optical, precision and photo instruments, while France and Italy are major producers in ocular optics and spectacles frames. In the field of clocks and watches, the dominant producer countries remain Germany and France. Over the last few years the relative position of German producers declined to the benefit of French producers. In 1983, some 58% of the EC production stemmed from Germany and only 31% from France. While production in Germany declined sharply by some 8% per year in volume from 1983 to 1992, the decrease in France was less dramatic (-1%). Consequently, French producers increased their production share to 40% in 1992, while that of Germany declined to the same figure.

ENVIRONMENT

The production process of instrument engineering goods does not harm the environment to any large extent, as it involves little use of polluting materials and energy. In the field of photographic equipment, there is one source of pollution in the form of chemicals used in the production and development of films. In the clock and watch industry, environmental concerns are related to the use of small batteries containing nickel-cadmium that is liable to pollute the ground water and endanger the population if disposed of improperly. In the medical device field, the main burden on the environment is solid waste disposal problems stemming from the extensive use of disposable, sterilised instruments and their associated packaging materials. To restrict environmental damage, there is an EC directive, requiring that all packaging materials be recyclable and recovered by the year 2000.

More important in this context, however, are the opportunities from which the industry may benefit. Increased concerns regarding environmental issues will generate additional demand in the course of the nineties as monitoring and analysing environmental damage becomes ever more important. This will benefit mainly measuring, precision and control instruments, but also optical precision instruments because the use of optical methods to measure environmental damage creates additional demand for this industry's products.

REGULATIONS

The instrument engineering industry as a whole will be influenced by the technical standardisation of machinery within the EC. The removal of non-tariff trade barriers within the EC will be further supported by the standardisation of metric regulations a particularly important element for the measuring, precision and control instruments industry.

In the field of medical equipment exports, the most important non-tariff trade barrier for European producers is the lengthy and, therefore, costly process of certifying the products in the USA.

Beside the EC directive requiring by the year 2000 the ability of all packaging materials to be recyclable and recovered, another EC directive requires that any medical device or product sold in the EC feature the EC stamp of approval, attesting to its conformity to EC law.

OUTLOOK

Prospects for the instrument engineering industry are somewhat pessimistic in the short term. The sharp downturn in investment activity in the industrialised world will negatively affect demand for the industry's products, particularly for products of measuring, precision and control instruments, and precision optical instruments; both suppliers of mostly investment goods. The weakness in consumer expenditures will also affect demand for clocks and watches and photographic equipment.

Table 8: Instrument engineering
Expected real annual growth rates

(%)	1993-94	1993-97
Apparent consumption	1.2	3.6
Production	1.3	2.7
Extra-EC exports	2.2	3.4

Source: BAK

In the medium term, however, prospects for nearly all subsectors of instrument engineering are quite good. In the field of measuring, precision and control instruments and precision optical instruments, prospects are favourable because the increasing automation of industrial processes will boost demand for testing, measuring and analysing instruments. In addition, environmental concerns are also likely to boost demand for these kinds of products. For photographic equipment, the outlook is somewhat more pessimistic since competition from the NICs and Japan is very strong. Demand for spectacles, lenses and frames is expected to remain strong in coming years: planned cutbacks in health expenditure in the industrialised countries are likely to have a negative effect on demand, however. Cuts in health expenditure will affect demand for medical devices as well. In the field of clocks and watches, the medium term outlook is somewhat pessimistic, as competition from outside the EC will further dampen EC production.

Written by: BAK

Measuring, precision and control instruments
NACE 371

Increased investment activities and the growing spread of electronic components in their products provided the industry with a favourable climate for production growth during the last decade.
Competition for EC producers increased from both intra-EC trade and increased imports from outside the community. As a result, the trade balance declined during the eighties and the beginning of the nineties, while still remaining positive.
In the recent past, the picture has changed as demand for products of the industry declined. This was due to the recession in the western industrialised world as well as to the loss of markets in Eastern Europe.
Prospects in the short term remain unfavourable, but in the medium term the industry should return to a stable growth path with the expected upturn in general economic activity. The industry should also benefit in the nineties from the tighter controls required to meet growing environmental concerns.

INDUSTRY PROFILE

Description of the sector

The industry of measuring, precision and control instruments covers the fabrication of:

- gas meters, water meters and other liquid supply meters (including petrol pump meters);
- measuring, checking or automatic control instruments and apparatus;
- equipment for navigation, hydrology, geophysics and metrology;
- drawing and mathematical calculating instruments;
- precision measuring instruments;
- precision balances, laboratory equipment and teaching equipment; and
- other precision equipment and apparatus.

The sector does not include electrical counters, or measuring, testing, regulating and control instruments, all of which are classified under NACE 344.

Compared to other branches of the manufacturing sector this industry carries a relatively small economic weight. Its output represents about 34% of that of the consumer electronics industry measured in value added terms for 1992.

Within the field of instrument engineering, the sub-sector of measuring, precision and control instruments is the most important, with nearly 40% of the output of the entire industry.

The largest producing country, by far, is Germany, with about 50% of total value added in the EC, followed by the United Kingdom (31%), Italy (10%) and France (4%).

Recent trends

During the last decade, producers of measuring, precision and control instruments experienced quite favourable demand conditions, driven by strong investment activity in the manufacturing sector. Average production growth was roughly 3.4% per year for 1983 to 1992, which was in line with the growth of manufacturing as a whole (2.8% per year).

During the same period, demand for the industry's products, as measured by apparent consumption, increased by 7.5% per year in value. The difference came from a 9.6% per year nominal increase in imports from outside the EC. Extra-EC exports had an annual growth rate of 4.9% for 1983 to 1992. As a result, the trade balance has been deteriorating over the last decade while still remaining positive. In 1992, exports to non-EC countries represented only about 21% of production compared to 24% in 1983.

The performance of the industry was strongest up to 1989. After 1990, production growth slowed down remarkably as investment activity in EC-manufacturing as well as demand from major export markets declined. During the same period the workforce was reduced from 130 000 employees in 1989 to 121 000 in 1992.

International comparison

The world's largest producing country in measuring, precision and control instruments is the United States with about 42% of the Triad's total (EC, USA and Japan). Japan represents about 32% and the EC 26%. Fastest growing, however, was Japanese production, whose share of Triad production in-

creased from 20% in 1983 to 32% in 1992; the United States' share declined during the same period from 51% to 42% in 1992 and the EC's, from 29% to 26% during the same period.

Foreign trade

International trade in measuring, precision and control instruments increased considerably during the last decade. Competition for EC producers sharpened, with imports from extra-EC countries rising by 9.6% per year in value from 1983 to 1992. Extra-EC exports, which were roughly twice as large as imports in 1983, increased by only 4.9% during the same period. Consequently, the trade balance deteriorated somewhat, though still remaining positive. In 1992, about 17% of EC demand was satisfied by imports, compared to 14% in 1983.

The United States, as the major player in the industry, is also the main competitor for EC producers with a share of about 40% of the total EC-imports. Another important supplier on the EC market are the EFTA countries, with a share of roughly 30% of total extra-EC imports. Competition from the USA has continued to increase during the last years, resulting in further gains in market share. The EFTA countries, on the other hand, lost market shares. One explanation could be the increased price competitiveness of United States products during the last years, thanks to the depreciation of the USD against European currencies. Japan, a minor player in terms of competition, lost market share as well. On the other hand, the developing countries, including the East Asian newly industrialised countries (NICs), managed to increase their market share. The United States is also an important market for EC manufacturers, while Japan is of secondary importance. Intra-EC trade increased as well, spurred by the advent of the common market. It more than doubled during the eighties, growing by about 8.7% per year in value from 1983 to 1992. Germany is the most important exporter within the EC, with about 34% of total intra-EC exports.

Figure 4: Measuring, precision and control instruments

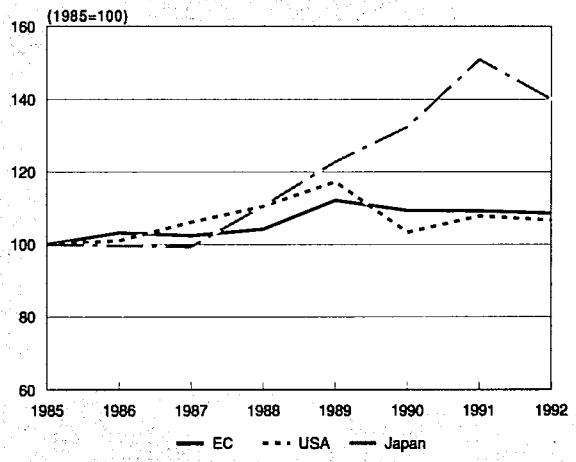
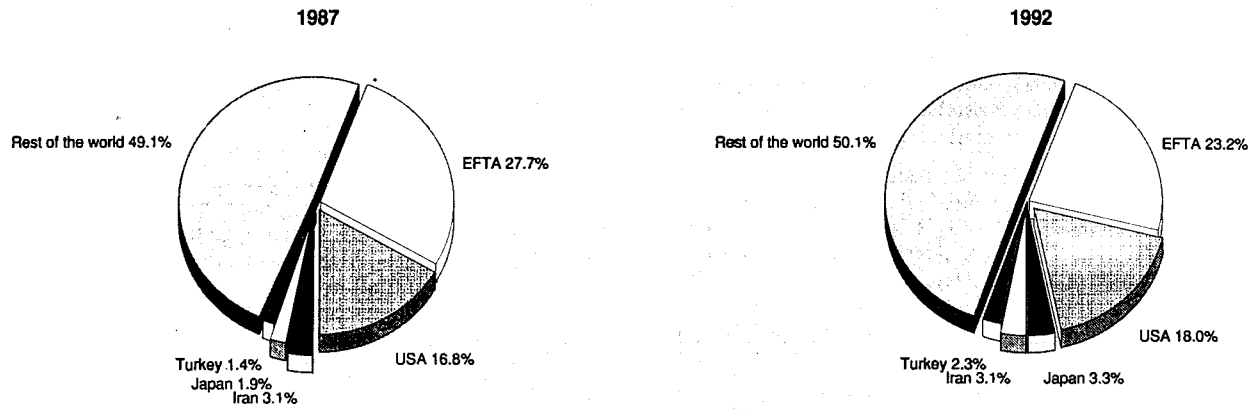
Source: DEBA

Figure 5: Measuring, precision and control instruments
International comparison of production at constant prices



Source: DEBA

Figure 6: Measuring, precision and control instruments
Destination of EC exports



Source: Eurostat

The share of intra-EC trade within total EC imports decreased from 62.1% in 1983 to 60.4% in 1992 since extra-EC imports have been growing at an even faster rate.

MARKET FORCES

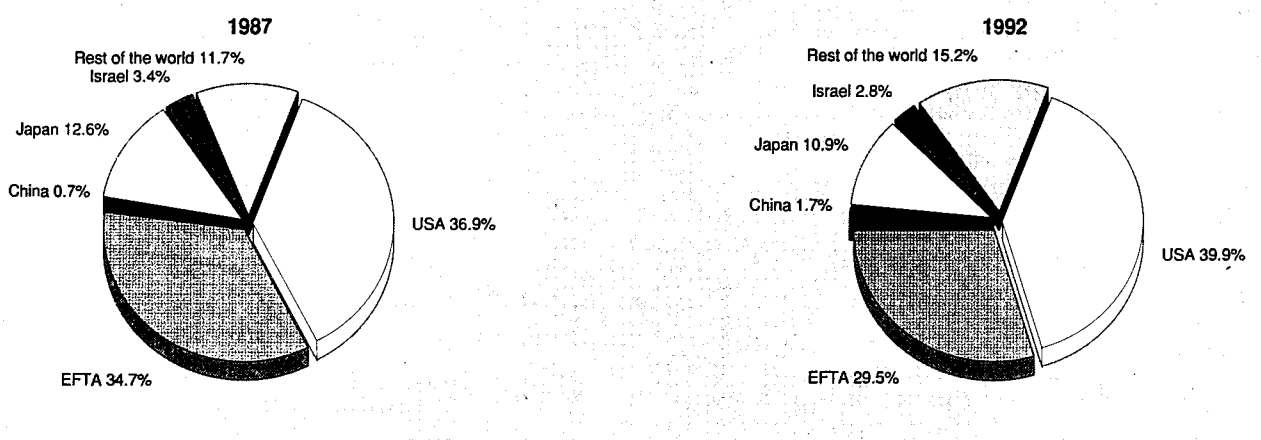
Demand

Strong economic activity in the industrialised world automatically spurs demand for measuring, precision and control instruments due to the fact that clients of the industry are found in every sector of the manufacturing industries, the service sectors, and even certain consumption products. In the field of measuring, checking and controlling instruments, which are used to automate, control and regulate production processes, the most important areas of application are not only in the fields of vehicle production, machinery construction, and environmental protection, but also in the chemical, pharmaceutical and food industries. In the field of instruments for navigation, hydrology, geophysics and metrology, the main clients are the aircraft and shipbuilding industries. The weighing instrument industry , which produces analytical, chemical and precision balances, is involved in industrial uses as well as in wholesale and retail trade. The necessity to modernise to stay competitive in an increasingly open economy, combined with high levels of capacity utilisation in a healthy economic climate, stimulate companies to invest in highly sophisticated equipment.

In addition, demand for the products of the measuring, precision and control instruments industry is stimulated by technological change, (the increasing rate of replacement of mechanical devices by electronic components), by system integration, (which requires integration with data processing systems), and by the growing use of sensors. In particular, the automation of industrial processes using data processing systems to allow the automatic readjustment of filling, dosing and conditioning processes, has given fresh impetus to the industry and stimulated the production of new generations of instruments.

The introduction of new technologies has also led to a shift in demand from mechanically regulated instruments to electronically regulated products. The share of electronically controlled products in the weighing industry, for example, is now above 90%.

Figure 7: Measuring, precision and control instruments
Origin of EC imports



Source: Eurostat

Supply and competition

During the second half of the last decade the United States has seen its production increase by around 3% per year, while EC-production increased by about 1.8% per year in real terms during the same period. The development of the industry in the United States has benefited from the increase in price competitiveness brought about by both the devaluation of the USD during the last years, and from a technological edge. Consequently, United States producers increased both their exports to the EC and their market share.

The lesser share of imports from Japan tends to hide the fact that EC producers are confronted with strong competition from Japan in a number of specific sub-sectors. In the weighing industry, for example, Japan producers are making efforts to penetrate the retail trade market by slashing prices. This development was also helped in the past by a decline of the Yen against EC currencies. Another possible factor in favour of Japanese competitors is the fact that EC enterprises in this sector are usually small or medium-sized, while Japanese enterprises are often larger. This permits them to benefit from a better availability of capital for research and development and, possibly, from synergies and from economies of scale. In addition, the advent of the EC common market in 1993 has spurred efforts by the Japanese firms to gain a foothold there. In the weighing industry for example, TEC and Ishida already have operations in EC countries, the majority being located in the United Kingdom.

Another important development has been the increase in competition from the East Asian NICs. This can be expected to continue in the future, particularly in the field of standard, less technically advanced devices, due to their lower labour and capital costs.

Intra-EC competition has strengthened during the last decade with intra-EC trade increasing by roughly 9% per year from 1983 to 1992. The advent of the common EC market has developed important driving forces behind the increase in trade between EC Member States. Two of these forces are the technical standardisation of machinery within the EC and the growing number of cross-border corporate partnerships between EC companies. This trend is expected to be reinforced during the next few years because of EC directives removing non-tariff trade barriers, such as differing metrological regulations in each country.

The most important exporters within the EC are Germany with about 34% of intra-EC exports, followed by France with 17% and the United Kingdom with 14%. The largest importers within the EC is France with about 21%, Germany with 20%, Italy with about 14% and the United Kingdom and the Netherlands with about 11% each.

Production process

Technological developments, such as the increased use of electronic components in products, have considerably changed relationships with up-stream industries. In the past, the production of mechanically regulated measuring, precision and control instruments mainly required the input of raw or partially processed materials which were then converted to high value added products. Manufacturers are increasingly unable to produce in-house all or a majority of the components for their products due to the rapid increase in the use of electronic components. The consequence has been an increase in subcontracting, particularly with electronic companies. In some cases, producers of instruments have reduced their contribution to the tasks of assembly and design of their products. Thus, know-how was shifted from the manufacturers to subcontractors. The trend for increased integration with data processing systems continues. In the sector of precision mechanics, for example, the integration of new data processing achievements has opened up new possibilities in drawing and design technology. Similar developments are also taking place in the fields of analytical equipment, process control systems, transducers, measuring devices and other measurement systems and sensors.

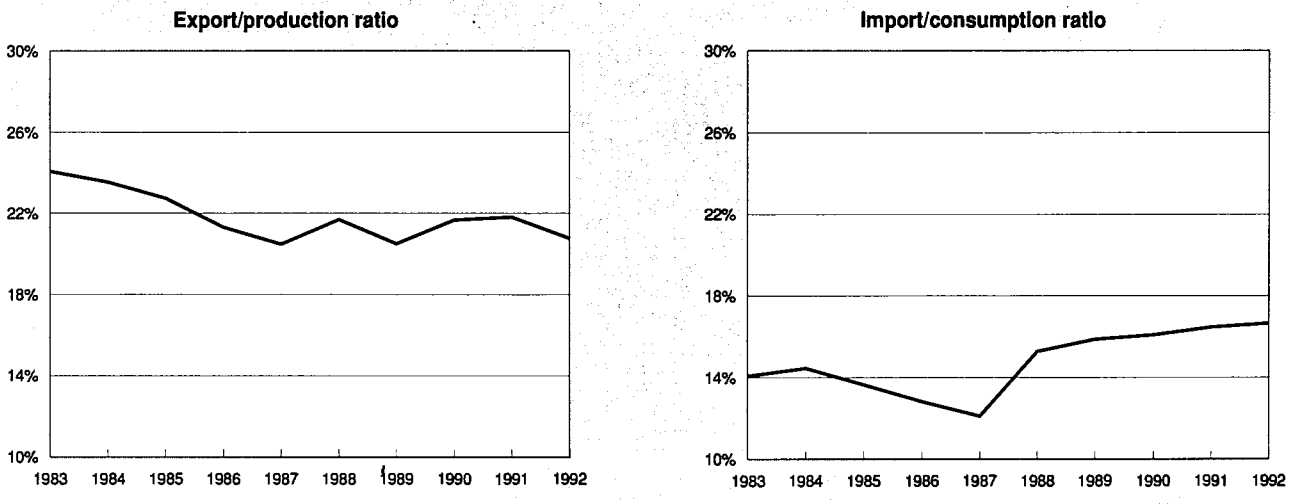
INDUSTRY STRUCTURE

Companies

In general, the industry consists of small and medium-sized companies concentrating their activities on one or two product lines. A few large companies produce a broad range of products in various fields of instrument engineering. Some are engaged in other fields of manufacturing as well, such as consumer electronics, computers and motor vehicles.

Depending on the product line, the structure of the industry varies. In the weighing industry there are about 350 firms employing some 20 000 people. The size of the enterprises range from firms employing only a few people to firms em-

Figure 8: Measuring, precision and control instruments Trade intensities



Source: DEBA

ploying a few thousand. Important companies in the weighing industry are Sartorius (D) and GEC Avery (UK). Enterprises in this industry are usually active only in their national market, at least as far as small and medium-sized companies are concerned. Other sub-sectors, such as the counting instruments industry consist mainly of medium to large manufacturing firms. A similar picture is found in the sub-sector of checking and controlling machines, which is fairly concentrated with about 80 producers worldwide. The main EC producers are Zeiss (D), Renault Automation (F) and Dea (I). In measurement and automation technology, the majority of the firms are small to medium-sized, with up to 200 employees, but a few large firms employ more than 1 000 employees. Important firms in this sector are Hartmann & Braun (D), Hottinger Baldwin (D), Krohne (D), Endress & Hauser (D) and Foxborro (UK), which was recently taken over by Siebe (UK).

In the field of automation technology, there are a few multinational companies active in various fields of manufacturing, such as Siemens AG (D), ASEA Brown Bovery (D) and Philips (NL).

Strategies

As previously mentioned, increasing international competition is expected to continue the foreseeable future. In the fields of highly sophisticated products, EC producers will face fast paced technological innovation, imposed mainly by Japan and the United States. In the field of the less technologically advanced products, standard instruments in particular, increased competition can be expected from the East Asian NICs who are very price competitive. Lastly, cross-border competition within the EC is expected to increase as well. In the fields of standard instruments, EC firms will need to invest in modernisation and automation of the production process to improve production efficiency and reduce costs. This will counteract the effect of their higher labour costs as compared to that of the East Asian NICs. Another possible strategy could be to relocate production facilities to countries with lower production costs. Spain, Portugal, Hungary and the Czech Republic are likely alternative locations.

In order to remain competitive in the field of highly sophisticated products, EC firms will have to increase their R&D expenditures considerably. The problem is that this high-cost strategy can hardly be financed by small or medium sized companies. A higher degree of concentration is thus becoming imperative if the industry is to survive and to prosper. Changes in that direction have already been happening. In the weighing industry for example, Toledo (F) was taken over by Mettler (D), GEC Avery (UK) took over Berkel and Testut (F) has bought Trayvou (F) and Lutrana (F). Similarly, the Precia (F) company took over Pesage Volumetrie (F) in 1990. In industrial process control, changes have occurred with the take-over of Foxboro by the British firm Siebe, which has thus become the world's second largest producer of these types of instruments, behind Honeywell. At the beginning of 1990, the Italian company Elsag, after selling Bailey Controls to the American Babcock Wilcox Group, bought the Sereg division of Schlumberger (D). In 1989, CGE-Alsthom (F) took over the industrial control operations of the British GEC.

Another possible strategy, particularly for specialised niche products, is for the smaller firms to increasingly limit their activities to design and assembly and subcontract upstream and downstream activities such as components production and marketing and service functions to other firms.

The marketing philosophy of the industry has evolved during the last few years. Most companies are now forced to operate at least on a pan-European level. Larger firms often operate on a global level. This tendency towards globalisation is likely to increase in the future as the EC common market becomes fully operative and as overseas markets become more open. The problem in gaining market shares in dynamic markets such as the East Asian NICs is that marketing functions and post-sale service functions cannot be satisfactorily provided by small or even medium sized firms. Cooperation agreements with local producers or co-ordinated efforts of EC producers to form joint service centres and marketing groups in these countries are possible answers to this problem.

ENVIRONMENT

The manufacture of measuring, precision and control instruments has little impact on the environment. More important in this context are the new opportunities that will benefit the industry that are emerging from the growth of environmental concerns within the manufacturing processes of other industries and utilities. Developing needs for measuring and analytical equipment for gas, vapour, dust and noxious substances in air and water, and for apparatus to investigate harmful effects on humans, animals, plants, soil and food will provide the industry with a growth in demand for its products. Beyond this initial source of demand for identification and monitoring apparatus, demand for instruments to regulate and reduce environmental damage (such as gas desulphurisation systems), will also develop.

REGULATIONS

In general, the industry should benefit from the technical standardisation of machinery within the EC, which should ease the development of trade between EC members' firms. EC Directives will remove non-tariff trade barriers, such as those caused by different meteorological regulations in each country.

In the field of electronic weighing machines, the Commission has applied anti-dumping duties on imports from a number of Japanese firms. Similar measures are being considered regarding electronic weighing machines produced in South Korea and Singapore.

OUTLOOK

Short term prospects for the industry of measuring, precision and control instruments are rather unfavourable. Production in the EC is expected to decline in 1993 and to remain flat in 1994, as the sharp cut backs in investment plans in nearly all EC countries further dampens demand for the products of the industry. The only country where demand can be expected to increase is the United Kingdom; demand from the United States will increase, but this will not compensate for losses on other export markets.

In the medium-term, demand as well as production will return to a stable growth path. The increasing rate of technological change, the dynamics of the common market, the development of new markets in South East Asia and in other NICs and the growing weight of environmental requirements in manufacturing and service industries will combine to offer a wide market base for increasing demand for the industry's products. A revival of demand from Eastern Europe, as well as increased demand from South America and possibly China, may provide

Table 5: Measuring, precision and control instruments

the necessary impetus for increased production in the second half of the nineties. To capture a large share of this additional demand, EC firms will have to increase their efforts to overcome competition from abroad, increase production efficiency to reduce costs, invest more heavily in R&D and expand their globalisation efforts.

Medical and surgical equipment and orthopaedic appliances
NACE 372

Increasing health expenditures resulted in a period of strong growth in the industry of medical and surgical and orthopaedic appliances during the recent past.
The ageing of the population, increasing health consciousness and product innovation were the most important driving forces for this development.
The industry is dominated by the United States, with roughly 70% of the world market. Thus, the main competitors of EC producers stem from there.
Medium term prospects for the industry are quite good, as demand for the products will keep increasing through the nineties. Increasing efforts to control health expenditure in most industrialised countries are expected to slow down the growth of demand for the products and to foster competition between manufacturers in the longer term. Increasing competition can be expected as well from harmonisation efforts within the EC.

INDUSTRY PROFILE

Description of the sector

The sector of medical and surgical equipment and orthopaedic appliances includes the following activities:

- manufacture of medical apparatus for diagnostic work;
- manufacture of medical, surgical and veterinary equipment and instruments;
- manufacture of dental instruments and apparatus; and
- manufacture of orthopaedic appliances, artificial limbs, eyes, teeth, etc.

The sector does not include orthopaedic footwear, which is found in NACE 452. X-ray apparatus and electro-medical instruments, including electro-medical diagnostic equipment, electro-medical treatment, electro-dental instruments, electrical hearing aids and pacemakers are also excluded; they are classified under NACE 344.

Within the larger sector of instrument engineering, the subsector of medical and surgical equipment and orthopaedic appliances represents about 30% of total production. The most important producer countries among EC members is Germany with more than 50% of the EC total; France follows, with 17%, the United Kingdom with 15% and Italy with 9%.

Compared to other sectors of manufacturing, this industry is of minor importance. Measured in terms of value added, its output represents about one third of that of consumer electronics.

Recent trends

During the recent past, the industry experienced a highly favourable development in the EC. Production increased by more than 6% per year in volume from 1983 to 1992, well above the growth rate of manufacturing as whole (2.8% per year). This rapid increase in production gave rise to considerable increases in employment figures (2.1% per year), to reach about 104 000 employees on the industry's payroll in 1992.

Production growth in the EC, however, was slower than the rise in consumption, as imports grew by about 9% per year in real terms, well above the rate of growth of exports. In 1983, imports represented only 82% of the value of exports. By 1992 however, the value of exports was only 91% of the value of imports. The EC trade balance became negative from 1991 on.

International comparison

The world's largest producing country of medical and surgical equipment and orthopaedic appliances is the United States, representing about two third of the Triad's total. Manufacturers in the EC and Japan are far behind, producing some 19% and 11% of the Triad's total, respectively. The United States also exhibited the most vigorous development during the last few years. Production there increased by more than 12% per year in value from 1983 to 1992. In the EC and Japan, production increased at a somewhat slower rate during the same period (9% and 8.4% per year, respectively). As a result, the United States production continuously increased its market share in the Triad, from 64% in 1983 to some 70% in 1992.

Foreign trade

The EC trade balance has deteriorated rapidly during recent years and has been negative since 1991. While exports increased by about 10% per year in value from 1983 to 1992, imports grew by approximately 13% per year during the same period. The most important competitors on EC markets are the United States and the EFTA countries, which represent between them nearly 80% of total extra-EC imports. While EFTA countries lost EC market share during the last several years, USA manufacturers increased their share of extra-EC imports from 46% in 1987 to 52% in 1992. This is mainly due to improved price competitiveness and technological advantages there. Japan, with about 13% of total extra-EC imports, lost EC market share as well.

On the export side, the EFTA countries and the United States are important markets for EC producers, with about 44% of total extra-EC exports. The United States, with consumption about three and a half times that of the EC, was the biggest outlet in 1987: by 1992, however, its share has declined to some 22%.

Trade among EC member countries grew at an even faster rate (about 16% per year in value) than extra-EC imports. As a result, the share of intra-EC trade out of total EC imports increased from 47% in 1983 to 51% in 1992. The most important intra-EC exporter is Germany, with about 27% of the total. Far behind are France (15%) and the United Kingdom (13%).

MARKET FORCES

Demand

The industry's rapid growth in demand during the last few years reflects not only the ageing of the population in industrialised countries but also the increasing health consciousness on the part of the population in general. Another important

Figure 4: Medical and surgical equipment and orthopaedic appliances
International comparison of production at current prices

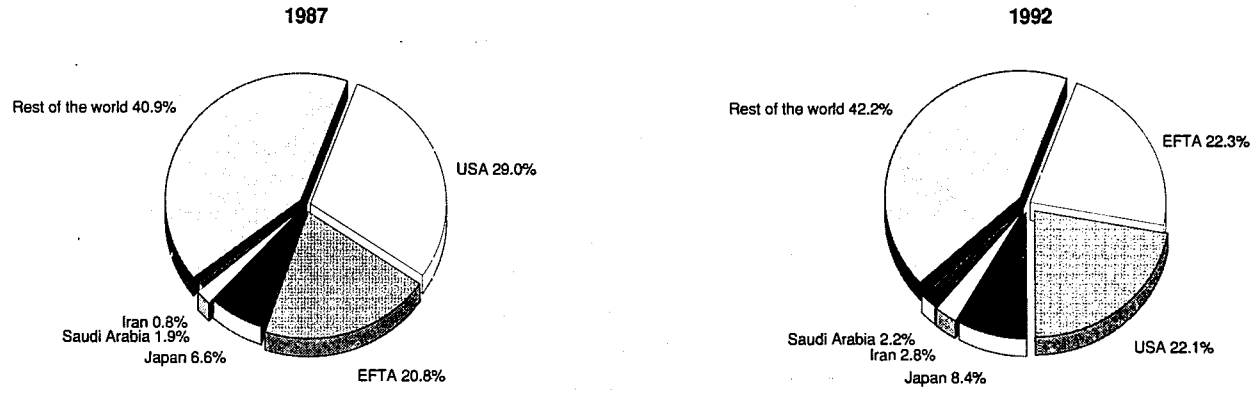
Figure 6: Medical and surgical equipment and orthopaedic appliances
Destination of EC exports



Source: Eurostat

factor was the role of product innovation, as new discoveries in medical science and the increasing use of advanced technology strengthened demand for the products of the industry. In the field of diagnostic apparatus, improvements took place in the analysis of results through the use of data processing systems. In this area, an important innovation occurred with the development of a new method of endoscopic treatment, a type of minimally invasive surgery. Under endoscopic view, treatments are conducted by ultrasound or by laser without causing the usual damage normally resulting from conventional surgery. New developments in this field are multi-functional endoscopes, which allow complete treatment without the need for changing instruments during surgery. Further developments are in the pipeline such as the combination of endoscopes and new optical systems (laparoscopes).

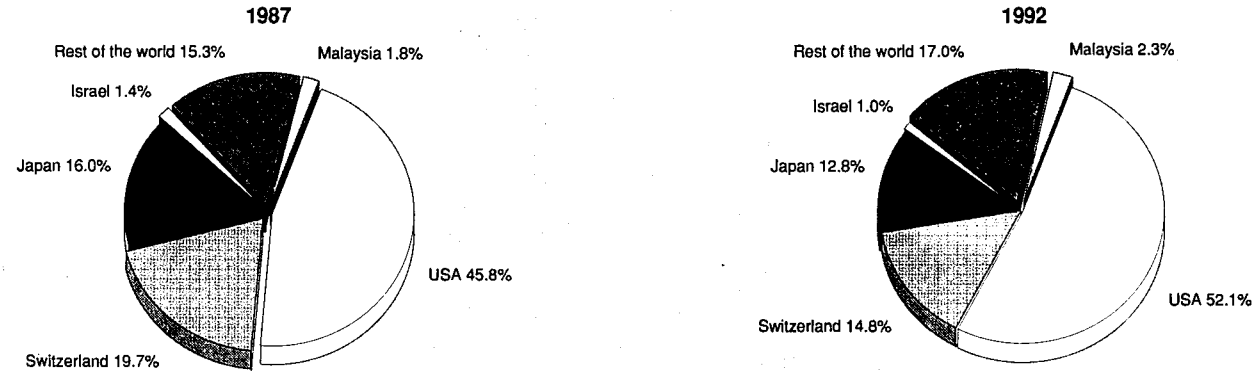
Picture quality from video cameras that are used to control laparoscopic treatment has now been improved by the use of electronic chips. In addition, data processing systems permit picture storage with virtually no loss in quality. All these developments contribute to improvements in diagnostic methods in general, as documentation of different phases of an illness is made possible. Anaesthetic devices also benefit from new technological developments since the identification, measurement and monitoring of anaesthetic gas is now supported by data processing systems. In the field of prosthetic and orthopaedic devices, bio-compatibility has become a major priority, leading to the development of new materials. In orthopaedic technology, the myo-electronic regulation of artificial legs and arms represents another important development. Also, demand for medical devices for operative and postoperative treatment is greatly increased by a growing tendency to use disposable and pre-sterilised instruments.

The availability of disposable instruments and easier to use modern medical equipment permit substantial savings in costs of hospitalisation by allowing many treatments to be performed at home. On the other hand, the spiralling growth of health costs in all developed countries is triggering revisions in national health policies. These take the form of putting caps on public costs by transferring an increasing share of costs to the patients. These developments will inevitably have a dampening effect on demand for the industry's products.

Supply and competition

The United States is the world's largest producer of medical and surgical equipment and orthopaedic appliances, as well as the largest consumer of these products (with consumption

Figure 7: Medical and surgical equipment and orthopaedic appliances
Origin of EC imports



Source: Eurostat

of about 60% of the world total). Thus, it is not surprising that the United States is also in a leading position as far as research and development are concerned. Exports of EC producers to the United States have been recently declining. The loss of price competitiveness, following the depreciation of the USD against European currencies and a growing technology gap are only part of the explanation. An additional factor resides in the lengthy and costly process of sanctioning a health product in the USA. This represents a huge barrier for the small or medium-sized firms, with little financial power, who make up the majority of the industry.

Japan plays a relatively minor role in EC trade of the industry's products, absorbing about 8% of total EC exports and providing about 13% of extra-EC imports. In some fields, however, Japanese companies are serious competitors, or in some fields, market dominators. In the field of flexible endoscopic instruments, the Japanese company, Olympus, dominates the world market with a share of roughly 85% of total world production. Japanese competition is also strong in the field of blood pressure instruments.

Imports from East Asian newly industrialised countries (NICs) have been increasing during recent years, mainly in low-end instruments. In the field of standard instruments for example, competition arises from countries like Pakistan as well.

The strong rise in intra-EC trade (16% per year in value) was mainly a result of increased efforts of companies to gain market share in the EC, helped by technical standardisation within the EC and by a more rapid approval of products. The continuation of this trend can be expected in the future, with the expected adoption of an EC directive requiring specific product characteristics before free movement in the EC would be allowed.

Production process

The industry is characterised by an increasing share of sub-contracting, as the very specialised character of the main components of their products, optical systems for instance, require input from other producers. This trend is expected to reinforce itself in the future. In particular, the trend for increased integration with data processing systems will require even more sub-contracting.

INDUSTRY STRUCTURE

Companies

The industry in the EC is characterised by a large number of small enterprises (less than 250 employees), usually specialised in narrowly defined niche markets, often producing a small number of closely related products. The few medium-sized and large firms in the industry produce a broad range of devices in the field of medical equipment and in other fields as well.

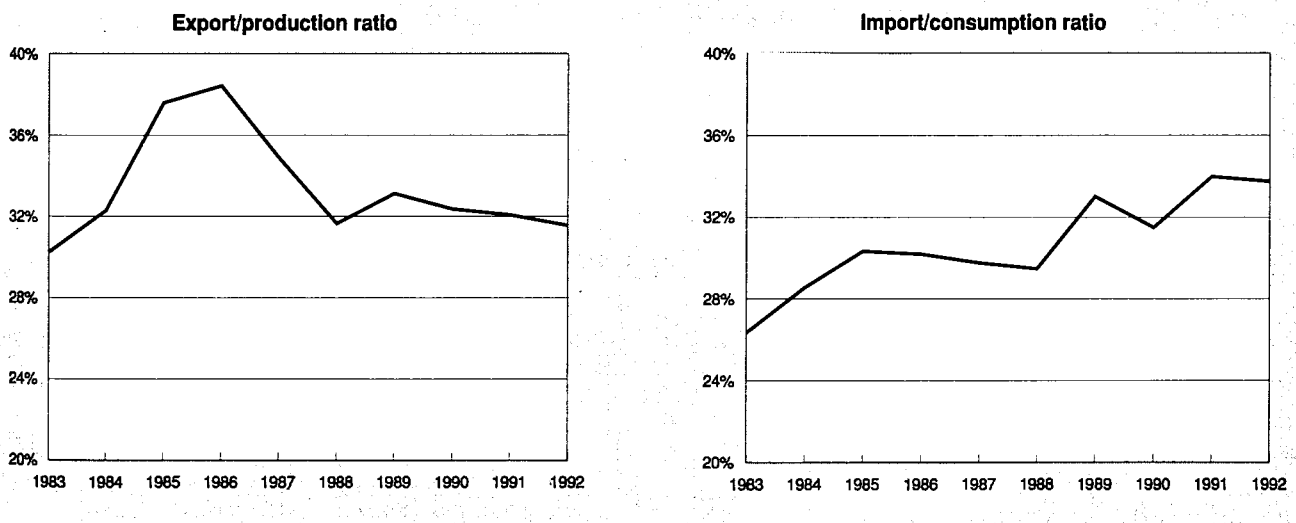
Along with the aforementioned company, Olympus, other important producers in fixed endoscopic devices are the medium-sized companies Karl Storz (D) and Richard Wolf (D), each holding about 35% of the world market. In the field of anaesthetic apparatus and equipment, the most important firms are Draeger Werke (D), l'Air Liquide (F), Ohmeda (UK) and British Oxygen (UK), all of which are producing on a global level. In the field of small instrumentation, Germany is home for a high number of small firms with about 100 employees each, that, in total, produce about 50% of total world production. Aesculab (D) is one of the few large companies in this area. In the other important countries of the EC, the structure of the small instrumentation industry is similar. In operative and postoperative treatment, important firms are the companies Beiersdorf (D) and Braun (D). In orthopaedic appliances, there are some 70 firms in the EC with a total of about 2 500 employees. The most important are Smith & Nephew (UK), Dow Corning (F), Otto Bock (D), Aesculab (D), Waldemar Link (D) and the Gebr. Martin (D).

The US firm Baxter is the world's largest producer of health care products, producing in nearly all sectors of medical equipment, e.g. blood bags, apparatus for diagnostic work, medical dressings, infusion sets, surgical gloves and more. Other important USA firms are 3M, Johnson and Johnson and Abbott. They mainly produce infusion sets and catheters, medical dressings, implants, dental materials and diagnostic devices.

Strategies

Competition among EC producers and from those in non-EC countries is likely to increase over the next few years. The technical standardisation within the EC is expected to strengthen competition from abroad, since USA and Japanese competitors will no longer be forced to adapt their products

Figure 8: Medical and surgical equipment and orthopaedic appliances
Trade intensities



Source: DEBA

to differing requirements in the various EC countries. On the other, hand this will also enhance the capability of EC producers to increase their share of the EC market. Due to its technological edge, the United States will remain the most important competitor, while in the field of standard instrumentation, competition stems mainly from Japan and the East Asian NICs.

The strategies of EC firms will continue to be oriented towards cost reduction in the field of standard instruments through the modernisation and automation of production processes, as well as by moving production facilities to low cost countries. In order to gain market share in growth markets, however, it will not be sufficient to simply improve the distribution chain there. Cooperation with producers in South East Asia and China and the formation of subsidiaries there will become a condition for success in these markets. For instance, the German company, Draegerwerke, plans a joint venture in China to produce low-end instruments.

In the field of highly sophisticated products, the position of EC producers is better thanks to better access to technological innovations: to maintain this edge will require increased investments in research and development. In German firms, this currently represents about 6-12% of turnover.

High levels of R&D expenditure, however, can hardly be expected from small or medium sized firms. The strategy for these firms will have to be the production of very client-specific products, designed for small niche markets. Another possibility is consolidating into larger firms, or at least cooperation in research and development. Weak cooperation between the EC's scientific research and industry communities is another problem that should be addressed. At present, the time lag between scientific discoveries and their actual application in a new product may be very long, much longer than is common in the USA.

ENVIRONMENT

The increased application of single-use disposable devices and sterilised instruments, and the disposal of their packaging materials are the main ecological issues. According to an EC Directive, all packaging materials will have to be recycled or recovered by the year 2000.

REGULATIONS

Besides the above mentioned EC regulation, there are a number of EC directives concerning the movement of medical devices in the EC. A directive concerning the health and safety of patients will become effective in July 1994. It will require any medical device or product, intended for use in the EC, to feature the EC stamp of approval attesting to its conformity with EC law. Free movement within the EC will be allowed once the product is in compliance with the provisions of this directive. Another EC directive which came into force in January 1993 is related to active implantable devices; it also requires the EC stamp to move around freely within the EC.

Another regulation concern for all health products bound for export to the United States is the product approval process there, which is considered by some to be a non-tariff trade barrier.

OUTLOOK

The demand and production of medical and surgical equipment and orthopaedic appliances is expected to develop quite favourably in the coming years. The increasing average age of the population in industrialised countries should provide the industry with a stable source of growth during the nineties. Fledgling demand from Eastern Europe, China and other South East Asian countries offers a huge growth potential as well.

However, demand growth is expected to be dampened by recent national health policy restructuring efforts, being taken in nearly all industrialised countries, to cap growth in health care expenditure. In addition, EC suppliers will face increased competition in their home markets from abroad, particularly from the United States, as well as from other EC producers.

Optical instruments and photographic equipment
NACE 373

The industry of optical instruments and photographic equipment enjoyed brisk growth over the last decade. It benefited from a favourable investment climate, as well from technological innovations resulting from optronics, the combination of optical devices with electronic components, and by the introduction of laser technology.
In the recent past, however, demand for the industry's products declined due to the current recession. Because of this, the short term outlook remains rather pessimistic.
In the medium term, the industry should enjoy a strong recovery thanks to increased investment activities in machinery and equipment and to growing environmental concerns.

INDUSTRY PROFILE

Description of the sector

The industry of optical and photographic equipment includes the following sub-sectors:

- spectacles, lenses, frames and mountings and equipment for use by opticians;
- optical precision instruments (other than optician items); and
- photographic and cinematography equipment.

Compared to other sectors of the manufacturing industry, the optical and photographic equipment industry is of minor importance, with value added being about 20% of that of consumer electronics.

In the EC, the sub-sector represents about 25% of the instrument engineering sector, with Germany being the most important producing country (45% of the EC total in terms of value added, in 1992), followed by France (28%), Italy (14%) and the United Kingdom (11%).

Among EC producers, there is a large degree of specialisation. Germany produces mainly optical, precision and photo instruments, while France and Italy are major producers in ocular optics, mainly spectacle frames.

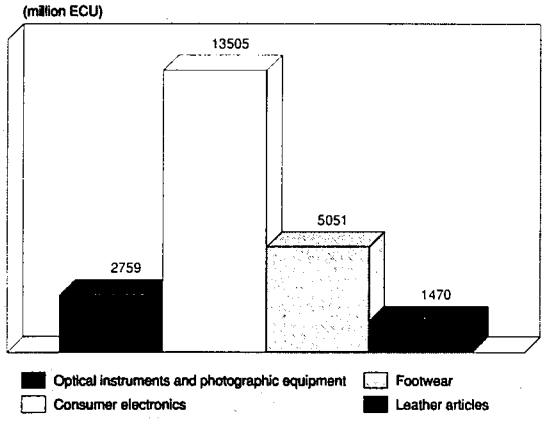
Recent trends

From 1983 to 1988, the industry's performance was quite favourable, with an average production growth of 8% per year in real terms. Production growth was slightly above consumption growth, thanks to strong export growth. In 1988, about 50% of EC production was exported to non-EC countries.

From 1988 to 1992, however, the picture changed. The production rate fell 1.2% per year from 1990 to 1992 as a result of a stagnation in consumption. During the entire period from 1983 to 1992, extra-EC exports grew at faster rates than imports. Since extra-EC imports are about 50% percent higher than extra-EC exports, the EC trade balance deteriorated dramatically from a deficit of approximately 630 million ECU in 1983 to about 1 560 million ECU in 1992.

Until 1990, production of optical and photographic equipment in the EC grew more or less at the same rate as manufacturing production as a whole. In the last two years, however, real production in the industry declined sharply, even while manufacturing production as a whole was stagnant. From 1983 to 1992, employment in the industry increased by about 1% per year, while employment figures in manufacturing as a whole declined by roughly 1% per annum.

Figure 1: Optical instruments and photographic equipment Value added in comparison with other industries, 1992



Source: DEBA

International comparison

The most important producer of optical instruments and photographic equipment is the United States, with more than half the Triad's total output in 1992. Japanese production represents about 31% of the Triad's output, while EC production stands at 22%. Regarding the development of production over time, however, the picture is different. While United States' production stagnated from 1985 to 1990, both Japan's and the EC's increased considerably during the last decade. As a result, the share of the US of total Triad production declined while the EC's percentage increased from 14% to 22% from 1983 to 1992.

Foreign trade

Producers of optical and photographic equipment in the EC have had to face strong competition from abroad which has caused the trade balance to deteriorate over the last decade. In 1992, about 60% of EC demand was satisfied by non-EC producers.

By far the most important competitor for EC producers is Japan. During recent years, however, the EC market share of Japanese producers has declined from 60% in 1987 to 50% in 1992. East Asian NICs and the United States have acquired this market share lost by the Japanese firms.

Important export markets for EC producers are the United States (32% of total extra-EC exports), developing countries, including the East Asian NICs (25%) and the EFTA countries (22%).

The most dramatic increase in competition, however, was seen among EC Member States. From 1983 to 1992, trade between EC countries increased by about 10% per year in value, while extra-EC imports rose by a only 7% per year. As a result, the share of imports within the EC out of total imports increased from 46% in 1983 to 53% in 1992. The most important intra-EC exporter was Germany with roughly 30% of the total, followed by the Netherlands (27%). The most dynamic increases during that period were French intra-EC exports (+16.8% per year in value), followed by that of Italy's (+13.5%) and the Netherlands' (+12%).

Due to the rapid rise of intra-EC trade, the import/consumption ratio has been decreasing. In 1983, about 67% of demand was satisfied by non-EC producers. By the end of 1992 this figure declined to 60%.

MARKET FORCES

Demand

Demand for optical instruments and photographic equipment as a whole has increased considerably over the last decade. From 1983 to 1992, EC consumption grew at an average rate of 4.0% per year in volume. Since the industry's sub-sectors follow unequal demand patterns, the analysis of the different sub-sectors should be done separately.

In the field of spectacles, lenses, frames and mountings, the growth in demand stems from both an increase in the number

Figure 4: Optical instruments and photographic equipment

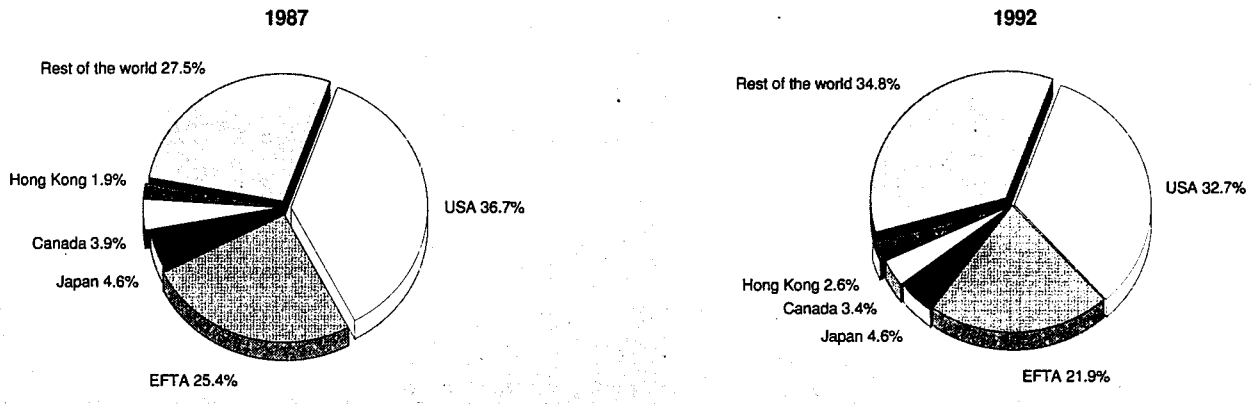
Destination of EC exports



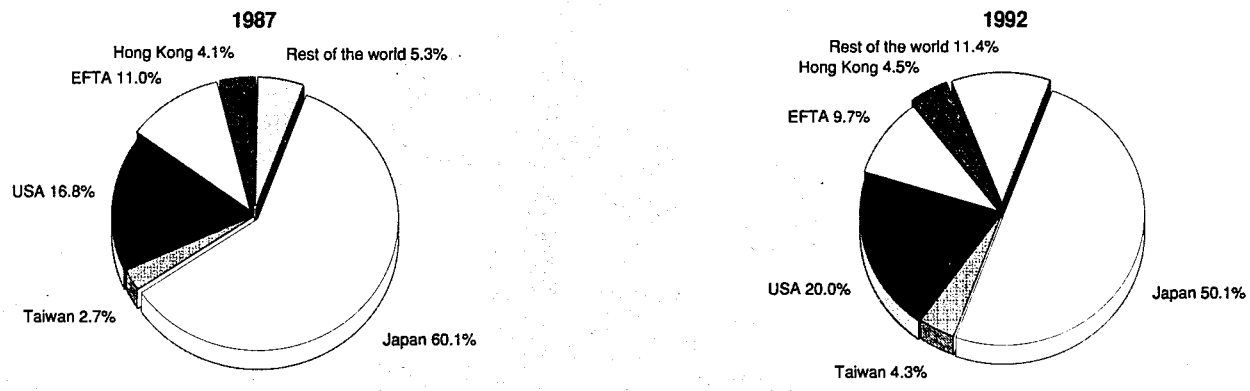
Source: Eurostat

of people wearing corrective glasses and from fashion considerations. In line with the increasing average age of the population, the number of spectacle wearers has been increasing steadily over the years. In Germany for example, about 50% of the population now wear spectacles or lenses.

Since spectacles are becoming more fashionable, demand has been shifting continually towards high quality products. Consumers now often own several pair of spectacles or lenses to satisfy various purposes. Demand for ophthalmic industry products has also been driven by technological innovation. This has resulted in improvements in the glasses as well as the development of new, higher priced products (continuously variable glasses, gas permeable contact lenses and special glasses for people working in front of monitors). From 1989 on, however, demand for products of the ophthalmic industry in the EC has been declining due to more restrictive refund policies introduced by social security systems. This development mainly effected the demand for prescription glasses. In addition, the recent recession has strengthened the downward trend in the low price segment of the market as customers there tend to only change their lenses instead of buying new frames as well. The high price segment, in contrast, performed quite well, since this type of product is relatively insensitive to cyclical fluctuations.

The precision optical instrument market is mainly found in industrial processes. These instruments are used to improve testing and measuring methods. A particularly important sector is the measuring, precision and control instruments industry. Increasingly in this industry, mechanical measuring processes have been eliminated by the introduction of optical methods. In some cases, advanced optical technology in industrial processes allows precise measurements to be obtained, without making contact with the object. This is the case for opto-electronic process control and sensor technology, microanalytical equipment, multiple co-ordinate measuring machines and high power telescopes. Technological innovations and increased investment activity in manufacturing industries have been the driving force behind the increase in demand for precision optical instrument industry products. Of particular importance has been the development of laser technology which is used in fields as varied as: soldering and automatic sheet cutting in the automobile and aerospace industries, the treatment of materials in medical technology and in performing endoscopic surgery. Another area of increasing importance is

Figure 7: Optical instruments and photographic equipment
Origin of EC imports



Source: Eurostat

the use of laser technology for the measurement of environmental pollution. The development and use of LIDAR (light detection and ranging) is replacing the traditional chemical analysis for measuring the concentration of pollutants in air and water.

Over the last few years, however, demand for precision optical industry products has declined as investment expenditure was cut back due to the current recession. In addition, the decrease in demand from the military sector has hastened the downturn. In Germany, for example, production of precision optical instruments declined by 10% in 1990 and by 3% in 1991. The downturn continued in 1992 as well, with a fall of about 4% in real terms.

In the field of photographic and cinematographic equipment, demand stems mainly from private households, but it also comes from specific manufacturing activities. In the photographic apparatus sector, product innovation has been the driving force for the increase in demand. The introduction of electronics was responsible for a move towards electronically controlled cameras, decreasing the amount of mechanical parts necessary. Technological improvements that make sophisticated cameras more user-friendly and improve picture quality have allowed cameras to be offered with features such as auto focus, auto rewind and auto flash. Recently, however, there appears to be a trend among customers to shy away from highly sophisticated cameras and move towards simpler, handier models or even towards throw-away cameras. At present, demand exhibits a downward trend that results from high equipment prices and "innovation fatigue" among consumers. The loss of markets in Eastern Europe has also reduced world demand. This development has been strengthened by the current recession, bringing about a decline in investments as well as in consumer expenditure on durables.

Another field of demand is the use of state-of-the-art special cameras and lenses in fields such as aerial and space photography, traffic and building access monitoring, medicine and science as well as studio and press photography. Demand for photographic and cinematographic equipment is also supported by the growth in importance of communication systems. Transmitted electronic images, videos and communications all require photographic or related optical equipment.

Supply and competition

In the field of photographic equipment, production growth in the United States and Japan has been declining since 1985 following the gradual maturation of their markets. In Japan in particular, demand for photographic equipment has decreased considerably in the recent past, giving rise to price wars among suppliers there. In addition, the consumer trend away from SLR cameras towards low cost compact cameras or even disposable cameras has caused sharp decreases in profits. There has been a rapid increase of imports into the EC over the past few years due to the sharp competition between Japan, the United States and, more recently, the East Asian NICs for EC market share.

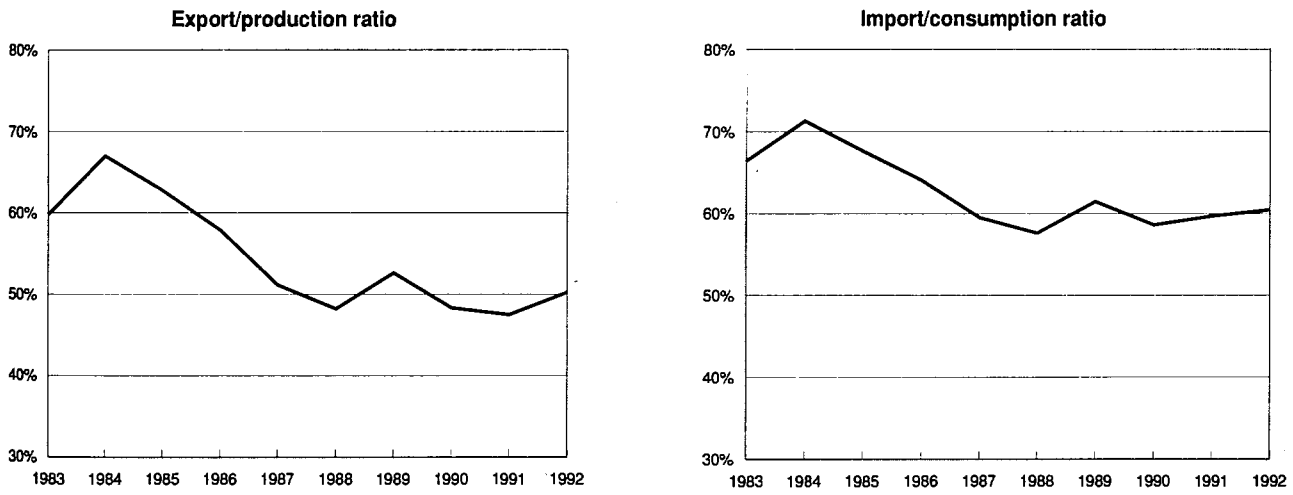
The few EC survivors in the field of photographic equipment face a tough struggle to retain their market share against Japanese and the US producers who are highly price competitive due to their large scale production. In particular, Japanese producers such as Canon, Olympus or Nikon are extremely efficient in both production and marketing and their size allows them to invest heavily in research and development.

In the field of optical precision instruments, the situation is characterised by the strong position of EC firms in producing state-of-the-art technology for the export market. The most important export market for these products is the United States where competition mainly takes place between EC producers.

In the field of spectacles, EC firms are world leaders. France and Italy, in particular, are strong exporters of fashion frames due to their excellent image abroad. In the production of spectacles, Germany is very successful in foreign markets. Competition from Japan and the East Asian NICs is on the rise. Imports into the EC of frames from the latter have been increasing, thanks to their price competitiveness, supported by lower production costs there. Japan has lately become a more serious competitor in the field of spectacles since the MITI is encouraging research and development activity in this sub-sector to help supply the rapidly increasing demand from the ageing population.

As a result of enhanced intra-EC trade, competition between EC member countries is on the rise. In the field of precision optical instruments, the high degree of specialisation of each firm forces producers to search for additional markets abroad since national markets are too small to permit them to reach economies of scale in production facilities. Intra-EC compe-

Figure 8: Optical instruments and photographic equipment Trade intensities



Source: DEBA

tition is likely to keep increasing, over the next few years, particularly after the remaining impediments to trade are fully eliminated in the common EC market.

Production process

Employment in the industry has changed very little from 1982 to 1993, increasing, on average, by about 1% per year. As production in volume rose by about 4.0% during that same period, it follows that productivity gains reached approximately 2.1% per year.

In most of the industry, the production process involves the assembly of large numbers of components with highly complex characteristics. Normally, at least some of these components are outsourced to highly specialised firms that produce to custom specification for a number of firms. In some cases, producers of optical instruments and photographic equipment concentrate mainly on design, research and development, while both production and assembly are subcontracted out.

INDUSTRY STRUCTURE

Companies

Precision optical instruments in the EC are frequently produced by firms that are active in the broader sector of instrument engineering. These companies are concentrated mainly in the field of measurement technology since it plays an increasingly important role in optical technology.

In the sub-sector of spectacles, lenses, frames and mountings, the industry is comprised of predominantly small and medium-sized firms, employing a maximum of 500 employees. Frame production is usually done by even smaller firms that employ less than 100 employees. Despite their small size, however, these firms are usually internationally active, with EFTA countries and the United States being their most important extra-EC outlets. The few larger companies in the sub-sector are Rodenstock (D), Bausch & Lomb (D), Carl Zeiss (D), Essilor (F), Luxottica (I), Safilo (I), De Rigo(I), Indo (E) and Pilkington (UK). Important Japanese companies are Seiko, Hoya and Nikon.

In the precision optical instrument sub-sector, Carl Zeiss (D), Schott (D) and Philips (NL) are among the most important suppliers. World wide there are about 12 producers in this area. Leica (CH/UK), specialised in optical instruments, has become a world leader in the sector behind the Japanese company Nikon (JPN).

In the field of photographic equipment, there are a few large, often highly specialised, manufacturers in the EC, such as Angénieux, a French manufacturer of camera lenses. Other important producers in this area are Agfa Gevaert AG (D), Carl Zeiss (D), Rollei (D), Minox (D), Linhof (D), Durst (I) and Bosch (D).

Strategies

EC photographic equipment enterprises face strong competition from outside the European Community, especially from the United States and Japan. As Japan is the most important producer of cameras, a closer look should be taken at this industry's strategy there. In the wake of the decrease in turnover and profits Japanese firms have suffered, companies there have had to rethink their strategies. One such change in strategy has been product diversification. This should cause the share of cameras in total turnover to keep declining. Canon, for example, has been very successful in this context, since about 80% of its turnover currently results from other products such as printers and copiers. In addition, Japanese manufacturers have also increased their marketing efforts in foreign markets, further exacerbating price competition in the EC. The creation of subsidiaries in low wage countries could help EC firms improve their price-competitiveness by shifting portions of production to these countries while restricting themselves mainly to research and development, design and, possibly, product assembly.

To maintain their advantage in the state-of-the-art precision optical instrument field, EC producers will have to increase their R&D expenditure, as well as to strengthen their presence in the fast growing South East Asian markets.

Increasing intra-EC competition in the field of optical precision instruments is likely to give a boost to mergers and acquisitions. Important regrouping has already taken place. The British firm Cambridge Instruments and the Swiss firm Wild Leitz merged to form a new group, specialised in optical instruments, under the name of Leica. In 1988, Wild Leitz took over one of its main competitors, Kern. And, in 1993, Angénieux (F) was acquired by SGS-Thomson (UK) and AML, a subsidiary of l'Air Liquide (F).

ENVIRONMENT

The production process of optical instruments and photographic equipment has a negligible effect on the environment. One area of environmental concern for the industry is related to the photographic equipment sector where chemicals used in the production and development of photographic films find their way into the soil and possibly into water supplies. Another problem in this context is the growing use of disposable cameras that add to the waste stream. Increased efforts at recycling would be beneficial for the industry in limiting environmental damage.

The industry may benefit from new opportunities emerging in the area of solutions to ecological problems. The precision optical instrument sub-sector, for example, depends to a considerable extent on demand for measurement and control instruments. Enhanced environmental monitoring and measuring requirements will likely boost demand for such instruments. Similarly, there will be an increase in demand for analytical instruments such as microscopes and optical instruments for physical and chemical analysis such as spectrographs, colorimeters and photometers. Demand for photographic equipment may also benefit from ecological concerns. The aerial and space photography fields increasingly use sophisticated cameras to monitor environmental damage.

OUTLOOK

The EC industry of optical instruments and photographic equipment is being hit by the current recession. The situation is not expected to improve until the end of 1994. Low investment activity in the manufacturing sector will particularly effect suppliers of optical precision instruments.

In the optical sub-sector, stagnant consumer demand and the failure of markets in Eastern Europe to recover will continue to weigh down production. Even the German optical industry, which had profited from the boost in demand brought about by the German reunification, faces a decrease in demand as well. In the medium-term, the outlook for EC producers is rather positive. The optical sub-sector will continue to benefit from the increasing of the population ageing population and

Table 5: Optical instruments and photographic equipment Expected real annual growth rates

(%)	1993-94	1993-97
Apparent consumption	0.2	2.6
Production	0.5	2.8
Extra-EC exports	0.8	4.5

Source: BAK

may also benefit from developing markets in Eastern Europe. Once the expected upswing in overall economic activity takes place, a recovery in demand for this sub-sector's products as a whole is expected.

The sub-sector of precision optical instruments will benefit from increased investment activity in machinery and equipment, as well as from ecological issues that are continually gaining importance in industrial production processes. For EC suppliers to survive in globalised markets, it is imperative that they increase their R&D expenditure and redouble their efforts to gain a foothold in the dynamic, growing markets of South East Asia. Other potentially important markets in the medium-term may be found in South America where demand is expected to surge once their economies finally take off.

Clocks and watches
NACE 374

The clock and watch industry in the EC is confronted with strong competition from abroad. While production in the EC declined by about 4% per year in volume from 1983 to 1992, consumption increased by about 3% during the same period. The most important competitors are China, Hong Kong, Switzerland and Japan. Nearly 50% of extra-EC imports stem from Swiss producers, mainly active in the field of top-of-the range watches. In line with the unfavourable development during the last years, employment fell by half from 1983 to 1992 The outlook for the industry in the medium term is somewhat more optimistic, thanks to the eventual economic recovery in industrialised countries and to the potential for increased demand from developing countries such as China and India.

INDUSTRY PROFILE

Description of the sector

The industry defined as clocks, watches and parts thereof includes watches, instrument panel clocks, clocks, control apparatus and timing devices using clock-work or synchronous motors and time switches, as well as clock and watch movements. The sector comprises mechanical, electrical and electronic watches.

The sub-sector of clocks and watches is the smallest among the larger sector of instrument engineering in the EC. In 1992, its output represented only about 5% of the total.

Germany and France are the most important producer countries within the EC. Their output accounts for more than 80% of the EC total. Far behind is the United Kingdom (12%) and Italy (7%). Germany is the main producer of clocks in the EC industry, France produces mainly watches and Italy is specialised in the production of cases, in particular gold cases.

The production structure in the EC underwent considerable changes during the eighties. West Germany was the dominant producer at the beginning of the eighties with nearly 50% of the EC total, but its relative position receded in the following years to the benefit of France, whose share of EC production surpassed that of Germany by 1987. In 1989, Germany managed to remarkably increase its production from the stimulation of demand it received from the reunification. In 1992, the share of Germany in total EC production was 42%. followed by France (40%), the United Kingdom (12%) and Italy (7%).

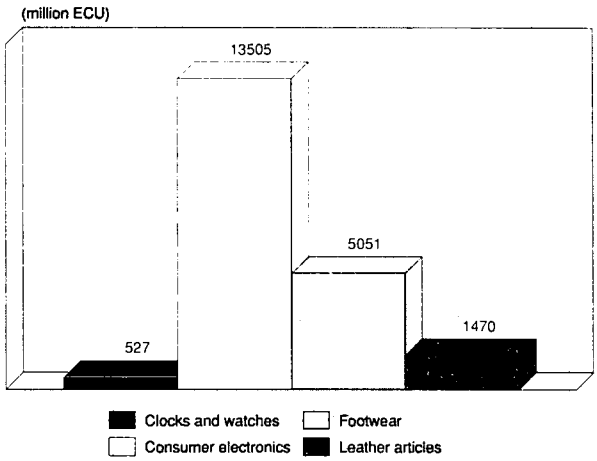
Intra-EC exports are similarly dominated by these countries who make up about 80% of the total. The most important intra-EC exporter is Germany with 45% of the total, followed by France with 20%.

Recent trends

The development of the clock and watch industry was characterised by sharp declines in production during the eighties and the beginning of the nineties. While EC production in manufacturing as a whole increased by roughly 3% per year in volume, the output of clocks and watches decreased by 4% per year during the same period. This decline was reflected in employment as well; while employment in the manufacturing sector declined by about 1% per year, the workforce in the clocks and watches industry fell by roughly 7% per year, shrinking to 18 000 employees in 1992, compared to 34 000 in 1983.

Consumption increased steadily from 1983 to 1992 (3.1% per year), reached 3 billion ECU at the end of the period and was mainly satisfied by fast increasing extra-EC imports.

Figure 1: Clocks and watches
Value added in comparison with other industries, 1992



Source: DEBA

Extra-EC exports increased at a similar pace but, given that imports are about three times as high as exports, the EC trade balance kept deteriorating with a deficit of about 56% of EC consumption in 1992.

International comparison

By far the most important producer of clocks and watches in the world is Japan, with a production value of about ten times that of the EC. Unlike the United States and Japan, however, production in the EC declined constantly to reach about 1.4 billion ECU in 1992. Production in the USA increased by roughly 5% per year in volume through the second half of the eighties. Japanese production increased by 11% per year in value, to reach about 14 billion ECU in 1992. Consequently, EC and USA producers saw their shares of world production drop dramatically. In 1983, Japan produced about 61% of the Triad's output, the EC roughly 21% and the United States about 18%. In 1992, the share of EC - and USA production dropped about 8%, while Japan's rose to more than 80% of the Triad's output.

Foreign trade

The EC clock and watch industry is faced with strong competition from abroad. Imports from outside the EC increased by 8.4% in value from 1983 to 1992. The most important competitors are Swiss producers with more than 50% of total imports into the EC, as Swiss companies are world leaders in high quality mechanical watches. Imports from the developing countries group (including the East Asian newly industrialised countries [NICs] originate mainly from Hong Kong (about 17% of total imports). This group is an important producer of electronic watches in the low price segment. About 14 % of imports are from Japan. All in all, 88% of demand in the EC is currently satisfied by products from without the EC.

EC producers of clocks and watches are highly export-oriented with about 73% of production being sold outside the EC. Exports from EC companies to extra-EC markets increased by 7.3% per year in value from 1983 to 1992. The most important markets for the EC are the developing countries with a share of about 40% of total exports and Switzerland with more than 30%. Despite the favourable development of extra-EC exports, the EC trade balance has been deteriorating during the same period; imports are presently almost three times as large as exports. Trade between members of the EC increased as well during the same period, but at a slower pace than trade with extra-EC countries. It grew at an annual average rate of 4.2% in value, compared to the above mentioned 8.4% annual growth rate of extra-imports. Consequently, the share of intra-EC imports out of total imports declined from 24.4% in 1983 to 18.4% in 1992. The most important exporter in the EC is Germany with about 45% of total intra-EC exports at present, followed by France with roughly 21%.

MARKET FORCES

Demand

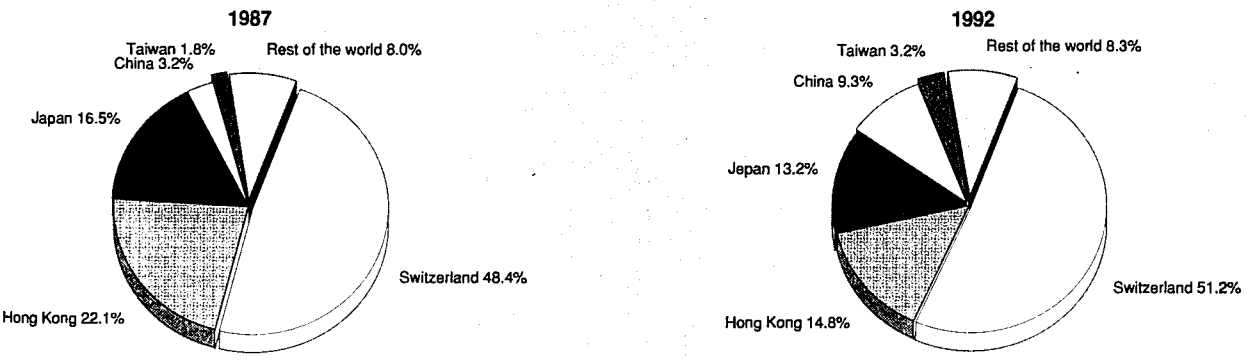
Demand for clocks, watches and components, depending mainly on consumer expenditure, increased steadily during the last years. Given the fact that the introduction of electronic components in this sector's products dates from the early 1960s, consumption was stimulated by fashion trends rather than by technological developments. Innovations, therefore, took place mainly in the form of design changes. Increasing affluence among consumers, in line with the healthy economic climate, resulted in a gradual shift away from cheap electronic watches produced in Japan and Hong Kong, to top-of-the-range watches. As a result, producers from Switzerland, the main suppliers of luxury watches, increased their market share in the EC considerably. In the last few years, technological innovation has been gaining in importance again. The recent decline in consumer demand hit nearly all EC producers of clocks and watches. Manufacturers who introduced new products managed to increase their sales. One such example is the German watch producer, Junghans, that introduced the first solar radio watch at the beginning of 1993.

Supply and competition

The EC clock and watch industry is faced with strong competition from abroad that has caused a rapid decline of its trade balance: the deficit tripled during the last few years and reached 1.7 billion ECU in value in 1992.

The most important competitors for EC producers are manufacturers from China, Hong Kong, Switzerland and Japan. Japan and Hong Kong mainly produce low-end electronic watches and dominate the world market with some 65% of total world production. Japanese producers, however, lost market share in the EC as imports from there declined from 16.5% of total extra-EC imports in 1987 to 13.1% in 1992. This development was mainly the result of the appreciation of the Yen against the European currencies. In particular, manufacturers of high quality watches lost market share in the EC, mainly to the benefit of Swiss producers, the largest exporter to the EC. Manufacturers from Switzerland (highly specialised in the production of top-of-the line mechanical watches) remarkably increased their EC market share during the last few years, largely a result of the success of the Swatch watch. Even in the segment of mid-range watches, the traditional field of EC producers, Swiss manufacturers enjoyed mounting success in the EC. This development is partly the result of

Figure 7: Clocks and watches
Origin of EC imports



Source: Eurostat

the different industrial structure of the Swiss industry. Swiss manufacturers are of international size, which enables them to not only be at the cutting edge concerning marketing and sales strategies, but also to benefit from economies of scale. EC manufacturers, in contrast, are usually small to medium sized. As a result, SMH, the Societe de Microtechnique et dHorlogerie (the manufacturers of Rado, Omega, Longines, Tissot, Certina, Blancpain and Swatch) enjoyed a surge in earnings despite weak and cyclical demand conditions in general. This is due not only to the success of the Swatch watch in the low price segment, but also to the popularity of high quality mechanical watches in the face of difficult demand conditions.

As already mentioned, EC manufacturers are mainly active in the field of mid-range watches. They are not able to compete in prices with electronic watches from the East Asian NICs, which benefit from lower labour costs as well as from a better availability of components for the production of electronic movements. In addition, the EC industry is confronted with a flood of imitation watches, largely from Hong Kong and China.

Taking into account that overall demand for watches is likely to decrease in the near future, in line with the economic slowdown in Europe and Japan, competition on EC markets can be expected to become even harsher. Prices will decline and the profit situation of EC firms will worsen. Efforts of EC producers to move up to the top-of-the-range segment can also lead to price decreases as market saturation in that segment is also reached. This has been happening already for French and German watch producers.

Production process

The sharp decline of EC production over the last decade, along with strong price competition from Japan and Hong Kong, have forced watch and clocks producers in the EC to modernise their equipment in order to reduce their costs. As a result, a substitution process of capital equipment for labour has been taking place. After reaching about 34 000 people at the beginning of the eighties, EC employment declined during the eighties at an average rate of more than 7% to 17 000 people in 1992. The strongest fall in employment could be observed in Germany (-10% per year from 1983 to 1992) and the United Kingdom (-6%).

In addition, EC producers tried to reduce their production costs by outsourcing parts of the production process to concentrate on the tasks of design, assembly and distribution. In particular, the production of movements was shifted to countries with lower labour costs and better availability of electronic components.

INDUSTRY STRUCTURE

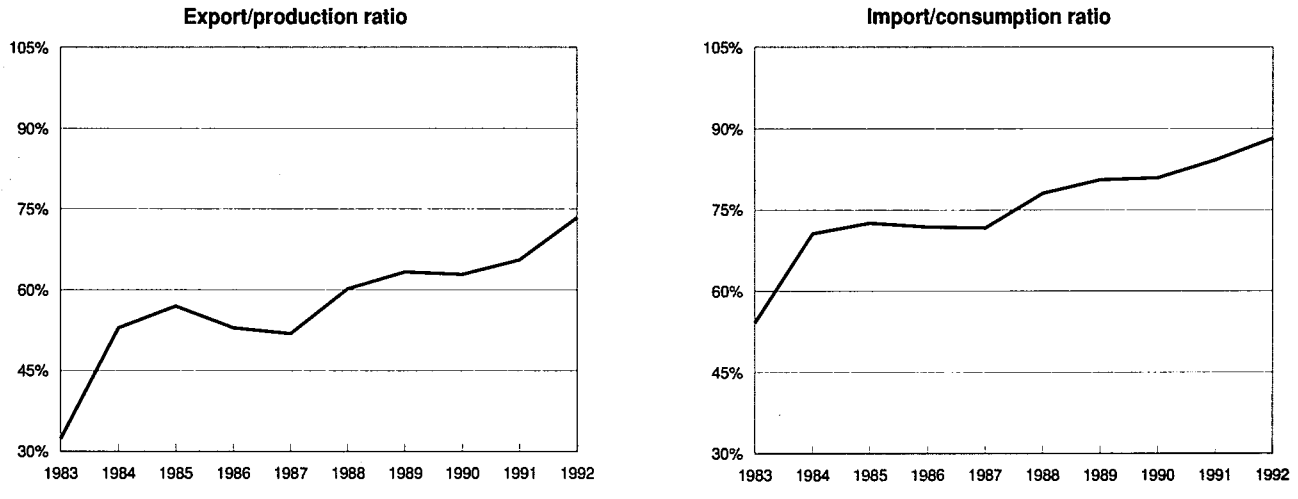
Companies

The industry's enterprises are highly specialised, each in narrowly defined areas. In the EC, the clock and watch industry consists mainly of a large number of small firms producing components, with a few larger companies employing more than 700 people. The larger companies are mainly in the field of case and movement production. The most important manufacturers in the EC are Junghans (D, 1 400 employees), Dufa-Kienzle (D, 800 employees) and Kundo Staiger (D). Other important firms are France Ebauches(F), one of the most important producers of movements in the world, and Vedette (F), operating in the field of clocks. Other companies are Herbelim (F) and Pequignet (F), producing in the high price segment. Most EC companies are active in extra-EC markets as well, with the United States, the EFTA countries and the East Asian NICs as their main export markets. The world's largest producers of clocks and watches, however, are the Japanese companies Citizen, Seiko and Casio. In Switzerland, the home country to the most important competitors for EC producers, SMH is the main producer of watches.

Strategies

The horological industry in the EC faces strong competition from Switzerland in the high-price segment, and from Japan and Hong Kong in electronic low-cost watches. The smaller firms producing in the low-price range have been particularly hit by competition, since they could not produce on a scale sufficient to permit low-cost production. The mid-range sector, however, is dominated by EC manufacturers, but even these are now faced with increasing efforts on the part of Swiss manufacturers to strengthen their presence in EC markets by supplying some of their products at very competitive prices. In anticipation for the onset of the common market in 1993, companies from outside the Community, mainly the Swiss and the Japanese, have been increasing their investments in the EC. Thus, the Compagnie Generale Horlogère, a subsidiary

Figure 8: Clocks and watches
Trade intensities



Source: DEBA

of the Hattori-Seiko group, has expanded its presence in France by making large investments there, while the Swiss SMH has taken over the rough-hewing manufacturing part of the German Porta.

In order to face up to these challenges in their domestic market, EC companies have increased their investments during the last few years. This has permitted firms in the mid-range sector to retain their place in the market by frequently renewing their product lines and by improving the quality of their watches.

To better meet with the intensification of competition, firms in the mid-range segment are being forced to regroup. In Germany, for example, clock producing Dufa-Kienzle took over the watch firms Haller and Buerk and the clock firms Peter-Uhren, Schmid-Schlenker and Patz. Kundo and Staiger, after working together in both R&D and the production of watches, merged in 1991. To strengthen their market position in Western Europe, Dugena from Germany incorporated into the Egona International Holding Ltd. Increased efforts in research and development are very important, as the success of the German Junghans illustrates. They managed to increase their turnover by 20% in 1992, mainly by introducing first the solar watch, then the radio set watch and most recently the first combined solar radio watch.

To streamline production costs, some EC firms increasingly subcontract the production of parts to other countries, mainly in South East Asia and in China; others established subsidiaries there. Thus, Ebauches (F) already has subsidiaries in Mauritius, Tunisia, Hong Kong and China.

ENVIRONMENT

Ecological concerns are of minor importance for the industry of clocks and watches. One ecological issue regarding the clocks industry is the disposal of the small nickel-cadmium batteries used to power electrical and electronic time pieces. The cadmium contained in these batteries may progressively seep into ground water. In the field of watches, another ecological issue is the use of nickel in cases.

REGULATIONS

Trade restrictions are relatively absent in this sector, although some restrictions still exist in France, the United Kingdom, the Netherlands, Ireland and Spain. The forthcoming directive on gold watches should facilitate trade in these products.

OUTLOOK

The recent decrease in world demand due to the recession will hit EC manufacturers in particular. The decline in demand for mid-range watches will cause serious declines in production in the short term. In the field of clocks, demand is hampered by low investment activity in the manufacturing sector as well. Production of top-of-the range watches is expected to show slightly better development since demand for this type of product is less sensitive to cyclical fluctuations.

In the medium term, the outlook for manufacturers in the EC is somewhat more optimistic, mainly a result of both the expected recovery in Western Europe, and of the huge demand potential offered by some developing countries such as China and India; the Eastern European markets are not expected to recover significantly in the nineties, however. EC producers will be faced with increasing competition from outside the community as well as from EC members itself. To survive in this highly competitive environment, EC producers will need to continually reduce their production costs and increase their efforts at product innovation.

The advent of the common market in 1993 did not drastically change the landscape for the industry in the EC since most of the firms were already operating internationally.

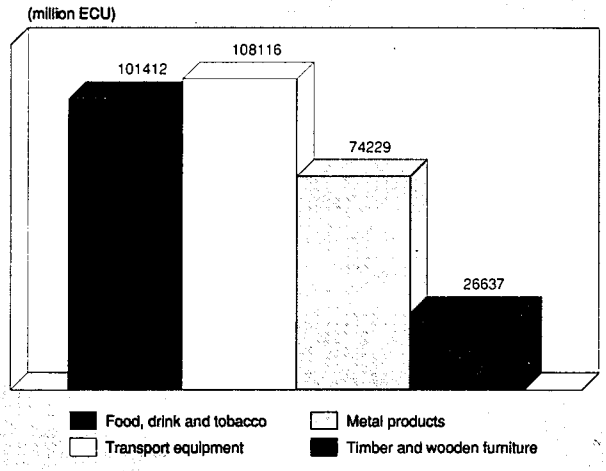
Overview
NACE 41-42

The European food industry, like other sectors, is affected by the world recession. However, comparison at Community level, between the recent trend of manufacturing output as a whole and that of the food industry reveals the typical counter-cyclical behaviour of the food industry. The European market is still characterised by the different consumption habits of the various regional areas, albeit with some common trends. Worthy of particular emphasis is the shift in consumers' preferences towards processed products, convenience foods and snack foods and their ever-increasing concern with nutritional, health and environmental problems.
The competitive environment is determined more and more by a small number of multinational companies. In many market segments, however, production and distribution are still on a national scale only while the degree of concentration of the industry and of distribution varies from country to country. Mergers and take-overs during the 1980s radically changed the company profile and the structure of the sector. During the last two years these activities, although not as intensive at world level as in the recent past, did include some major operations.

Figure 1: Food, drink and tobacco
Value added in comparison with other industries, 1992



Source: DEBA

INDUSTRY PROFILE

Description of the sector

This industry comprises all processed food products, beverages and tobacco classified in NACE groups 411 to 429. In Europe the food and drinks industry is the most important branch of activity in the whole of manufacturing industry in terms of the value of production and one of the most important in terms of added value.

Recent trends

The food industry as a whole displays growth rates which are typical of sectors whose expansion has ceased. The outstanding feature is the steady growth of both apparent consumption and production. At constant prices the average annual growth rate is 2.5% over the period 1983-92 for both production and apparent consumption, with a speeding-up of the growth rate in the second part of the decade (3% in the period 1988-92).

The attractiveness of this industry to the major financial and manufacturing groups is due to this steady growth, and it is particularly during recessions like the present one, that the counter-cyclical nature of most agri-foodstuffs sectors becomes most advantageous. In 1992, the food industry's production index showed a cumulative rise of 20% since 1980 with average annual growth of 2% during the last two years. For the manufacturing industry as a whole the production index declined by 0.4% over 1990-92.

The interest displayed in the food industry is also attributable to its profitability. In 1989, for the hundred leading industrial groups in the EC, agri-foodstuffs companies showed the highest net profit/turnover ratio (7.7%), compared with 5.3% for the chemical industry and 4.7% for the automotive industry. This tendency is due, despite the fact that most of the agri-foodstuffs sectors are no longer growing, to the vigorous spread over the last decade of new convenience products with a higher added value than the traditional products. These characteristics have kept employment levels fairly steady throughout the last decade, despite the sharp drop in the number of persons employed in 1992 (down 2.4% on 1991).

Extra-EC exports have increased slightly since 1989, when their value rose by about 17%. Despite a small increase in imports the Community balance of trade has improved steadily, showing a surplus of ECU 6601 million in 1992, 22% higher than 1991. The meat processing sector, together with the processed fruit and vegetables and oils and fats sector, are the only food categories showing a trade deficit.

International comparison

The market for (fresh and processed) foods and beverages in the OECD in 1990 amounted to over 1 600 billion dollars on the basis of purchasing power parity, representing a volume of expenditure greater than that of transport (1 422 billion), clothing and footwear (731 billion) and furniture and electric domestic appliances (688 billion).

The EC, with over 550 billion dollars, is the largest market, followed by the United States (471 billion) and Japan (197 billion). In the United States the food industry is the second-

largest manufacturing sector after transport. US production in 1992 is estimated at about ECU 321 billion, representing a real growth of 1.5% compared with 1991. The average annual real growth in production of 1.3% during the period 1985-92 was appreciably lower than that recorded in the Community. In contrast to stable growth and the characteristics of maximum expansion, the food industry in the United States is going through a period of pronounced change. During the last ten years there have been about seven thousand mergers and/or take-overs. At present, the 50 leading producing companies account for 50% of the market, which is twice the share they had ten years ago.

Foreign trade

Although growing at a moderate rate, extra-EC exports during the last four years still represent only a small share of production (6.15% in 1992) and have not yet recovered to the figure of the early 80s. On the other hand, intra-Community trade has grown steadily, and twice as fast as extra-EC exports.

Extra-EC imports have increased significantly in real terms during the last four years, with an average rise of 4.8% over the period 1988-92. Even so, during the same period both the growth in exports in real terms and the marked improvement in the terms of trade have led to a significant improvement in the trade surplus, which doubled between 1987 and 1992.

The share of exports to the EFTA countries, the United States and Japan has decreased steadily over the last five years, chiefly to the advantage of Eastern Europe. The changes in flows in terms of geographical areas have, however, mainly hit the United States, which has lost some of its relative importance both as a destination area for Community exports and as an area of origin of EC imports.

MARKET FORCES

Demand

Demand for food products in Europe is continuing to grow, overall, very slowly indeed, at a rate close to zero. The stable rate of population growth and the increase in purchasing power explain, in the first case, the extremely small rise in consumption in real terms and, in the second, the steady decrease in the proportion of expenditure devoted to food, which is now down to well below 20% in some countries.

However, both the level of expenditure on food and the basket of goods purchased are determined not only by economic or demographic factors but also by different regional habits. With regard to the different patterns of food consumption, four main regional areas can be distinguished: area 1, comprising Germany, Benelux and Denmark, where the diet includes a large traditional component (a substantial proportion of meat, butter, chocolate, biscuits, etc.); area 2, comprising the United Kingdom and Ireland, where there is a large proportion of traditional beverages, especially beer; area 3, comprising Greece and Portugal, where there is a typically Mediterranean situation, with a consumption pattern which we could call first generation: extremely high consumption of fresh products and few prepared, innovative and convenience products; area 4, comprising Italy, Spain and France, again with a Mediterranean pattern, but a second-generation one: products - both fresh and processed - with a high health value, side by side with convenience products. The latter area is a market of primary importance, as the three countries in question account for over 50% of total food expenditure in the EC.

Despite regional differences, however, some common features have emerged during the last few years. Traditional foods, which are still the most important component of food expenditure, are tending to account for a smaller proportion, at the expense, in particular, of products such as bread, butter, sugar, jams and unprocessed meat, excluding poultry meat. Prepared products, on the other hand, continue to consolidate the growth they recorded throughout the 1980s: the main reasons appear to have been their greater tastiness together with retention of their full nutritional value. On the other hand, consumption of alcoholic beverages - spirits and ordinary table wine - is declining appreciably and this trend is hardly counterbalanced by the more widespread consumption of mineral waters and other health drinks. The entire drinks sector is characterised by the appearance of many new products tending to take the

place of established beverages, thanks to a new image created by publicity campaigns centred around health consciousness.

Supply and competition

The countries with the highest degree of vertical integration and concentration in many primary and secondary agri-foodstuffs-processing sectors are Germany and the United Kingdom, accounting for 22.1% and 21% respectively of Community added value in 1992. Germany, the United Kingdom, France, Spain and Italy combined contribute over 80% of added value generated at Community level.

Owing to the persistence of deep-rooted regional consumption patterns, even the largest multinationals operating in the sector tend to locate their production unit in the main markets in order to keep more closely in touch with consumers' preferences and tastes. Production and distribution also vary widely from country to country as regards the degree of concentration. In Northern Europe it is very high, whereas in the countries of Southern Europe production is very fragmented, with an overwhelming predominance of small and medium-sized local firms. In the United Kingdom, for instance, many public companies are operating, and 18 of these are among the 50 leading European companies (in terms of turnover). In Italy, by contrast, only three companies are among Europe's leading 50. In the 1980s, however, a number of structural changes speeded up the process of convergence towards more homogeneous development. The main forces behind the change are both external to the industry, namely the advent of the single European market, and internal, namely technical innovations with regard to both production processes and products. These structural changes now taking place have created and will promote further concentration and competitive forces driven by multinational companies.

Production process

Companies have reacted to change by investing heavily in increasing their own production capacity, in new technology and in the modernisation of machinery and production services. The expansion of the market and the increase in competition at European level has in some sectors (especially primary processing) heightened the importance of economies of scale, but there have also been many product innovations, all aimed at creating both horizontal and vertical product differentiation.

The introduction and recent spread of scanners at points of sale in modern distribution networks will certainly also lead to considerable changes in the product logistics and marketing data-processing systems of companies engaged in production and distribution.

INDUSTRY STRUCTURE

Companies

The change during the 1980s radically altered the international competitive scene. According to the "Fortune" ranking of the main food companies, only four groups appeared constantly

among the first ten between 1985 and 1990: Unilever (UK/NL), Nestlé (CH), ConAgra (USA) and Sara Lee (USA).

Recent events involving the Ferruzzi Group (I) will very probably have a serious impact on the international competitive situation. This will depend on the fate of Eridania Beghin-Say, the leading company in the agri-foodstuffs activities of the Ferruzzi Group, which in 1991, was sixth in the world and fourth in Europe among the leading food companies.

However, still as regards world ranking, it should be emphasised that with few exceptions, European food companies handle a much smaller volume of business than the world giants, especially the American firms, and that among the main European companies/ groups, the British are far ahead of the rest at least in terms of size.

The number of companies operating in the European food industry as a whole is rather high. However, the marked concentration of food turnover among the leading ten concerns whose respective parent companies are situated within the EC secures for them a substantial and growing share of the overall market (about 20% in 1991). The biggest company in Europe, by turnover alone, is Nestlé, followed by Unilever and BSN.

Strategies

The need to rationalise and consolidate the acquisitions of the past years and the gradual worsening of the general economic and financial situation of companies has slowed down merger and take-over activity at world level. It should be stressed, however, that the European market has been affected only partly by this situation. Despite the recession, there has in fact been an increase in the number of take-overs and mergers in Europe during the last two years. A significant proportion of this growth is attributable to the opening up of the markets of Eastern Europe and especially the reunification of Germany. Another reason is that small and medium-sized companies in Southern Europe are attractive to those in the North. The reason for this flow lies in the considerable growth potentials, which many countries of Southern Europe offer for some segments of the market.

The increase in take-overs, both within and outside the individual countries, is mainly accounted for by leading European multinationals: Unilever, Nestlé, BSN and Ferruzzi. It should be noted, however, that in 1992, although the number of operations increased, the average sum involved was considerably smaller than in the recent past. This is due to the fact that there are fewer potential targets and that the price of possible further take-overs is too high. In addition, there has also been a change in take-over and merger strategies. Companies which intend to embark on a new line of business or to expand their activity at Community level are tending more and more to create a pan-European network of small and medium-sized firms rather than take over a single large company. In an increasingly competitive market it is becoming necessary, in order to survive and grow, to develop the ability to react quickly to changes. The flexibility with which small firms operate, producing niche products or products aimed at a particular geographical area, gives them an undoubted strategic advantage over larger companies, who in turn respond by taking over small specialised production units.

REGIONAL DISTRIBUTION

Analysing the internationalisation strategies of the major European groups in the EC, recent studies have revealed the existence of different "geographical leadership areas" within which these companies propose to expand and extend the

marketing of their products. Very basically, the following main areas can be distinguished: the Italy-France-Spain triangle, in which BSN, Ferruzzi and Unilever are operating on a substantial scale; the Germany, France, UK triangle, in which Nestlé and Unilever are operating, and, lastly, the German-British-Dutch triangle, in which Unilever is the main operator.

ENVIRONMENT

The food industry - confined as it is to processing operations, as distinct from farming - cannot be regarded as one of the more polluting sectors. The problems are due to the recent development of modern distribution methods requires the massive use of packaging.

For certain materials recycling is not necessarily the best option from an environmental and from a cost point of view. Secondly, packaging is regarded as a necessary part of market strategy and in many cases is actually a vehicle for expansion thus any standstill provision could pose serious problems. Furthermore, European legislation foresees the standardisation of food packaging, especially in the case of fresh fruit and vegetables. In some cases there is a trade-off between the need for harmonisation of the legislation concerning food products, the perceived need to establish product and packaging standards and environmental requirements. On the other hand, a new possibility is offered by biodegradable products used for packaging, although their high cost could jeopardise the competitiveness of the companies which use them. For these reasons, environmental problems must be viewed within the broader context of the harmonisation of Community legislation.

REGULATIONS

The legislation produced at Community level deals particularly with the following groups of subjects:

- elimination of the obstacles to the free movement of goods, from the technical and tax points of view;
- protection of public health and the final consumer;
- economic and technological aims.

There is a horizontal legislation dealing with general aspects such as packaging materials, labelling, the use of additives, the characteristics of the production process, etc. Vertical legislation, on the other hand, deals with individual sectors, such as jams, honey, chocolate products, etc.

The most recent directives have dealt chiefly with the hygiene and health aspects of food production. Directive 95/3 of March 1993 concerns co-operation between the EC and the Member States in tackling the scientific problems relating to food processing and its effect on human health. Furthermore, in June 1993 the Council finally approved a directive imposing further hygiene requirements for food products, with special attention to the premises where firms produce.

OUTLOOK

The growing importance of processed products in the diet of European consumers reflects the vitality of this industry. Nevertheless, production activity is expected to slow down in this sector, too, during the next few years. This will apply to most sections of the industry, and, in particular, there is expected to be a big drop in the production of the alcoholic

Table 9: Food, drink and tobacco

Source: Eurostat

beverages sector, while that of the slaughtering and meat processing industry will cease to grow.

Food trade within and outside the EC, although growing, is not a significant indicator of geographical specialisation, because there are still wide differences in eating habits and tastes at regional level. Nevertheless, the proportion of exports to production is tending to increase, particularly in some subsectors characteristic of Mediterranean diet (pasta and preserved tomato products).

The growing bargaining power of the major distributors will be the major characteristic of the competitive environment that companies will face. Small and medium-sized firms will find themselves increasingly squeezed between the commercial power of organised distribution and competition from the big companies. The strategic choices open to small firms are thus reduced to a dual option: either to pursue a niche strategy or to become suppliers of unbranded products for the distribution channels.

Finally, the future of many European agri-foodstuffs companies will be determined by the outcome of the GATT negotiations and by the effects of the reform of the CAP (common agricultural policy) on the prices and on the availability of agricultural raw materials.

Oils and fats
NACE 411

Consumption of oils and animal fats remained stable over the last 12 years. The major development has been substitution of animal fats by vegetable fats and growing preference for low-fat content products as well as more geographically spread consumption of olive oil. With the sole exception of olive oil, self-sufficiency is well on the low side in the oils and fats sector. On the contrary, EC production of margarine takes place in line with demand, so there is full self-sufficiency in the sector.
Growing industrial concentration has improved productivity primarily by rationalising the production process through technological change. Increasing international competition and the introduction of innovative products are major expected developments.

INDUSTRY PROFILE

Description of the sector

The sector's main products are:

- Products of processing of oilseeds intended for final human and animal consumption including vegetable oils, oilcake, flours etc. and raw materials for pastry making, sugar confectionery and preserves industries; products for the production of celluloid, electrical insulating materials, candles, paints, fuels, glycerine, linoleum, lubricants, varnishes, soaps, etc.;
- Products of the processing of olives, from which olive oil is obtained, with different names depending on the production method employed and the quality of the product;
- Margarine, reduced-fat and low fat spreads and blended spreads (mixtures of butter fat and vegetable fat in various percentages), which represent a further stage of processing of vegetable and dairy fats;
- Oils and fats from land and marine animals.

The extensive range of products, particularly for human consumption, may lead to the EC adopting a classification based on the definition of three broad groupings: butter, margarine and mixed fats. These groupings are further subdivided according to fat variations.

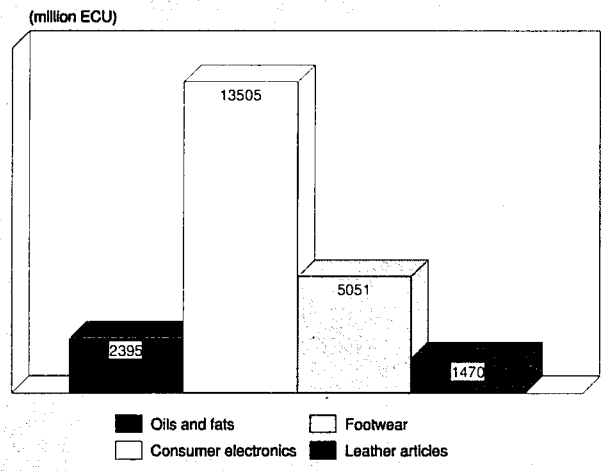
Recent trends

In 1992 the sector's total added value amounted to ECU 2 395 million, having declined by 6.5% in nominal terms compared with the previous year. The countries most responsible for this adverse trend were Spain, Italy and Denmark, while Belgium, France, the Netherlands, the United Kingdom and Germany recorded increases. Denmark, Spain, France, the Netherlands and the United Kingdom account for about 80% of EC value added. In the period 1988-92, consumption and production rose by 2.6 and 2.8% respectively, representing a slight slackening of growth compared with the period 1983-88.

In 1992 per capita consumption in the Community amounted to 15.9 kg of oils and fats, made up of 5.1 kg of margarine and 10.8 kg of other oils and fats for human consumption. On the other hand, per capita consumption of butter in 1992 was 3 kg.

The balance of trade continues to show a deficit. Despite the fact that 80% of world production of olive oil is accounted for by the EC, the overall balance of trade of the oils and fats industry is structurally negative because the industry is heavily dependent on foreign countries for supplies of oilseeds, other vegetable oils and oilcake. The recent recession in Europe caused a drop in sectoral employment of 2.8% in 1992.

Figure 1: Oils and fats
Value added in comparison with other industries, 1992



Source: DEBA

Foreign trade

The Community imports oilseeds, vegetable oils, oilcake and flours (notably from the United States, Brazil, Argentina and Malaysia), while it exports olive oil and modest quantities of margarine. Over the period 1987-92 the combined share of the US and EFTA in extra-EC imports declined from 25.4% to 8.3% of the total. Extra-EC exports of oils and fats are being absorbed at an increasing rate by the US market which has come to account for 11.3% of the total compared to 6.5% in 1987. Around 13.4% is absorbed by EFTA countries.

In the olive oil subsector 90% of production is consumed by the producing countries although growing demand from countries that are not traditional consumers is increasing trade flows. The main exporting area is the Mediterranean basin, which normally accounts for 97% of world exports, 60% of which come from the Community. Spain, Italy, Greece, Tunisia and Turkey are traditionally the main exporting countries.

MARKET FORCES

Demand

Oilcake and flours for animal feed, and also vegetable oils, are obtained from oilseeds. The sector's economy is therefore dependent on the movement of prices for oilseeds, oils and oilcake. Seed oils can be consumed in the pure state or in the form of prepared oils or fats, such as margarine.

Animal feed

Demand for oilcake and animal feed derived from oilseeds fluctuates due to the composition of the animal feed and the fact that they can be substituted by cereals, corn gluten feed and green fodder. The basic factors influencing the demand for and composition of feed are the production trends in the EC and world stock farming and hence the demand for the various types of meat.

Human consumption

There are significant differences in consumption patterns between Member States. In the Mediterranean countries olive oil and seed oils are much more used than in Northern Europe where consumption of margarine is more widespread. For instance, per capita consumption of margarine in 1992 was over 8 kilograms in Germany, Benelux and Denmark, but less than 2 kg in Italy, Spain and Greece (Source: Consumer Europe). On the other hand, consumption of other oils and fats (mainly olive oil and seed oils) amounted to 32.3 kg in Greece, 27.2 kg in Spain and 11.4 kg in Italy, but was less than 7 kg in France and Benelux and only 0.6 kg in Denmark.

The principal variables influencing consumption, apart from eating habits, is relative prices, consumer concern about health, introduction of new products and legislative factors, such as the restrictions imposed by some Member States on the marketing of products based on vegetable fats. Substitution between olive oil and seed oil can take place due to price

Figure 4: Oils and fats

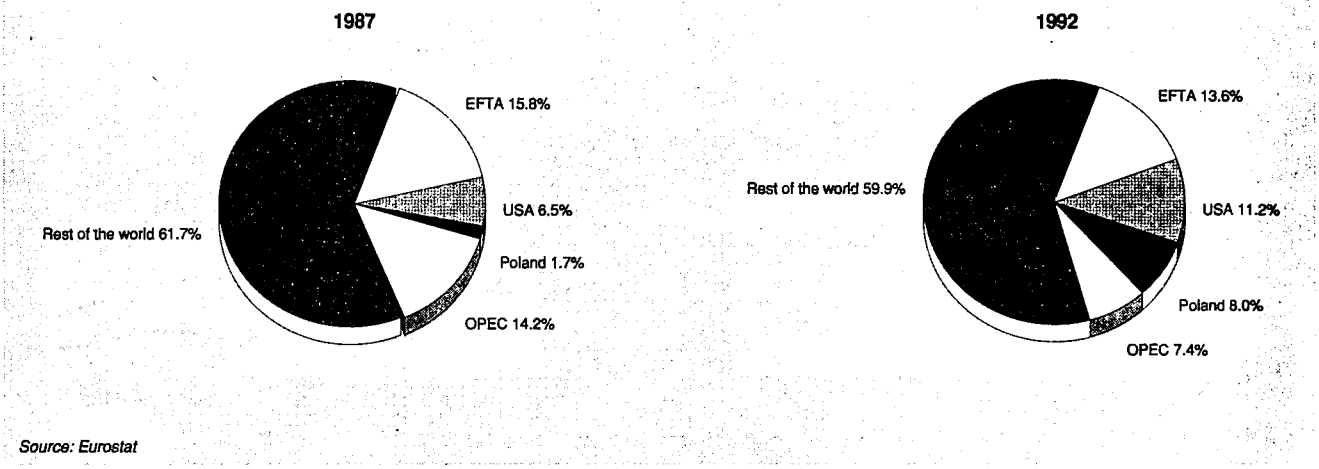
Figure 6: Oils and fats
Destination of EC exports



Source: Eurostat

differentials and consumer perceptions. On the other hand, substitutions between saturated and polyunsaturated fats and between fats of animal origin and vegetable fats are chiefly attributable to the greater attention paid to health issues.

The changes which are taking place in consumer patterns are leading to an increase in consumption of vegetable oils and fats at the expense of animal fats and butter. Furthermore sales of mixtures of fats and new products with a low fat content are expected to rise. These developments will undoubtedly be assisted by the removal of the remaining legislative restrictions on the introduction of such products into some national markets.

Supply and competition

Oilseeds are processed in two stages, not always integrated in the same company:

- the processing of oilseeds into crude oil and protein meal;
- the refining, hydrogenation and fractionation of crude oils and fats.

The olive oil subsector is characterised, in the case of Italy and Greece, by the presence of many small firms operating on a local scale, together with a few medium-sized and large companies. Spain, on the other hand, has a production structure with high-capacity factories. This gives the Spanish industry unquestionable competitive advantages. EC companies are encountering competition from countries such as Argentina, Brazil and Malaysia which are developing and expanding their production capacities. Regarding the margarine industry, it is highly concentrated and production location corresponds to the size of consumer markets.

Production process

The processing of oilseeds is capital-intensive and involves a high degree of mechanisation which has enabled the introduction of significant technological innovation. However, the productivity gains have been significantly counteracted by rising labour costs.

The bulk of margarine output comes from large and highly mechanised plants whereas, in the case of olive oil, production structures in the Community are still somewhat varied making it difficult to introduce process innovations.

INDUSTRY STRUCTURE

Companies

After significant merger activity the European leadership of the oilseed-crushing and refining sector was held up till 1992 by the Ferruzzi group via Cereol, with an 18-20% share of the market. The Unilever group (UK-NL) holds an important positions in many European markets as regards margarine. ADM and Cargill (USA) operate as major crushers in Europe.

In the olive oil sector, co-operative enterprises play a rather prominent part, especially in Spain. In the edible oil sector, the first three groups, Ferruzzi, Unilever and Elosua (Spain) hold a combined market share of 45-50%. In the margarine sector the three leading companies, Unilever, Vandemoortele

(Belgium) and Rau (Germany) account for 60-65% of the market share.

Strategies

The sector's strategic response to changing market conditions consists of concentration and rationalisation of the production structure, aiming primarily towards cost reduction. There have been a series of take-overs of national companies by multi-nationals, which have reduced the role of small and medium-sized firms to operating in niche markets or becoming suppliers of the modern distribution chains for branded products.

The competitive strength of the large companies lies in product diversification given that product typology is experiencing significant growth that provides great opportunities for those introducing new innovative market segments.

From the strategic point of view, increasing importance is attached to brands and advertising and policies widening the

Source: IMACE

product range. The EC has financially supported generic advertising for olive oil.

The most important operations leading to external growth in recent years have been: the take-over of Novenyolajipari es Mososzergyarto Vaallalat (Hungary) by Ferruzzi (I); Unilever's (UK/NL) traditional share in Unilever-Is (Turkey) was increased to a full share holding; the take-over of Aceites Españoles SA (E) by Elosua SA (E).

REGIONAL DISTRIBUTION

The production of olive oil is concentrated in Spain, southern and central Italy, Greece and Portugal while the oilseed processing industry is located mainly in Germany, Holland, Spain, France and Belgium. The production of margarine is concentrated in Germany, the United Kingdom, Holland, Belgium, France and Denmark.

ENVIRONMENT

The main ecological problem affecting the industry is connected with the disposal and processing of solid urban waste. National and Community legislation is increasingly tending to regulate the characteristics of product packaging, including their chemical composition. The volume and chemical content of the packaging is subject to legislation. Consumers, becoming increasingly concerned about ecological problems, are likely to show greater preference for products packaged in the most environmentally friendly manner.

REGULATIONS

For olive oil EC regulations operating through subsidies and price intervention are aiming to:

- Provide producers with a guaranteed income (production subsidies);
- Facilitate marketing within the Community (consumer aid);
- Assist exports (export compensation);
- Support the EC market (price intervention).

The use of price intervention has been limited. Vegetable oils however are exempted from export compensation, consumer aid and price intervention. Finally, regulation 2568/91 and subsequent amendments thereto (Regulations 356/92, 1429/92, 1683/92) aim to provide quality control of the oils, as a safeguard for the consumer. As concerns oilseeds, the support regime has been completely reformed. Farmers now sell oilseeds at world market prices and receive compensatory support in form of per hectare payments.

OUTLOOK

The process of substitution between animal fats and vegetable fats might continue during the coming years. Innovative low fat products may well have possibilities of expansion at the expense of traditional products. During the coming years we may witness an increase in competition at international level (and therefore the process of concentration already in progress will probably speed up) and the removal of the legislative restrictions limiting the entry of mixtures of fats into certain national markets. The United States market will continue to be characterised in the coming years by an advantageous trend of consumption of olive oil. Finally, there are clear possibilities of expansion at international level, especially for large companies which are active in diversification.

Meat
NACE 412

The introduction of free market policies in Eastern Europe coupled with economic recession have resulted in a dramatic decline in fresh meat production. In fact, long-term stability of world trade is jeopardised by the changing conditions in East European countries, given their role as major meat producers. The GATT Uruguay round, which should be completed in the near future, will establish the new trading rules for the meat market with repercussions on the retail side. The propensity towards consumption of meat with a low fat content is continuing to grow. For some years, beef has been replaced by other types of meat which, with the same protein content, contain less fat. There has also been a substantial increase in output of processed meat-based products.

INDUSTRY PROFILE

Description of the sector

The main products of the sector can be classified according to:

- the type of meat: beef, pork, mutton, poultry, horse meat, etc.;
- the degree of processing of the product: fresh meat (sold in portions, packaged or combined with other food-preparation ingredients), or preserved pork- and beef-based products, including sausages, dressed pork products (charcuterie), ham and bacon.

The degree of diversification of enterprises is generally on the low side, especially as regards the very large number of small and medium-sized enterprises. Only the big groups strategically diversify their activity into other food sectors and/or undertake downstream integration: the main enterprises in the dressed pork sector seek to achieve economies of scale by marketing various types of fresh products (for instance dairy and cheese products), while the main enterprises in the poultry sector generally tend to operate in the animal feeding stuffs sector.

Recent trends

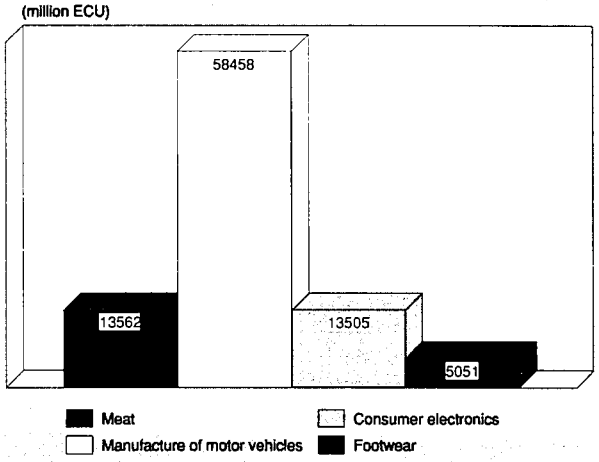
In 1992 the meat sector achieved an added value of ECU 13 500 million. The economic importance of the slaughtering and meat processing industry is quite high and comparable to that of the consumer electronics industry. Over 83% of the added value was generated in France, United Kingdom, Germany, Spain and Italy.

The largest increases in added value were recorded in Greece and the United Kingdom. In the former, value added almost doubled compared to 1991. On the other hand, negative trends have been recorded in France and Spain.

Real growth rates for production, consumption and trade during the period 1988-92 averaged at a lower level compared to the 1983-88 period with production and consumption retreating the most, while the growth rate for exports maintained recent trends. In 1992 total production of meat at current prices was 4.9% higher than the previous year, whereas the growth rate of apparent consumption increased slightly by 5.3%.

In terms of physical quantities, consumption in 1992 amounted to about 81 kg of meat per head per year, including 2.5 kg of canned meat and about 2 kg of frozen meat. These averages, however, conceal substantial differences between the individual countries, as consumption of fresh meat ranges from 67 kg

Figure 1: Meat
Value added in comparison with other industries, 1992



Source: DEBA

in the United Kingdom to 100 kg in Denmark (Source: Consumer Europe 1993).

Overall, 1992 saw a shift in demand towards the various types of white meat (especially poultry) at the expense of red meats. There was a substantial increase in total demand for meat in Spain and Portugal where the development of consumption patterns had been lagging behind.

The swine population had been decimated by disease in 1991 and was down to around 100 million heads in 1992. During the same period Community production of beef fell sharply (by 5%) to a total of 8.2 million tonnes. Most affected were the territories of Germany, where a fall of about 20% in output was coupled with a decrease in the number of animals slaughtered (-5%). For the first time in the last ten years, employment in the sector declined by 1% in 1992.

International comparison

In the world context, the Community is the leading producer of beef, mutton and goat meat and the second-largest producer of pig meat, after China.

Source: DEBA

The livestock population of the United States is being slowly built up again, and this is reflected in a steady increase in domestic production and higher exports, especially to Japan. At the same time the United States has signed voluntary agreements which actually limit exports to its main suppliers, especially in Oceania.

Foreign trade

The balance of trade, which had shown a surprising surplus in 1991, swung back into deficit in 1992. A trade surplus had been achieved in 1991 for the first time in the last ten years, but the balance became negative again in 1992. This was due to a fall in exports (-0.7% in nominal terms) and an increase in imports (7.4%, again in nominal terms).

Approximately 20% of EC output constitutes intra-EC trade. The trade flows of beef and pig meat move mainly from the producing countries in Northern Europe towards the Mediterranean countries (especially Italy and Spain). Some 5% of Community output is accounted for by extra-EC trade. Compared with 1987, the figures for 1992 show a drastic drop in exports to the United States. There was also a further decrease in exports to EFTA countries. EC exports of mutton, lamb and goat meat are negligible.

Extra-EC imports account for 20% of the total, the main suppliers being Argentina, New Zealand, Brazil and some East European countries.

MARKET FORCES

Demand

The proportion of consumption of fresh meat in total consumption remains unchanged and is estimated at around 70-75% in terms of volume and 65-70% in terms of value. The propensity towards fresh meat is greater in the Mediterranean countries. The dressed pork and canned meat products sector is substantial in France, Italy and Germany.

Figure 4: Meat

Source: DEBA, Census of Manufacturers, Nikkei

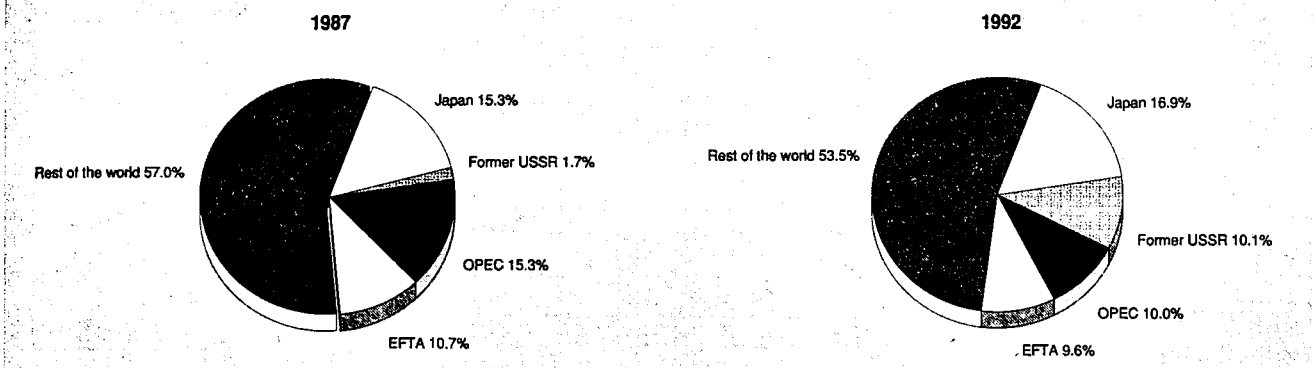
Figure 6: Meat
Destination of EC exports



Source: Eurostat

For some time now preferences in meat consumption have been shifting towards "white" and lean meats at the expense of beef. This is attributable to the greater attention paid to health problems, especially by consumers in the more industrialised countries. In addition, the price differential in favour of poultry meat has definitely stimulated demand in the face of declining disposable incomes during the current recession. Other kinds of meat which are proving successful, are dressed pork products and fresh products sold ready-prepared in portions with a high added value.

It is worth mentioning the high consumption of lamb in the United Kingdom, where 30% of the Community's sheep are concentrated. Production of this type of meat is likely to increase, thanks to support provided by the Common Agricultural Policy.

Supply and competition

The meat sector is particularly fragmented, with the actual position varying greatly from country to country. In Italy there are many processing firms, but they are definitely declining in number. The trend is the same in Ireland, Greece and Portugal. There is a higher degree of concentration in Germany, the Netherlands and Denmark. The growth in the size of firms is now proving to be a strategic factor not only for the reduction of costs and operating charges, which, among other expenses, are rising continuously, but also for winning larger market shares. The greatest concentration of production has taken place in the preserved animal products and canned meat sector.

The loss of traditional sales points for food as against the rapid growth in the number of sales points in the modern distribution network has enhanced the bargaining power of distribution enterprises.

Production process

The added value per employee in this sector is rising steadily. Unit labour costs show no sign of decreasing and meat as a product does not lend itself to the introduction of technological innovations capable of generating major economies of scale. In recent years, however, there had been an increase in investment projects aimed at rationalising the production process, by the introduction of automation in the phases which require less manual skill. The present acute recession and the need to reorganise the production process by making it more capital-intensive are the factors responsible for the fall in employment.

INDUSTRY STRUCTURE

Companies

The meat and meat-based-product industry embraces some 8 000 firms whose production in 1992 is estimated at around ECU 79 billion at current prices.

Co-operatives, which account for a significant share in total supply, are widespread in the Community. Recently these types of enterprise have increasingly assumed an entrepreneurial structure in order to meet the "threatening" globalisation of markets, sometimes by joint ventures with private enterprises.

In Italy, Germany and France, public slaughterhouses are found in many places, but the share of butchered meat provided by private establishments is rising everywhere. 76% of pig slaughtering activity in the Community is distributed among an immense number of firms, while the remaining 24% is accounted for by the twelve largest enterprises in the sector. Denmark has the highest concentration of pork slaughtering firms with the three leaders accounting for 89% of the market. It is followed by the Netherlands where the three leading enterprises control 38% of the market.

With regard to cattle slaughtering, 80% of the market is shared among the very large number of small and medium-sized enterprises located in the Community countries, while the remaining 20% is held by the twelve largest enterprises. Here again, Denmark has a high degree of concentration, with 67% of the market shared among the country's three largest enterprises. Germany comes next, with its three leading enterprises having 29% of the market.

In the fresh beef sector special mention should be made of Socopa (F), Inalca-Gruppo Cremonini (I) and Sogé viande (F), which together hold 4-6% of the EC market but operate exclusively in their own countries. In the fresh pork sector, Annuss Fleisch (D), West-Fleisch (D) and Süd-Fleisch (D) together have a market share of 4 to 4.5%. In the mutton and lamb sector, HL Foods (UK) and Socopa (F) account for 15-16% of sales. In the poultry sector, Paribas (F), Sipa (I) and AIA-Gruppo Veronesi (I) cover 15-18% of the total market. Lastly, Nestlé (CH), Unilever (NL) and BP Nutrition cover 9-11% of the processed meat market.

Strategies

The successful strategies adopted by the principal European meat-producing enterprises can be summarised as follows: to improve efficiency of production in order to increase market shares; to penetrate other foreign sales markets by means of international agreements and merger and acquisition operations; to develop and consolidate commercial relations with the major organised distribution networks; to recruit professionals and specialists in an effort to boost marketing strategies; and to control the entire trading chain.

Furthermore, the individual EC Member States are making efforts to obtain acceptance at Community level in order to

protect their own typical products, especially in the delicatessen subsector.

The most significant acquisitions which have taken place in the EC, particularly in Italy: Kraft has acquired Fini, Invernizzi and Negroni; Nestlé has acquired Vismara, Locatelli, Kings and Herta. BSN has acquired Galbani.

Other recent operations include the following: Cavaghan & Gray Ltd (UK) has acquired Emile Tissot Foods Ltd (UK); Tyson Foods Inc (USA) has acquired Purina Mills Inc (USA); Gouessant (F) has acquired Pic'Grin (F) and Sodelor (F); Campofrio SA (E) has acquired Campocarne SA (E); MBO has acquired Wirral Foods Ltd (UK).

REGIONAL DISTRIBUTION

The map of stock farming in the EC has been redrawn since the five East German Länder became part of Germany. In the case of beef production, 85% of output comes from France (Normandy and Brittany), the United Kingdom (Cornwall), the Netherlands, Northern Italy and, obviously, the new German Länder. About 80% of pork is farmed and slaughtered in Denmark, the Netherlands, Northern Italy, France (Normandy and Brittany), the German Länder and Eastern Europe. Nearly 90% of poultry meat is produced and processed in Germany, Spain, France, Italy (particularly in Emilia-Romagna and Veneto), the Netherlands and Eastern Europe. About 86% of sheep and goat farming for slaughter purposes is concentrated in Ireland, Scotland, England and Wales, the southern regions of Italy, France and Spain and the German Länder.

ENVIRONMENT

When looking at the ecological problems connected with the slaughtering and meat processing industry, one must start with stock farming. Territorial concentration, especially in pig farming, creates problems of soil pollution and, above all, the underlying strata. This calls for the introduction of policies to control the disposal of manure and in some extreme cases for restriction of livestock numbers and density.

Slaughtering inevitably results in certain by-products which are not as such suitable for human consumption. These are organic substances and therefore perishable. Fortunately, there is a large and well developed industry which processes these substances for other purposes, e.g. animal feed and fertilizers.

REGULATIONS

As part of a set of measures for reforming the common agricultural policy, Regulation EEC 2078/92 for the protection of the rural environment has been issued. This regulation lays

down guidelines for farmers who employ production methods and engage in other activities which are useful for the protection of the rural environment.

The events of 1991 which seriously threatened the health of animals in the Community made it necessary to draw up Directive 92/102 on the identification and registration of stock farms and livestock. Health Regulation 91/497 (29/6/91) subsequent amendments were designed to regulate production activity in abattoirs, cutting shops and cold stores. However, Directive 92/120 (17/12/92) authorises Member States to grant temporary derogations until the 31st of December 1995 to factories which manufacture products of animal origin for human consumption.

Italy, which has many abattoirs which do not comply with the Community rules, has not stepped up investment in fixed capital to the extent expected from implementation of the directive. Consequently there is now massive resort to the postponements and derogations provided for by the directive. Following the publication of Regulation 675/92 it is possible to identify the maximum limits for residues of veterinary medicines whose presence is tolerated in foodstuffs of animal origin and especially in meat.

Lastly, there are two further EEC directives: one, issued on 29 July 1991, amends and codifies Directive 64/433/EEC concerning health problems connected with intra-Community trade in fresh meat and can be extended to the production and marketing of fresh meat; the other, issued on 10 February 1992, amends and updates Directive 77/99/EEC concerning health problems connected with intra-Community trade in meat-based products and amends Directive 64/433/EEC.

OUTLOOK

Developments in the medium term will depend chiefly on changeable international agreements and on the course of EC legislation. Pig farming is tending towards overproduction. Potential economic recovery in Germany is likely to lead to a situation favourable to the industry, but somewhat of a burden for the stock farming sector.

Over the next few years industrial production of meat will continue its present trend towards concentration both owing to the entry into force of Directive EEC 497/91 and because of the ever-keener international competition within the Community. Many marginal enterprises will therefore be squeezed out of the market.

Internal consumption will continue to grow slowly but steadily and will shift more and more towards high quality products with a high added value. The chief problem is set consumption patterns, whose disadvantages can be overcome by operators directing attempting to decisively challenge consumer habits.

Modern distribution will make it necessary to maintain a relationship of competitive co-operation in order to avoid triggering a spiral of beggar-thy-neighbour low-price policies that jeopardise the quality of meat produced.

Exporting to the markets of the former USSR and Eastern Europe is a source of opportunities and risks. Political reform has brought about a decline in agricultural production, creating potential markets for processed products and there is also the possibility of joint ventures with local enterprises for financing modernisation of the local production structure. There is still, however, the risk connected with the increase in imports of livestock from those countries - a problem which the Community has recently had to face.

The risks for the industry can be summed up as follows: the difficulty of countering the replacement of beef by white meats; the inadequate degree of support offered to the market by the common agricultural policy (CAP); the increasing bargaining power of distributors; the unlikelihood of survival in the market of small enterprises because of the intensification of competition.

Arising opportunities are considered to reside in: the potential for greater market segmentation and the spread of new products; the possibility of product differentiation through the introduction of quality brands; investment, acquisitions, joint ventures and trade agreements with Eastern European countries.

Dairy products
NACE 413

The EC is the largest milk producer in the world. In 1992 its share of milk deliveries in the OECD stood at 45%. In 1989 milk production accounted for 18.1% of total agricultural production with half of it produced by Germany (the leading producer) and France. After the downward trend of the market for dairy and cheese products in 1990, prices recovered slightly in 1991 thanks to the stabilisation of world markets following the radical changes which took place in Eastern Europe. In recent years there have been signs of a stabilisation in milk consumption and a decline in butter consumption. The most vigorous sectors are still those of yoghurt, desserts, light and new cheeses and partly skimmed milk. Community production of milk and cheese products is showing a surplus. The problem of stocks of powdered skimmed milk has become acute again, while butter stocks have declined. Take-overs and mergers in recent years have considerably changed the scene altering competition patterns.

INDUSTRY PROFILE

Description of the sector

The main products of the sector can be subdivided into:

- products for final consumption: fresh and long-life milk, butter, cheese, fresh products (cream, fermented milk, desserts, fresh cheese), powdered milk;
- products which are ingredients for the secondary processing industry and are in the nature of commodities: powdered milk, butter, butterfat, casein, powdered whey.

These products are used both in the food industry and in the animal feed industry, where proteins and fats are particularly suited. In confectionery, the use of egg albumen has been replaced by the use of concentrated whey protein.

Dairy-product and cheese enterprises usually diversify into related sectors, achieving economies of scale with regard to: transport (other fresh products), marketing (delicatessen products); and packaging (canned vegetables). Dairy firms are rarely diversified into non-food sectors.

Recent trends

The added value of the sector in 1992 was ECU 10.2 billion with 80% accounted for by France, Germany, the United Kingdom, Italy and the Netherlands. During the five-year period 1987-1992 employment fell by 10.7%, including a 2.5% drop in 1992.

Over 1983-1990 production in real terms rose at an average annual rate of 1.7%. Since then there has been some levelling off. In 1992 falling imports and rising exports allowed for a moderate trade surplus.

From 1993 onwards Italy accepted the new production level. For the 1993-94 season the Community has provisionally increased the quota to 900 000 tonnes for Italy, 100 000 tonnes for Greece and 500 000 tonnes for Spain.

International comparison

Contrary to what occurred in the EC, output in the US for dairy and cheese products increased by 3% in real terms in 1992 (although it should be borne in mind that this figure includes the rapidly-growing segment of ice creams and desserts).

Consumption trends, if broken down by family product, reflect changes in consumption patterns similar to those in Europe, the most dynamic products being those with a low fat and calorie content, at the expense of products containing more fats. Consumption of yoghurt has fallen due to market saturation. US exports increased in value by 67%, leading to the first surplus since 1972. The US dairy and cheese product industry is now exporting 2% of its output, compared with 1.1% in 1989.

The EC is the major world exporter of dairy products (in 1991 it retained its overall 49.5% share of exports on the world market) followed by New Zealand and Australia with world-market export shares of 19% and 8% respectively.

Foreign trade

Sales of dairy and cheese products in non-EC countries contracted in 1986 and again in 1990, in the latter case owing to the Gulf war. Over the last two years there has been an improvement in the balance of trade, which became more marked in 1992. In many countries the dairy and cheese product industry is highly fragmented and most enterprises do not succeed even in attaining national stature. This type of struc-

ture, together with the high incidence of transport costs, induces operators in the sector to turn mainly to the domestic market, neglecting intra-Community trade (intra-EC trade is 17%) and neglecting extra-EC even more (extra-EC trade is 6%). The main recipients of extra-EC exports are the OPEC countries, followed by the United States. The proportion of extra-EC imports in total consumption is marginal.

MARKET FORCES

Demand

Of the milk produced in the Community, 20% is consumed in the liquid state, while the remaining 80% is used for producing cream and fresh products (8-9%), butter and cheese (50-60%), powders (15-16%), feed for livestock (4-5%) and other minor products.

The change which is taking place in the pattern of consumption of food products is also affecting consumption of dairy and cheese products.

With the exception of Germany the early 1980s saw the start of the decrease in consumption of butter due to competition from margarine. In recent years, on the other hand, sales of butter are being threatened by a new generation of yellow fats, called spreads - products containing a mixture of butterfat and vegetable oil. On some markets they account for a significant proportion of trade in fats. In 1992, per capita consumption of butter was about 3 kg for the Community as a whole.

Consumption of liquid milk is declining, except for Germany and Portugal. The preference for semi-skimmed milk reflects preference for light products. Milk is encountering competition chiefly from soft drinks and fruit juices. Producers have tried to counter this phenomenon by producing milk with added

vitamins or flavourings. Per capita consumption of milk in 1992 was around 73 litres. The preference for fresh low-fat "health" products has led to a substantial increase in consumption of the great variety of yoghurts and fresh white and light cheeses, which are markedly invading the markets. In 1992, per capita consumption of cheese in the EC was 13 kg and that of yoghurt 9 kg.

The quantities of butter, powdered milk and cheeses which are not in demand within the EC find an outlet in the international markets. World demand is, however, declining owing to saturation of consumption in developed countries and an increase in production in some importing countries. Furthermore, some of the latter are diversifying their sources of supply away from the EC.

Supply and competition

The recent introduction of the milk quota system in the Community has triggered a restructuring process which is changing the pattern of the European industry. Despite the fact that various mergers between leading co-operatives have taken place in some North European countries, the dairy and cheese product industry in the Community as a whole displays a low degree of concentration. The value added per employee contracted by 2.5% in 1992, while unit costs increased sharply (by about 8%).

A drastic change in the organisation of the new German Länder, connected with the need to reach EC standards, has led to a reduction in milk deliveries, reflected in a significant decline in production not only of butter but also of cheese and condensed milk.

Production process

In recent years technology has succeeded in diversifying the range of dairy and cheese products. Innovation is constantly taking place with the object of addressing precise consumer preferences and needs. At the same time the industries are introducing new technology to achieve economies of scale. The process of ultra filtration is making it possible to rationalise the components of raw materials and to introduce milk derivatives which are novel from the point of view of composition. It is only the traditional product lines that are less suited for technological improvements, with the result that production costs remain high.

INDUSTRY STRUCTURE

Companies

Despite the many changes which are still in progress, production in many Community countries is extremely fragmented. It should be remembered that producers' organisations (especially co-operatives) play an important role as regards liquid milk and butter in the markets of Ireland, Belgium, the Netherlands, Germany and Denmark. In Spain, on the other hand, an important role is played by partly state-owned enterprises.

The total number of firms in the sector is around 6 500 and the countries with the highest average intake per enterprise are the Netherlands and Denmark, while the lowest rate is recorded in Italy. In some countries the industrial structure is made up of sector leaders which operate surrounded by a large number of smaller enterprises operating in local areas and specialising in production of typical products.

About 15-20% of the market for milk for use as food is held by Parmalat (I), Sodiaal (F), MMB (UK). 35-40% of the market for yoghurt is held by BSN (F), Nestlé (CH) and Sodiaal (F). 25-30% of the market for fresh cheese is held by BSN, Unilever (NL) and Philip Morris/Kraft (USA). 60-65% of the market for powdered milk is held by Nestlé (CH), France Lait (F) and HL Foods (UK).

Strategies

Dairy products face competition from related food sectors which have a better profile from a health view point. That has revived efforts to increase the number of milk-based products made available to the public.

For historical reasons a significant proportion of the production and distribution of liquid milk is in the hands of co-operatives. Although the latter have adopted an industrial-type decision-making structure, they still have difficulties in pursuing a market-oriented diversification policy owing to the close link with the contributing members. Consumers tend to associate milk, cream and some types of cheese not so much with a particular producer or brand but with the geographical area of origin. Butter, on the other hand, tends to have a stronger brand association.

The constraints imposed by the Common Agricultural Policy and the degree of maturity reached by traditional products in this category have caused the leading enterprises to turn to products with a greater added value. These enterprises apply new production and packaging technologies and pursue a policy of product differentiation and market segmentation by expanding their production in the range of "light" products or products containing mixed vegetable and animal fats, known as spreads. Producers invest heavily on brand marketing efforts.

ENVIRONMENT

Cattle farming leads to pollution of the soil and of ground-water strata. The processing and manufacturing industry is faced with ecological problems from the angle of management of urban solid refuse and hence that of the regulations governing the nature of packaging. Germany is highly committed in this respect. With the rapid spread of production of UHT milk, some enterprises have started to introduce recyclable dark-glass bottles.

REGULATIONS

The organisation of the dairy and cheese product market, which began to operate on the 29th of July 1968, is governed by Basic Regulation 804/68, subsequently incorporated in the regulations determining: the market support system; the introduction of levies on cheeses, butter and powdered skimmed milk; the management of disposal of stocks by means of special sales; the gradual harmonisation of the hygiene and quantity standards applying to milk; and the introduction of milk quotas (Regulations 856/84, 857/84, 1447/84, 1527/88 and subsequent decisions) and co-responsibility levies.

(1) Including former East Germany.
Source: Eurostat

There have been many acquisitions, mergers and arrangements between private and co-operative enterprises, bringing about a considerable change in the structure of supply. The acquisition of local enterprises has been the method used by many to penetrate foreign markets. The biggest operations of recent years are: the acquisition made by BSN (F) of Galbani (I); the acquisition of Giglio (I), Farm Best (USA) and Milk Maid (USA) by Parmalat (I); the acquisition of Tallinn Margarine Factory (Estonia) by Unilever PLC (UK); the acquisition of Sandhurst Dairies (AUS) by QUF Industries (AUS); the acquisition of Sussex Dairies (UK) by Unigate (UK); the acquisition of Ala Zignano (I) by Polenghi Lombardo (I).

REGIONAL DISTRIBUTION

80% of the milk collected and conveyed to processing and manufacturing enterprises comes from France (Normandy and Brittany), the United Kingdom (Cornwall), the Netherlands, northern Italy, Spain and the new German Länder.

Germany, Spain and the United Kingdom, France and the Netherlands are major producers of fresh products and cheeses. The latter are also produced in Denmark. Powdered milk is chiefly produced in factories located in Northern Europe.

OUTLOOK

Prospects are linked to international agreements influencing extra-EC trade and by future EC agricultural policy and legislation. Further concentration and internationalisation of the industry is expected to be a major characteristic.

There may be a growth in the milk and cheese sector owing to the variety of low-fat products. The niche market for cream

may show a sharp growth in sales. The present decline in sales of butter will be halted only if the producers succeed in improving flavour and creaminess.

The main risks present for the sector can be specified in the replacement, in the consumption basket, of dairy and cheese products by substitute products containing a mixture of fats and intensifying global competition coupled with a reduction in market support schemes that will prove particularly painful for the small producer. Regarding opportunities they are mainly applicable for the leading enterprises that will pursue further their globalisation process and introduce further technological change.

Fruit and vegetable processing and preserving
NACE 414

Although the market as a whole is going through a phase of slow growth demand for industrial products has been stronger at the expense of fresh products. The growing demand for natural foods without additives is an incentive for companies to diversity their products. The introduction of new types of fruit juices, products based on exotic fruits and innovative vegetable products is helping to increase sales in this subsector. The sector is dominated by multinationals, which are able to invest heavily in order to compete with other food sectors. However, many small and medium-sized firms survive by taking advantage of market niches. High labour costs in the EC handicap Community production in relation to products from Eastern European and the less developed world.

Source: DEBA

INDUSTRY PROFILE

Description of the sector

The sector's main products are:

- vegetable preparations in cans, cartons, etc., dried or irradiated products, soups, juices and sauces;
- fruit preparations in cans, cartons, etc., jams, jellies, juices and syrups.

Recent trends

Over the period 1988-1992 production rose by 4.1% in real terms while consumption increased at an average annual rate of 5.3%; hence the trade balance has constantly been negative. In the early 1980s, the introduction of advanced technologies resulted in labour being increasingly replaced by capital in the production process; during recent years this has ceased to be the case, and employment rose as a result. In 1992, however, the European recession caused employment to fall again by 2.7%.

International comparison

For tomato-based products, North America is the biggest processor in the world, with just under 45% of total processing, while the EC processes around a third of the total quantity of raw material supplied to the industry. For processed tomato-based products and for peaches in syrup, the EC's self-sufficiency ratio was over 100% in 1992, whereas for other products it is still a net importer of enormous quantities. Community production of pineapples in syrup is negligible and, for prunes and raisins falls far short of that of the leading producer, the United States.

The United States is both a big producer and a big exporter of dried fruit and tinned fruit juices and vegetables. The EFTA countries have only a modest market for tinned fruit and vegetables. This is due to the fact that the prices of the fruit and vegetables processed industrially in these countries are distinctly on the high side.

Foreign trade

Extra-EC imports increased substantially, at an average rate of 8.4% while extra-EC exports rose slowly, at an average annual rate of 1.1%. The balance of trade has always been negative and the gap is widening. In 1991 the ratio of exports to imports had deteriorated to 40%. This is due to the competitive pricing of extra-EC imports from non-EC countries bordering the Mediterranean basin and to the steady erosion of competitiveness of EC exports, including finished products, because of the high competitiveness of similar products in Eastern Europe and Asia.

In 1992 26.4% of EC exports went to the United States, 22.4% to the EFTA countries and 4.5% to Japan. Exports to the Middle East are also significant although they have been encountering difficulties from non-EC competition. There are no significant differences between these figures and those for 1987. Over 50% of imports come from Eastern Europe and developing countries with Turkey and Brazil being the most significant. Imports from the US and EFTA are quite limited.

The volume of intra-EC trade is more substantial in comparison to extra-EC trade and over the last decade it has been increasing its significance in overall EC trade.

MARKET FORCES

Demand

Demand for processed fruit and vegetable-based products is growing, and suggests possibilities for new products thanks to a tendency towards uniformity of consumption and greater demand for prepared foods. Products which have contributed to the expansion of the market are tinned tomatoes and fruit juices, which meet consumer preferences for genuine, light products. EC imports of concentrated exotic juices, especially from South American countries, are sought after by the European juice-processing industry. During the last 20 years a wide range of new exotic fruits has entered the market. Avocados, pineapples and kiwi fruit were regarded as very special luxury products only a couple of decades ago. The demand of the entire sector at European level has been boosted by investment in publicity and product innovation undertaken by the multinationals operating in this sector.

Demand for processed fruit and vegetables, as, for example, prepacked and sliced vegetables, is growing considerably. The best-selling products are: ready-to-serve vegetable soups, prewashed and pre-sliced carrots and onions, and ready-prepared mixed salads. Despite the success of these products, great efforts still need to be made in advertising to overcome consumers' doubts about the freshness of prepared vegetables, especially in countries which usually consume the fresh product.

Supply and competition

The industry is becoming more and more concentrated and many small firms are being absorbed by the multinationals or manoeuvring themselves in market niches. The multinationals have the capacity and resources for organising diversified production coupled with trading, advertising and R&D policies. The smaller firms generally have a firmly established

reputation at local level, helping them to concentrate on high-quality market segments.

The main countries producing tinned vegetables are those along Europe's Mediterranean seaboard which enjoy a favourable climate: Spain, Portugal, Italy and Greece. Fruit juices are imported from countries that produce exotic fruits while tomato pulp comes chiefly from Turkey and Israel.

Regarding tomato-based products it is worth noting the high degree of processing that takes place in major producing countries. A group of countries, comprising Chile, the United States, Canada, Tunisia, Portugal and Peru, use around 80% of their production for processing. High degrees of specialisation are also found in Israel, which processes 70% of its production, and also in Italy and Greece, where 60% is normally processed. An intermediate position is occupied by Argentina and Venezuela (50%), Algeria (45%), Taiwan and France (35-40%), Spain and Brazil (30%).

Production process

Automation in picking and gathering of fruit and vegetables have developed substantially in recent years. A sophisticated selection of hybrids have helped to gradually improve ripening.

The absence of innovation in the tinned products subsector is the main reason for its loss of market shares to the benefit of deep-frozen products in recent years. The latter category has expanded greatly with the wide use of freezers by households. In the industrialised countries the market for deep-frozen products is now completely integrated into the distribution network. There is at present a balance between the two subsectors which are faced with competition from other subsectors such as fresh products and packaged long-life products. New processes - such as irradiation, extrusion and filtration techniques - have been adopted in the market for tinned fruit and vegetables in order to improve the nutritional value and organoleptic qualities of the products. The innovations resorted to by the preserving and canning industry are those used in other sectors, such as the chemical, energy and plastics industries.

INDUSTRY STRUCTURE

Companies

The multinationals are present in force on the tinned fruit and vegetable market, especially in Northern Europe while

Source: DEBA

Mediterranean countries tend to have more fragmented markets, with small and medium-sized firms. In 1991, the leading companies and the EC market shares in the various subsectors were as follows:

- Deep-frozen fruit: Unilever (UK/NL), Nordstern (D), Oetker (D), Prieto (E), Hengstenberg (D), Danisco (DK) which together had an 81% share;
- Tinned vegetables: Bonduelle (F), CGC (F), Grand Met (UK), HL Foods, Suiker Unie, Heinz (USA) had a 42% share;
- Frozen vegetables: Solcco (F), Pomona (F), Champix, Peyronnet, Casino had a market share of 35%;
- Tinned and packet soups: Heinz (UK), Unilever (UK/NL), Campbell Soup (USA), BSN (F), CPC (USA), Nestlé (CH) had an 82% share;
- Dehydrated soups: CPC (USA), Nestlé (CH), Unilever (UK/NL), Gallina Blanca (E), BSN (F), CSM (NL) held a 90% share;
- Tomato puree and ketchup: SME (I), Nestlé (CH), BSN (F), Heinz (USA), Mars (USA), CPC (USA) had a 54% share;
- Dehydrated sauces and condiments: CPC (USA), Nestlé (CH), RHM, Reckitt & Colman, Dalgety, Sara Lee had an 88% share.

Strategies

During the 1980s, countries such as Italy and Spain witnessed a change in the structure of supply in the tinned fruit and vegetable market towards growing concentration, by way of many take-overs and mergers. In the other European countries the multinationals have for many years shared the markets of the individual countries between them, leaving room only for niche enterprises. The most significant take-overs in 1992-1993 were: Hillsdown Holdings PLC (UK) by Beledia NV and Svanso Import A/S (DK) by Miko Konserves A/S (DK).

REGIONAL DISTRIBUTION

Fruit and vegetables have to be canned in factories close to the picking areas. The European regions involved in this market are: Navarra-Rioja, Andalusia, Estremadura and Aragona in Spain; Languedoc, Roussillon, the Loire Valley, Provence and Aquitaine in France; central and western Macedonia and Thessaly in Greece; Emilia Romagna, Lombardy and some southern regions in Italy.

ENVIRONMENT

The by-products and waste products of this industry do not have any significant impact on the environment. However, the problem of the volume and composition of packaging in connection with the disposal of solid urban waste.

REGULATIONS

Regulation (EEC) No. 525/87 introduced a system of aid for production of tinned pineapple and Regulation (EEC) No. 762/89 introduced special measures for some types of pulse products. Directive (EEC) No. 88/593 introduced specific rules concerning the disclosure, on the labels on jellies and jams, of any sulphur dioxide residues and concerning authorisation for the use of red fruit juice as a colouring agent in some jams.

The regulation system takes account of the interests both of agricultural producers and of traders. Producer prices for some fruits and vegetables which are to be processed and canned are particularly important for certain regions and the support system is even more important for enabling them to contend with the price competition generated by products from the underdeveloped countries.

OUTLOOK

Future prospects for tinned fruit and vegetables vary from subsector to subsector. There may be an increase in the number of consumers during the next few years, because the pattern of food consumption is moving towards growing appreciation of products with a high service content. Factors contributing to the growth in demand will be innovations in packaging and the use of new production processes chiefly designed to improve quality. All this will probably have the effect of speeding up long-term growth.

The tinned products subsector and that of their most direct substitutes, deep-frozen products, are also positively influenced by demographic trend towards single number or generally smaller sized households and the growing participation of women in the labour force which tend to boost sales of convenience products.

Processing of fishery products
NACE 415

Seafood consumption in the EC has shown a dramatic expansion over the last ten years. As a result, the EC industry developed sharply under the influence of large powerful agro-food companies. Since the supply of raw material of certain popular species by the EC fishing fleet does not meet industry requirements, large amounts of processed seafood are purchased in third countries, widening the negative trade balance. The market segment which shows the fastest growth is that of fish-based prepared dishes as these products match the changing social habits of EC consumers.

INDUSTRY PROFILE

Description of the sector

The outputs of the fish and seafood processing industry can be divided into five major categories:

- Frozen fish (excluding whole fish), e.g. frozen fish fillets, which are partly processed items using basic raw seafood material and can be either further processed into prepared dishes or consumed in that form;
- Dried, salted and smoked fish, e.g. smoked salmon, salted cod, consumed without any further industrial processing;
- Prepared or preserved fish, e.g. tuna cans, prepared dishes, surimi, which are ready to eat items;
- Aquatic invertebrates frozen dried or salted e.g. cuttlefish fillets, frozen mussels, which can be either further processed into prepared dishes or sold to consumers in that form;
- Crustaceans, molluscs and other aquatic invertebrates prepared or preserved e.g. crab cans, shellfish salads, which are ready to eat items.

The EC production of prepared or preserved fish exceeded 1 million tonnes in 1991, 55% of total EC production of processed fisheries products (2.1 million tonnes). The frozen fish (excluding whole fish) category ranks second with 450 237 tonnes (22% of total EC production).

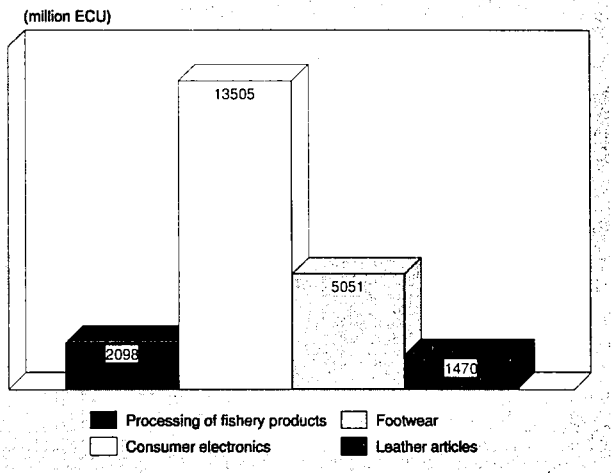
Recent trends

The fish processing sector is a rather concentrated industry with 75% of the products being manufactured in five Member States. The major producer is Spain with almost 24% of the total production, followed by Germany (17%) followed by the United Kingdom, Denmark and France with roughly 11% of total production each. The production of preserved fish dominates in most EC countries with the exception of Greece where the smoked or salted seafood products (e.g. salted anchovies) are the main manufactured items, while Ireland and the Netherlands produce mainly frozen fish fillets.

The apparent consumption of processed fisheries products has shown a dramatic increase over the past ten years having almost doubled. Meanwhile, EC production experienced an increase of 69% over the same period. As a result extra-EC imports grew strong at an average rate of 8.8% per annum while extra-EC exports remained fairly stable. Consequently, the trade balance deteriorated sharply over 1983-92 reaching a deficit of over 2 billion ECU with an export/import ratio as low as 25%. In terms of employment, the fish processing sector shows unsteady trends over the past ten years.

Since 1991, most of the EC Member States have been experiencing adverse economic conditions and the development

Figure 1: Processing of fishery products
Value added in comparison with other industries, 1992



Source: DEBA

of the fish processing industry has been hampered by the drop in consumer demand and by a sharp increase in cheap imports from developing countries. The number of employees in the industry is shrinking (9 000 jobs lost since 1989) as a consequence of the difficulties of the smallest firms to compete on this rapidly evolving market, and the rising importance in mergers and acquisitions.

Foreign trade

The EC is a net importer of processed fisheries products. Few of the fisheries landings are used by the fish processing industry because they are too costly and mostly directed towards the fresh market, and do not fit the industry needs of constant sources of calibrated supply of raw material throughout the year. The two major imported items which are used for further processing are aquatic invertebrates frozen, dried or salted (33% of total extra-EC imports in 1991) and frozen fish (27%) which are both lacking in the EC landings and more expensive than similar products purchased from third countries. Extra-EC exports are dominated by prepared and preserved fish (38% of the extra-EC exports in 1991) and

by semi-processed materials imported from third countries and re-exported after repackaging under a European brand.

The negative trade balance is therefore structural and the situation is not expected to improve in the future. The EC fisheries sector suffers from severe resource depletion and more extra-EC countries are now able to supply processed seafood products at EC quality standards and attractive prices.

The main suppliers of processed products are the EFTA countries which supply mostly frozen fillets of white fish (mainly cod, haddock, and saithe) and salted or smoked fish (smoked salmon from Norway). They are followed by Thailand, Morocco and USA where the seafood canning industry is healthy and expanding, while Argentina and Asian countries offer large quantities of processed shellfish.

Individual EC Member States primarily trade between them. Extra-EC exports are primarily directed towards the EFTA countries, the USA, Japan and the OPEC.

MARKET FORCES

Demand

The demand for fisheries products has grown dramatically over the past ten years due to a growing public awareness of the importance of fish as part of a healthy diet and the relative aversion of northern Europeans to fresh fish. The latter, combined with factors relating to changing social patterns, has boosted the consumption of processed items which rose from an average of 6.7 kg per person in 1983 to 9.8 kg in 1991, with further increases anticipated.

The market for fish-based ready to eat meals is the most rapidly growing market in all the EC Member States with the exception of Greece and Portugal where the purchasing power of customers is low. Reasons for this fast expanding market include changing social factors such as the growing participation rates of women in the labour force and the declining average household size. Some giant agro-food firms

such as Unilever (UK/NL) and Nestlé (CH) dominate this market segment and use their advertising power to attract consumers.

The consumption of canned fish is steadily rising throughout the EC thanks to the marketing efforts of the leading firms which have adopted product differentiation policies through high quality standards and the introduction onto the markets of new forms of products such as tuna-based salads and elaborated mackerel-based preparations.

Lastly, the EC market for surimi seems to offer good prospects. It was estimated at 34 000 tonnes in 1990 and is expected to grow up to 50 000 tonnes in 1994. France and Spain clearly appear as the leading markets in Europe for these products. Other major markets include UK and Italy. The German market for this product is small as there is no traditional preference for crustaceans.

Supply and competition

A growing number of developing countries is becoming capable to supply quality products at low prices, dragging the EC industry into a restructuring phase. Since the EC industry cannot compete in terms of labour costs, a great amount of research has been devoted to alternative products of high quality standards, matching EC customers preferences. Further, mergers and takeovers have been aiming towards economies of scale in production and distribution. As a result, whilst the EC industry was characterised by a large number of independent small-scale units in 1983, the processing industry now includes an increasing component of large agro-food firms or holding companies. These factors helped boost productivity in the sector from 24 000 ECU per employee in 1990 to 25 000 in 1992.

The major competitive variable for the industry is the production cost. Over the last three years, the average price of cod and haddock, which are widely used in the preparation of fish-based ready meals, rose by as much as 40% due to a shortage in production (e.g. average price of imported cod rose from 1.06 ECU/kg in 1989 to 1.50 ECU/kg in 1992). This urged the industry to look for cheaper alternative species and the most powerful firms that had the financial and technical strengths to test and promote new products (e.g. Alaskan pollack or New Zealand hoki) were able to remain competitive on this market segment.

In an effort to secure supply sources, leading EC processing companies increasingly resorted to joint-venture in third countries where resources are presumed abundant. This is in par-

ticular the case for Pescanova S.A. (E) in South-America and Africa, Pêche et Froid (F) and Compagnie Saupiquet (F) in West Africa and the Indian Ocean.

Production process

Production processes of fisheries products are now characterised by a certain degree of automation. Although research still focuses on the definition of new processing machines to save manpower, a great amount of work is being devoted to extending the shelf-life and quality of the end-products.

The Individual Quick Freezing (IQF) process is now an established preservation technique which allow the processor to supply the customer with frozen seafood in small, ready-to-cook quantities instead of solid blocks which had to be cut or thawed prior to packaging or use. The benefits of IQF have led many companies to invest in this freezing method, despite the high initial costs and the need for skilled staff. Another broad principle to extend shelf-life by up to three weeks without freezing is to apply temperature treatment after packing the raw material. This is done by using both vacuum packs and microwave pasteurisation. This technique is more economical as it entails energy savings with shorter time required for temperature treatment. Many processing plants throughout the EC are already using this means of conservation. The products preserved in this way are also much more convenient for consumers to microwave than frozen meals.

Intense product development has been taking place in the packaging industry. Notably, plastics have been developed with special properties such as thermal resistance, reducing the use of the traditional aluminium containers.

INDUSTRY STRUCTURE

Companies

The number of processing firms amounted to 1 860 in 1983, reaching a peak of 2 630 in 1988, before steadily decreasing to reach the 1991 number. A study carried out by Cofrepêche within a EC contract indicated that there were about 2 300 companies active in the fish processing sector in 1991. More than 55% of them are concentrated in Italy, France, and Spain where the number of small-scale units remains high. Another group of countries including the United Kingdom, Denmark and Germany hosts 29% of the total number of EC processing companies. The number of employees decreased by 11% over the 1983-88 period, increased by 9.8% between 1988 and 1989 and steadily decreased after to reach the 1992 figure of 82 900. Although no precise figures are available on the size of the firms, the average number of employees per firm is likely to have decreased from 50 in 1983 to 38 in 1991.

The largest EC processing company is Pescanova S.A. This company specialised in the processing and marketing of frozen seafood products turned over 399 million ECU in 1991. It is a vertically integrated company operating some 140 freezer

fishing vessels worldwide through participations in 50 companies located in Spain, South Africa, Namibia and South America. It also owns processing plants, a distribution network, and is involved in aquaculture. Most other firms are specialised in the manufacturing of frozen processed fisheries products. Only Compagnie Saupiquet, Pêche et Froid and Trinity Alimentari Italia SpA (I) are fish canning companies.

Strategies

Motivated by the dramatic expansion of the EC market for processed seafood products, the two multinationals Nestlé and Unilever have moved via acquisitions to gather within their respective groups the most efficient fish processing enterprises. Besides these leading agro-food groups, some holdings like United Biscuits (UK), Hillsdown Holdings (UK), Albert Fisher (UK), RT Holding Artlal (B), IFM-Bongrain (F) have invested in the fish processing sector through takeovers of existing companies. Other broad strategic actions involve differentiation policies concentrating on preparation and packaging.

ENVIRONMENT

The main environmental issue relates to the depletion of raw material supplies from the excessive exploitation of fish stocks. The EC has financed numerous projects in this area paying attention to the proliferation of aquaculture. The other major issue relating to the fish processing industry is connected with occasional death of dolphins caught in tuna fishing operations. As a result, the USA declared an embargo on raw tuna in 1990. This embargo concerned primarily South-American countries (particularly Mexico, Venezuela) but eventually led to a boycott of tuna cans manufactured in France, Italy and Spain as these countries were buying raw material from South America. On December 31, 1991 the EC through the ratification of a Protection of Wildlife Agreement has classified dolphins as a highly protected species. The embargo was lifted in 1992 for France when the French canning industry undertook to buy dolphin-safe tuna. Spanish and Italian cans remain embargoed.

REGULATIONS

The two key regulations for the fisheries product processing sector are:

Council Directive N° 91/493/CEE of 22 July 1991 laying down the health conditions for the placing on the market of fishery products, completed by Council Directive 92/48/CEE of 16 June 1992 on the health conditions onboard certain fishing vessels. This key regulation harmonises practices within the EC and requires the hygiene standards of all establishments where fishery products are prepared, processed, chilled, frozen, packaged or stored to be approved by a competent authority. This directive also applies to processing units of third countries exporting products to the EC to guarantee the safety of imported products at levels matching those of EC products.

Council Regulation (CEE) N° 3759/92 of 17 December 1992 on the common organisation of the market in fishery and aquaculture products. This regulation focuses on marketing standards, producer's organisations, and prices of the products with special reference to the EC canning industry.

OUTLOOK

The EC processing industry is anticipated to suffer somewhat from the recession in which the EC has stepped into over the last two years. However, the check in apparent consumption

and production is not expected to be dramatic neither prolonged. Globally, fish consumption is expected to further increase over the 1993-97 period and the industry should follow accordingly. Imports are anticipated to continue increasing as EC waters will continue to deplete, propelling the industry to purchase raw materials in third countries. As exports will not show significant progress due to the structural deficit of the EC in seafood products, the deficit of the trade balance will widen.

The industry is represented at the EC level by: Association des Industries du Poisson de la CEE (AIPCEE). Address: Avenue de Cortenbergh 172/6, B-1040 Brussels; tel: (32 2) 735 8170; fax: (32 2) 736 8175.

Deep-frozen products
NACE 412.21, 414.1, 415.1

Demand for deep-frozen products is has been expanding rapidly for a number of years. The growth of the market is connected with the development of an efficient distribution structure. This is one of the reasons why consumption is highest in the countries of Northern Europe.
The growth in demand and good profitability make this field of business highly attractive. The market is dominated by a small number of firms but niche markets allow local producers to co-exist alongside the multinationals. In certain market segments, saturation is leading to higher degrees of concentration via mergers and acquisitions.

INDUSTRY PROFILE

Description of the sector

The sector comprises a large number of food products processed by deep-freezing technology to preserve their organoleptic and nutritional characteristics. In the food industry, deep-freezing technology, which includes not only the industrial process but also the cold chain (storage, transport and domestic conservation) is undoubtedly the most important technological innovation since pasteurisation and sterilisation. The main NACE headings included in the sector are deep-frozen meat (412.21), deep-frozen vegetables (414.1) and deep-frozen fish and derivatives (415.1)

Recent trends

During the past five years production and apparent consumption in real terms can be estimated to have increased at an annual average rate of 6% and employment at a rate of over 3%. In 1992, growth was slower than in the preceding years, especially in the countries with lower per capita consumption. The recession has had an adverse effect in the countries where deep-frozen products have been most recently introduced and are consumed less regularly.

Within the EC consumption patterns can be separated into two distinct groups. In the Mediterranean area, where deep-frozen products are in the initial stage of development and in Northern Europe where demand might have exhausted most of its growth potential. In the latter group, Denmark, the UK and Sweden have a per capita consumption that averages at 35 kg compared to only 6 kg in most Mediterranean countries with the exception of Spain where consumption has more than tripled over the second part of the 1980s.

The most attractive growth rates are recorded in the more innovative, convenience-oriented segments: in particular, ready-to-serve meals have increased over the past ten years at a rate of over 10%. Meat has experienced the fastest growth, followed by potato by-products and vegetables.

Foreign trade

Trade is mainly in deep-frozen raw materials. The Mediterranean countries, for instance, import unpackaged deep-frozen fish from Northern Europe and package the fish in local production plants. The EC also imports deep-frozen concentrated citrus fruit juices from South America and the United States for use in the preparation of fruit juices and soft drinks. Significant import flows also come from Scandinavian countries (fish) and Eastern Europe.

MARKET FORCES

Demand

The chief factor responsible for the success of deep-frozen products is the possibility of storing at home products with the same nutritional characteristics and flavour as the corresponding fresh product. Apart from replacing other preservation technologies, deep-frozen products are actually taking market shares from fresh products.

In countries where the consumer is fully convinced that the product is good, per capita consumption is high. In the countries of the Mediterranean area, which have the lowest per capita consumption, deep-frozen products are used for their great convenience. They are only consumed occasionally, and consumption is in some cases limited by the small number of homes with freezers.

The level of consumption of the various types of deep-frozen products is connected with the specific eating habits of each country. Consumers prefer products which are consumed on a large scale in the fresh or processed state. In Italy for example, the most important segment is that of vegetables, whereas fish products come first in Spain, potatoes in Belgium and meat in the Netherlands.

The use of deep-frozen products in the restaurant trade has a considerable effect on the overall level of consumption. In the Community countries, with per capita consumption of between 8 and 44.8 kg, the restaurant trade accounts for a proportion of demand ranging from 22% in Great Britain to

44% in Germany. In the United States, where per capita consumption of deep-frozen products is 52.2 kg, the restaurant trade represents over 55% of the market and in Japan as much as 76%. The smaller importance of the catering channel in Europe is attributable to a more traditional type of restaurant cuisine. The expansion of fast food outlets should boost consumption of deep-frozen products in the EC, too.

Supply and competition

The number of plants in the leading EC countries has not changed during the last few years. The number of producers is highest in France (412) and lowest in the Netherlands (30). The high market fragmentation is attributed to low entry barriers for production while distribution and advertising are characterised by higher barriers.

The data on consumption and the concentration of supply suggest that there are considerable differences in plant capacity. In Germany, where consumption is highest, the number of plants is much lower than in France. The situation is even more marked in Great Britain.

Production process

Technological development is aimed at achieving high quality standards. The most difficult stages are upstream and downstream of the industrial process, because the system of legal provisions and supervision measures relating to production of raw materials and marketing of finished products creates very strong vertical integration. The main technological limit lies in the impossibility of deep-freezing large pieces, owing to the legal restriction fixing the maximum duration of the product-freezing process.

INDUSTRY STRUCTURE

Companies

About 800 producers of deep-frozen products are operating in the EC. There is a medium level of concentration, with the leader (Unilever-UK/NL) holding an 18% share of the market and the four leading companies combined accounting for 41%.

The degree of concentration is highest in the recently developed markets; the companies which shape the market are building up a strong leading position. The growth in consumption is tending to reduce the barriers to the entry of new competitors.

Three main strategic groups can be distinguished:

- multinational companies with wide product diversification; chief among these are Unilever and Nestlé (CH). The strategic aim is to control the market in order to maintain profitability;
- specialised multinationals: McCain (NL), the leader of the potato and derivatives section and the second-largest European company after Unilever, Grand Metropolitan (UK), Bonduelle (F) concentrating on vegetable products;
- national companies generally characterised by good product diversification. The most representative are Pescanova (E), the leader in Spain and Portugal; United Biscuits (UK), which holds about 12% of the British market; Ortiz-Mirko (F) and Danish Danisco (DK), with 11% shares in France and Denmark respectively. Another company in this category was Italgel belonging to the SME Group (I), with nearly 20% of the Italian market, but it was taken over by Nestlé in 1993.

OUTLOOK

The deep-frozen products industry is one of the few manufacturing sectors to maintain good growth rates. Average per capita consumption in the EC might in grow in the future to approach the higher level of US consumption figures. The current recession has had less adverse effects than in other food sectors.

The potential for further growth in commercial brands poses risks for the smaller producers while the further development of technologies for packaging fresh products in a controlled atmosphere poses risks for the sector as a whole. Opportunities present for the sector include the expansion of demand in the countries of Eastern Europe, more widespread ownership of microwave ovens and deep freezers, growth of modern distribution and expansion of fast food outlets.

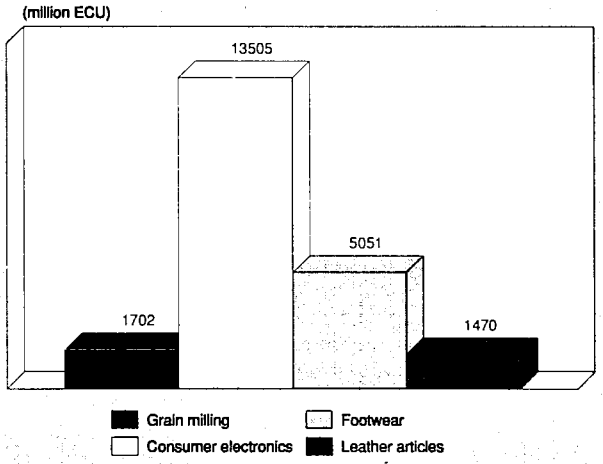
Grain milling
NACE 416

The grain milling industry comprises of about 3 000 mills and provides the link between the agricultural sector and the processed finished products. Production of soft-wheat flours, hard-wheat semolinas and rye flours in the EC amounts to around 30 million tonnes. The grain milling sector has reached the peak of its growth. Demand for flours and flour-based products is on the whole stable. Changes within the sector are due chiefly to demand from the processing industry for flours.
Concentration of supply is going ahead in the sector with the closure of marginal units and take-overs of mills by the larger groups. Grain milling technology has reached a high level, especially as regards plant automation. Although technological change has improved product quality and added efficiency into the production process, capacity utilisation is still relatively low in some major producing countries.

Figure 1: Grain milling
Value added in comparison with other industries, 1992



Source: DEBA

INDUSTRY PROFILE

Description of the sector

The grain milling industry, includes the milling of grain into flour, bran making, seeds and grain milling husking. Produced flour is mainly intended for the baking industry although its use can vary significantly across Member States.

Recent trends

Apparent consumption of the grain milling industry's products is stable. From 1983 to 1992 it increased at current prices at an average annual rate of 1.4%, representing a real growth of 0.5%, which is indicative of demand saturation. Production in the EC increased particularly during the period 1988-1992 after having remained virtually unchanged for five years. The modest gains in production were mainly supported by moderate increases in extra-EC exports and a sharp fall in imports (by 25% per year at current prices). These trends became dominant from 1989 onwards, practically minimising the share of extra-EC imports in consumption. With regard to employment, the closure of many small units and technical modernisation led to a gradual fall in the number of persons employed: this is at present 36 000, which is 25% less than in 1983.

Foreign trade

While the share of extra-EC imports in apparent consumption fell from 6% to less than 1% in 1992, exports have continued to rise. The balance of trade has been improving over the last ten years, and shot up substantially from 1989 onwards, with extra-EC exports rising to twenty times the value of extra-EC imports.

Intra-Community trade declined from 1983 to 1992 at an average annual rate of 2.4% at current prices. Intra-EC trade accounts for 5% of production and 90% of total imports. The grain milling industries in the Member States meet a large proportion of domestic requirements for flours and other cereals derivatives, while the EC as a whole is practically self-sufficient.

The destinations of extra-EC exports show that only a small proportion is destined towards industrialised countries. In particular, the share of the United States, Japan and the EFTA countries is less than 2% and has fallen particularly since 1987. Imports are now almost insignificant; the largest decrease, however, has been in imports from the United States, in terms of both quantity and percentage. Middle Eastern countries - Algeria, Libya and Syria - represent the core export market accounting for almost 35% of the total. Eastern European economies are emerging export destinations with the republics of the ex-USSR alrcady accounting for 12% of total exports.

MARKET FORCES

Demand

Derivatives of cereal crops are largely basic food products. The increase in per capita incomes and in population in some developing countries has led in recent decades to a growth in demand for cereals and their derivatives which has made these countries major net importers, owing to the widening gap between consumption and production.

The finished product of the grain milling industry is chiefly a raw material for various food subsectors (manufacture of pasta, bread making, bakery products, packaged flours etc.). While total demand for flour-based products is more or less stable within the EC, substitution is taking place depending on the predominant food patterns and lifestyles. For example, the volume of the bread market in the EC has decreased by

2% during the last five years, whereas the share of the pasta products market has grown by 18% (a loss of 380 000 tonnes in the first case and an increase of 440 000 tonnes of finished products in the second).

With regard to the key final markets for the grain milling industry, the bread market is declining. The main countries in terms of per capita consumption are Germany (80 kg), Italy (68 kg) and France (62 kg). For pasta, Italy alone accounts for over 50% of the volume of the EC market, with per capita consumption of 27 kg, followed, a long way behind, by France (7 kg). There have, however, been large increases in consumption in all the EC countries except for marginal markets such as those of Portugal and Greece.

The biscuit market has also shown modest growth at Community level (+3% per annum in volume during the past five years), with Ireland ranking first in terms of per capita consumption with 14 kg, followed by the United Kingdom and Denmark (about 10 kg) and Italy (9 kg). The largest increase in recent years was, however, in Germany. On the other hand, the retail market for flours has reached an advanced stage of maturity in the EC. (Source: Consumer Europe 1993).

Supply and competition

International trade in cereals is characterised by large volumes, with exports monopolised by a few countries (the United States, Canada, Australia, Argentina, the EC) and by trade concentrated in the hands of a few multinationals. The volume of international trade is considerably smaller for the products of the grain milling industry. The EC has, however, a solid competitive position with a 60% share in international flour trade. The member countries generally have a high degree of self sufficiency, varying with the greater or lesser degree of fragmentation of supply.

Production process

The grain milling industry has reached a degree of technological maturity with regard to plant. Innovations relate mainly

to improving flours (specific characteristics and stable quality standard for final users, processing industries and, to a smaller extent, consumers). With regard to the production process, productivity has increased steadily (added value per employee at 1992 prices has increased, overall, by 64% over the last ten years). Total production capacity has also increased, but there are still wide differences in the degree of utilisation of plant capacity, with substantial excess capacity in some cases. In the production of soft grain flour, for instance, utilisation of capacity ranges from 70-80% in France and Germany to 60% in Italy and only 35% in Spain. For semolina, Italy, by far the largest producer, has a degree of utilisation of less than 70%, while the figure for Germany is close to 90%, although production has declined.

INDUSTRY STRUCTURE

Companies

During the past twenty years the Community grain milling sector has become much more concentrated with the number of mills falling from 11 000 to the present 3400. There are still many small units, many of which are not included in the official statistics, especially in the major producing countries such as Italy and France. Thus, taking only mills covered by censuses, the United Kingdom, with around 80, has an annual output per unit of 48 000 tonnes of flour and semolina, while the figures for Italy (820 mills) and France (890 mills) are lower at 8400 tonnes and 6000 tonnes respectively. Germany (8500 tonnes) and Spain (5800 tonnes) are at the same level of production per unit, while Belgium (21 000 tonnes), Denmark (20 000 tonnes) and the Netherlands (26 000 tonnes) achieve higher average production figures. The grain milling sector in the EC is extremely fragmented partly owing to differences between national markets. Furthermore, there are various types of enterprises: companies forming part of the processing industry (making sweets, pastas, feeding stuffs etc.), export-oriented companies engaged in the cereals trade and mills, whose sole activity is grinding.

Strategies

The grain milling industry is characterised by a low degree of flexibility and diversification of production. On the strategic plane an interesting aspect in recent years has been the ten-

Source: National Milling Associations

dency towards mergers between mills and some big food processing companies (for instance, the take-overs by Barilla in Italy), a trend which is largely due to the quality demanded of the raw material. A limit to such integration is, however, imposed by the fact that many processing industries, for instance the bakery products industry, need access to a wide range of flours with specific characteristics. The process of concentration is likely to continue in the future, especially owing to take-overs of mills by large groups.

REGIONAL DISTRIBUTION

Within the EC, the Italian grain milling industry, with an output of around 3.6 million tonnes in 1992, accounts for over 70% of production of hard wheat semolina, most of which is used in the pasta products industry. Five times as much soft wheat flour as hard wheat semolina is produced in the EC, and the geographical distribution of production is more balanced: five countries (Germany, Italy, France, and United Kingdom and Spain) have an 80% share. Germany is also the main producer of rye flour. Among the countries named, the United Kingdom had highest added value for the grain milling sector as a whole in 1992, followed by France and Italy.

ENVIRONMENT

From the environmental point of view, the main problem of the grain milling industry in the past was that of the water used for washing the cereals after mechanical cleaning. In most cases this system has been replaced by pneumatic cleaning, which reduces waste water to a negligible quantity.

REGULATIONS

Activity as regards rules and regulations is aimed particularly at closer harmonisation of Community laws on labelling, additives, contaminants, the use of other substances such as gluten in flours, etc. One example is the permitted maximum limits for pesticide residues in cereals, which are still governed by directive (EEC) 86/362, amendments to which are at present being drafted. There are also proposals for new directives relating to additives, for which the general principles were harmonised by Framework Directive (EEC) 89/107. For example, for flour-processing agents the EC Commission plans to draft a specific directive, in view of the problems concerning some of these substances which are still being examined by the Scientific Committee.

Regulations 2081/92 and 2082/92 are amongst the latest developments. The first concerns the protection of designations of origin and geographical indications relating to agri-food products; the latter deals with the possibility of obtaining Community certification of specific qualities for a number of products (including pasta products, biscuit-making products, pastry-making and bread-making products). The framework of Community rules concerning organic methods of production of agricultural products and products for human consumption has also been completed.

OUTLOOK

The grain milling sector does not at present offer any great opportunities for the development of demand within the EC. Consumption of flour and flour-based products is as a whole stable and any growth in some subsectors is generally at the expense of others. The changes are chiefly in quality and may relate, in particular, to the demand from the secondary flour-processing industry for flours with increasingly specific characteristics. There may be opportunities for expansion of exports provided that the destination area, at present highly concentrated in the Mediterranean basin, is widened to new markets. With regard to the structure of supply, there will probably be a further reduction in the number of production units and an increase in utilisation of production capacity, especially in an important country such as Italy. The key factors for success for companies in the grain milling sector will increasingly lie in rationalisation of production processes and procurement policies.

Risks for the sector include: the low profitability, higher increases in processing and labour costs than in flour prices, falling demand for flours for bread making and growing international competition. Opportunities include: the opening up of new markets for both flours and processed products, rationalisation and diversification of production.

Industrial baking
NACE 419

The factors which have favoured growth of this sector are the emergence of new patterns of consumption coupled with supply concentration. The sector has benefited from less fixed mealtimes with greater emphasis on breakfast and health foods. Market fragmentation has been accentuated as marketing-oriented firms capture a growing share of the market, through the introduction of new products and the revival in demand for traditional products. In addition, investment in advertising has contributed to a partial standardisation of demand. The future should see further erosion of individual bakers' production by the industrial groups.

INDUSTRY PROFILE

Description of the sector

NACE group 419 comprises five branches:

- 419.1 and 419.2: Industrial bakeries and other establishments making bread and confectionery
- 419.3: cakes and flour confectionery production
- 419.4: rusk making
- 419.5: biscuit factories

Small firms tend to operate in the making of bread and confectioneries while the rest of the sector is more geared towards larger scale production.

Recent trends

Over the last ten years apparent consumption and production have grown at the same rate of 3.3% at constant prices. Employment has also risen, but at the slower annual rate of 2%. Over the first half of the 1980s the sector expanded slowly and imports rose sharply. Since then a recovery in production has started to reverse the trend with extra-EC exports growing stronger. The latter developed are expected to persist in the future.

Foreign trade

Extra-EC imports account for less than 1% of apparent consumption and have remained at that level over the last ten years. Despite strong growth they account for barely a tenth of the value of internal Community trade. Although most extra-EC imports come from non-EC European countries their share has declined over the last five years mainly to the benefit of US products. Extra-EC exports account for 3% of production and this figure has remained virtually unchanged over the last ten years. The two main destinations are the EFTA countries and the United States.

MARKET FORCES

Demand

The demand for bakery products has risen steadily, partly due to the different nutritional values of the industry's products. Rising demand is explained mostly from higher appreciation for pleasure-eating (traditional confectionery and biscuits) and growing health consciousness for some traditional products such as individual-bakery bread as well as new products.

New products are emerging fast and centre around whole wheat and healthy ingredients, confectioneries and bread substitutes. Industrial bread companies are seeking mainly to provide a complete service at non-specialised sales points without altering traditional consumer patterns although the revival in demand for traditional products is fostering attempts to create market niches by offering bread-like substitutes.

A special feature of the market is the regionalisation of consumption, with marked differences in both quantity and quality. Per capita consumption of bread is a little over 10 kg in Portugal, around 30 kg in Denmark, Greece and the United Kingdom, close to 50 kg in Belgium, Luxembourg and Spain and reaches or exceeds 60 kg in France, Italy, Germany, the Netherlands and Ireland (Source: Consumer Europe 1993). There are also marked differences in the amount of biscuits and confectionery eaten but, with one or two exceptions, per capita consumption is highest in the Nordic countries.

Supply and competition

Supply comes from three strategic groups; individual bakers, small and medium-sized firms operating at regional level and marketing-oriented national and multinational companies. Bakers in the first group dominate the market for bread and confectionery and are capable of meeting consumer specific requirements at local level. Their position is threatened by the entry into the market of marketing-oriented companies

and the development of "in-store bakeries" in supermarkets. Small and medium-sized firms are of considerable importance in all sections of the industry. Their survival depends on specialisation, local reputation and the continued existence of fragmented distribution structures.

Large companies benefit from the standardisation of consumption in some areas (e.g. biscuits), marketing campaigns and the diversification of production. Large companies are attempting to dominate various market segments via acquisitions of smaller firms and by expanding their own product range. The first strategy has been more appropriate for products with a short shelf life, like bread and fresh confectionery.

Production process

Production technology is finding fresh applications in identifying new areas particularly in the more industrially oriented section of the market. New substitutes for bread are in many cases similar as commodities and derive from traditional products such as crackers and breadsticks. The development and greater reliability of the cold chain has also stimulated the production of fresh and frozen confectionery at industrial level too. Individual producers bake more and more with closely controlled raw materials (enriched, semi-processed flours).

INDUSTRY STRUCTURE

Companies

Supply is extremely fragmented, but large companies are gradually becoming stronger. However, it is only in Great Britain that they occupy a major position in the sector as a whole: Associated British Foods and Rank Hovis McDougall together hold half the market. Important companies are also found in other countries, but their main strength lies in industrial bread. The names are Barilla (I) in Italy, Pain Jacquet Sa (F) in both France and Germany, Anheuser (D) and Allied Lyons (UK) in Spain. In the market for bread substitutes, BSN (F) and Barilla together hold about 40% of the European

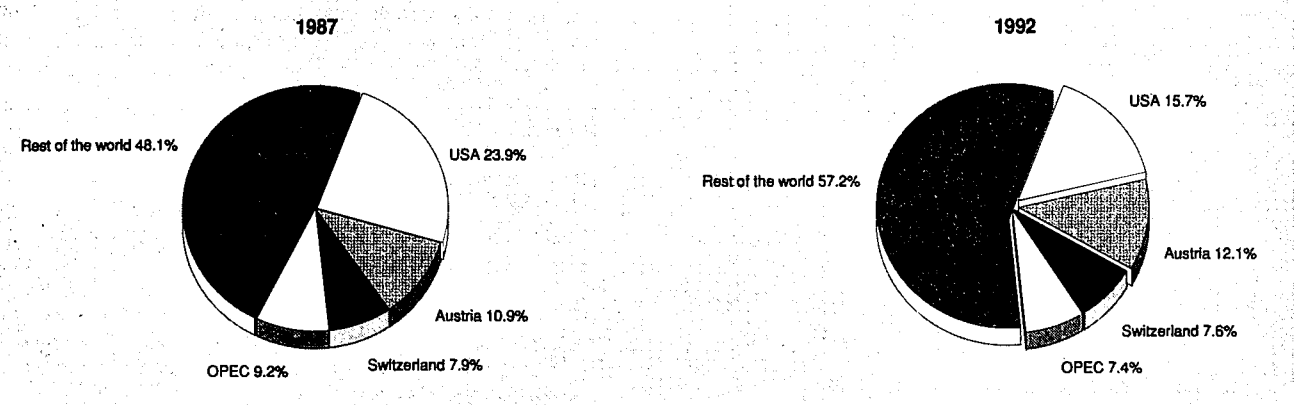
Figure 6: Industrial baking
Destination of EC exports



Source: Eurostat

market while SME (I) has sold Pavesi to the Italian leader. Nestlé (CH) also operates in the market but has a smaller share.

In the case of biscuits, the size of the British market is reflected in the overall share of United Biscuits, the joint European leader. United Biscuits, BSN and Barilla together hold about 50% of the European market. The supply of industrial confectionery is less concentrated. The biggest companies are Barilla and Allied Lyons, which together hold around 20-25% of the market.

Strategies

The positions held by the major companies stem from the diversification of production and external growth, achieved by acquiring or allying with local firms.

The French group BSN, which is the leading European competitor in the case of biscuits, has favoured take-overs, the biggest of which have involved the Italian company Saiwa (sold by Nabisco) and the Irish firm W & R Jacob.

Barilla has invested heavily in advertising and has moved through acquisitions in the industrial bread sector - where it has become market leader- in industrial confectionery for catering (Unione Laboratori) and in the actual bakery sector, where it has bought its main Italian competitor Pavesi from the SME group.

Allied Lyons uses both strategies; among the 50 or so joint ventures set up throughout the world the one with the Spanish firm Panrico stands out; the company has also bought Picard (F) in the bread substitutes sector.

United Biscuits has strengthened its position in Europe with purchases in Denmark (Oxford Biscuits), Hungary (84% of Gyori Keksz) and Finland (49% of Fazer Biscuits).

REGIONAL DISTRIBUTION

The location of bakeries is influenced by the difficulty of keeping individual bakery products (bread and confectionery), or industrial confectionery products in line with the marked differences in regional consumer preferences. In some cases, moreover, the cold distribution chain is unreliable with a consequent shortening of product shelf life.

ENVIRONMENT

The major issue is the disposal of urban solid waste and companies are expected to encounter increasingly harsher regulations regarding the volume and physical composition of packaging material. Innovation in the area of packaging both for storage and marketing purposes is becoming a major challenge.

OUTLOOK

The trend towards the substitution of locally made bread for industrially produced bread is expected to persist. The single European market and technological innovation are important factors behind the shift to larger corporate scale. However, health consciousness, preferences for fresh products and diverse regional consumer patterns will sustain small scale production at artisan bakery level. Subsectors such as snacks, healthy whole wheat and dietary products as well as products geared towards pleasure-eating will expand further.

Risks for the industry relate to traditional biscuit products which are facing the prospect of declining demand, the growth of in-store bakeries at non-specialised sales points, competition between market segments. Emerging opportunities relate to "industrialisation" of the individual bakery segments with consequent standardisation of consumption between regions, establishment of an eating pattern favourable to carbohydrates.

Sugar
NACE 420

The EC is the world's largest producer of sugar. Sectoral developments are governed by a set of import levies, export refunds and production quotas that are due for revision in 1993. Despite aims for self-sufficiency the EC has been the world's leading net exporter.
Production is highly concentrated primarily as a result of cross-border mergers between sugar companies and the reduction in the number of establishments due to rationalisation in the production process.

INDUSTRY PROFILE

Description of the sector

Sugar can be extracted from sugar cane or sugar beet, the latter being used for the whole of EC production. Beets produced are processed by a small number of high capacity factories.

Recent trends

The EC's share of world sugar production, at nearly 15 million tonnes, is 16%. The trend of production fluctuates widely with weather conditions and has been trending down over the period 1981-92. Consumption, bordering on 12 million tonnes, represents 11% of the world total. The average annual growth rate from 1981 to 1992 was 0.8%. Extra-EC exports rose at much the same rate (0.7%) and fluctuated between 2500 and 3500 tonnes depending on the world market.

Since the increase in Germany's production quota for the 1990/91 season, due to reunification, the quotas have remained unchanged. Production increased by 11% when the German quota was raised but subsequently fell by 7% during the next season and by 3% in the 1992/93 season, bringing it back to its 1989/90 level.

Foreign trade

The agreements of the Lomé Convention are still in force: the EC is still importing 1.3 million tonnes of sugar from Africa, the Caribbean and the Pacific (ACP) (the price corresponds to the EC intervention price). These quantities come on top of the internal surplus production and add to the amounts available for export. The main countries which import sugar from the EC are the OPEC countries (41.5%), the EFTA countries (7%) and the former Soviet Union (5.9%).

The volume of internal trade depends on the relationship between the production quota assigned and consumption. The countries where production exceeds domestic demand are: France (with a production/consumption ratio of 2.21), Denmark (2.15), Belgium (2.06), the Netherlands (1.8), Ireland (1.59) and Germany (1.43). The import-export balance is positive for these countries, but negative for the others.

MARKET FORCES

Demand

In the EC, 71% of the sugar is used by the food industry while 29% is for direct consumption either as such or as an ingredient. Sugar is used as an ingredient also by the chemical industry, pharmaceutical industry and in several other products.

The share of direct consumption ranges for 16% in the Netherlands to 45% in Italy. Italy, with the lowest per capita consumption (15.6 kg) ranks second for direct consumption. On the other hand in Belgium, which has the second highest total per capita consumption in the EC after Denmark, the quantity used for direct consumption is 11.6 kg. From 1982 to 1992 per capita consumption remained almost unchanged both in the individual countries and at Community level.

Direct sugar consumption is declining in all countries because eating habits have changed (i.e. less home-made desserts, jams, etc.); at the same time, indirect sugar consumption has increased through higher consumption of ready-made pastry, jams, etc. As a result, total sugar consumption not only has been maintained, but has also slightly increased in the past 10 years.

Sugar is also encountering competition from low-calorie sweeteners, for which an annual average growth rate of over 10% is recorded. The market for sweeteners is now equal to 15% of the value of direct consumption of sugar.

Supply and competition

The competitive situation is largely governed by Community policies for this sector. Sugar production goes deliberately beyond the quota set, because of the potential demand existing for EC sugar. Exports to the world market are encouraged, where prices are lower. The EC regulation system is aimed at supporting the countries whose production system is the weakest.

Economies of scale are achieved primarily by increasing the production capacity of plants. Average EC production per plant is 73 000 tonnes; this figure falls to 39 000 tonnes in Spain and reaches 149 000 tonnes in the Netherlands. Despite the rise in average productivity due to a reduction in the number of plants, costs remain fairly high compared with those of the main competitors outside the EC.

Production process

The production process is complex and consists essentially of a series of successive extractions, concentrations and purifications. The process consumes enormous quantities of energy, and consequently the industries in this sector generally produce their own energy. Plant development is aimed at op-

timisation of the production process (extraction yield and energy saving) and automation.

Processing is highly seasonal since beet is planted in spring and harvested from September to November. The product cycle of beet sugar, in which the EC industry specialises, includes the following phases:

- extraction of content via beet slice treatment with steam and immersion into hot water tanks to produce a raw juice;
- purification, evaporation and crystallisation of the juice;
- processing of crystals to obtain sugar in its marketable form.

INDUSTRY STRUCTURE

Companies

The sector is highly concentrated, with oligopolistic tendencies, especially in Ireland, Greece, Denmark, Belgium and Italy. In all the countries the production quota of the two leading companies is not less than 55%.

The four leading companies account for 50% of Community production. The two largest total shares are held by Ferruzzi (I) (25%), the undisputed leader in Italy and the co-leader in France, and by Süd Zucker (D) (24%). The latter controls Sugana (A), Tirlemont (B) and has expanded in East European countries.

Strategies

Companies pursue three basic strategies:

- cutting costs in order to increase profitability in the domestic market and be able to operate in markets outside the EC;
- taking over of other companies in the sector.
- aim to remain competitive in the world market.

Acquiring plants in the EC chiefly means acquiring production quotas. For example, prior to recent events, the Ferruzzi Group, after becoming the European leader by taking over most of the Italian companies and Béghin Say, was expanding in the world market by taking over three major Hungarian producers. Tate & Lyle (UK) took over Alcantara (P) and has interests in the Australian Bundaberg Sugar and the Hungarian Hajdusagi Cukorgyar. Furthermore, many companies are diver-

sifying into other sectors, especially the agricultural raw materials trade and the corresponding processing industries (paper, processing of cereals for the production of starches and alcohol, etc.).

REGIONAL DISTRIBUTION

The main regions where the production/consumption ratio is higher than 1 are Oceania (ratio: 3.2), Central America (2.15), South America (1.14) and Europe (1.13). Especially Cuba, with production 8.1 times greater than consumption, accounts for nearly a quarter of world sugar exports. The EC ranks second with a 23.7% share.

World consumption is growing steadily, stimulated by the developing countries where income elasticity of demand is still quite high, while the market has stopped expanding in the industrialised countries.

ENVIRONMENT

The sector is characterised by the enormous emission of liquid effluents with a high concentration of organic substances, which in the past has created problems of eutrophication of river water. Polluting emissions have decreased by 30% in the last ten years. The European sugar industry allocates 10% of its manufacturing margin to protect the environment.

REGULATIONS

The regulation of the sector dates back to 1968. The provisions are centred on a system of production quotas by country (and by production plant within the individual countries) and of guaranteed prices. These prices are, however, guaranteed until Quota A (the basic quota) and Quota B (the safety margin) have been reached; beyond these quotas (C Sugar) the price

is fixed by the world market, in view of the production surplus and the fixed imports from the ACP countries.

For exports of sugar within Quotas A and B the price differential between the internal market and the world market is totally financed through production contribution. This contribution amounts to 2% of the price of A sugar and 39.5% of price of B sugar and is paid by the beet growers (60%) and the sugar manufacturers (40%).

The price system is differentiated according to the specific requirements of the Member States, in order to eliminate production weaknesses.

OUTLOOK

Low population growth and low income elasticity of Member States domestic demand for sugar imply a fair degree of market saturation. Hence, increases in consumption are likely to be marginal and likely to arise from increased industrial rather than domestic demand. In the long run, barring changes in the laws and regulations in force, the trend of production will be stable.

The industry is represented at the EC level by: European Committee of Sugar Manufacturers / Comité Européen des Fabricants de Sucre (CEFS). Address: Avenue de Tervuren 182, B-1150 Brussels. tel:(32 2) 762 0760; fax: (32 2) 771 0026.

Cocoa, sugar confectionery, ice-cream

NACE 421

Over the last decade, the sector has expanded rapidly primarily due to the strong performance of extra-EC exports. Although production and consumption are increasing, changes in consumer patterns due to health concerns are affecting the industry significantly. Hence, product innovation and the creation of new market segments is an important strategic supply-side variable.

The presence of a significant number of multinationals in the sector is responsible for the tendency towards internationalisation of brands and standardisation of consumption as all major food multinationals are active in the sector. There is steady growth and favourable profit margins in most industrialised countries although per capita consumption by country does reveal considerable differences in the size of markets.

INDUSTRY PROFILE

Description of the sector

NACE 421 is made up of three sections:

- the cocoa and chocolate industry;
- the caramels and related products industry (sweets, chewing gums, jellies and nougats);
- the ice cream industry.

Recent trends

The main economic indicators show the positive trend of the sector over the last decade. From 1983 to 1992 the annual average increase at constant prices was 5.5% for exports and 3.5% and 3.7% respectively for production and apparent consumption. The balance of trade was positive throughout the period, with an average annual increase of 9% at current prices. During the last five years a significant increase in exports to countries outside the EC has boosted sectoral growth. Numbers employed fell from 1983 to 1987 at an average annual rate of 2.1%. Conversely, over the last five years employment recovered slightly rising by 1.2%, but no further gains could be recorded in 1992.

International comparison

Production and consumption of cocoa derivatives and sugar confectionery in the three main trading blocs, the EC, the United States and Japan, show the importance of Europe in the world picture. The Japanese market is small compared with that of many other industrialised countries while the US market is slightly smaller than the European market.

Foreign trade

Extra-EC imports account for about 2% of apparent consumption. Their share has shrunk since 1983. At current prices, the trend of imports has been positive, but the rate of growth is much slower than that of trade between the member countries. Imports have come mainly from the EFTA countries, whose share increased considerably from 1987 to 1992. The proportion of EC imports accounted for by the United States also increased, but is still small.

Intra-EC trade, representing 88.1% of total imports, increased at an annual average rate of 10.3% from 1983 to 1992. Intra-EC trade represented about 16% of apparent consumption in 1992. Exports, which have grown more than production during the last five years, go to different trading areas. From 1987 to 1992 the shares of the three main destination areas, EFTA, the United States and Japan, decreased. Whereas 62% of exports went to the three trading blocs in 1987, their share was down to 48% in 1992.

MARKET FORCES

Demand

The products which form part of the sector differ in nature and uses. Cocoa derivatives and ice creams are chiefly eaten for pleasure as snacks and desserts. Confectionery products, on the other hand, definitely rank as luxuries.

Calories content is regarded as very important for all products: for sugar confectionery, however, it is very often regarded as an adverse factor, whereas for ice cream and chocolate it may be a factor for success, especially when these products are used as snacks for the target groups, made up of children, young people, sportsmen and women.

Product innovation has to some extent changed the fortunes of some products. In the confectionery subsector, the introduction of sugar-free products has stimulated the growth in demand, especially in the adult target group. In the field of cocoa derivatives, the new versions of bars eaten as snacks have a lower calorie content and present a healthier image of the product.

All segments are characterised by the important role of impulse buying. The ice cream market and, to a lesser extent, the chocolate market are also affected by a substantial seasonal variation of demand. Consumption of ice cream tends to be concentrated during the summer months, when demand for chocolate, especially in hot countries, is lowest.

Per capita consumption of confectionery products, both sugar-based and chocolate-based, is very high in Germany (17.1 kg), Great Britain (14.1 kg), Belgium and Luxembourg (13 and 14.3 kg respectively) and the Netherlands (10.4 kg). In France, Spain and Italy per capita consumption is much lower, at 6.9, 5.5 and 3.6 kg respectively. (Consumer Europe 1993).

In the case of ice cream, the estimates of per capita consumption are difficult to interpret because of a number of factors. First of all, it is difficult to estimate the incidence of products made by small firms which form an important market segment in Italy, Spain and Greece. Secondly, the unit of measurement used for estimates, generally the litre, does not take account of the different characteristics of the products, especially as regards their consistency and the quantity of air incorporated during whipping. The average per capita figure in the EC is 5.9 litres, with no major differences between countries, except in the case of Portugal (2.1) and Luxembourg (18.4). (Source: Consumer Europe 1993).

Supply and competition

The cocoa/chocolate subsector is characterised by high concentration of supply. The market leaders are multinationals capable of controlling the supply of a product subject to wide

Figure 4: Cocoa, sugar confectionary, ice-cream

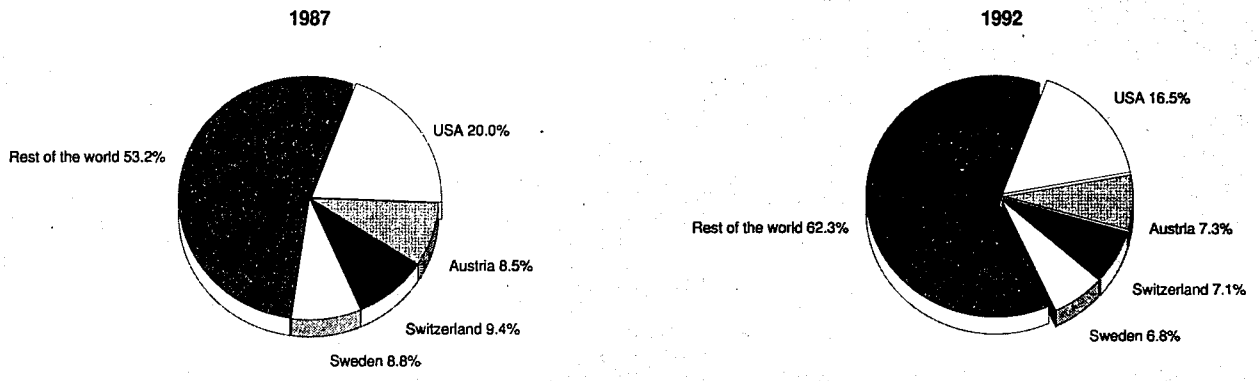
Destination of EC exports



Source: Eurostat

price fluctuations as in the case of cocoa. The supply of confectionery products is diversified: in this subsector, a large number of medium-sized firms distributing at national level operate side by side with the multinationals. In the ice cream subsector there is a third competitor: products made by small, non-industrial local firms. These ice creams provide for a considerable proportion of consumption in Italy, Greece and Spain. The productivity of the sector has grown almost continuously since 1985 at an average annual rate of 6%. The increase in labour costs is smaller (annual average rate of 5%).

The leading countries for production of cocoa derivatives and sugar confectionery are Germany, the United Kingdom, France and the Netherlands. Production in these countries (excluding Luxembourg and Portugal) accounts for about 80% of the total for the EC in 1991. The geographical breakdown of production is in line with that of consumption by country and area.

Production process

Product innovation plays a very important role in the sector; the main variable governing consumption is impulse buying, and the consumer is therefore particularly sensitive to the new products offered by the industry. In the cocoa subsector, the effect of fluctuations in the price of the raw material is of relative importance. Companies which supply the final consumer, most of which purchase semi-manufactured cocoa products have diversified the subsector by introducing a large number of products based on variety and richness of ingredients.

INDUSTRY STRUCTURE

Companies

In the ice cream sector (including small firms), Unilever (UK/NL) and Nestlé (CH) hold a combined share of around 40%. In the confectionery subsector the market is less concentrated. The main multinationals are Nestlé, Cadbury Schweppes (UK), Ferrero (I), Wrigley (DK) and the two US companies Philip Morris and Mars. The pronounced fragmentation of the subsector, with the resultant formation of market niches, makes it impossible to suggest an estimate of company shares. In the field of cocoa derivatives the main competitors are Nestlé, Mars, Philip Morris, Ferrero and Cadbury Schweppes.

Strategies

The policy pursued by the multinationals relies on all the variables of the marketing mix and also on external growth and extra-sectoral diversification. Investment in R&D makes it possible to launch successful and innovative products on the market. A recently introduced segment is that of chocolate-coated ice cream bars; Unilever, which launched the product with the Winner brand, was followed by Mars, with the brand of the same name and with Bounty (both brands previously belonged to the chocolate snack market).

Product innovation and the introduction of new brands is chiefly a characteristic of the ice cream market. Distribution is of special importance for ice cream, for which the cold chain is used, and for chocolate, during the months when temperatures are particularly high. Lastly, the high proportion of products bought on impulse calls for immense investment in advertising, which is another obstacle preventing small firms from entering the market. Important changes in the structure of supply include the increase in Nestlé's total share thanks to the take-over - in 1993 - by its food-sector financing company SMI (I) of 61% of Italgel (I), a company which produces ice creams and deep-frozen products. Towards the end of the 1980s the Swiss firm completed two other important operations, the take-over of Buitoni-Perugina (I) and of Rowntree (UK). Philip Morris, which operates in the food market via Kraft General Foods, established its position by the take-over of Jacobs Suchard AG (CH).

REGIONAL DISTRIBUTION

Cocoa is a colonial product; as in the case of coffee and tea, there is a clear distinction between producing countries and consuming countries. The main producing areas are West Africa and South America. Consumption of cocoa is still strongly concentrated in the industrialised countries. Over the years, the relative importance of the United States has declined in favour of Europe.

REGULATIONS

The EEC Directive on cocoa and chocolate was adopted in 1973. It allowed in the United Kingdom, Denmark and Ireland the use of vegetable fats other than cocoa butter.

In the medium term the Commission will re-examine the subject and adapt the directive to the new rules and regulations on labelling.

OUTLOOK

Owing to the diversification of the product, segments which are at different phases in their life cycle constantly exist side by side. The more traditional products, such as sugar sweets and chocolate bars, reached the end of their expansion phase some years ago. New products (for instance, bars eaten as snacks and sugar-free products) which are being launched on the market at short intervals, are in the initial phase and are constantly being replaced by new versions. At present the

recession, which is adversely affecting all sectors, chiefly penalises impulse buying and products which are not capable of reviving the interest of consumers.

Risks for the sectors are specified in the accentuation of the tendency towards consumption of health products and falling consumption by the main target group: children. Opportunities for the sector include the growing tendency towards snacks and the internationalisation of brands and standardisation of consumption.

Compound feed
NACE 422

The structure of both supply and demand differs between the two sections of the compound feed industry, producing for livestock and domestic animals respectively. The first section is extremely fragmented and operates in a market now at a high; the second is highly concentrated and is expanding rapidly.
In the animal feed section there is strong competition between companies, with profit margins being cut as a result. Competition centres on pricing policy and lowering costs.
By contrast, in the pet food section large sums are being invested in research and development and in advertising with the aim of establishing a brand policy to boost market shares and above all profitability.

INDUSTRY PROFILE

Description of the sector

The industry comprises of two subsections:

- the animal feed section which embraces the various activities involved in the production of livestock feed;
- the pet food sector which makes products for domestic animals and is divided according to the physical structure of the product, which may be dry (dehydrated) or in juice (in cans).

Pet foods account for not more than 5% of the whole sector by volume but for over 20% by value. In addition, pet foods are going ahead fast, while animal feeds long ago reached saturation point.

Recent trends

For the sector as a whole, the growth rate of EC production is still positive but is tending downwards. Real average annual growth running at 3.1% over the five years 1983-88, fell to 2.3% from 1988 to 1992 (including pet food).

Production follows the demand curve as imports and exports are of little consequence; extra-EC exports account for 3.6% of production and imports for 2.5% of apparent consumption (including pet food).

Production is rising at more than the average rate for the manufacturing industry as a whole. The pet food section has a real growth rate above the average for the sector running at 6% per annum over the last five years. These products are still at the introductory stage in some countries and consumption is increasing exponentially.

Employment has fallen in line with the average figure for the manufacturing sector. As regards productivity, added value per employee (including pet food) rose by an annual average of 4.9% from 1983 to 1992. In the immediate past, growth has been more modest with a 2.7% increase in 1992 over the previous year.

Foreign trade

Trade trends show a varied pattern. There was a linear increase of imports, which maintained a 2 - 2.5% share of consumption. The share of exports in production varies from a minimum of 2.5% in 1987 to a maximum of 3.6% in 1992. These differences are due in part to the productive capacity installed in the EC and in part to the fluctuation of world raw material prices.

From 1987 to 1992, the United States and EFTA share of imports rose while their share of exports fell. Over the same period, intra-EC trade increased by an annual average of 12.2%; in 1992, this trade accounted for 11% of consumption.

MARKET FORCES

Demand

Overall demand for animal feed is stable and is affected primarily by changes in cattle stock which are not always adequately offset by changes in pigs and poultry stocks. Industrial feeds still account for around 40% by value. The Netherlands and Italy, with 46% and 53% respectively spend the highest proportion on commercial feeds.

The price of materials has forced a change in the composition of compound feeds. Cereals are progressively being replaced by oilseed cakes and meals. Today, cereals account for 30% of the raw materials used, oilseed cakes and meals for around 25%, by-products of the food industry for 18% and manioc for 5-6%. This trend is likely to be reversed with the cereal price decline due to CAP reform.

Source: DEBA

The countries where animal feed is produced on an industrial scale there is a search for increasingly convenient compound feeds. By contrast, where the sector is fragmented, preference is tilted towards simple or cereal-based feedstuffs.

The demand for pet foods has special features. Products with high added service content are gaining ground all the time as family incomes increase and less time is available for activities in the home. As a result, consumption of pet foods is rising, boosted by vigorous marketing by firms in the sector which, thanks to high productivity, are investing large sums in advertising and product quality and diversification.

Supply and competition

The picture of competition within the EC shows that production is highly concentrated with consequent economies of scale in a number of countries (Northern Europe) but extremely fragmented in the Mediterranean area (Italy, Spain, Greece), due to the small scale of stock farms there and the close link with agricultural organisations. Domestic production is self-sufficient in the individual countries. Exports of compound feed are handicapped by the high incidence of transport costs.

In the case of pet foods, there is a flow of trade from the countries where the market is saturated to countries where it is still developing. However, in the latter cases development seems to be taking place quite fast.

Production process

New materials account for such a high proportion of production costs that technological advances have less impact. The industry is nevertheless maximising productive efficiency by automation.

The best results in terms of cost competitiveness are obtained by better-planned purchasing and better product distribution. The ability to keep stocks down to a minimum according to demand opens the way to substantial savings. Small local firms often keep their costs at a sufficiently competitive level thanks to flexibility of production which enables them to gear their output to demand with low transport and storage costs.

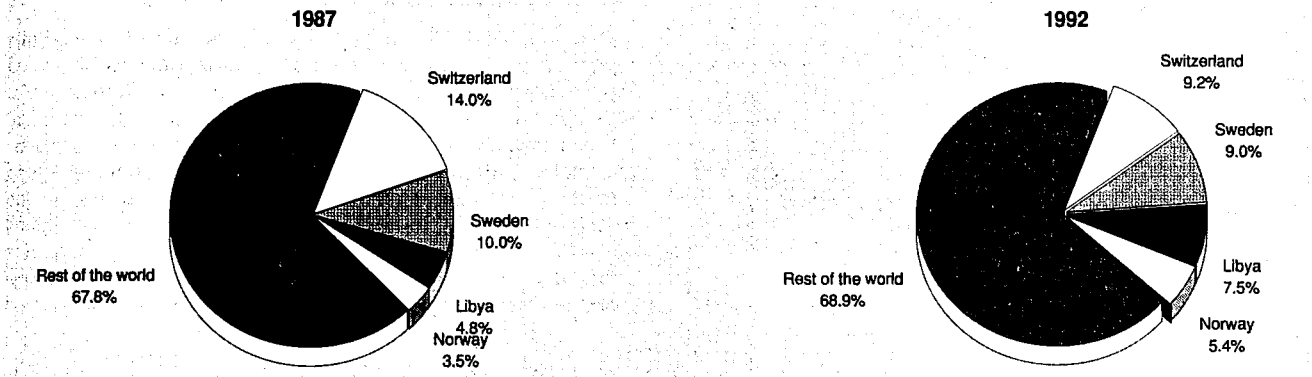
Figure 6: Compound feed
Destination of EC exports



Source: Eurostat

The pattern of pet food production is set by marketing, and principally by research and development of new products, in order to widen the range and improve the organoleptic properties which are decisive for product success.

INDUSTRY STRUCTURE

Companies

Feed supply is fragmented and shared between a few big companies and many small-capacity firms. The total number of production plants is around 4 300. They are generally located in the areas with the highest concentration of livestock farming; this applies in particular to the smaller firms because the area served is limited.

Of particular importance in this section are major firms of the private sector belonging to the top ten for each country. Co-operatives and consortia, according to FEFAC estimates, account for over 30% of compound feed produced in the Community. In Great Britain and Belgium co-operatives are not a major element, but in the Netherlands they account for 40-50% of production. There are very few multinationals. One of them, like Purina Ralston, Denkavit, BP Nutr (Hendrix) and Kofu, with a number of plants in the main Community producing countries. The incidence of transport costs and feeding patterns on livestock farms, which vary from country to country, account for the predominance of local firms as regards supply.

The European market for pet foods is dominated by four multinationals with production structure covering the whole of EC territory. Mars (USA) has over 50% of the market, thanks to the leading position of Unisabi in France, Elfem in Germany and the Netherlands, Dolma in Italy, Pedigree P.F. in the United Kingdom. Quaker (USA), and controls about 15% of the EC market; Nestlé (CH) and Dalgety (UK) both have under 10%. Some small and medium-sized enterprises operating at regional or national level have significant shares.

Strategies

Production capacity is under-used (35 - 40% of potential) in the animal feed section. In the short term, the reorganisation of many plant in search of economies of scale has led to the closure of less efficient firms as operators expected.

The competitive strategy of the biggest firms focuses on research and development and technical assistance. In the first case, the aim is to produce better-quality feed in an attempt to differentiate from competitors and keep or increase profits.

Other	6 318	6 426
Total	110 150	110 388

(1) Excluding Greece, Luxembourg and former East Germany
Source: FEFAC

The aim of technical assistance is to win loyal customers and to counter in some measure the effects of increased competitiveness. Small firms, with lower transport and management costs, pursue aggressive pricing policies.

The main strategic variables of the pet food industry are the introduction of new products and a brand policy backed by heavy investment in advertising.

ENVIRONMENT

The compound feed industry has a vital role to play in improving the quality of meat. It is important to note that feed is the biggest cost element in meat production. Producers are always looking for the highest possible conversion rate between feed consumed and meat produced. To this end, widespread use is made of legally authorised substances which improve this rate. Apart, obviously, from monitoring by the accredited official bodies, improvement of the technical characteristics and nutritional quality of feed will help to correct this state of affairs. Vocational training for breeders is important, backed by technical assistance from the big firms.

OUTLOOK

In the short term, the demand for compound feeds is expected to remain largely stable, due to the small increase of livestock. The recession, which has hit all Member States, will affect the sector in 1994. Another factor is that the meat market is at full growth; this is affecting prices and is therefore likely to make breeders less willing to spend.

The demand for pet food will go on rising rapidly (5%) but consumption may slow down in 1994. Risks for the sector include: lower Community support for some imported raw materials, less cattle breeding and increased competition and low price policies. Opportunities include: replacement of cereals by other high protein and energy value raw materials, increased feed consumption by the poultry and pig sectors, progressive raising of feed quality standards.

Written by: Prometeia Calcolo Srl
The industry is represented at the EC level by: European Federation of Compound Animal Feeding Stuffs Manufacturers (FEFAC). Address: Rue de la Loi 223, B-1040 Brussels; tel: (32 2) 230 8715; fax: (32 2) 230 5722.

Miscellaneous food products
NACE 417, 423

The products included in NACE groups 417 and 423 recorded good growth over the past decade. The categories with the greatest development potential at present are pasta, ready-to-serve thick soups and diet products, while the markets for tea and vinegar are stationary. The most important multinationals of the food industry operate in most subsectors of the miscellaneous food products and their brand products have substantial shares in all the markets of the Member States.

INDUSTRY PROFILE

Description of the sector

The sector covers production of pasta products (NACE 417) and of various commodities which constitute completely different markets (NACE 423): tea, coffee, chicory and other coffee substitutes; vinegar and other food dressings; diet products; ice; prepared desserts; preparations for clear soups, ready-to-serve thick soups and sauces; food products not included in the other NACE groups.

Recent trends

Pasta

Production of pasta in the EC is in excess of 3 million tonnes. The main indicators for the pasta sector display a positive trend. Over 1981-1991 the volumes produced in the EC increased at an annual average rate of 2.5% while apparent consumption rose in real terms by 1.5% per annum. Over the last five years the average rate of growth increased to 3% for production and 1.7% for apparent consumption.

Trade has expended significantly with extra-EC exports growing on average by 16.7% per annum and extra-EC imports 11.7%, in current prices. In 1992 the number of persons employed in the sector was 19 300, down 16% on 1983. From 1989 onwards, however, employment remained virtually stable.

Other food products

NACE Group 423 covers a variety of products with different market trends and growth rates. However, overall production and apparent consumption showed an annual average growth of about 8% at current prices from 1983 to 1992. Extra-EC exports increased by 6.4% per annum, while imports rose at an annual average rate of 1.7%. Employment rose substantially, by 14% during the period under review. The main subsector in terms of value is that of hot drinks. Among other food products, condiments and dressings (except for vinegar and salt), ready-to-serve soups and diet and baby foods have in recent years recorded growth rates ranging from 2% to 5% per annum in terms of volume.

International comparison

The EC is the leading world market for pasta, with a volume of around 2.7 million tonnes. Average per capita consumption (8.4 kg) is, however, equal to that of the United States, a growth market amounting to 2 million tonnes. The volume figures for the countries of the former Soviet Union are at the same levels, with per capita consumption of 7 kg. Japan's per capita consumption is very much lower (1.3 kg) and the total remains stable at 160 000 tonnes.

The EC, the United States and Japan are not coffee producers. The EC is the main net importer of green unroasted coffee; average per capita consumption is around 4 kg, which is slightly higher than the figure for the United States, where the market is contracting. In Japan per capita consumption is 2.8 kg but demand is growing steadily. That country grows a modest amount of tea (3.5% of world production of raw material), but per capita consumption is less than 1 kg, as in the United States and the EC.

Foreign trade

Pasta

Under the powerful stimulus of extra-EC exports, whose share of production rose from 3% in 1983 to 7% in 1992 in terms of value, the balance of trade in pasta has grown strongly at current prices in recent years, at the rate of 17.4% per annum. Intra-EC trade has also increased rapidly (by 14.5% per annum at current prices). Italy alone exports nearly 90% by volume of the pasta products manufactured in the EC and has won large market shares not only in the EC but also in some EFTA countries and Japan. The share of the latter regions and of the United States in extra-EC exports has decreased compared with 1987.

Other food products

Extra-EC imports remained substantially stable over the last decade. Consequently, their share in production decreased (from 5.6% in 1983 to 3.4% at present in terms of value). On the other hand extra-EC exports increased, pushing up the trade surplus. Intra-EC trade also increased considerably, representing in value almost twice as much as extra-EC exports and four times as much as extra-EC imports.

The significant weight of hot drinks in this subsector is evident in international trade. In 1992, imports of green unroasted coffee amounted to over 1.8 million tonnes, having increased at an average annual rate of 2.4% in volume from 1985 onwards. Conversely, imports of tea, at around 200 000 tonnes, fell by 1.9% per year over the period 1986-1991.

MARKET FORCES

Demand

Pasta

Italian traditions serve as a sufficient explanation for the country's leadership in this subsector. The cessation of growth in demand in Italy is due to high per capita consumption, amounting at present to nearly 30 kg per year. The spread of the Mediterranean diet has stimulated higher consumption in nearly all the EC countries. Over the last five years the highest growth rate was recorded in Denmark, but the country with the highest per capita consumption after Italy is France (7.1 kg), followed by Portugal (5.4 kg) and Germany (5.1 kg). (Source: Consumer Europe 1993).

Other food products

Demand for tea in the EC has long ceased growing, chiefly because of the decline in per capita consumption in United Kingdom - the traditional tea-drinking country together with Ireland - from 3 kg to 2 kg during the last few years. Demand is being affected particularly by the strong competition from other non-alcoholic beverages such as soft drinks. The drop in the Anglo-Saxon countries has not been counterbalanced by the increases recorded in other countries such as France and Italy. Furthermore, per capita consumption there is low and tea is still a "special" product not firmly established in European food culture, except in the Anglo-Saxon countries.

Consumption of coffee is more solidly based in Europe. Over the last five years EC demand has risen by 1.4% per year in volume. Per capita consumption is highest in the Northern European countries, and specifically, within the EC, in Germany (8.5 kg), the Netherlands (8.3 kg) and Denmark (6.8 kg). (Source: Consumer Europe 1993). Italy is, however, the second market in terms of value after Germany, while the United Kingdom accounts for 45% of the volume of consumption of soluble coffee.

Demand for ready-to-serve soups is ceasing to grow. The United Kingdom is the country with the most firmly established industrial tradition in this subsector and accounts for 50% of consumption of tinned soups in the EC. The Netherlands and Belgium also have high per capita consumption levels. Germany is the largest market for condiments and dressings, consumption of which is highest in the Northern European countries. Mayonnaise and salad dressing are still growing, although slowly, while demand for vinegar is stable. The main vinegar producers are Germany and France (53% of EC production) but per capita consumption is highest in Denmark and Belgium.

Supply and competition

Pasta

The EC pasta industry meets the whole of internal demand. Italy has large shares in the main Community markets. For instance, imports of Italian pastas account for 25-30% of consumption in France and Germany.

Other food products

The subsectors included in NACE Group 423 are characterised by the strong position of multinationals, which operate in the individual national markets either directly or with brands which have been taken over. The degree of concentration of supply is generally medium to high and the critical factors for success are investment in advertising and distribution. Brand policy predominates in the markets in question, supported by the great importance of modern distribution.

Production process

In the pasta subsector, Italy enjoys a kind of technological and qualitative leadership. Technological development has been concentrated on perfecting the fundamental phase of drying, which gives the pasta its flavour and consistency. In Italy, plant capacity and utilisation has increased. Average output per plant is around 13 000 tonnes, exceeded only by that of France (28 800 tonnes per unit).

With regard to tea, the production process is basically confined to packaging the imported product, whereas the coffee-drying industry has a more sophisticated technology, especially in the roasting phase. The technology of soluble coffee is very complex and requires substantial investment in plant.

INDUSTRY STRUCTURE

Companies

The number of industrial producers of pasta fell from over 300 in 1981 to 254 in 1991. The concentration of supply has increased owing to the many take-overs of national companies by multinationals. The market leader in Europe is Barilla (I) with a 23% share, followed by BSN (F) with 16% and by Nestlé (CH).

In the hot drinks subsector, multinationals are well to the fore, especially Unilever (UK/NL) and Teekanne (D) for tea and other infusions and Philips Morris (USA), Sara Lee (USA) and Nestlé (CH) for coffee. Together with Lavazza (I), the last three groups hold nearly 60% of the coffee market. Nestlé alone accounts for about half the supply of soluble coffee and coffee substitutes.

The multinationals are also extremely active in the subsector comprising condiments and dressings, ready-to-serve soups and diet products. Unilever, Philips Morris with Kraft General Foods, Nestlé, HJ Heinz (USA), Campbell Soup (USA) and CPC (USA) are the major players.

Strategies

In addition to take-overs, which are particularly important in the pasta subsector, strategies are based on the popularity of product brands and large investment in advertising. Despite wide-spread product differentiation, product innovation is considered to be relatively poor.

REGIONAL DISTRIBUTION

In the production of pasta, Italy has a 70% share, followed by France (9%) and Germany (8%). The hot-drinks subsector is characterised by processing of imported raw materials. Distribution of production approximately coincides with consumption. The United Kingdom dominates the tea market and is among the main world net importers of raw material (for other vegetable infusions the largest market is Germany). Germany is the leading importer of unroasted coffee, with a 34% share of the EC total of over 1.8 million tonnes imported in 1992. With regard to product groups such as food dressings (excluding tomato derivatives) and ready-to-serve soups, the highest consumption levels are generally in the Northern European countries. Germany and the United Kingdom are the largest markets.

OUTLOOK

The sectors in question do not, as a whole, present any great opportunities for development as far as demand in the EC is concerned. The highest growth rates are likely to occur in the case of condiments, except vinegar, and above all in that of ready-to-serve soups, thanks to their convenience for the consumer. These products do, however, run up against opposition in the Southern European countries with eating traditions which do not favour their use. For pasta there is very great growth potential outside Italy, but for the time being the greatest opportunities for the industry are to be found in exporting and particularly in penetrating markets in Eastern Europe. Consumption of tea has long ceased to increase. The coffee market, which is much larger, has consumption levels which it would be difficult to increase any further.

Risks for the sector are more evident in the case of hot drinks: especially for tea due to competition from other non-alcoholic beverages while the spread of health-conscious life styles poses a risk for future demand for condiments. Further opportunities exist for pasta reflected in its rising export potential over the recent past. Finally, there is a growing interest for tea-based cold drinks and good prospects for ready-to-serve soups due to their convenience aspect compatible with modern life styles.

Alcohol and spirits
NACE 424

The spirits sector accounts for about a quarter of the wider market for alcoholic drinks. In relation to other alcoholic drinks (beer, wine, etc.) spirits have the highest bottling strength, although the manner in which they are consumed often makes their serving strength comparable with other alcohol drinks. Spirits are penalised by high taxation and in some markets by government restrictions on advertising and promotion.
The European market is made up of a few multinationals and a large number of local producers. Spirits are distributed mainly through specialist firms and the trend is to build sales through both traditional retail outlets and supermarkets.

INDUSTRY PROFILE

Description of the sector

The sector comprises two main categories of product: ethyl alcohol of agricultural origin and spirits as opposed to spirit drinks. Official statistics treat the first as spirit drinks and the second as industrial. Ethyl alcohol is used in a variety of alcoholic drinks, vinegars, pharmaceutical products, cosmetics and other industrial products.

The three main categories of alcoholic drinks are:

- whisky, particularly Scotch, but also Canadian, Irish, Bourbon and other non-Scottish whiskies
- vodka, rum, gin, brandy (including also cognac, armagnac, French eaux-de-vie and various German brandies); and
- punch and cocktails, liqueurs, pastis/anisette (the French national liqueur), bitters and grappas (widely drunk in Italy) and other minor types.

Recent trends

Value added was ECU 3 353 million for 1992, which was 2% down on the previous year. The United Kingdom and France jointly accounted for 48.3% of European added value, with Spain contributing 15.4%, Italy 14.3% and Germany 12.3%.

From 1983 to 1988, production and consumption declined at an average rate of 1.1% and 2.3% per annum, respectively. However, from 1988 to 1992, small improvements materialised in an average growth rate of 0.3% in both production and consumption. The number of people employed in the sector has been falling for the last ten years due to declining output and to technological improvements in areas such as bottling.

International comparison

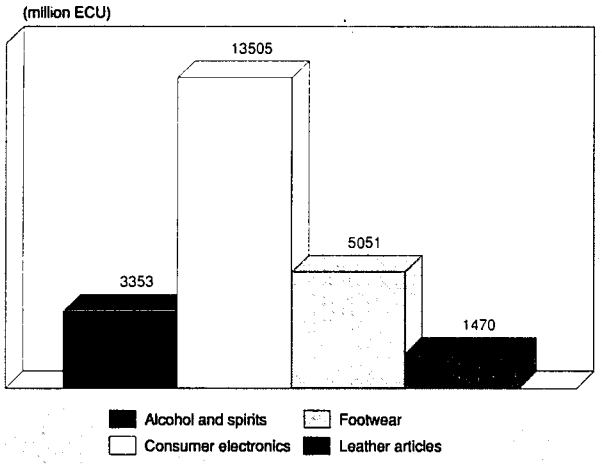
In 1992, the alcoholic drinks industry (beer, wine and spirits) grew by 2% in the United States with an output worth around 23 billion dollars. Different spirit drinks performed in different ways, but overall spirits recorded a decline amounting to 1.5% in current values, with production worth 3.3 billion dollars.

Foreign trade

The Community is the major world exporter of alcoholic drinks, with products such as scotch whisky, brandy (cognac, armagnac and Weinbrand) being the leading exports, although products such as gin, vodka, rum and well-known liqueurs, which are sold virtually throughout the world, must not be overlooked.

In 1992, over 40% of Community exports went to the United States and Japan; the latter's share rising from 9.7% to 15.7% between 1987 and 1992. Almost 33% of Community imports

Figure 1: Alcohol and spirits
Value added in comparison with other industries, 1992



Source: DEBA

came from the United States and the EFTA countries. Five years earlier the figure was 20.3%. The biggest share is held by the United States, rising from 14.2% in 1987 to 26.8% in 1992.

MARKET FORCES

Demand

Although there are regional differences in production (Scotch whisky and gin in the United Kingdom, corn brandy in Germany, anisette or ouzo in Greece, brandy and eaux-de-vie in France, grappa and bitters in Italy, and brandy in Spain) there is an increasing demand form consumers to have available to them a greater range of spirit drinks. During 1992, average European consumption was estimated at 5.7 litres per head. The figure for individual countries varied, however, from 14 litres in Greece to 3 litres in Italy.

The success of multinational drinks companies has increased the availability of different drinks in different markets. Recently, the demand for alcoholic drinks has fallen in Italy

and the United Kingdom, partly because of the state of the economy, and in the case of the United Kingdom, because high taxation has made these drink products expensive and so adversely affected sales. By contrast, demand has risen in countries like Germany, Spain and France. In Germany the reason is to be found in reunification, because spirits are very widely purchased by people living in former East Germany, where consumption in 1991 was estimated at 16 litres per head. The higher demand in Spain stems from higher average wages per head and the removal of tariff and trade restrictions since Spain joined the EC. The reason for increased demand in France is an effective marketing and distribution policy and the fact that drinkers enjoy the additional products now available to them.

Supply and competition

The main operators in the alcoholic products industry are the multinationals which, are securing new markets for their international brands. Supply is highly concentrated in the United Kingdom and France, but is very fragmented in Germany. In Greece, a large number of local producers exist side by side without any major multinational presence. The markets for aperitifs and regional products (grappas) are very fragmented in Italy and have reached saturation point. Competition between international brands is very fierce with each company carrying a broad product range.

Production process

Alcoholic drinks are produced by fermenting and filtering agricultural products such as grapes, fruit and grain. The production of distillates is based on a tradition and culture of rural economies. This background is still to be found in drinks such as Scotch whisky, although there has been a general move to large scale plants.

INDUSTRY STRUCTURE

Companies

International drinks such as whisky, gin and rum, which are distilled and distributed by the leading multinationals operating in the alcoholic products market often belong to companies registered in the United Kingdom or the United States. They compete vigorously with local firms for market share and the two groups provide consumers with a wider choice of spirit drinks across the EC. Small firms are often able to establish niche market opportunities by specialising in the production of local specialities.

At the European level, the leading distillers and distributors of alcoholic products are: Guinness (UK), Pernod Ricard (F), Grand Met (UK), Allied-Lyons (UK), Martini & Rossi (I) and Seagrams (USA). These six firms control over 40% of the EC market.

Strategies

Over the last ten years, the drive to consolidate and increase the market shares of the major brands on the world market has led to a series of take-overs which have modified the ownership structure. The most recent are as follows: Pernod Ricard has acquired Irish Distillers (IRL), and Guenther Reh AG (D) has acquired Langenbach & Co GmbH/Hermann Kendermann GmbH (D).

ENVIRONMENT

The alcoholic products industry is paying more attention to environmental issues centred on packaging. It is also reviewing disposal of waste which, in many cases, can be passed back into the agricultural system in the form of animal feed. The industry is particularly concerned that Member States tackle environmental issues through a uniform approach so as not to be faced with many different forms of legislation which could act as barriers to trade.

Looking at the future and the tax incentives recently introduced by the Community, alcohol of agricultural origin may find uses in new directions, for example as an additive for fuel for land vehicles in place of lead tetraethyl. This might help to alleviate, in some measure, the problem of atmospheric pollution.

REGULATIONS

Regulation 1576/89 defines the various categories of spirit drinks and lays down specific rules for the labelling of products.

OUTLOOK

If the recent growth of consumption recorded in some Member States is to continue, it will be in the face of factors such as high prices sustained by the taxation of spirit drinks at a level much higher than that levied on other alcoholic drinks and campaigns to cut down alcohol consumption generally.

Production and apparent consumption are forecast to decrease slightly in the mid- to long-term. In contrast, extra-EC exports are expected to grow slightly.

Firms operating in the sector will continue to market the typical features of their products as they seek to establish their brands in the appropriate sector of the individual country market they have chosen for that particular brand.

Wine
NACE 425

The wine market has been shrinking since the late eighties. This is in line with the trend for consumption of all alcoholic products as a result of consumers' greater awareness of health problems and the campaigning of increasingly active health protection groups.
Recent trends have revealed changing consumer preferences and ordinary and table wines are losing market shares to quality wines. Changes are taking place in the distribution of wine which is increasingly being sold by modern distributors and through networks specialising in the sale of alcoholic products.

INDUSTRY PROFILE

Description of the sector

The variety of products marketed is so wide that it can be sub-divided under many headings, the chief of which are:

- by colour (red, white, rosé)
- by quality (table, IGT, DOC, DOCG, VQPRD etc.)
- by alcoholic strength
- by type (still, sparkling, fortified, etc.)
- by method of packaging (bottles and flasks of different capacities, "brik"-type cartons, bag-in-box, cans, etc.)
- by geographical area of origin

"Wine coolers" are a fairly new development, widely sold on the United States market but meeting resistance in the traditional wine-drinking countries, which are reluctant to accept such major changes.

Total Community added value amounted to 2407 million ECU in 1992. Three major producing countries accounted for 78.8% of this figure - Spain with a 28.9% share, France with 33.7% and Italy with the lower figure of 16.2%.

Recent trends

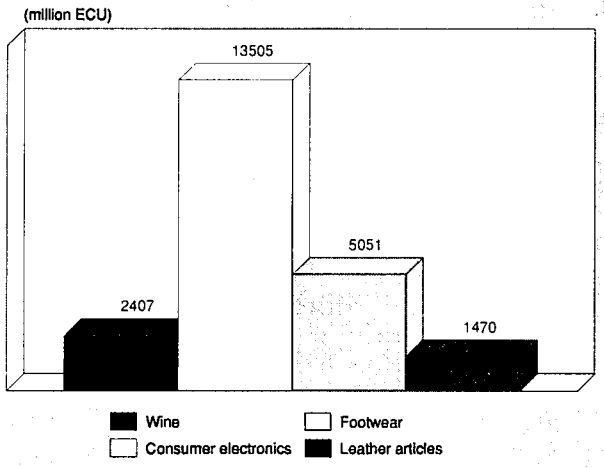
Cyclical variations are quite common in this sector particularly due to varying weather conditions. During the 1983-92 period, consumption rose by a real annual average of 1% and production by 0.4%. Exports fell sharply at an annual average rate of 6.8%. Since 1989, the trade balance has become steadily worse due to a big increase in imports and a marked drop in exports. From 1991 to 1992, both production and consumption fell by 1% and exports by 2.4%. The trade balance was 4.3% down as a result but was steadily favourable. The downward trend of the sector, worsened by the current recession in Europe, was reflected in lower employment (down 2.9%).

In 1990 and 1991 too much wine was produced and was handed over to the intervention scheme for compulsory distillation. In response to the falling trend of wine drinking, the Community introduced a system for the up-rooting of vineyards in order to reduce total European production. However, the effectiveness of these measures was partially offset by higher vineyard yields.

International comparison

The last forty years have witnessed a tremendous expansion of wine growing throughout the world. The Community is the leading producer with over 60% of world production, followed by the CIS, the United States (15% of the total) and Argentina. Production in the former USSR countries which had grown rapidly over the previous 35 years, fell back unexpectedly from 1985 onwards because of the campaign against alcoholism.

Figure 1: Wine
Value added in comparison with other industries, 1992



Source: DEBA

Foreign trade

The EC is the leading figure in the world wine market despite the fact that exports are declining. Italy is the leading exporting country in terms of quantity but France stays easily in the lead in terms of earnings. Spain is by no means negligible exporter while Germany and the United Kingdom are the world's biggest importers.

From 1987 to 1992, the share of Community exports going to the United States fell from 56.2% to 40.3% but the share going to the EFTA countries and Japan increased (from a combined share of 18.9% in 1987 to 24.7% in 1992).

Over the same period, the shares of EC imports by country of origin were up for the United States and the EFTA countries but down for Japan and the rest of the world (rising from 15.8% to 24% for the first group and falling from 20.7% to

13.6% for Japan and from 63% to 42.7% for the rest of the world).

In both 1991 and 1992, the Commission organised the sale of stocks of alcohol compulsorily distilled from wine. Until now uses have been found for all these stocks in the fuel sector both within the Community and in the Caribbean, Central America and Brazil.

MARKET FORCES

Demand

A distinction must be made between the countries where wine is traditionally regarded as a popular drink, as in the case of France, Italy and Spain and the countries where beer is traditionally the popular drink, as in the case of Germany and the United Kingdom.

In countries like France, Italy and Spain where wine production and drinking are part of the popular culture, falling sales reflect a change in consumers' tastes and strong competition from alternative products. Sales of quality wines are increasing, however, and for the next few years the trend in this subsector is expected to be upward. The "vin de pays" subsector, with a medium price range, is also expanding.

By contrast, in countries where beer is the popular drink, wine sales have been rising in recent years; but in these countries also, the demand for wine can be affected by concern for health and the recession. In the late eighties and early nineties wine consumption did, however, increase in both quantity and value.

In addition to the lower sales of table wines, there has also been a further change in consumers' tastes. Red wine has lost ground in the market, while light white and rosé wines are meeting with more success. The reason is to be found in the fact that consumers are looking for light wines which go well with light meals. In consequence, French, Italian and Spanish producers have turned to new methods of fermentation

in order to produce lighter red wines. Sparkling wines are greatly appreciated on the European market.

The present sales position is critical for wines with a high alcohol content, such as sherry and port. In the United Kingdom, which is the market with the highest sales, more enthusiasm is being shown for lighter varieties of these two products. The trend is the same for the various types of vermouth and flavoured drinks.

In 1992, average annual wine consumption per head in the Community was around 37 litres, with variations between countries. France leads with 64.5 litres per head, followed by Italy with an average of 61.6 litres and Luxembourg with 58.2 litres. In the same year, per head consumption in Portugal was 57 litres while the figure for Spain was only 43 litres. These countries are followed by those which by tradition have never drunk much wine but beer instead; the most noteworthy are Germany and the United Kingdom with 22.8 and 10.4 litres per head respectively.

Supply and competition

The European wine industry is very fragmented. Over the last few years, however, increasingly market-oriented groups with multinational interests have been emerging.

In the major wine producing countries, particularly in southern Europe, production is in the hands of thousands of small growers with a family property and vineyards producing unspecified quantities. Trade associations in the sector are trying to stimulate the total production of such growers on the sole basis of area cultivated and average harvest. It is, therefore, very difficult to determine the size of the market, the more so because the calculations are complicated by the long time which wine sometimes needs to mature.

Competition within the Community involves chiefly products in the middle-high range. The countries mainly concerned are France and Italy. Italian wine is facing competition particularly from Spain, Greece and the North African countries. In general, European production as a whole is suffering from competition from the major world growers of wine grapes, which include Turkey, the CIS, Chile, California, Japan, Algeria, Morocco, Romania, Bulgaria and South Africa.

Production process

Wine is made by two different processes known as white and red vinification; there have been no major changes in these processes over the years. The sector is so fragmented that it

Source: Eurostat

is difficult to give a complete picture of the production techniques employed.

Small growers use methods which are difficult to control and give widely varying results; the supply includes products of very different qualities.

Associations and private wine co-operatives tend to invest more in advanced technologies because they are more interested in renewing and up-dating their plant in order to achieve economies of scale and improve product quality.

INDUSTRY STRUCTURE

Companies

The sector comprises a vast number of operators at various stages of the production chain. There is a very high degree of agriculture/industry integration, due to much interaction between the various stages of production.

Associations now vinify around an 80% share of the total processed product in Italy and about 60% in France. Groups operating on a wider than national scale account for only 15% of the European sales. They are Pernod Ricard (F), Allied-Lyons (UK), Seagrams (USA) LVMH (F), Castel Frères SA (F) and Grand Met (UK).

Strategies

The main reasons why it is not easy to define operators' strategies in this sector are the extreme fragmentation of the wine-growing and producing industry and the vast range of products available on the market. Every subsector differs as regards production process, production structure, way of reaching the final market, type of packaging and bottling, methods of consumption and section of the market served.

There have been some take-overs in this sector over the last ten years led in 1992-1993 by the following: Castel Frères SA (F) acquired Société des Vins de France (F), Caviro (I) acquired the Carapelli (Poggese) brand (I), Guenther Reh AG (D) acquired Langenbach & Co. GmbH/Herman Kendermann GmbH (D).

REGIONAL DISTRIBUTION

The parts of the Community where grapes are grown and wine production plant are located are widely scattered over large areas. Grapes are grown more especially in certain regions of the various producing countries.

- in Italy, where grapes are grown principally in Sicily, Apulia, Veneto, Emilia-Romagna, Piedmont, Tuscany and in smaller quantity in Latium, Valle d'Aosta, Valtellina, Trentino-Alto Adige and the Cinque Terre;
- in France where grapes are grown in Languedoc-Roussillon, Gironde, Burgundy, the Loire Valley, Alsace, Champagne, Provence-Cote d'Azur, Pyrenées and Charente;
- in Spain where grapes are grown in La Mancha, Logrone, Navarre, Tarragona, Saragossa, Valencia, Alicante, Murcia, Andalusia, Rioja, Malaga and Jerez de la Frontera;
- in Germany, where grapes are grown along the Rhine and Mosells, in Franconia and Württemberg.

ENVIRONMENT

The sector has no serious impact on the environment except by way of the quantity of pesticides used in grape growing. This sector too has recently seen the spread of integral/organic cultivation methods which further reduce environmental pollutants.

Wine sold in bottles involves the problem of recycling the glass which has always created logistic difficulties; to eliminate this problem some companies have promoted the sale of wine in cardboard "briks".

REGULATIONS

Council Regulation No. 24 of 4 April 1962 laid down the principles for the organisation of the wine market. The major legislation approved by the EC was Regulation No. 822/87. The purpose has been to promote the free movement of wines throughout the Community by protecting both the quality image and the consumer at the same time.

Regulations 2392/89 and 997/81 lay down specific rules for labelling, while Regulation 3895/91 specifies in addition that labels for sweet dessert wines, semi-sparkling and effervescent wines must show alcohol content by volume.

Recently, a communication of the EC Commission has been published on the development and future of the wine sector (COM/93/380) in view of a reform.

OUTLOOK

Trends for the wine market over the next few years will depend on consumers' views on health problems, life styles and available incomes.

The market may be expected to expand in Germany and the United Kingdom but the larger French and Italian markets will continue to contract.

In the United States, sales of red wine will continue to increase, partly due to recent research claiming that this product has properties which help to prevent and cure heart complaints. In the coming years this trend may perhaps also influence the countries of Europe.

It will increasingly be producers' policy to up-grade their brands as a vital means of attracting and keeping loyal customers. Supermarkets will continue to extend the range of wines on sale, but specialist retailers will still have an important role in this market.

Brewing and malting
NACE 427

The sector holds the dominant position among alcoholic drinks. Production and consumption of beer have been virtually unchanged over the last ten years. The levels of consumption reached in many North European countries seem to suggest that these markets are now saturated. Further possibilities for growth are developing in the countries round the Mediterranean and particularly in Spain.
Health and safety on the road constraints plus the reduction in the 18 to 35 years old population group constitute the major threat for consumption. On the hand, the development of new market segments may provide an effective way out of the present stagnation. In particular, alcohol-free, low-alcohol and light beers constitute the basis for diversification to meet drinkers' new demands.

INDUSTRY PROFILE

Description of the sector

The sector comprises the malting and brewing industries. Beer is brewed from barley malt made in malt-houses. According to the production process beers may be classified into the following three main categories:

- bottom fermentation beer;
- top fermentation beer;
- spontaneous fermentation beer (typical in Belgium).

Beers are also classified according to alcohol content. The sector also includes non-alcoholic beers, normal beers (table and premium), special beers and double malt beers. According to the degree of malt toasting, beers can be divided into light and stout ales.

Recent trends

Over the last ten years, apparent consumption and production of beer, at current prices, have risen by about 3%. The same indicators at constant prices record a downward movement and stagnation of the market. Extra-EC exports have risen by 3% in constant prices in 1992, and their share accounted for 4.5% of the value of production in the same year. Imports have risen much faster, but their share of apparent consumption is very small (less than 1% in 1992).

Employment has been falling by an average of 3% annually from 1983 to the present. The figures for the most recent years seem to indicate that employment trends are a little less unfavourable, this is due to signs of recovery over the last five years, thanks to good export performance, with an 8.6% increase at current prices and 7.5% at constant prices.

International comparison

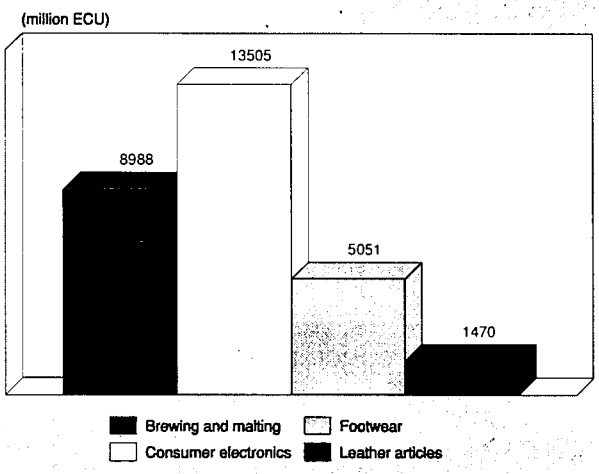
The international picture highlights a growing Japanese market while the United States and European markets have reached full growth. In the late eighties, growth in Japan reached about 5% due to the fact that beer consumption is much lower than in other industrialised countries (about a quarter).

By contrast, European markets, where there is a long tradition of beer drinking, are reaching saturation (north European countries).

Foreign trade

Intra-EC and extra-EC trade account for about 5% of the value of production. Over the last ten years, internal trade has accounted for over 90% of total imports. Extra-EC imports account for a marginal share of consumption even though they did record an average annual increase of over 20% from 1988 to 1992.

Figure 1: Brewing and malting
Value added in comparison with other industries, 1992



Source: DEBA

The three main trading blocs - the United States, EFTA and Japan - do not contribute significantly to EC imports, a large part of which in fact come from the rest of the world. From 1987 to 1992, the EFTA countries lost importance as exporters to the EC; their share fell and was overtaken by that of the United States which gained ground in the Community market. It has been Mexico that has achieved the most spectacular market penetration in the last few years by supplying almost a quarter of the imported beer into the EC market.

Even though beer exports rose and the trade balance remained favourable, the relationship between exports and imports changed over the last ten years. In the early 1980s exports were about 20 times higher than imports but this figure had fallen to 10 by the early nineties. The United States are the main outlet for European exports but their share has fallen over the last five years. Against this, exports increased to Japan and other countries outside the three main trading blocs. The share of exports to EFTA countries remained constant from 1987 to 1992.

MARKET FORCES

Demand

Per capita consumption of beer varies very widely in the EC countries. The biggest consumers are in North Europe: Germany (144.2 litres), Denmark (128.2 litres), Belgium and Luxembourg (112.0 litres), the United Kingdom (102.6 litres) and the Netherlands (90.2 litres). Consumption is stable, except in Germany, due mainly to competition from alcohol-free drinks and the emergence of a powerful "health" and "road safety" trend.

Among the Mediterranean countries, the market in Spain is growing and per capita consumption has reached 70.5 litres. Italy is at the back of the queue with a per capita consumption of about 23 litres. After a period of sustained increase (seventies to early eighties) the Italian market seems to have reached full growth. Consumption in France and Greece is around 40 litres per head.

One of the reasons for the different levels of consumption is competition in the Mediterranean countries from another major alcoholic drink - wine. In Greece, Italy and France wine is the alcoholic drink most widely and frequently drunk. Against this, consumption of beer, in Mediterranean countries, is affected by seasonal factors, young peoples preferences and outdoors eating habits. The perception of beer as a thirst-quenching drink means that it is drunk most during the summer months; the length of the summer has often determined the size of the market. The growth of beer bars has created an image of the product which does not really attract consumers or favour higher consumption at home.

The most dynamic segments of the market are light and alcohol-free beers. At the moment they account for only a very small proportion of total sales. They are however becoming important as they offer a new image of beer in general, more in line with consumers' concern for health, and they are capable of appealing to new target groups (for example, women and teenagers).

Supply and competition

The main beer producers in Europe are Germany and the United Kingdom. This domination stems from beer's historically important place in the range of beverages drunk. Malt production capacity is highest in the same two countries, followed by France. The main feature is the strong presence of multinationals. Take-overs in recent years have created a strategic situation in which local producers suffer and are marginalised (except in the extremely fragmented German market).

The current trend is for international brands to impose themselves increasingly; their spread is linked with the presence of the multinationals in the various countries, through take-overs or contracts with local companies. These contracts are for production under licence or for exclusive import and distribution rights. Concentration and the need to cut production costs have led to the closure of many breweries. Except for Germany, Belgium and the United Kingdom, no country now has more than 30 breweries. In the first three countries, the amount of beer brewed, but more especially the fragmentation of supply, are reflected in the number of establishments: 1290 in Germany, 121 in Belgium and 99 in the United Kingdom.

INDUSTRY STRUCTURE

Companies

Two European groups are the leaders; they are Heineken (NL) and the BSN group (F). They are also among the world leaders; Heineken with a 4.5% share is third in the sector, while BSN with 2.4% is fifth.

Heineken's share is over 50% in the Netherlands and about 25% in France where it is second biggest; it has 20% of the Spanish market (through its partner El Aguila) and 25% of the Italian market.

The BSN group leads in France (the Kronenbourg and Kanterbrau breweries produce nearly 50% of the total) and in Italy, through Peroni, with about 40% of the market. The company is among the leaders in Belgium, Spain and Greece.

The third biggest European company is Bass (UK) with a 22% share of the British market.

The three world leaders, Anheuser-Busch Inc. (USA), Philip Morris-Miller Brewing (USA) and Forster's Brewing Group (Australia) operate in Europe with their own divisions or through marketing agreements with major European firms.

Strategies

The leading firms have expanded in Europe mainly by acquiring local companies and by granting concessions by contract for the production under licence or the distribution of their own brands.

Heineken produces locally in the Netherlands. France (Société Générale de Brasserie, the second biggest firm in the market), Greece, Spain (with a majority share in El Aguila), Italy (through controlling interest in Birra Dreher, the second biggest firm on the market) and Ireland.

The BSN group leads in its own country, with a 100% holding in Kanterbrau and Kronenbourg). BSN has become stronger on many markets by way of joint ventures with European firms and take-overs carried through over the last few years. In Italy, BSN leads through its holding in the Peroni company. The group has shareholdings in Belgium (Alken-Maes), Spain (Mahou, and Cervezas San Miguel since 1992) and Greece.

The strategy of all the multinationals named is to diversify production between sectors, to create an international market for their own brands and to introduce new products (alcohol-free and light beers).

ENVIRONMENT

The main ecological problems affecting the sector relate to packaging. While the industry mainly uses returnable packaging, non-returnable bottles and cans, particularly for home consumption, raise the problem of containers, recycling and waste disposal. For home consumption, 330 ml bottles are mainly used but the expansion of supermarket sales has made returnable empties unpopular. Can packaging restricts recycling efforts as no widespread aluminium recycling efforts have been established.

REGULATIONS

The "pure beer law" (Reinheitsgebot) in force in Germany since the 16th century and in Greece since 1922 has come under dispute in the Community. According to this law, beer must be made only of four ingredients: hop, malted barley, yeast and water. The enforcement of this law for imported beers in practice prevented the marketing of many types of beer brewed in the EC from ingredients not allowed by the pure beer law.

In 1987 the European Court of Justice made two rulings finding against the two Member States on the grounds that, by prohibiting the sale of beers legally brewed in another Member State but not in compliance with their laws, they were in breach of their obligations regarding the free circulation of goods as laid down in Article 30 of the Treaty.

OUTLOOK

The high levels of consumption in the northern countries suggest that demand will stay at its present level or decline. Germany would seem to be the only exception to this trend. In that country, further room for growth is foreseen, due to the current success of new segments of the market for low-alcohol beers.

Source: Prometeia

The Spanish market offers the most interesting prospect in southern Europe. Sales are still showing sustained growth and the vigour of the market suggests that the product will make further inroads and that consumption will increase at the expense of wine.

Wine consumption is often used as a guide for determining the situation of the beer sector. In Italy, falling wine consumption has for a long time fuelled expectations that beer drinking will increase. At the moment, however, the real alternatives to alcoholic drinks are alcohol-free products, chiefly soft drinks, and mineral waters.

Risks for the industry relate to population changes and increasing emphasis on the health and safety factors to the disadvantage of all alcoholic drinks. Emerging opportunities relate to the development of alcohol-free or low alcohol beers, and especially light beers, whose main drawing card lies in the close association with the taste and image of more traditional products, stronger outdoors eating habits and consumer targeting of the elderly and teenagers particularly through alcohol free drinks.

Soft drinks, mineral waters

NACE 428

The market for soft drinks is expanding continuously, while mineral waters are growing the fastest. Despite raising environmental issues, the use of PET plastic containers has slackened the grip of the distributive factor and has widened companies' action range.
There has been increased concentration in the mineral water branch as a result of take-overs but local firms are still strong, more especially in areas where glass containers are still used on a large scale. The market for soft drinks is controlled by multinationals. Isotonic beverages continue to experience strong growth.

INDUSTRY PROFILE

Description of the sector

The sector covers ready-to-drink soft drinks, water based drinks, optionally sweetened, acidulated, carbonated and which may contain fruit, fruit juices and salts.

Production in the sector is not specialised. Its geographical distribution depends on national consumption and the existence of springs in the case of mineral waters. In the mineral water market, companies (multi-national and national) draw mainly from licensed springs. In the soft drinks sector, the multinationals operate with international brands and produce in the individual countries.

Recent trends

The market has expanded enormously over the last ten years. At current prices, the average annual increase has been around 9% for both production and apparent consumption, which is equivalent to 4.5% in real terms. Extra-EC exports have risen by an average of 9% (7% in real terms) and the trade balance has shown a constant and fast growing surplus. Employment has been virtually unchanged.

The market for mineral waters has grown more than that for soft drinks. Any further expansion of the mineral waters branch depends in particular on higher demand in countries where the product is still at not well established e.g. the United Kingdom.

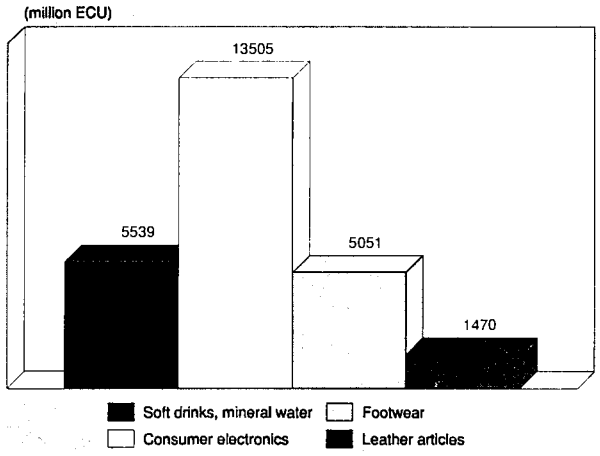
Added value is the highest in Germany followed by France, Great Britain (due to the large volume of soft drinks) and Spain. Even though the size of the Italian industry is much the same as the French and bigger than the Spanish, its added value is much lower.

Foreign trade

Trade is mainly between Member States. Intra-EC imports account for over 90% of total imports and this has been the case since the early 1980s. In extra-EC trade exports are five times greater than imports. In relation to production and consumption, extra-EC trade is insignificant, as exports account for barely 2% of production and the figure for imports is virtually nil.

Until recently extra-EC exports were primarily absorbed by the US and EFTA countries while since 1992 Japan is rapidly gaining importance as an external market. Extra-EC imports come mainly from the EFTA countries and to a small extent from the United States.

Figure 1: Soft drinks, mineral waters
Value added in comparison with other industries, 1992



Source: DEBA

MARKET FORCES

Demand

The growth of the market has benefited from the general trend towards health products, with a consequent move towards the consumption of soft drinks at the expense of alcoholic drinks. Total per capita consumption figures are very high. The leading drinkers of mineral waters per capita are the Italians (115 litres) followed by the Germans, French, Belgians and Luxembourgers (80-90 litres). Per capita consumption of soft drinks is highest in Great Britain (over 100 litres) followed by Germany, the Netherlands and Spain (Source: Consumer Europe 1993).

The market for mineral waters has achieved the highest growth as it has been replacing drinking water, particularly in countries where the quality of the latter is becoming worse and consumers are becoming more health conscious. A powerful stimulus to the market has been given by the convenience arising from the use of plastic containers for carbonated waters, using PET in particular, compared to glass. Although packaging is

gaining importance in product differentiation there are divergencies between countries. Germany is a noted example where awareness of environmental problems and legal restrictions have slowed the progress of plastic containers. Overall, in the soft drinks market, plastic packaging has been a growth factor and has given special impetus to home consumption.

Supply and competition

There is little competition between Community countries and even less from outside the EC. Regarding national markets, the rapid growth of the mineral waters branch has attracted the attention of major multinational companies. However, internationalisation has been limited by the fragmentation of supply, with its numerous brands and springs, matched by the regionalisation of consumption. In the soft drinks market a major factor has been the presence of multinationals which, by making use of advanced marketing techniques, have brought soft drinks to the centre of the market for non-alcoholic drinks. In addition, the market is now so partitioned that a growing range of consumer preferences can be covered.

Production process

The use of PET has enabled firms to widen their range of distribution, thus favouring a moderate measure of concentration in production. The most recent innovation are light and fruit-based soft drinks and flavoured and slightly carbonated mineral waters.

INDUSTRY STRUCTURE

Companies

Over the last few years supply has become more concentrated in the mineral waters sector. Two multinationals, Nestlé (CH) and BSN (F) control 30-35% of the Community market. Nestlé and BSN are the two leaders in France with about a 70% share, followed by Castel. In Italy, the four leading groups (Garma, Nestlé, BSN and San Benedetto) control over 50% of the market. In Germany, supply is more fragmented: the main firms have no more than a 10% share each (Ueberkinger, Bitburger Brauerei, Brau & Brunnen). The soft drinks market

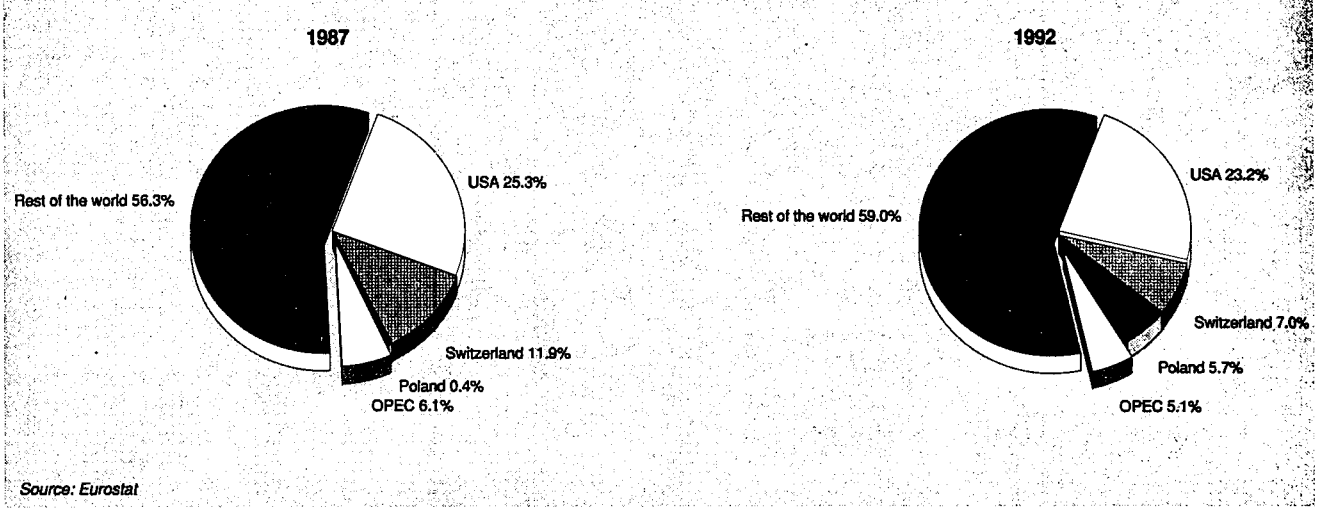
Figure 6: Soft drinks, mineral waters
Destination of EC exports



Source: Eurostat

is more concentrated than the mineral waters market, two companies - the leader Coca Cola (USA) and Cadbury Schweppes (UK) control 45% of the Community market. However, it is important to note that Coca-Cola is a brand owner more than a producer, operating a licensing system (although the company has recently started to take over some of its bottlers, e.g. in France, Belgium and the Netherlands).

Strategies

Take-overs started a little later for mineral waters than for other branches of the food industry but have significant enough to change the pattern of supply. The outstanding example is the take-over by Nestlé of Perrier, the leading world group. However, in the wake of this deal the Swiss multinational had to undertake, by decision of the EC Anti-trust Commission, the sale of the Volvic brand to BSN, as well as a further eight other Perrier brands held by the Société commerciale des eaux du bassin de Vichy, which will go to Castel. Through Perrier however, the Nestlé group now controls many major springs in a number of countries (United Kingdom, France, Spain, North America, Italy).

BSN, which trades in Italy through Italaquae, has reorganised its holdings in that country by selling Fabia and Sangemini to Terme di Acqui and by concentrating its efforts on the Ferrarelle and Boario brands. The Italian market has also been entered by Garma, which has bought the market leader, Fonti Levissima, together with other brands.

In the soft drinks sector, the multinationals generally operate in the various markets either by granting production licences to national firms or through their own establishments. In this market, strategy concentrates on marketing policies, distribution, diversification of products and investment in advertising. In the soft drinks markets generally and in the market for mineral waters in particular, local firms have nevertheless maintained a major role, especially in market areas where glass containers are still used on a considerable scale and distribution is the decisive factor.

ENVIRONMENT

The soft drinks sector is affected by the environmental debate, which concerns in particular plastic containers. The Community has tried to deal with the question of packaging through Council Directive 85/339/EEC on the use, recycling, re-use and disposal of containers for consumable liquids. This Di-

rective has been applied in different ways in Member States, with consequent obstacles to the free movement of products.

In Denmark, apart from 3,000 hectolitres per annum per producer, beer and soft drinks must be marketed exclusively in approved re-usable containers, and this restriction has been upheld by the European Court of Justice. In Germany, manufacturers and distributors must take containers back for recycling. In the case of drinks, a deposit of 0.50 DM has been introduced for non-returnable containers. In France, a decree was promulgated in April 1992 concerning the disposal of waste containers and the same issue was dealt with in Belgium by an agreement reached in 1990 between the government, producers, distributors and users of containers; the Netherlands have set the target of reducing container waste by 10% by the year 2000 and of increasing the percentage of containers recycled. Italy has also adopted legislation on the disposal and recycling of containers for consumable liquids. In particular, Law 475/88 sets minimum targets for the recycling of containers (50% for glass and metal, 40% for plastics and poly-composites and from March 1993 onwards there should be penalties for failing to meet targets. In 1992, at Community level, the EC Commission in any case approved a draft directive aimed at harmonising Member States' policies on containers.

OUTLOOK

The demand for non-alcoholic drinks still has ample room for expansion. Overall, growth margins depend on a further drop in the consumption of alcoholic drinks. The highly fragmented markets and the continued existence of geographical areas where consumption is still very limited suggest that markets will grow steadily.

In the soft drinks sector, isotonic drinks and still drinks (including fruit-based drinks) are currently being introduced or having their life cycle extended. The introduction to the European market of decaffeinated colas is a positive response by the industry to consumers' differing requirements. The market for drinks taken with meals also offers growth possibilities for mineral waters. A further growth factor is the increasing demand for health products in general. Here, mineral water is a direct competitor of soft drinks.

Regarding risks to market outlook one would include health attitudes working against carbonated drinks, increased costs resulting from legislation concerning the disposal and recycling of containers. Regarding opportunities the expansion of mineral water in certain national markets seems likely while growing health consciousness should be working in favour of mineral waters and light drinks as well as the wider use of sports drinks.

Tobacco
NACE 429

Over 1983 to 1992 production and apparent consumption of tobacco products in the EC at constant prices decreased steadily. The whole market is sustained by the cigarette branch, albeit subject to legislative restrictions and anti-smoking campaigns. Possibilities for expanding production are connected with exports, which have risen rapidly in recent years.

INDUSTRY PROFILE

Description of the sector

Within the tobacco sector the following activities can be distinguished:

- growing and initial processing of tobacco;
- manufacturing of tobacco products.

The principal outlet for industrial processing of tobacco is the smoking-tobacco market, covering the following finished products:

- cigarettes, cigars, cut tobaccos for hand-rolled cigarettes and pipe tobaccos;
- snuffs and chewing tobaccos.

The most important production subsector is cigarette-making.

Recent trends

Although over 1983-1992 apparent consumption and production declined in real terms exports grew favourably. The stagnation in the sector affected the trend of employment, which fell at an average annual rate of 5% during that period.

However, strong export performance to non-EC countries, particularly over the period 1988 to 1992, helped to halt the sharp decline observed over the first part of the 1980s allowing production and apparent consumption to stage a weak recovery. In recent years, however, imports have also increased considerably.

The main producing country in the EC is Germany, which in 1992 accounted for 29.7% of the total number of cigarettes made. Next come Great Britain and the Netherlands, with 17.9% and 12.7% respectively. The leading producers are different for the other categories. In 1991 Belgium produced 26.6% of the EC's output of cigars and Denmark, with a volume share of 29.8%, was the biggest producer of pipe tobacco, while 49.8% of tobacco for hand-rolled cigarettes was produced in the Netherlands.

International comparison

EC production of cigarettes in recent years was comparable to that in the United States, but displayed a more favourable trend. In 1992 the number produced reached 708 billion, with an average annual increase over the last five years of 1.7%, against 654 billion in the United States and an average decrease of 1%. During the same period, apparent consumption increased in the EC at an average annual rate of 0.8%, to 615 billion cigarettes, while in the United States it fell gradually to 500 billion cigarettes. The Japanese market is about half the size of the EC market; production and consumption (303 billion cigarettes in 1989) are stable. The world picture shows no change, with the important exception of China, which leads for both production and consumption (1600 billion cigarettes in 1989); and substantial growth is still taking place.

Foreign trade

The EC's balance of trade in tobacco products has constantly shown a surplus over the past decade, with an improvement in the trend during the last few years. From 1983 to 1992 the proportion of output exported to non-EC countries, increasing at an average rate of 4% per annum. With regard to destination areas, the share of the EFTA countries and the United States decreased during the last five years.

Similar trends were observed with respect to extra-EC imports which, however, represent only a small proportion - about 1% - of consumption. Overall, the EC had, in 1992, a 27% share in the volume of world imports and a 35% share in world exports of cigarettes.

Intra-EC trade at current prices grew at an average annual rate of about 7% during the past decade. In 1992 its value was about double that of extra-EC exports and more than five times that of extra-EC imports. The leading net importers in the EC are Italy, France and Spain. The country with the highest level of exports in terms of value is the Netherlands, followed by the United Kingdom and Germany.

MARKET FORCES

Demand

Overall demand for tobacco products in the EC ceased to grow long ago. The market is, however, sustained by the cigarette subsector, which is the most important, with a 90% share in terms of value, the volume of output having increased by 4% during the last five years while that of other products fell. Consumption of tobacco is adversely affected by awareness of the health risks, the increase in taxes on cigarettes and the limitations imposed on advertising. Filter cigarettes represent over 95% of sales in the leading markets, with the partial exception of France (80%). Consumers are turning more and more to cigarettes with "mild" tobacco mixtures and a low tar-condense and nicotine content. Targeting of female smokers is increasing.

Within the EC, the market which has shown the greatest growth in recent years - leaving aside Germany, where it has benefited from the reunification process - is that of Spain. Spain is the only country among the main cigarette consumers where per capita consumption has appreciably increased; elsewhere - particularly in Italy and the United Kingdom it has decreased.

Supply and competition

The state of competition in the sector is affected in some of the countries with the highest consumption by the presence of state monopolies which control at least half of the market. Apart from this aspect, supply is characterised by the multinationals in the sector, which rely on a high degree of brand loyalty. The increase in taxes has accentuated the segmentation of the market, a large section of consumers having changed to less expensive brands.

INDUSTRY STRUCTURE

Companies

The tobacco products sector is characterised by the high concentration of supply. In the cigarette subsector, for example,

Figure 4: Tobacco

the share of the four leading companies (monopolies or multinationals) in the five main markets ranges from 85% to 95% in volume. In 1991 the monopolies held nearly 50% of the market in France (Seita) and Italy (State Monopoly) and 66% in Spain (Tabacalera). Within the EC the main private tobacco companies are in the United Kingdom: these are multinationals such as BAT Industries, Hanson/Imperial and Rothmans International, the only companies capable of holding their own against the American multinationals (Philip Morris, American Brands, RJR Nabisco), with substantial shares in various markets. In particular, BAT Industries ranks third in Germany with a 21% share in terms of volume in 1991, behind Philip Morris (33%) and Reemstman (24%); Rothmans International controls 13% of the French market, preceded by Seita (48%) and Philip Morris (24%).

The penetration of the multinationals in the EC countries is assisted in some cases by agreements with the monopolies. In Italy Philip Morris sells its products to the State Monopolies, which distribute them through their own channels, while some of the tobaccos are produced directly by the Monopolies under licence, as is also the case in Spain with Tabacalera. There are also, however, some cases of alliances between the multinationals themselves: Rothmans, for example, markets the Philip Morris and BAT Industries brands in the United Kingdom and promotes and has rights for some American Brands cigarettes outside the United States.

REGIONAL DISTRIBUTION

At world level there is a certain degree of overlapping between production of leaf tobacco and finished products. Asia provides the largest proportion of raw material, thanks in particular to China, which alone accounts for about 40% of world production in terms of volume, followed by the United States with 10%. The EC share is 6% and, within it, Italy and Greece together provide about 80% of production. China is also by far the leading cigarette-producing country. It is followed, far behind, by the United States, with a volume of 12% in 1992. The EC, which is the main importing area for leaf tobacco, produced 13% of world output of cigarettes in 1992.

REGULATIONS

The development of legislation has a considerable effect on the market for tobacco products, especially in the case of cigarettes. The most important limitations imposed on con-

sumers and on the industry result from the gradual spread of the ban on smoking in public places, the requirement that warnings about the harmful effects of smoking be shown on packaging and the restrictions on advertising. An EEC directive has prohibited TV advertising, but the possibility of a decision to prohibit all direct or indirect advertising of tobacco is still under discussion, and is being opposed by some EC Member States. The tobacco industry has had to and is still having to take action to implement the 1988 EEC directive which called for a reduction in the tar-condense content to 15 mg per cigarette with effect from 1993 and to 12 mg from 1998 onwards. Lastly, proposals for harmonising the level of taxation in the various Member States are being examined at EC level.

OUTLOOK

Despite the legislative restrictions and the anti-smoking campaigns, the market for tobacco products has not collapsed and has actually grown slightly in recent years, mainly thanks to cigarette consumption. The expansion is, however, mainly

due to the reunification of Germany. During the next few years the volume of cigarettes smoked, too, is likely to decrease, as has already occurred in the case of other tobacco products in the main EC markets, except Spain. The difficulties imposed on consumption by legislation and the social pressure against smokers might lead to a reduction in their number. The best opportunities for companies in the sector are provided by the increase in exports to the countries of Eastern Europe and to developing countries, where consumption is growing.

Overview

NACE 43, 44, 45

The sector can be divided into the upstream industries of textiles and leather and the downstream industries of clothing and footwear.
There is significant linkage between the two with the clothing industry absorbing half of the output of the textile industry and the footwear industry absorbing almost half of the leather production.
The industry is important in employment terms with a labour force of around 2.7 million people in 1993. This, however, represents a decline of some 27% over the previous decade. Growth in production in the sector lagged behind growth in consumption between 1983 and 1993, leading to a sizeable balance of trade deficit.
The output of the industry can be either mass-produced items or higher quality goods serving market niches. The former is now subject to intense competition from low cost producers in developing countries and EC companies have yielded market share to these countries in recent years. The higher quality end of the market is less determined by price, and EC firms possess a competitive advantage in relation to design, market response and distribution.

INDUSTRY PROFILE

Description of the sector

This overview covers the four related industries of textiles, leather, clothing and footwear. NACE 43 covers the textile industry which produces natural and synthetic fibres, NACE 44 covers the tanning and dressing of leather. NACE 451 and 452 comprise the footwear industry covering mass produced indoor and outdoor footwear, hand-made footwear and other special footwear. NACE 453 covers the manufacture of clothing and clothing accessories from various materials.

The textile industry covers a variety of production processes - fibre preparation, spinning, weaving, knitting, finishing and dyeing, and uses both natural and man-made fibres. It includes the manufacture of household and technical textiles - the latter being a rapidly growing sector. The clothing industry covers the manufacture of garments and clothing accessories.

The two industries together account for some 9% of manufacturing employment in the EC, employing nearly 2.7 million people in 1992. In terms of value added, the industry is mainly concentrated in Italy, Germany, France, and the UK.

EC foreign trade in textiles and clothing is subject to the MFA (Multi-Fibre Arrangement), which dates from 1974. Under this, bilateral agreements to limit imports of textile and clothing, from developing countries and NICs, are negotiated by the EC. The USA follows the same practice. In the GATT Uruguay Round, which was concluded in December 1993, it was agreed to phase out the MFA over a period of ten years from 1995. The intention was the eventual integration of the textile and clothing trade into the GATT, on the basis of strengthened GATT rules and disciplines.

The footwear industry absorbs just under half of leather output in the EC, with the garment industry accounting for over one fifth.

Recent trends

Overall consumption rose significantly faster than production in the period 1983 to 1993, with the value of production falling in the 1990s. Production growth was sluggish in the latter half of the 1980's partly a result of the poor export performance in that period.

Extra-EC exports grew rapidly in the early 1980s, dipped in the 1986 to 1988 period but recovered to a 1992 level 73% above the 1983 level in current prices. Extra-EC imports grew dramatically in the late 1980s and early 1990s. However, this growth slowed significantly in 1992. Between 1983 and 1992, the average real annual extra-EC import growth rate was over twice the extra-EC export growth rate.

Employment fell in the sector by a total of 22%, from 1989 to 1993. The largest fall in percentage terms was in the leather industry, in which employment fell by 38%.

Footwear is the most export oriented of the four industries with over one fifth of its output going to extra-EC markets. Textiles and leather have similar export orientation with about one-sixth of production value sold outside the EC while about a tenth of clothing production is sold outside the Community.

Textiles and clothing

Both the textile and clothing industries have suffered from falling production in recent years. Production rose from 1983 to 1986, but then fell off, to reach nearly 10% below the 1985 level in 1993. Consumption in both textiles and clothing has risen, by 1.1%, per annum between 1983 and 1992. This has however been accounted for by imports growing faster than exports, especially of clothing. Despite expanding EC exports of textiles and clothing, the trade balance deteriorated continuously between 1983 and 1992, reaching a deficit of 13.5 billion ECU in 1992. Employment in both industries has been falling, on account of increasing labour productivity in both, as well as on account of market trends. In 1993 it is estimated that total employment was 23% below the 1985 level - a loss of over 700 000 jobs, of which 400 000 were in textiles and 300 000 in clothing.

International comparison

The EC is the origin of 20% of world production of footwear. In the leather industry, Europe (primarily the EC) represents nearly half of world trade, with the value of leather production over three times the level of the USA and Japan production combined.

Production of textiles and clothing is 37% larger in the EC than in the USA, and more than 4 times as large as in Japan. From 1985 to 1992, in current prices, production has increased most in the USA (19.6%), followed by the EC (14.8%), and Japan (11.8%).

In the USA the rise in production has been related to strongly expanding exports. In 1992, these were close to the level of Japanese exports, although they are still much lower than EC exports.

In recent years, textile and clothing production has decreased most strongly in Japan and the EC, while in the USA there was a slight recovery in 1992, mainly in textiles. In the EC, production decreased more rapidly in clothing than in textiles, whereas in Japan the textile industry was more badly hit than clothing.

Foreign trade

The ratio of extra-EC exports to extra-EC imports hovered around parity up to 1986 but subsequently fallen to just over two-thirds in 1992. Leather is the only industry to display a ratio in excess of one, while footwear, which had a ratio of 2:1 in the early to mid 1980s dropped below one in 1991, although there was some recovery in 1992. Consistent with the deterioration in the trade balance, extra-EC imports now account for a greater proportion of total trade than in 1983.

EFTA countries are the principal destination for EC exports in 1992, accounting for nearly 32% of exports for the sector. The USA remained the second most important destination, although its significance has decreased in relative terms since 1987.

China has nearly doubled its percentage share of EC imports since 1987 and is now the single most important source of imports. In particular it accounts for 15% of imports in both footwear and clothing. Other East Asian countries are also important sources of materials and goods: South Korea and Indonesia in the footwear industries and India in the leather sector.

Total production in the EC fell by 3% in real terms from 1983 to 1993. In that period, the proportion of production exported to extra-EC markets increased by 20%. Intra-EC trade rose by 99%. This suggests a declining dependence on national domestic markets and increased geographical diversification, particularly to destinations within the Community.

Import penetration rose to about one fifth of total consumption in 1992 from under one sixth in 1982. Penetration is highest in clothing, at almost 25%, and in footwear, at almost 24%. Apart from the leather industry, which experienced an increase of 24% and textiles which increased by 34%, import penetration has increased significantly in each of the other sectors.

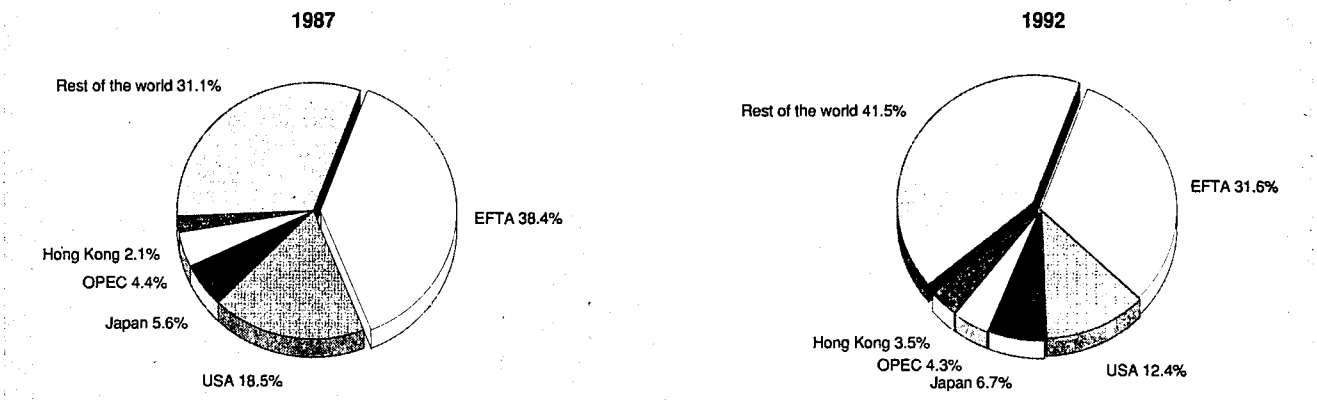
Textiles and clothing

During the last ten years, the volume of exports of textiles and clothing from the EC has been growing at an annual average rate of 5.2%. Imports, however, have grown much faster, at an annual average rate of over 13%.

The clothing industry in particular has had to face increasing competition from lower-cost countries, even though its export record has been a good one. its exports have, not unexpectedly, been in a higher price bracket than its imports.

Clothing manufacturers have to an increasing extent been resorting to outward processing trade (OPT). This involves the

Figure 4: Textiles, clothing, footwear, leather
Destination of EC exports



Source: Eurostat

export of EC fabrics to nearby countries in East Europe and the Mediterranean rim, for making up into clothing. This clothing is then re-imported into the EC. Such imports now make up some 10% of EC clothing imports.

OPT has helped the EC textile industry, and has helped EC clothing manufacturers who practice OPT to keep up their level of profitability. It has however, at the same time, been one of the factors which have reduced EC clothing production.

In 1992, 60% of EC exports of textiles and clothing went to 10 countries, among which were Switzerland (10.9%), the USA (10.3%), and Austria (9.9%). These are also the largest EC customers for textiles and for clothing separately. In comparison with 1988, export shares tended to decrease for the major customers and to increase for the smaller ones,. like Poland, Tunisia, and Morocco. These increased their imports from the EC mainly in textiles, in relation to expanding clothing OPT.

Among major countries of origin for imports, China and Hong-Kong were the largest suppliers to the EC of clothing in 1992, while Turkey and China were major textile suppliers. Thus, China appears as the major country of origin for textiles and clothing in 1992. Mediterranean countries increased their share in total imports between 1988 and 1992.

MARKET FORCES

Demand

The nature of the products of all four sectors is such that fashions and tastes are key factors in determining demand. Product life cycles can be very short as fashions change quickly. This forces companies to be ready to respond very quickly to shifting demand requirements and has moved producers towards shorter production runs and quick-response manufacturing. Most of the primary fashion centres of the world - Paris, Milan and Barcelona - are located in the EC. Thus EC producers have a competitive advantage in relation to speed of response to demand changes.

Product innovation in the downstream industries is driven by changing fashions and the developments of new fabrics in the textile sector. Thus, developments in the textile industry itself allow innovations in the clothing sector.

Textiles and clothing

Spending on clothing as a proportion of total consumer spending in the EC decreased over the decade, but the absolute level of consumption rose.

The apparent consumption of textiles and clothing has grown less, as an annual average, between 1988 and 1992 (0.2%) than between 1983 and 1988 (1.8%). While consumption of knitted fabrics increased from 1988 to 1992, woven fabrics lost ground. Among textile end-uses, household textiles and technical textiles also showed a fall in consumption in those years.

Both textiles and clothing have had to face difficult market conditions due to several factors, including growing import competition and declining production in end-use sectors. Important market shares within the EC have been lost to lower-cost imports from countries like China, Turkey and Hong Kong. Exports to advanced countries like the USA and EFTA countries have had to face similar difficulties as within the EC, but textile exports to East Europe and the Mediterranean rim have expanded owing to higher outward processing trade flows.

Footwear and leather

The output of the clothing and footwear industries are almost completely directed to final consumer markets and is therefore affected by income developments in the general economy. Some output is sold to manufacturing or service industries, especially medical clothing or protective footwear. On the other hand, textiles and leather, are largely used as inputs into other industries, rather than being sold to end consumers.

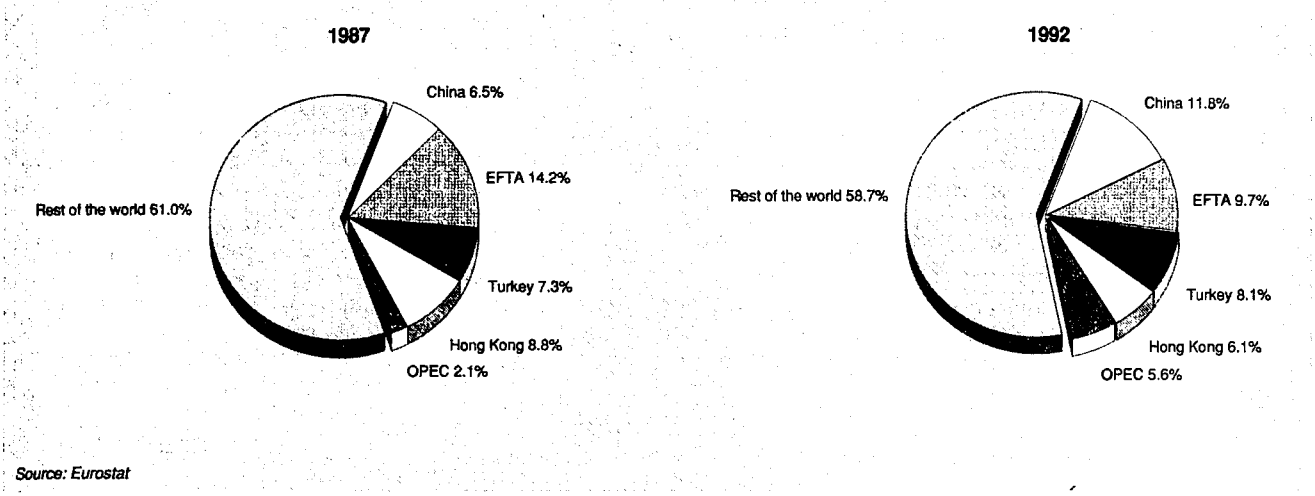
While both footwear and clothing are necessities up to a certain income level, they become discretionary beyond this level.

The EC market for these two products can be divided into mass produced items and high quality goods for which price is less of a determinant. The market for mass produced items is being increasingly supplied by low-cost imports from newly industrialised or LDCs. In the mass production market, price remains a key consideration and EC producers have lost market share because of the inability to compete with firms whose labour costs, in particular, are much lower than their own. In the high quality products, price is not as important and price elasticity is lower.

Supply and competition

Production in the EC lagged behind growth in consumption between 1982 and 1991, as cheaper imports gained increasing market share. Much of this is due to the competitiveness of companies in countries with lower labour costs, especially in East Asia. This fall in production has been accompanied by a structural rationalisation in the sector, with larger firms closing plants and some smaller firms closing altogether.

Figure 5: Textiles, clothing, footwear, leather
Origin of EC imports



Source: Eurostat

Some firms in the sector have relocated production plants to lower labour cost countries in order to achieve lower costs of production and aid competitiveness.

Distribution in the industry has become increasingly concentrated as some of the larger producers have either developed their own retailing networks or entered into alliances with existing retail chains.

Investment in the sector in the recent past has focused on modernisation and automation rather than expansion, and overcapacity is not a problem, particularly in up-market products.

In the context of the completion of the EC internal market, national quotas will disappear and the use of Article 115 of the Treaty of Rome, which allows a country to exclude imports which would cause a serious market disruption, is likely to be greatly reduced.

Export development, seen as a key strategy throughout the sector, is hampered by trade restrictions in some of the potential destinations. Japan, for example, operates a restrictive trade policy vis-a-vis footwear and leather production.

Production within the EC is hampered by the difficulty or cost of obtaining raw materials from LDCs. Increasingly, LDCs are attempting to develop downstream industries and retain their raw materials for domestic value-added production at home. A case in point is the leather industry, where rawhides previously exported are being processed further in the country of origin. Production is also hampered by the costs associated with meeting environmental regulations which are more stringent than those in developing countries.

The industry is somewhat vulnerable to the volatility of world commodity prices, e.g. wool, cotton and raw hides. Profitability has been squeezed in the EC in recent years as wage cost outstripped productivity gains and the pressure of cheap imports prevented EC producers from increasing their own prices. Other costs, such as those due to expanding up-market output ranges, and the associated advertising and promotional costs to establish a market foothold, have squeezed margins further. However, the EC industry possesses a significant competitive advantage in the areas of design and quality.

Textiles and clothing

EC textile and clothing manufacturers have to achieve international competitiveness, while having among the highest labour costs in the world. Although labour costs have increased rapidly in lower-cost countries, disparities between them and developed countries still remain strong. The textile industry is considered as capital-intensive, but labour in the clothing industry still remains a major means of production. Recent innovations in technology point to a reduction in labour content in the long-term, but few clothing manufacturers are in a position to invest heavily in new and innovative machinery in the near future.

Competition in clothing has focused in recent years on reduced production costs through delocalisation strategies to lower-cost areas outside the EC. Among these, outward processing has developed rapidly. EC fabrics are sent (mainly) to East Europe and the Mediterranean rim, and re-imported as made-up garments to the EC under reduced tariffs and special quotas. This has favoured the competitiveness of clothing manufacturers in the EC, but also the EC textile industry through the utilisation of fabrics of EC origin.

Part of the textile industry operates in the highly innovative field of industrial textiles, in connection with other industry sectors like automobiles, aeronautics or medicals. Competition mainly operates between industrialised countries, based on research and development efforts and investment in new technology. Unlike the clothing industry, the EC still has a strong competitive position in this area.

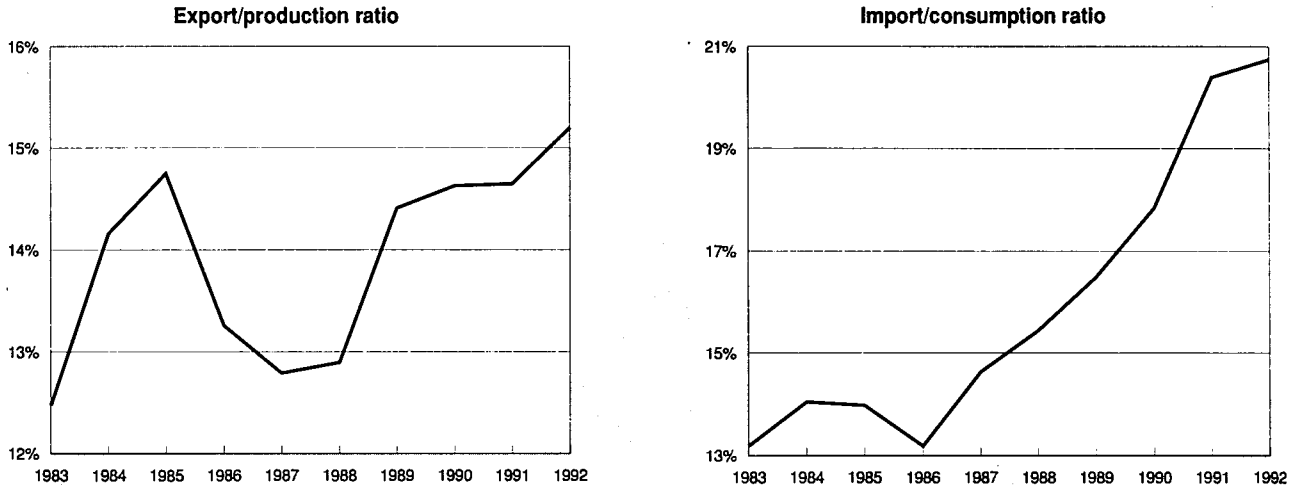
Production process

Employment in the industry has decreased dramatically since the MFA was introduced in 1973. Much of this decline can be attributed to technological advances and the inevitable shedding of labour. There is substantial use of outworkers, in footwear and certain sectors of the leather goods industries. While the introduction of technology in the clothing and footwear sectors was more limited than in textiles and leather, the application of computer aided design (CAD) and computer aided manufacture (CAM) have become more widespread.

The use of just-in-time (JIT) systems has also become an important feature within the industry particularly in the clothing and footwear sectors. An example of an integrated JIT manufacturing and retailing is the Benetton group which links retailers, production units and warehousing and allows rapid response to market changes or trends.

In addition, the level of labour skills is higher in the EC than elsewhere (including the US), giving EC producers a competitive advantage in the production of higher quality products. The EC-sponsored RETEX programme is enhancing the quality of labour in the regions where it is being implemented. The FORCE and EUROFORM Programmes also assist in the vocational training of workers for the industry.

Figure 6: Textiles, clothing, footwear, leather
Trade intensities



Source: DEBA, OETH, Cotance

Product innovation and development is an important strategy for EC industry, particularly in the context of declining competitiveness for mass produced goods.

Textiles and clothing

In the EC stock of spinning machinery, nearly 60% are short-staple spindles, used for fibres such as cotton, and nearly 40% long-staple spindles, used for wool and other long fibres. This contrasts with the worldwide situation, where short-staple spindles predominate. The difference reflects the fact that the EC is a large wool producer on the world level.

In weaving, the EC textile industry uses a high proportion of modern shuttle-less looms, unlike many Asian countries. Knitting machinery has become increasingly automatic and capital-intensive in the EC, as well as in other developed countries.

Technological innovation in clothing has been more in the use of new fibres and fabrics than in the process of manufacture, which is still relatively labour-intensive, but even so there have been important productivity gains in this sector.

Recently investment has decreased both in textiles and in clothing. Due to its more capital-intensive nature, investment in the textile industry is still more than four times larger than in clothing, in ECU terms.

From 1988 to 1992, investment in textiles and clothing decreased by an annual average rate of 3.5%; it fell by 4% in textiles and increased slightly by 0.5% in clothing. After 1991, investment decreased in clothing also.

INDUSTRY STRUCTURE

Companies

There are approximately 160 000 firms in the EC industry employing 2.7 million people, despite the sharp reduction in the number of employees over the past decade. A significant number of firms within the sector are small, employing less than 20 people. In the leather industry north European tanneries tend to be larger than their southern counterparts. Italy has the lowest ratio with an average of 10 workers per plant compared to an average per plant of 90 workers in Germany.

Most of the smaller firms supply domestic or neighbouring markets and the level of extra-EC exports from these firms is low.

Textiles and clothing

In terms of turnover and employment, the EC textile and clothing industry is mainly incorporated within enterprises employing more than 20 people, although a large number of small firms operate in clothing. In 1992, the industry was composed of 143,000 enterprises, of which 117,000 had less than 20 employees.

The small size of most firms is a major feature of the clothing industry, while in the textile industry, given higher capital requirements and technological skills, the average firm is larger.

Among the largest textile and clothing companies within the EC, several have their activities as well in textiles as in clothing (e.g. Coats Viyella UK), Benetton (I) or Courtaulds (UK)). Others are specialised in certain product lines, like the large Belgian carpet manufacturer Beaulieu.

Strategies

Faced with competition from low cost producers abroad, EC producers have reacted by moving up-market into the production of higher quality goods, which are less price sensitive and are not amenable to the same degree of mass production as standard items. This strategy is consistent with the spirit of the MFA as originally constituted. Northern European countries in particular have moved towards producing higher quality goods. Countries such as Spain, Greece and Portugal have not moved as quickly towards up-market goods, and remain vulnerable to low cost competition from outside the EC.

In the downstream industry of footwear the move away from mass produced items has necessitated increased investment in advertising, branding, adoption of quality management systems of production and distribution, and the implementation of JIT systems. In the leather and leather goods sector, companies have also identified more profitable, though often relatively small, market niches.

The prospect of a move upmarket by East Asian producers however, will increase the competitive threat faced by the industry in the EC and further strengthen the need for quality in production and distribution.

Textiles and clothing

Both textile and clothing manufacturers have to operate in a highly competitive industry. Technological innovations, and new production management strategies, such as quick-response and just-in-time, have helped to improve the industry's competitiveness.

In textiles, modern automatic technology has made it possible for medium-sized plants as well as large plants to be viable. Textile firms now tend to be less vertically organised than previously, and prefer to specialise on a limited number of processes.

The clothing industry has made several advances in the sphere of automation, but because of its continuing reliance on many labour-intensive processes, manufacturers have increasingly explored the possibility of subcontracting outside the Community, especially for long-run and lower quality products. The countries of East Europe and the Mediterranean rim have been important here because of their proximity.

REGIONAL DISTRIBUTION

Textiles and clothing

The textile industry is located in a relatively small number of regions, with a heavy population of workers. The clothing industry is more widely spread, in relatively smaller pockets of employment.

When the two industries are considered together, a number of regions stand out for their heavy concentration of employment. Employing more than 150 000 workers are Lombardia (I) and Cataluna (E). Employing between 100 000 and 150 000 are four regions - Veneto (I), Bayern and Nordrhein-Westfalen (D), and Norte (P).

There are eight regions employing between 50 000 and 100 000, three each in Italy and France, one in Germany and one in the UK. There are fourteen regions employing between 25 000 and 50 000.

The figures are more significant when looked at as a proportion of all industrial employment in a region. Regions with over 30% of industrial employment in textiles and clothing are Norte (P), Kentriki Makedonia (GR), Dytiki Ellada (GR), and Castilla-la Mancha (E). It is noteworthy that the last three are not included in those areas with the heaviest absolute level of employment.

Regions with 20-30% in textile and clothing employment, as a proportion of industrial employment, are nine in number, including two in Portugal and two in Greece. Two further Greek regions have textile and clothing employment of 15-20%. It is evident that in Greece and Portugal, two of the EC's least prosperous Member States, regional dependence on the textile and clothing industries is of considerable importance.

Footwear and leather

The industry is of considerable social and economic importance in certain regions of the EC, which tend to have both the upstream and downstream industries. Three Italian regions the Marches, Tuscany and Veneto account for almost two-thirds of footwear employment in Italy. The centres of Santa Croce sul Arno, San Miniato, Castelfranco, Montopoli and Fucecchio produce about 90% of all Italian sole leathers. Thus, structural changes affecting the industry tend to have a disproportionate effect on these regions. To date contraction of the leather industry has hit northern EC countries most severely but is increasingly affecting southern Member States.

ENVIRONMENT

Compliance with national and EC regulations imposes costs on EC producers which are not felt by producers in other countries where such regulations and controls are much more limited or not implemented vigorously by the authorities.

Textiles and clothing

In the manufacturing processes, textiles pose greater difficulties than clothing. There is heavy use of energy in man-made fibres, and many cleaning processes with natural fibres (as well as the use of pesticides etc. in their growth). The danger of pollution in water - used widely for many textile processes - has been countered by EC and national regulations (which affect industry generally) on effluents discharged to water.

Clothing manufacture raises fewer environmental problems. Here however the question of the final disposal of garments raises difficulties for synthetic fabrics, because these are not biodegradable, unlike fabrics made from natural and cellulosic fibres.

There are heavy costs involved in improving environmental standards. The EC Commission has estimated that environmental costs in dyeing and finishing account for between 3.5% and 9.2% of total costs, depending on the Member State involved.

An American study of a polyester garment has shown that one of the greatest sources of environmental damage arises from the laundering and cleaning of clothing. It found that over 80% of energy requirements were related to consumer use, as well as 90% of solid waste emissions.

REGULATIONS

Textiles and clothing

The EC negotiated in December 1992 an extension of the MFA (Multi-Fibre Arrangement) for another year, and of the then existing bilateral textile arrangements for two more years. A further extension of one year was agreed in December 1993. The MFA makes provision for quotas on imports of particular textile and clothing products, negotiated through bilateral agreements.

Within the GATT and the Uruguay Round negotiations, which were concluded in December 1993, provision was made for the phasing out of the MFA over a ten year period from 1995. The intention was the eventual integration of the textile and clothing trades into the GATT, on the basis of strengthened GATT rules and disciplines. Market access negotiations were to be concluded by April 1994.

The transitional arrangement will have three phases, with an assessment of the situation before the end of each phase. The agreement contains a specific transitional safeguard arrangement which could be applied to products not yet integrated into the GATT.

In connection with the MFA and the related bilateral trade agreements, the European Commission has launched a textile anti-fraud initiative (TAFI) for the detection of anomalous imports. This initiative aims at preventing certain economic operators from subverting the intentions of the MFA agreements.

In 1991, the European Commission launched an export promotion scheme (EXPROM), which seeks to develop new markets outside the EC, including those for EC textile and clothing products, by investigating the potential of new markets and supporting exploratory missions and trade fairs.

The establishment of OPT quotas at EC level from 1st January 1993, as part of the Single Market process, requires the elimination of disparities in the interpretation of OPT regulation 636/82 between Member States. The European Commission

has proposed revisions to the regulation which aim to harmonise its application throughout the EC.

In the field of intellectual property rights, the European Commission has proposed EC internal legislation regarding the protection and registration of trademarks, models and designs in textiles and clothing. These anticipate forthcoming results from the concluded Uruguay Round.

In the area of research and development, the textile and clothing sectors have achieved much success and are one of only two sectors to have been invited to coordinate their research as part of a targeted programme under the Brite/Euram, and participate also in technological initiatives regarding SMEs. For SMEs, the initiatives developed by the European Commission, in the framework of programmes such an Interprise and Euro-partenariat, represent a helpful contribution to co-operation and the improvement of business contacts.

In 1992, the European Commission adopted a new RETEX programme, aiming at a diversification of production activities in those regions which are strongly dependent on the textiles and clothing industries, and have been defined as assisted regions by the EC. RETEX mainly focuses on "soft" measures, i.e. on the improvement of know-how within firms, cooperation between firms in the same region or sector, and the use of new technologies to improve quality.

The European Commission, in association with professional organisations also continues its initiatives as regards the improvement of statistical and economic information e.g. short-term and structural data and analysis, and the study of prospective scenarios for the industry, namely in the framework of the OETH.

Footwear and leather

In the footwear industry, bilateral trade arrangements existed at national level to control the import of low cost products from Asian and East European countries. These have been largely phased out and trade policy is increasingly determined at EC level. Many EC countries also provided assistance to domestic producers but most of these have been phased out and are being replaced by centralised EC programmes.

OUTLOOK

The recovery in world economies, while slower than expected, will lead to an increase in demand for the output of the industry although there may be some shifting of the importance of specific products within the sectors.

Imports are likely to continue to make inroads on EC markets due to their greater price competitiveness and the impact of a freer trade regime. Countries with low import penetration at present may be most at risk. Export market development will continue to be a key strategy for EC producers with new markets appearing for footwear and leather goods in increasingly prosperous Asian NICs. Success in this regard may depend on gaining access to markets currently protected such as the Japanese market.

In the longer term the ability of EC producers to develop higher quality products, to find new uses for existing products, and to respond quickly to market changes will determine their performance. The possibility of East Asian producers following EC firms up-market remains a threat and only serves to emphasise the need for quality and service in the manufacture and distribution of products. The EC leather industry is expected to face increased competition from developing countries in the purchase of raw materials and in the demand for finished leather. Within the footwear sector the move up-market by some developing countries means that new additional locations will begin to compete with EC producers.

The increased demand from East Europe provides an opportunity for EC producers, but one in which they will face substantial competition from the lower-cost producers. The admission of greater quantities of imports from East Europe will increase competition at the lower end of the EC market.

Textiles and clothing

Both the textile and clothing industries of the EC have been affected by the recession of the early 1990s, which itself has reflected that in the world economy as a whole. Even in 1993 the EC textile and clothing industries have remained depressed. In the first half of the year the volume of textile production was some 8% below that of the same period of 1992. Clothing production was down by a similar amount.

Employment in textiles and clothing together fell by 124 000 in 1991 and fell by 153 000 in 1992. In 1993 the fall was even greater, at 170 000 or over 9%.

The trade balance in textiles and clothing continued to deteriorate in 1993, and reached a level of over 14 billion ECU, nearly 6% above the 1992 deficit.

The slow rate of recovery of the world economy, including that of the EC, does not hold out good prospects for an upturn in the textile and clothing industries in the short to medium term. Some help however may be given by the strengthening of the USD since the last quarter of 1992. This has worked to the disadvantage of US exporters, and of exporters in those countries (such as Hong Kong) whose exchange rates are traditionally linked to that of the USA. Those EC member states who have substantially devalued their currencies since September 1992, on the other hand, have potentially benefited more than the average.

The consequences of the advent of the EC's Single Market at the beginning of 1993 are not yet clear. It may well affect the distribution of imports among member states, and may also lead to an increase of imports, if previously unfilled MFA quotas are now taken up.

It was one of the aims of the Uruguay Round of the GATT to phase out the MFA, and to return textiles and clothing to GATT rules. The agreement reached in the negotiations, which was concluded in December 1993, was to phase out the MFA over a period of ten years from 1995.

The phasing out of the MFA will occur gradually. In the medium term the recovery of the EC and the world economy will be among the principal factors affecting the EC's textile and clothing industries. Apparent consumption of EC textiles and clothing is expected to fall slightly in 1993-94. Production is expected to fall by 3.5% during this period, but exports are expected to rise by 1.5%.

During the period 1993-97 the EC's apparent consumption of clothing is anticipated to rise by 1% per annum, and that of textiles by a similar amount. production of clothing is expected to fall by 2% per annum, but that of textiles to remain unchanged. Exports of both are likely to rise - exports of textiles being linked partly to the expected growth in OPT.

In the longer term, a further growth in the delocalisation of clothing production to neighbouring lower wage countries is a strong possibility. As regards the textile industry, this is now very capital-intensive. Its growth will be linked partly to the fortunes of EC clothing manufacture. Growth will also depend on future high-tech developments, including those in technical textiles. If these developments continue to be successful, and market specialisation continues to be pursued, there might be little incentive for the industry to follow the clothing industry in delocalising production to lower wage countries.

Textiles
NACE 43

The textile industry comprises the production processes of fibres preparation, spinning, weaving, knitting, finishing and dyeing. It uses both natural and man-made fibres. The textile industry accounted for 3.5% of the value added of manufacturing industry in the EC in 1992, 4.1% of turnover and 5.5% of employment.
EC production of textiles (in volume) has been falling since 1990, and in 1993 was 7% below its 1985 level. Imports have increased faster than exports, and the trade balance became negative after 1986, but the exclusion of raw material imports would show an EC trade surplus of manufactured textiles. The sector's competitiveness has been influenced in particular by the evolution of exchange rates, especially against the USD.
Substantial fabric exports go to East Europe and the Mediterranean rim, for subsequent processing into clothing for re-import into the EC. This is OPT (outward processing trade). Household textiles and carpets are the second most important end-use, after clothing, followed by technical and other textiles.
Regionally, the industry is concentrated in a relatively small number of districts, of high textile employment. Employment in textiles as a whole has decreased, especially in the period since 1989, partly because of market changes and partly because of investment in modern technology which has led to increased productivity.
There are a number of environmental problems associated with the textile industry. These have been addressed by both national and EC regulations affecting water and air quality. The slow rate of recovery of the world economy does not hold out good prospects for the EC textile industry in the medium term. The EC's textile industry is however now very capital intensive, and firms in the industry are adopting strategies appropriate to modern competitive conditions. Much depends on the health of the EC's clothing industry, which itself has been depressed. The outlook for the textile industry also depends partly on the effects of phasing out the MFA (Multi-Fibre Arrangement): this was agreed upon in the Uruguay Round of the GATT.

INDUSTRY PROFILE

Description of the sector

The textile industry (NACE 43) covers a variety of production processes (preparation of fibres, spinning, weaving, knitting, finishing, dyeing, and also knitwear products) using various types of natural fibres (e.g. cotton, wool, linen, silk) and man-made fibres (e.g. synthetic, cellulosic, carbon, glass etc.). Products include clothing fabrics, household textiles and industrial textiles as end-uses, or as inputs to other industries (e.g. clothing, car upholstery).

In terms of value added, the textile industry represented 3.5% of manufacturing industry in 1992. The EC textile industry is mainly concentrated in Italy (36% of production), Germany (18%), France (15%), and the UK (11%). In comparison to the manufacturing industry, the textile industry represents 5.5% of employment and 4.1% of turnover in 1992.

Recent trends

EC production of textiles (in volume) rose steadily until 1987, at a comparable pace to that of total manufacturing. However, production has been declining since 1990, and in 1993 was 7% below its 1985 level (1985=100). Apparent consumption increased in real terms over the period 1983 to 1992 by 1.1% per annum, while production rose by 0.3% per annum. From 1991 to 1992, production in current prices decreased by 1.8%, while apparent consumption fell by 1.6%. In 1992, employment was 18% below its level in 1985.

The value of EC production (at constant prices) has followed a different trend from that of production in volume. It increased from 1983 to 1991, and has since declined, but was still nearly 5% above the 1985 level in 1993. Quality changes, which were not picked up in the price deflator, may account for the apparent discrepancy with the volume trends.

As imports increased faster than exports, the trade balance became negative after 1986 and more than doubled in 1991 alone. The trade deficit reached 3.8 billion ECU in 1992.

Employment in textiles was some 1.5 million in the EC in 1992, of which one quarter was in the knitting industry. Employment decreased steadily between 1983 and 1992, resulting in a reduction of 23%, or some 420 000, during the decade. This evolution was combined with a steady rise in productivity.

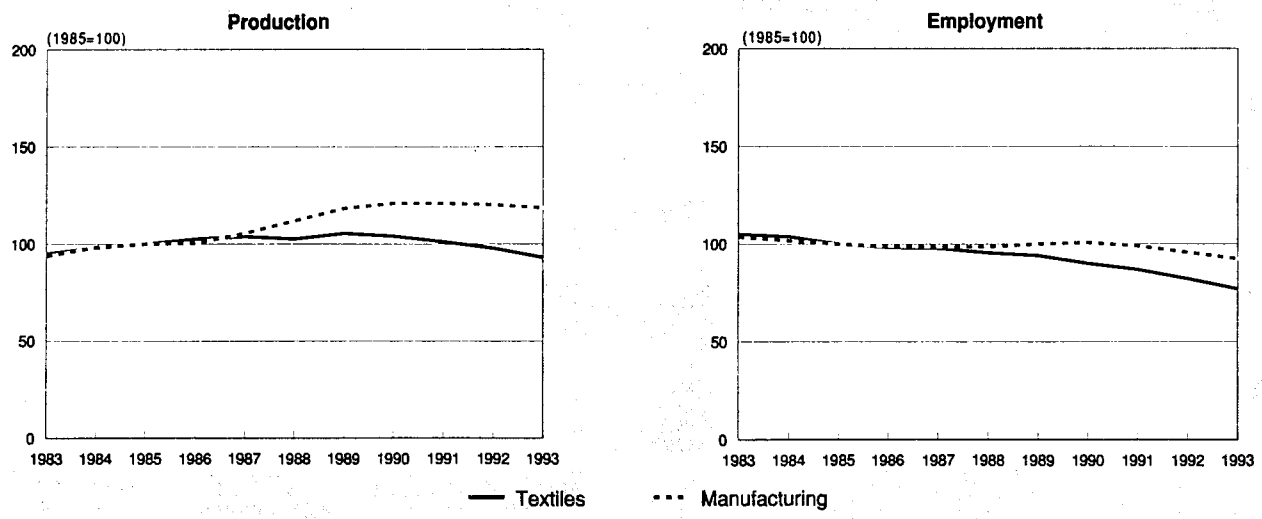
Figure 3: Textiles
Production in constant prices and employment compared to EC manufacturing (1)



(1) Firms of all sizes are considered.
1993 are Eurostat estimates.
Source: OETH. DEBA

Estimates for 1993 confirm the downward trend in production and employment. In particular, employment is expected to fall to only 77% of its 1985 level.

International comparison

EC textile production was twice the level of USA production in 1992, at current exchange rates, and 4 times larger than production in Japan. The EC and USA industries increased their production in current prices at different growth rates between 1985 and 1992 (14% in the EC against 29% in the USA), while in volume terms the EC textile industry has shown a decline in recent years in opposition to the recent recovery in the USA.

In Japan, however, the decline of production was stronger than in the EC. In volume terms Japanese textile production was at 86% of its 1985 level in 1992.

In the EC, apparent consumption increased by 19% between 1985 and 1992 while USA consumption went up by 28% during the same period, but apparent consumption in Japan actually decreased.

In comparison to the EC, USA exports are at a lower level (representing 20% of the value of EC exports in 1992), but they nearly tripled from 1985 to 1992. Textile exports from Japan are higher than USA exports, although they increased less over the period. EC exports increased less than exports from either the USA and Japan.

Foreign trade

Extra-EC exports and imports of textiles both increased between 1983 and 1992, with imports increasing more rapidly than exports. This resulted in a trade deficit after 1986. As the EC textile industry has to import most of its natural fibres (e.g. cotton and wool) to be used as raw materials in the spinning, knitting and weaving processes, the trade deficit is mainly related to these imports. The exclusion of raw material imports would show an EC trade surplus in manufactured textiles of 1.9 billion ECU in 1992.

Extra-EC exports of textiles rose less in recent years than before 1988, but extra-EC imports rose faster. The export/import ratio consequently deteriorated sharply, extra-EC exports

Figure 4: Textiles
International comparison of main indicators in current prices

representing 82% of extra-EC imports in 1992, as compared with 106% in 1986. Intra-EC trade (in current prices) steadily increased during the decade, but the share of intra-EC imports in total imports into EC countries fell from 65% in 1986 to 61% in 1992. Rising imports drove the import/consumption ratio up from 13.7% in 1983 to 18.3% in 1992.

The largest textile export market for the EC is the USA, followed by Austria, and Switzerland, followed by Japan and Sweden. All these countries took a lower percentage than in 1988. A striking feature of the change in exports since 1988 has been a rise from 1.6% of the total to 4.6% in the case of Poland, 2.6% to 4.1% in the case of Tunisia, and 2.6% to 3.9% in the case of Morocco - all countries involved in OPT (outward processing trade) for the EC clothing industry, i.e. the export of cloth, for making-up into garments, and re-importing. In 1992 Poland was ranked first in OPT imports of clothing into the EC. According to Eurostat data nearly 10% of EC textile exports in 1992 were for OPT purposes.

Turkey was the largest source of imports of textiles into the EC in 1992 (10.6%), together with China (8.9%). They have both increased their share since 1988. In that year, Switzerland had been the largest source of imports, but had fallen to fourth place (6.9%), after Austria in third place, in 1992.

In terms of product lines, EC exports and imports mainly consist of cotton products, which represent 60% of exports and 85% of imports. EC exports of wool products represent 25% of total exports of textiles, for which the EC is one of the largest world exporters. Woven fabrics accounted for 91% of fabric exports in 1992, and knitted for 9% (excluding fully-fashioned).

Textile exports other than yarn and fabrics represented some 36% of total textile exports. These were carpets, household textiles and technical textiles, and non-woven fabrics, in order of size. Fabrics represented 51% and yarn some 13% of total textile exports.

On the import side, woven fabrics accounted for 92.5% of fabric imports, and knitted for 7.5%. Imports other than fabrics represented 29% of the total. Fabrics represented 43% and yarn some 28% of total textile imports.

MARKET FORCES

Demand

The growth of apparent consumption of textiles, in current prices, has slowed down in recent years. In terms of constant prices the movement was even slightly negative. The decreasing share of household expenditures on clothing had a negative impact on final consumption, combined with the worsening balance of trade in clothing and depressed general economic conditions. Technical textiles products also suffered from declining production in end-use sectors like the automotive industry. In terms of consumption, clothing remains the major textile end-product with 53%, followed by technical and other textiles (20%), household textiles (15%) and carpets (12%).

Compared with 1988, the consumption of fabrics fell by 9% in volume terms, with a fall of 12% in woven and a rise of 6.5% in knitted fabrics. The consumption rose also for fully fashioned knitwear. The consumption of textiles in non-clothing uses increased by 2%, largely on account of an increase in carpets (19%). There was a fall of 7% in the consumption of household textiles and of over 3% in that of technical textiles.

Strategic trends towards policies of quick-response, reduced stocks, just-in-time deliveries and the development of outward sourcing strategies, under which garments are manufactured

outside the EC using fabrics of EC origin, have had an increasing and favourable impact on the demand for EC produced fabrics.

Expenditure on clothing is highly sensitive to income levels and fashion trends. For household textiles, another major textile end-product, fashion sensitivity has lost some of its influence, due to difficult economic conditions in recent years. It has been estimated that fashion affects only 20% of households in the purchase of household textiles. Retailing patterns in household textiles are thus more price-led than fashion-led.

Technical and other textiles (including non-woven goods) have replaced household textiles as the second most important market. These textiles include carbon, glass, aramid and other special fibres, in addition to conventional textile fibres. The products go into such high-tech uses as defence equipment, high-speed trains, aircraft and racing cars, as well as leisure products such as mountain bicycles, tennis racquets and golf clubs. Technical textiles are often divided into industry textiles, transportation, geotextiles, technical apparel, medical and leisure textiles. The industry acts as a subcontractor for other industries, and there therefore have to be close links between the producers of technical textiles and the final users of them.

Unlike clothing and household textiles, technical textiles of this advanced type are exposed to import competition from advanced rather than low-cost countries.

Supply and competition

Although machinery equipment in the EC textile industry remains globally the most modern worldwide, this position has been affected by a decrease in investment in recent years. This evolution is related to persistent high interest rates and to the constraints of an overcapacity of textiles on the world level. In addition, based on data provided by ITMF, the low rate of utilisation of machinery in comparison to the EC's main competitors (76% in the EC against 97% in Taiwan and 91% in the USA, for spinning and weaving) represents an important competitive disadvantage.

The sector's competitiveness is also influenced by the evolution of European exchange rates, in particular against the USD. Following the fall in the dollar after the mid-1980s, the competitiveness of the EC textile industry deteriorated, as was illustrated by the evolution of EC exports to and from the dollar zone. The export/production and import/consumption ratios have continuously increased since 1988. The trend may however be changing with the recent increase in the strength of the USD.

Among competitive factors, labour costs play an important role. This mainly concerns the clothing industry, as labour-intensive production is far more important in the downstream and less capital-intensive activity of garment production. Labour costs in spinning and weaving are however from four to twenty times higher in EC countries, as compared with developing countries.

Wage disparities are also significant between Member States, especially as between Southern and Northern EC countries. In recent years, labour costs have increased worldwide. Growth rates have in some developing countries been higher than in EC countries (e.g. Turkey, Taiwan, South Korea), although

More than 20	14 500	23.2	79.4	81.3

(1) Estimates.
Source: OETH, DEBA

the wage gap still remains important. USA labour costs in spinning and weaving represent only some 50% of EC labour costs in such Member States as Germany, the Netherlands, Denmark and Belgium, but Japanese labour costs are the highest worldwide.

Although labour costs have risen in all EC countries, the EC textile industry has also increased its productivity (value added per person employed) over the last decade. The productivity index was at 134 in 1992, compared to its 1985 level.

The EC textile industry depends greatly on extra-EC imports of natural fibres as raw materials. Raw material prices tend to be higher in the EC than in the USA or in developing countries. Over the past two years, the world price of cotton has however decreased by 30% from previously high levels. Present low world cotton inventories exert less downward pressure on world prices, which are expected to rise in 1993/94. As compared with cotton, wool prices have decreased even more since 1988.

Production process

The EC textile machinery market showed mixed trends in 1992. In spinning, there was a severe fall in shipments of short-staple (cotton) spindles. In contrast, there was an increase in shipments of long-staple (wool) spindles. In weaving, deliveries of shuttle-less looms to the EC fell substantially.

In the EC stock of spinning machinery, 58% are short-staple spindles (used for such fibres as cotton), 38% long-staple spindles (used for wool and other long fibres) and the remaining 4% open-end rotors. These shares are not representative in terms of production capacity, as open-end rotors are judged to be 5 times more productive than spindle machinery. Worldwide, short-staple spindles account for 87% of total textile machinery, while long-staple spindles account for 8% and open-end rotors 5% of the total.

Open-end rotors are relatively less important in the EC, than in many other countries, as they are mainly used for other fibres than wool - the EC is a large wool producer on the world level.

Asia accounts for 62% of the world's short-staple spindles and 42% of long-staple spindles. Open-end rotors are mainly used in East Europe and the former Soviet Union (58% of the world total).

Knitting machinery has become increasingly automatic and capital intensive, especially in the more developed countries.

In weaving machinery, the EC textile industry uses a high proportion of shuttle-less looms (40%), these being the most modern machinery used in the weaving process. In contrast, shuttle-looms are the major type of machinery used in Asia and South America. Recent investment trends worldwide have been mainly in shuttle-less looms.

INDUSTRY STRUCTURE

Companies

In 1992, the EC textile industry contained nearly 63 000 firms, of which 77% were firms with less than 20 employees. These small firms employ 21% of the total workforce (310 000 employees) and generate 19% of total turnover. From the early 1980s, small textile firms increased their share of both employment and turnover in all major EC countries. In the USA, small firms represent only 30% of the total number of firms in the textile industry.

Both small and large textile firms have suffered from the overall decline in production and employment in recent years, but smaller firms have performed better. While the total decline in EC textile employment from 1988 to 1992 was nearly 14%, firms with less than 20 employees decreased their employment by only 4%.

In terms of turnover, nearly 24% is concentrated among the fifty major firms, and the three biggest firms (Coats Viyella (UK), Benetton (I) and Beaulieu (B)) represent 5% of the

Table 7: Textiles

Source: Comitextil, Textilwirtschaft, DABLE

total. The concentration decreases rapidly, as the following fifty firms (i.e. 51-100) only add 6% to the share of total turnover. Large firms (more than 500 employees) are mainly to be found in the UK, Germany, Italy and France. The three largest EC textile companies are also to be found among the 10 major world companies. These are dominated by the Japanese company Kanebo. Major USA companies are Sara Lee, Burlington and Spring.

Strategies

EC investment in the textile industry has continuously decreased over recent years. From 1988 to 1992, the fall was 15%, in current prices. Italian companies were the major investors, and in 1992 they generated 30% of total EC investment in textiles, followed by Germany (21%) and France (16%). In terms of investment per employee, the major investment efforts were made by Belgian, Dutch and German firms. The lowest level of investment per employee is to be found in Portugal and Spain.

Strategy regarding textile mills has changed over time in certain instances. In the 1960s and 1970s, for example, several 'supermills' were built in the UK, and it was thought that in this way the plants would be able to meet low-cost imports head-on. In practice many of these plants were not efficient, and were not able to meet import competition. The textile industry had to adapt to smaller, more specialised plants, producing quality products for specific markets.

Now there is an emphasis on quality throughout the EC, but modern automatic technology has made it possible for both large and medium-sized plants to be viable, provided that they are flexible, have a quick response time, and are closely geared to the needs of their customers, both manufacturers and retailers.

Modern textile plants in the EC are competitive by world standards. Subcontracting relations have gained in importance over recent years, both within and outside the EC. Textile firms tend now to be less vertically integrated, relying more on subcontractors, and to concentrate on a limited number of processes.

REGIONAL DISTRIBUTION

The main textile regions of the EC can be classified by size of employment. According to Comitextil data, the largest regions, those employing 100 000 or more, are Lombardia (I), Cataluna (E) and Norte (P). The next largest textile regions, employing between 50 000 and 100 000, are both in Germany - Baden-Wurttemberg and Nordrhein-Westfalen. The 5 largest regions represent nearly 30% of total EC employment in textiles.

The smaller textile regions are spread more widely. Regions employing between 25 000 and 50 000 workers include Veneto, Piemonte and Toscana (I), Rhone-Alpes (F) and West Yorkshire, Derbyshire and Nottinghamshire (UK).

There are a number of textile regions employing between 10 000 and 25 000 workers. These are in Portugal, Belgium, the UK, Italy, France, Germany and Denmark. It is interesting that, included among these, are the once prosperous UK cotton regions of Greater Manchester and Lancashire. In Belgium both the regions of this size are Flemish - West- and Oost-Vlaanderen.

ENVIRONMENT

The textile industry uses natural fibres, as well as man-made fibres (cellulosic and synthetic). Wood pulp is the basic element in producing cellulosic fibres, while synthetic fibres are produced from oil derivatives (the main synthetic fibres are polyamide, acrylics, and polyester). The production process therefore uses natural resources - water, land, animals, wood pulp, and oil.

The production of textiles requires considerable volumes of water - in the production of fibres, in processing fibres and in fabric finishing, among which dyeing and finishing require the most water.

During processing wool has to be cleaned and degreased and cotton has to be washed. Chemical applications are used in the processing of both man-made and natural fibres, to obtain easy care properties, fast colour, soil resistance, crease resistance, handle, flame retardancy etc. Dyes may cause particular problems of colouring rivers and streams, although not necessarily with seriously harmful effects.

Then there are the environmental problems, common to all consumer products, connected with packaging. And once the textile product is in the hands of consumers, repeated laundering consumes much energy and detergent (as shown in a study by Franklin Associates for the American Fiber Manu-

facturers Association), and gives rise to a great deal of water-borne effluent.

Final disposal is another problem. Products made from natural fibres, and also from cellulosics, biodegrade effectively. However, polyester, nylon, polypropylene and acrylics are persistent, yet account for 65% of total fibre usage in textiles.

The growing level of pollutants in the environment, including those connected with the textile industry, are being increasingly controlled by legislative control on discharges to water, air emissions and waste production, by active regulatory bodies on national and EC levels. There has for example been much EC legislation on emissions to water, and this has affected the textile industry, with its heavy water usage.

The Fifth Framework Programme for the Environment, proposed by the EC Commission in 1992, encompasses all environmental issues manufacturer and users will have to integrate into their strategy in the future.

There are costs as well as benefits in the improvement of environmental standards. The Communication of the European Commission to the Council on the competitiveness of the European textile and clothing industry, concluded that environmental costs in dyeing and finishing account for between 3.5% (Belgium) and 9.2% (Germany) of total costs. Member States with lower costs at present are likely to see an increase, as environmental policy is strengthened.

Expenditure on the environment is often considered as an additional cost which detracts from the competitiveness of the industry. A recent study by the European Commission (The State of the Environment in the EC) shows however that there is a correlation between the environmental standard maintained by a firm and its competitive position. The more dynamic enterprises are in fact increasingly using the environment as a tool in their strategy to strengthen their market position. It is argued that the additional short-term costs involved (R&D, new investment, advertising etc.) are generally more than offset by the long term benefits (increased market shares, product differentiation, etc.) of such a policy.

OUTLOOK

During most of the 1980s the EC textile industry saw a rise (in current prices) in apparent consumption, production and extra-EC exports. In the recessionary period of 1990-92 however, apparent consumption and production rose little in current price terms, and fell slightly in real terms.

The slow growth of GDP in the leading EC countries, together with the slow growth of their trade, was a major reason for the continued state of depression in the EC's textile industry, which saw in 1993 further falls in production and especially employment.

The recession in the EC reflected that in the world economy, although there was some recovery in 1992 in the USA. More recently, the strengthening of the USD has worked to the disadvantage of USA exports, and of the exports of those countries whose exchange rates are traditionally linked to that of the USA. This has influenced the competitiveness of the EC textile industry, although those Member States who have substantially devalued their currencies since September 1992 have benefited more than the average.

Even in 1993, however, the EC textile industry has remained depressed. In the first half of the year the volume of production was some 8% below that of the same period in 1992. Exports were also down, as were imports. The deficit on the textile balance of payments was estimated to rise to nearly 4 billion ECU in 1993.

Employment continued to fall in 1993, with a decrease of some 95 000, or 6%. The absolute level of the fall was greater than that in either 1991 or 1992.

Apparent consumption has continued to fall, and in general demand was weak in 1993.

The slow rate of recovery of the world economy, including that of the EC, does not hold out good prospects for an upturn in the industry in the short to medium term. Much depends on the demand from the clothing industry in the EC, which has also been depressed. Sales of household textiles have recently been stronger in several Member States, although imports have been important here. Technical textiles, of developing importance in the EC, have however also suffered from the recession.

The EC OPT (Outward Processing Trade) regulations require the export of EC-made fabrics for subsequent making up in other countries - mainly in practice those countries bordering the EC. The extent to which the existing trend towards more OPT continues will depend partly on the harmonisation of the rules for implementation of the OPT regulations, that is being undertaken by the EC Council.

The Single Market has given the impetus for the re-consideration of the OPT regulations. It may affect also the distribution among Member States of imports of textiles and clothing under MFA quotas, because country quotas have been abolished. But it is as yet too early to say what the effect of this has been.

Another important factor is the conclusion of the Uruguay Round of the GATT, which will bring increased import competition.

Bearing in mind all the various factors, the industry may well suffer further falls in production and apparent consumption in 1993-94. In the following years apparent consumption may increase again, while production is expected to follow a zero-growth pattern in real terms. It is estimated that between 1993 and 1997 the average real annual growth rate of production will be 0%, and of apparent consumption 1.0%.

Investment in the EC textile industry fell off in 1992, but is likely to rise again. The industry has now become very capital-intensive, and has seen large rises in productivity. In the long term its growth will depend partly on future high-tech developments, including that in the field of technical textiles. If these developments continue to be successful, and provided that there is a positive economic environment, there might be little incentive for the industry to delocalise production to low wage countries. Developments in market or product specialisation, and also in the flexibility of organisation, will also be important factors. Bearing in mind all these factors, restructuring in the EC textile industry still has a long way to go.

Clothing
NACE 453

The clothing industry covers the manufacture of garments and clothing accessories, but not the manufacture of knitwear. The EC's apparel production is based 55% on man-made fibres and 45% on natural fibres. The clothing industry employs 1.2 million people in the EC - some 25% fewer than in the textile industry. The clothing industry accounted for 1.7% of the value added of manufacturing industry in the EC in 1992, and also for 2.5% of turnover and 3.4% of employment.
The EC spends a higher proportion of income on clothing than either the USA or Japan, but the proportion has been declining. The volume of EC's production of clothing has been decreasing since 1987 and in 1993 was 15% below its 1985 level. The trade balance is negative and has been deteriorating. The industry has had to face strong growth of imports from low wage countries, in spite of import quotas under the MFA (Multi-Fibre Arrangement).
Clothing exports are mainly directed towards other developed countries, and the internal market of the EC is also a major customer. Outward processing trade (OPT)) has been a growing activity, moving labour-intensive making-up operations to nearby lower wage countries.
Employment in the industry has been declining - the industry lost nearly 280 000 jobs in the period 1983-92, of which 75% were lost within the last 5 years (1988-92). This was due to increasing productivity, as well as to market changes. Regionally, the clothing industry is widely spread across the EC, in smaller pockets than the textile industry. Its environmental problems are not serious, although the final disposal of garments made from synthetic fibres remains a problem.
The outlook for the clothing industry depends partly on the effects of phasing out the MFA, which was agreed upon in the Uruguay Round of the GATT. Moves towards higher quality, new fibres and fabrics, and quick turn-round time - as well as the further development of OPT - will be factors helping the firms in the industry. This is however likely to lead to further reductions in the size of the industry's labour force.

INDUSTRY PROFILE

Description of the sector

The clothing industry covers the manufacturing of garments and clothing accessories. It is strongly linked to the textile industry which provides various types of fabric (woven, knitted, or crocheted). It does not cover production of knitwear. Statistically, the knitting industry is included in textiles - NACE 43. Relying on textile production and imports for the supply of fabrics, apparel production is based 55% on man-made fibres, 30% on cotton, and 15% on wool.

In comparison to total manufacturing, the EC clothing industry represents 2.5% of turnover, 1.7% of value added and 3.4% of employment, based on firms with more than 20 employees.

The production of clothing reaches from the design stage (styling, prototyping, definition of collections) to development (fabric sourcing, pattern making, the planning of cutting), and manufacturing (cutting, sewing, pressing, finishing).

In terms of clothing products, different classifications can be used: e.g. men's, women's and children' wear, outerwear and underwear, woven clothing and knitwear, low, medium, and high-quality wear.

With an employment of over 1 million, the clothing industry is one of the major job suppliers in the EC. In terms of production, the industry is mainly concentrated within Italy (37%), France (22%), Germany (17%), and the UK (10%).

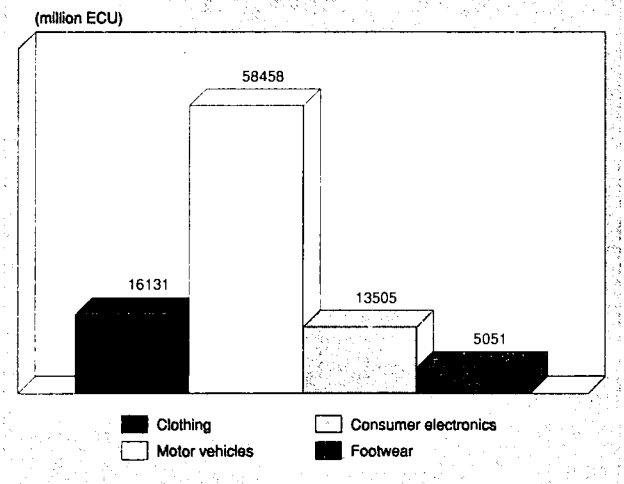
Value added in comparison with other industries, 1992



Source: DEBA

Recent trends

EC production of clothing (in volume) rose until 1986 but has decreased steadily since 1987. In 1993, production was 15% below its level in 1985. While on the basis of real annual average growth rates, apparent consumption slightly increased between 1983 and 1993 (0.9%), production decreased by 1.1% during the same period.

The value of EC production of clothing (in constant prices) has followed a different trend. It has been rising since 1983, and in 1993 was 11.3% above its 1985 level. This can partly be explained by the fact that the value of production is derived from the value of turnover, which in some cases includes subcontracting outside the EC. Part of the explanation may also be that there has been an increase in quality, not caught by the price index used to deflate the figures.

The trade balance, already negative in 1983, deteriorated continuously and reached a peak deficit in 1991 of 10 billion ECU. In particular, the EC clothing industry has had to face a growing impact from lower-cost countries, whose clothing

imports to the EC increased by an annual real average rate of 11.4% between 1983 and 1992.

For the first time since the beginning of the 1980s, the trade balance improved slightly in 1992 (with a deficit reduction of 2.6%, as compared to 1991).

Employment in clothing followed a downward trend during the whole period 1983-1992, and nearly 280 000 jobs were lost in these ten years. Simultaneously, the clothing industry generated continuous improvements in productivity.

International comparison

In 1992, EC production of clothing in current prices was 11% higher than in the USA and 5 times higher than in Japan. USA exports in 1992, although expanding on account of the then favourable exchange rate, were 40% of the EC exports. Japanese exports were even lower, although in terms of the export/production ratio, Japan has the most export-oriented clothing industry. In 1992, 14% of production was exported, against 12% in the EC and 5% in the USA.

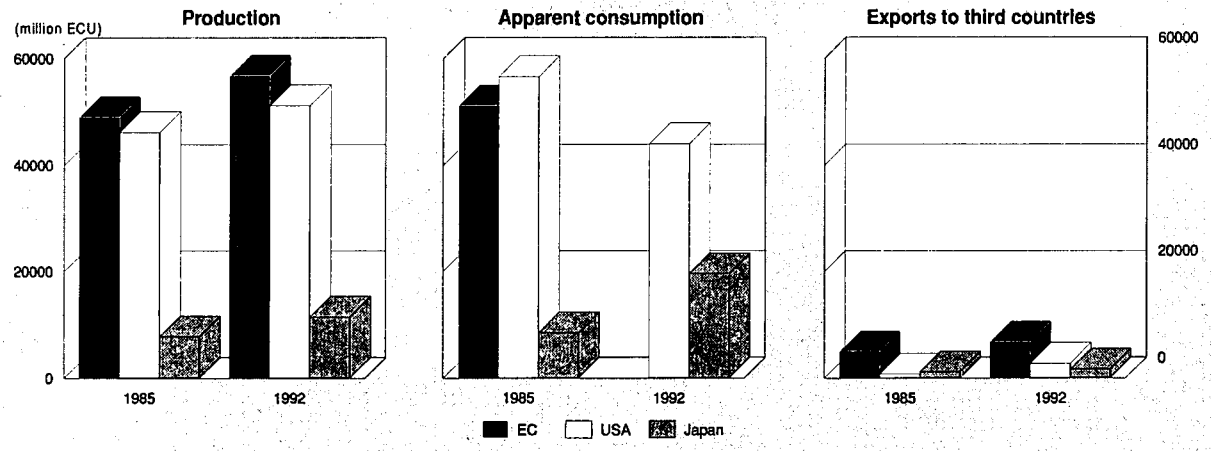
In terms of trends, USA clothing production has declined since 1988, and was 5% lower in 1992 than in 1985. EC production started to decline earlier, in 1987, and decreased more rapidly, being nearly 15% lower in 1993 than in 1985. In volume terms, the Japanese clothing production decreased continuously between 1985 and 1992, although compared to 1985, the level of production has fallen less than in the EC.

On the world market for clothing, major shifts in market shares have benefited Far East suppliers like Hong Kong, Thailand, and China, whose exports to third countries have risen dramatically over recent years. Among countries nearer the EC borders, export-oriented clothing industries have developed mainly in Turkey, Tunisia and Morocco, and recently among East European countries. These have been partly linked to the development of outward processing strategies on the part of European clothing firms.

Foreign trade

For more than a decade, the EC clothing industry has had to face increasing competition from lower-cost countries,

Figure 4: Clothing
International comparison of main indicators in current prices



(1) For 1992, average exchange rates for that year have been used.
For 1985, in order to avoid problems of comparison which are due to exchange rate movements, the 1992 exchange rate was also used.

mainly in the Far East and Mediterranean rim, through growing clothing imports in the low- and medium-price and quality segments of the market. The terms of trade index, comparing prices received for exports to those paid for imports, increased in 1992 to nearly 115, as compared to 1985.

Between 1983 and 1992 extra-EC exports of clothing nearly doubled, but imports to the EC tripled. In 1992, imports represented 16.6 billion ECU, or 25% of EC apparent consumption of clothing, against 12.6% in 1983.

In 1992, EC clothing exports to third countries represented only 40% of imports from these countries. This ratio had been 60% in 1983.

EC exports of clothing are mainly oriented towards other developed countries, such as the EFTA countries, the USA and Japan. The main extra-EC customers are Switzerland (16.4% of EC exports of clothing in 1992), Austria (12.3%) and the USA (12%). These main customers tend to buy a lower share of total EC exports than they did in 1988. The destination of EC exports has become less concentrated, as other markets have gradually developed. For EC clothing producers, the internal EC market still remains a major customer, as intra-EC exports are double extra-EC exports. The share of intra-EC imports in total imports represented 43% in 1992, although this share had decreased from nearly 49% in 1983.

The main countries of origin for extra-EC imports of clothing are the lower-cost countries, in terms of labour costs and raw material prices. While Hong Kong was the major supplier to the EC in 1988 (17.1% of the total), this position has shifted to China in 1992 (14.3%), the most rapidly expanding clothing supplier in terms of exports to the EC. As labour costs rise in the traditional low-cost countries like Hong Kong and South Korea, clothing production has moved to even cheaper Far Eastern countries like China, Indonesia, the Philippines, and - more recently - Vietnam and Laos. Apart from these Far Eastern countries, most other suppliers are geographically close to the EC, such as Tunisia, Turkey, Morocco, and Poland.

For some Mediterranean countries, notably Turkey, clothing exports to the EC are mainly direct exports of garments. For Poland, on the other hand, 75% of clothing exports are linked to previous EC exports of fabrics, in the framework of outward processing trade (OPT) subcontracting relations. In Tunisia and Morocco - also important for OPT - links to EC firms tend to be closer, and several are in the form of joint-ventures or capital ownership.

MARKET FORCES

Demand

EC spending on clothing (including footwear) as part of total spending on consumer goods has shown a downward trend over the last decade, but the proportion of consumer expenditure on clothing is higher than in the USA or Japan. In the EC, the share of consumer expenditure on clothing decreased from 8.4% in 1980 to 7.3% in 1992. Equivalent shares in the USA and Japan in 1990 were 5.5% and 6.3% respectively.

Consumer expenditure on clothing, in absolute terms, has followed an upward path in most EC countries. This trend has been related to decreasing relative clothing prices, compared with all consumer prices. The volume of retail sales of clothing reflects this, and was at a level of 111 in 1992 compared to 1985. Declining EC output of clothing from 1983 to 1992 meant that, despite an expanding market, EC clothing producers lost market share during this period.

In terms of product lines (in numbers of garments), apparent consumption has been strongest for shirts, jerseys, and blouses. Consumption has increased for most clothing products, but

More than 20	11 384	14.2	65.8	67.7

(1) Estimates.
Source: OETH, DEBA

slight falls in demand occurred in 1992 for trousers and parkas. At the same time, EC production of these products declined, widening the gap between the size of the EC market and the market share held by EC producers. For shirts, the market share held by EC producers was 40% in 1992, although the market share for jerseys was at 66%. For men's coats, the market share held by EC producers represented only 27% of consumption in 1992. An increasing part of the demand for clothing has been supplied by extra-EC imports.

The decrease in EC production can be linked to important price differences between EC produced items and imports from outside the EC. These are mainly explained by substantial labour cost differences, as clothing manufacture is a highly labour-intensive process. A recent study by the Institut Français de la Mode (IFM) showed that, at identical fabric costs, the cost of clothing production in the EC could be nearly twice the total cost in Morocco or Tunisia. Price differences with Far East suppliers like China can be even higher.

Partly because of the influence of cheap imports on the low-quality segment of the clothing market, there has been a swing from cheap, low fashion, mass produced items in recent years towards higher quality, more classic, yet individual clothing. Consumer demand has grown to become more and more subject to fluctuations in fashion and taste. In response to these changes, EC clothing producers are moving towards shorter production runs and quick-response manufacturing. In the fashion-led segment of the market, consumption trends cannot be fixed for a whole season in advance, thus making long runs difficult. The success of companies like Benetton (I) indicates that quick response to fluctuations in consumer preferences, within a season, can be a major element of success.

Supply and competition

EC clothing producers have to operate in a highly labour-intensive environment, although recent technological innovations (e.g. CAD - computer-aided design) indicate that the labour content could become less important in the long run.

Growing import competition from lower-cost countries, mainly due to important wage differences, have forced EC firms to adopt delocalisation strategies in order to achieve lower costs of production. The development of these strategies has also been influenced by increasing pressure on prices from traders and organised retailers within the EC. International subcontracting, under the form of outward processing trade (OPT), has expanded in recent years. Fabrics of EC origin are exported to lower-cost countries like Poland, Tunisia, or Morocco, to be processed into garments and reimported as clothing into the EC. Such production may be granted special quotas and tariff conditions (such as duty paid on value added only).

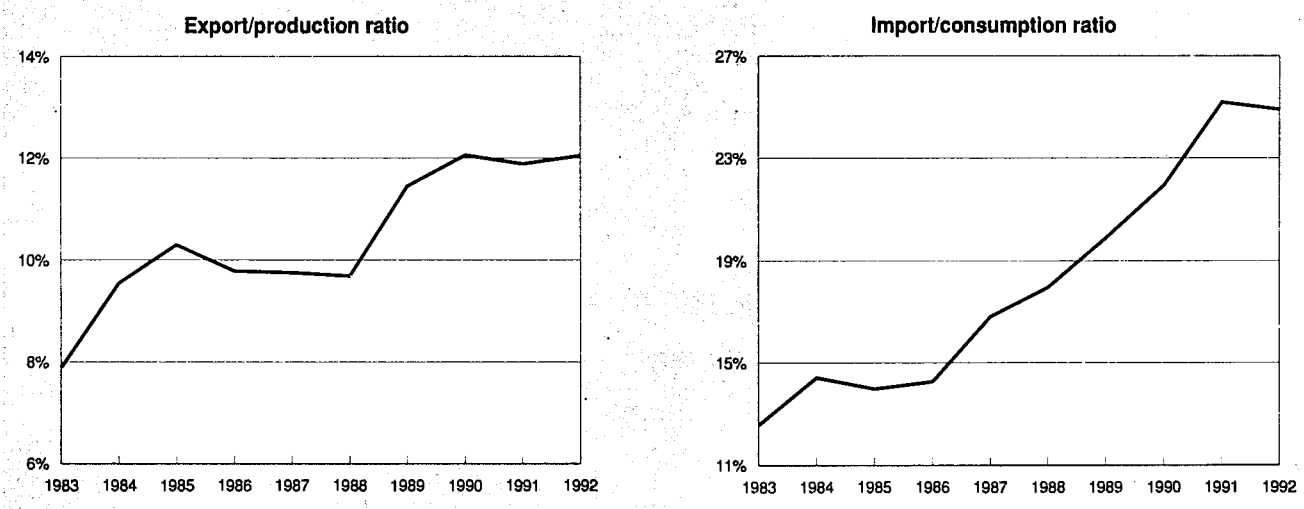
OPT clothing imports into the EC represented in 1992 about 10% of total imports of clothing, or nearly 134 000 tonnes. These imports result from previously exported EC fabrics on a CMT (cut, make and trim) basis. Between 1988 and 1992, OPT imports of clothing to the EC increased from 9% to 10%, as a share of total imports. They increased by 66% in volume during the same period. The major OPT importers in the EC are Germany (62% of OPT imports), France and the Benelux countries.

The major countries of origin for OPT imports are either located in East Europe or the Mediterranean rim. This indicates that proximity of the subcontracting country is an important element of OPT strategy.

As quick-response systems, reduced stock policies and just-in-time strategies develop, delivery times appear as an essential element of OPT. Average lead times for orders in China or other Far East suppliers range between 4 to 7 months. In East Europe and the Mediterranean countries, the lead time is 3 to 6 weeks, depending on the availability of fabrics. But the selection of potential subcontractors always takes place within a certain price range. Therefore, distant countries can be expected to be less attractive OPT partners for the EC as long as nearby subcontractors remain price competitive.

The competitiveness of EC clothing producers is strongest in the higher-quality and fashion-led segments of the market. Among factors which can determine the competitive advantage of EC manufacturers - in addition to movements in exchange

Figure 8: Clothing
Trade intensities (1)



(1) Firms of all sizes are considered. Trade data includes raw materials and excludes knitwear.
Source: OETH, DEBA

rates and inflation - are quality, reliability (in respect of delivery times), short cycle time, availability of high-quality fabrics, technical know-how, production flexibility, and the possibility of repeated runs. These competitive criteria, it is claimed, are better fulfilled by EC producers than by their foreign counterparts in lower-cost countries.

Production process

The production of clothing includes various manufacturing stages, from design to final packaging. At the design stage, the product is styled, materials (fabric and accessories) are selected, and a prototype is developed. Once collections are defined, the product enters the development stage, where the actual manufacturing is prepared through the making of patterns, material requisition, and the planning of cutting. Manufacturing consists of fabric cutting, sewing, pressing and finishing.

In comparison to the textile industry, technological innovation in clothing has been less in the use of sophisticated machinery than in the development of new types of fibre (e.g. microfibres) and fabrics. Important productivity gains have however been realised in terms of production time, quality, and the reduction of losses e.g. through electronic cutting control, laser cutting, automatic sewing machines, and the computer management of production and stocks.

Investment is relatively low compared to other industries (23% of the level of investment in textiles). In 1992, the EC clothing industry invested 893 ECU per employee, in comparison with 2 872 ECU per employee in the textile industry. Being a largely labour-intensive industry, investment in new technology is naturally more limited in comparison to more capital-intensive industries.

INDUSTRY STRUCTURE

Companies

The clothing industry includes a large number of small and medium sized firms. In 1992, the industry was composed of nearly 80 500 companies, of whom 86% had less than 20 employees. These represented 34% of employment and 32% of turnover. A large part of these small manufacturers operate as subcontractors for larger producers or traders.

As a labour-intensive industry, the clothing industry has few entry barriers in terms of capital required. In addition, many firms have a local and family background from which some have expanded to become larger international groups. But most firms continue to operate on a local level.

Among the largest clothing companies, firms like Coats Viyella (UK) and Courtaulds (UK) produce textiles and clothing, whereas others like GFT (I) or Steilmann (D) mainly buy-in fabrics, and concentrate on clothing. Classification by turnover therefore has to be looked at carefully, as activity definitions are not entirely comparable.

Although some companies are specialised in certain products (e.g. Levi-Strauss Europe in jeans and related products, Escada (D) mainly in women's wear), most large companies have a diversified range of clothing lines, operating at the same time in knitwear, women's outerwear, children's wear and sportswear - Steilmann is an example of this.

Strategies

Among the main EC clothing producers, different marketing and selling strategies have been adopted. While some firms follow specialisation strategies in terms of product lines and/or markets, others use a more diversified approach, operating within several different product groups, combined to more export-oriented selling policies. Companies like Hugo Boss (now belonging to Marzotto SPA (I)) focus on high-quality men's wear, whereas a company like Laura Ashley (UK) has diversified beyond the limits of clothing, into home textiles and decoration accessories. While Triumph (D) exported only 4% of its production outside Germany in 1991, Escada's (D) exports reached 65%.

In terms of production strategies, companies choose between their own production, and local or international subcontracting, or a mixture of both. These options depend on criteria like quality, price, and short-cycle or long-cycle products. As proximity to the subcontractor and long-term relationships have developed, regional textile and clothing areas like Prato in Tuscany or the "Sentier" in Paris find their 'metier' in short-cycle products, while long-run and often lower-quality products are processed within lower-cost countries outside the EC.

The Directorate General for Industry of the European Commission is sponsoring a major study of European subcontracting in the clothing sector. The aim of the study is to give a full picture of the extent of subcontracting within the EC, and to assist in developing relevant policies.

REGIONAL DISTRIBUTION

According to Comitextil data, the largest clothing producing region in the EC is Lombardia (I), with over 75 000 employees. This is followed by Veneto (I) and Bayern (D), both with between 50 000 and 75 000 employees.

In the regions with between 25 000 and 50 000 employees, Italy again predominates, with four regions. Also in this category are Nordrhein-Westfalen (D), Ile de France (F), Cataluna (E), Norte (P), and Greater Manchester (UK).

There are some twenty-five regions in the EC with between 10 000 and 25 000 employees. Among these, six are in the UK, four each in Italy, Spain and France, three in Germany, and two in Portugal.

Compared with the textile industry, the clothing industry appears to be spread in a larger number of smaller pockets throughout the EC. This suggests that, as regards regional vulnerability to any decline of the industry, the regions dependent on the textile industry, being more concentrated, may be the more vulnerable.

ENVIRONMENT

As regards the process of manufacture, the clothing industry gives rise to fewer environmental problems than the textile industry. As regards use, the pollution caused by repeated washing and cleaning, and the energy used, are of considerable environmental importance.

The recycling of clothing is a common activity, particularly that of wool clothing. Recycled wool may not need dyeing and does not have to be scoured, thus saving water and energy. The final disposal of clothing may give rise to problems, however, since synthetic fabrics are not biodegradable, although natural and cellulosic fabrics are.

The EC is in the process of introducing a system of 'eco-auditing', through the use of which firms will be able to monitor the environmental effects of their production processes. This affects all industries. Another scheme which affects many individual products is that of 'eco-labelling'. This undertakes to give on the label of a product full details of its environmental history, and also deals with the problem of disposal. Much work has been carried out on this scheme, which involves a detailed study of each product to be labelled, with international agreement on the final eco-label. The process has taken longer than was anticipated, but is now well under way, and is beginning to produce agreed eco-labels for a number of products, including clothing products.

OUTLOOK

The production of clothing in the EC continues to suffer from the recession of the early 1990s. Production in the first half of 1993 was at 8% below its level in the same period a year earlier. It was running at less than 90% of its 1985 level during this period, as well as in the whole of 1992.

Both imports and exports of clothing (extra-EC only) were down in early 1993 on the 1992 level. Although exports were above their 1985 level, imports were as much as two and a half times as high.

The foreign trade balance deteriorated again in 1993, with the estimated deficit rising to over 10 billion ECU.

Employmcnt in 1993 continued to fall, with the absolute fall of some 75 000 being greater than that in 1991 or 1992.

The apparent consumption of clothing, in real terms, rose in the EC by 1.1% per year in the period 1983-88, and in 1988-92 by only 0.7% per year. Production decreased in both periods, but the rise in exports was strong, even in 1988-92.

Given the continuation of the recession, apparent consumption is expected to fall slightly in 1993-94, although this may not be universal in the EC, since there has been a small pick-up in retail sales in some countries. Production is expected to fall by 4% during the 1993-94 period, but exports are expected to rise.

During the period 1994-97 apparent consumption of clothing is anticipated to rise by 1% per annum. Production is expected to fall by 2% per annum, but exports to increase by the same amount.

In the medium term, much will depend on the world economic situation. In clothing, in particular, the development of sub-contracting abroad will be of great importance, but will of course affect production much more than consumption. Another important factor is the conclusion of the Uruguay Round of the GATT, which will bring increased import competition. Already, the ending of the country import quotas, with the advent of the Single Market, is likely to strengthen competition from imports.

More open access to imports from East Europe will be a factor making for greater competition in the EC clothing market. Links between EC manufacturers and those in East Europe may strengthen as a result.

The EC clothing industry has to be prepared therefore for continued strong competition from abroad, as well as within the EC itself. It has already moved up-market, in a move to weaken import competition, and this process will no doubt continue.

Footwear
NACE 451, 452

The EC is one of the world's largest footwear markets but increasing consumption over the last decade has been accompanied by much smaller increase in production. There was rapid growth of extra-EC imports in both value and volume terms. Italy accounts for almost half of the value of EC production and over half of extra-EC exports. Increased competition from lowlabour cost countries has led to relocation of EC manufacturing facilities to lower labour cost Mediterranean countries, and to developing countries. The structure of distribution is changing - a number of large manufacturers are developing their own retail chains as well as factory outlets, while some of Europe's large fashion groups now have manufacturing interests in footwear. Technology developments in the industry, particularly computer-based applications, have shortened production lead times enabling quick response to fashion changes and the introduction of just-in-time (JIT) manufacturing.

INDUSTRY PROFILE

Description of the sector

The different types of footwear produced within the Community are classified in NACE codes 451 and 452 as follows: mass produced outdoor footwear (451.1) mass produced indoor footwear (451.2), special types of footwear (451.3), and handmade footwear (452). It is also common to classify footwear into broad groups by the major material of the upper - leather, synthetic, rubber, textile and other. Some of Europe's large fashion groups have interests in a number of sectors which includes the manufacture of footwear to sell through their own outlets.

Recent trends

The EC footwear industry employed approximately 301 000 workers in 1993 (including firms with less than 20 employees) according to the Confédération Européenne de l'Industrie de la Chaussure (CEC). Eurostat data, which excludes firms with less than 20 employees, estimated total employment in 1992 as 234 500 workers. This difference reflects the importance of small enterprises in the footwear sector.

The industry is relatively labour intensive. The value of production in 1992 was 18.8 billion ECU including labour costs of 4.1 billion ECU, equivalent to 22% of production value. Total value added for the industry in 1992 was estimated as 5.1 billion ECU. Apparent consumption in 1992 was marginally higher than production reflecting a small deficit on extra-EC trade.

The deficit in the EC's footwear trade balance in 1992 was 288 million ECU and, following an even larger deficit in 1991, was only the second ever year a deficit was recorded. This trend is symptomatic of the increasing vulnerability of the EC footwear industry to low-cost extra-EC producers. Production value data for the EC footwear industry points to stagnation during the 1980s with some recovery in recent years, mainly as a result of very strong growth in Italy, although some of this recovery may be more apparent than real. In addition to trade data, other indicators such as volume of production, employment and value-added show a less favourable trend in the development of the EC footwear industry.

Italy is Europe's major footwear producer accounting for 49% of the total value of EC production in 1992. The next largest producer, France, accounted for 15%. Other major producers are Germany (11%), Spain (10%) and the United Kingdom (9%). Portugal is another major European producer.

The CEC estimate that 1992 footwear production will be 1.08 billion pairs, with leather footwear accounting for two out of every three pairs of shoes produced in the EC. The importance of different types of footwear production varies across Member States. The production of leather footwear accounted for 88% of footwear produced in Portugal, 80% in Germany, 70% in Italy, and 74% in the Netherlands in 1992. Over 50% of Belgian output is slippers and approximately 30% of footwear produced in the United Kingdom is synthetic or rubber uppered. In France, slippers account for 32% of production while textile uppered and synthetic uppered footwear account for 12% and 11%, respectively.

The 1980s was a difficult period for the European footwear industry, although modest growth resumed in recent years following substantial rationalisation in the earlier part of the decade. However, import penetration by low-cost producers remains a key feature of the sector, rising in each of the ten years to 1992 except for 1992 itself.

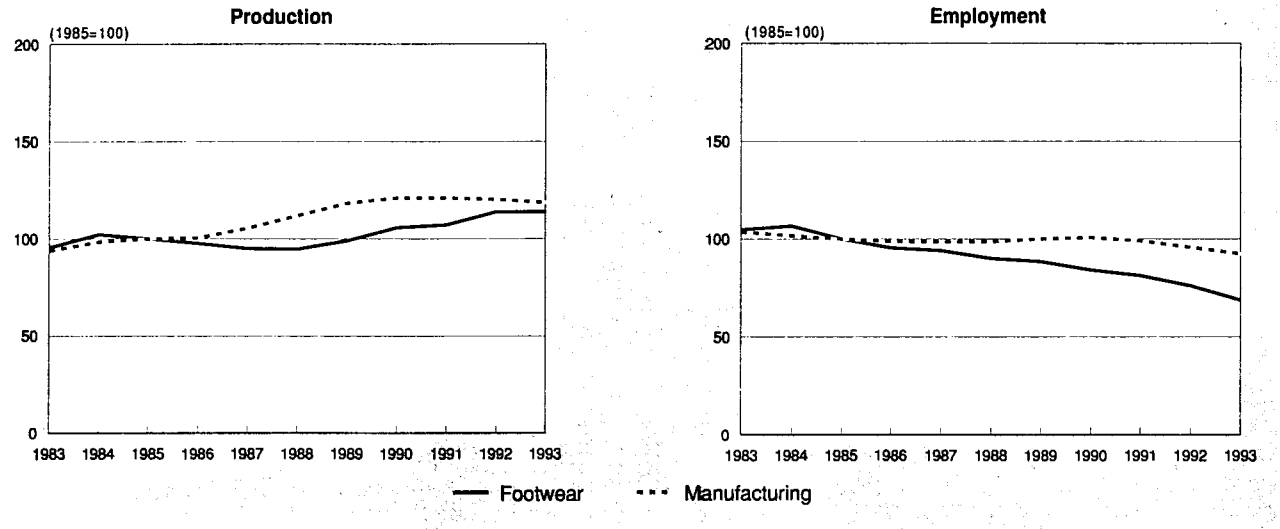
Figure 3: Footwear
Production in constant prices and employment compared to EC manufacturing



1993 are Eurostat estimates.
Source: DEBA

While production by EC companies increased in recent years, apparent EC consumption grew more rapidly with EC producers continuing to lose considerable market share to extra-EC imports. Between 1986 and 1992, the value of apparent consumption grew by 59% in current prices, while the value of EC production over the same period rose by 36%. There has been somewhat of a turnaround in the footwear industry in recent years compared to the early to mid-1980s, with strong real annual average growth rates of EC production and extra-EC exports in the latter half of the period. The turning point appears to have been 1988 and the value of production in constant prices shows continuous, albeit slow, growth each year since 1988. It is estimated that from 1988 to 1992, the value of EC production in constant prices increased by 20%.

However, rising production values over the last four years paints a somewhat misleading picture. Some of the problems which beset the industry in the early 1980s still remain and are reflected in other indicators such as the trend in employment, in value-added, in the number of shoes produced in the EC and in the deteriorating EC trade balance. While the value of production deflated for increases in producer prices has risen in recent years, the actual volume of production has fallen and stocks have also increased. In contrast to Eurostat constant price data, CEC estimates of shoe production volume indicate an overall fall of 5% in 1992 and of 3% in Italy (Eurostat constant price data shows growth of 17%).

In addition, analysis of trends for individual Member States indicate that the value of production in constant prices fell in most Member States in recent years and only Italy recorded a significant increase. A substantial portion of the growth in the value of production in Italy is a result of adding value, often through marketing or presentational inputs, to completed or almost completed shoe imports and re-exporting at much higher prices. Thus, while the value of production in constant prices rose by 24% (1.5 billion ECU) in Italy over the 1990-92 period, imports rose by 74% (0.4 billion ECU) and value-added in constant prices fell by 6% (0.1 billion ECU). Overall, value-

Figure 4: Footwear

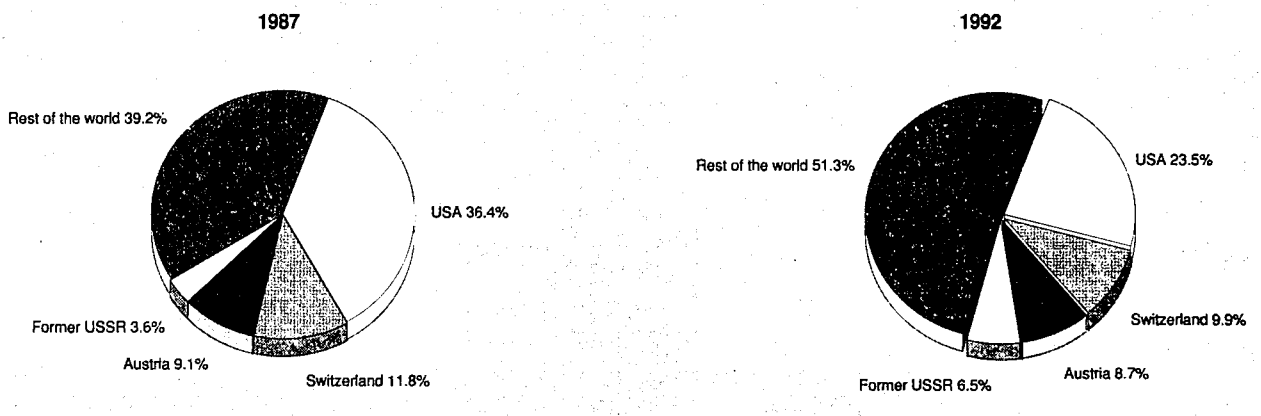
Destination of EC exports



Source: Eurostat

added in the EC footwear industry has fallen slowly but continuously in constant prices since 1984, declining by 13% over the 1988-92 period. Similarly, employment in firms with over 20 workers declined by 36 500 to 234 500 over the five years to 1992.

The footwear industry within the EC is dominated (in value terms) by five Member States - Italy, France, Germany, Spain, the United Kingdom and Portugal. Their relative importance has, however, declined marginally. They accounted for 93% of the value of EC production in 1992, compared to 94% in 1983. However, the relative importance of Italy has increased considerably while that of the other four, particularly France and Germany has decreased. Almost all of the growth in production recorded over the 1988-92 period was in Italy, with an overall increase in the value of production in constant prices of 62%. In contrast, over the same period, France, Spain and the United Kingdom recorded little or no growth while production in Germany declined sharply. Small increases in production were also recorded in the Netherlands and Portugal. Portugal was the only Member State to record continued growth throughout the 1980s but real output fell marginally during both 1991 and 1992.

CEC data indicates the volume of all footwear remained almost constant between 1988 and 1992, but that the quantity of non-leather footwear production decreased by 6% to 706.7 million pairs. Most of this decrease occurred during 1992 and is reflected both in the overall fall in footwear production of 36.5 million pairs and a rise in slipper production of 9.7 million pairs.

International comparison

The EC is a major producer of footwear, accounting for around 10% of global footwear production and 20% of world footwear exports. Footwear production is, however, dominated by low-cost developing countries and newly industrialised countries (NICs), with the United States and Japan accounting for only 3% and 4%, respectively, of world footwear production. In contrast to the European experience, the footwear industry in the USA has contracted considerably over the last ten years, with the value of production in current prices falling by 46% over the period 1983-92. The corresponding statistic for the EC was a growth of 62%. Similarly while production value in constant prices increased by 14% over the 1985-92 period in the EC, it fell by a third in the USA.

Foreign trade

International trade in footwear is not covered by the Multi Fibre Arrangement (MFA) which governs trade in the textile and clothing sectors. The EC footwear sector is heavily dependent on international trade, with 22% of EC production exported to extra-EC destinations in 1992. In current prices, extra-EC exports have increased by 10% since 1986, while the current price value of extra-EC imports increased by 130% over the same period. By 1992 extra-EC imports accounted for 24% of apparent consumption in the EC, compared to 16% and 13% in 1986 and 1983, respectively. However, some of this increase includes growth in imports of partly finished shoes for further production.

Increasing import penetration of the internal EC market is now reflected in an overall trade deficit on footwear trade. Traditionally the EC recorded a surplus in footwear trade but, despite a sharp slowdown in imports in 1992 and a continued rise in extra-EC footwear exports, a further deficit, albeit smaller, of 288.2 million ECU was recorded.

Extra-EC imports are spread across a variety of footwear types with textile uppered footwear accounting for 28% of the total by volume in 1992. Leather footwear accounted for a further 26% of the volume of extra-EC imports, with slippers and synthetic-uppered footwear accounting for 19% and 13%, respectively. In contrast, the majority of extra-EC exports were leather-uppered in two out of every three pairs in 1992.

The EC has a trade surplus in footwear with the USA, Japan and the EFTA countries. However, it has a large trade deficit in footwear trade with developing countries and with the former Eastern Bloc. The leading market for extra-EC exports is in the EFTA countries, the other important market being the USA. However, the importance of the USA as an export destination has declined. Italy is the EC's major exporter, accounting for 54% of extra-EC exports in value terms. Other major extra-EC exporters include Germany, Spain, France, Portugal and the United Kingdom. In 1992, Italy, Spain and Portugal were the only EC Member States with a surplus in the value of their extra-EC trade.

The majority of extra-EC imports to the Community come from developing countries and their value has been increasing steadily. The United States and EFTA countries accounted for only 10% of extra-EC imports in 1992, compared to 18% in 1987. The largest growth in imports to the EC in nominal terms has been from China. China and Vietnam are the largest exporters of footwear to the EC. Germany is the largest importer of extra-EC footwear, importing 34% of the total value

of extra-EC imports in 1992. Italy, the United Kingdom and France are also major importers in value terms.

MARKET FORCES

Demand

Most footwear is purchased by individual consumers. Spending on footwear tends to be cyclical, expenditure being reduced or deferred in recessionary times with a compensating upturn during a recovery. Contract sales to major customers such as the military, or industries requiring specific work or safety footwear are important niche markets.

While having a fashion content, footwear is seen primarily as a necessity and a smaller proportion of income is spent on footwear as income rises. Some niches within footwear, in particular the market for trainers and certain segments of the ladies footwear market, are strongly influenced by fashion trends. In addition, demand for sports footwear has been boosted by higher levels of sports participation. Increased fashion demand has also resulted in increasing usage of coated fabrics and textiles, rather than leather, for uppers or lining material.

Both volume and value figures show the largest market for footwear in the EC are Italy and Germany, each accounting for 26% of the value of consumption in 1992. France (20%) has the highest per capita consumption of footwear, 5.99 pairs per annum in 1992 compared to an EC average of 4.63 pairs. Comparison between Members States show significant differences in prices paid per pair - reflecting to some extent greater quality and fashion consciousness. The price paid per pair is highest in Italy.

Innovations in manufacturing technology have helped maintain the competitiveness of European footwear producers. Increasing use of Computer Aided Design (CAD) and Computer Aided Manufacture (CAM) has allowed European manufacturers to introduce quick response and just-in-time manufacturing to compete with low-labour cost countries as well as allowing the production of high quality low-volume runs to take account of fashion trends.

The importance of these technological developments for the competitiveness of EC manufacturers is closely linked to their proximity to the large European market. Footwear technology, by comparison with many industries, is relatively basic and in general is not proprietary. Most technological advances are embodied in capital equipment and the machinery manufacturer will readily sell their product to buyers in NICs and developing countries. The key for EC manufacturers is the utilisation of such advances to maximise their proximity to the world's most lucrative footwear market and to the footwear industry's leading fashion centres. Even these advantages are being negated. Low cost producers close to the European market in North Africa and East Europe may become more important in the medium. However, European manufacturers can now use CAD systems to transmit new designs on-line to production facilities in low cost countries.

Supply and competition

Distribution of footwear has traditionally been mainly through independent retailers, but the retailing sector has become more concentrated. The importance of larger generalist stores and multiple retail chains have increased at the expense of independent retailers and has led to shifts in relative bargaining strengths of retailers.

Some large manufacturers such as the Bata Organisation (F) and Bally (UK) have also established retail arms with outlets in a number of European countries. Other manufacturers such as André (F), Charles Jourdan (F), Clarks (UK), Eram (F), and Salamander AG (D) also operate retail units both within their own domestic markets and in other Member States. Footwear manufacturers are also becoming increasingly involved in direct selling to customers through factory shops and "seconds" shops. Clarks International have opened five Clarks factory shops as well as two K Shoes factory shops. Manufacturers are also seeking to benefit from the move by retailers towards combining their clothe lines with accessories. Increasingly, footwear companies are attempting to link with retailers or operate in-store concessions.

The key competitive advantages of EC footwear manufacturers, under pressure from lower priced imports, is based on time and service quality, with successful EC manufacturers offering strong commitments on price, delivery performance and flexibility. In response to the needs of the retail groups, footwear manufacturers are increasingly adopting quick response strategies, although the number of companies using this strategy remains relatively low by comparison with the clothing sector. Many SMEs have adopted these strategies.

With a large number of firms, the presence of few restrictions on extra-EC imports and few barriers to intra-EC trade, the internal EC market in footwear is relatively competitive. Internal EC competition increased in the run up to the completion of the single market in 1993, with some of the larger retail chains expanding into other EC Member States. However,

ongoing recession in major EC markets has dampened the impact of the single market during 1993.

The removal of customs and other physical barriers to intra-EC trade has led to a reduction in transport cost and delivery time. This benefits firms who are dependent on markets in other Member States and those competing on the basis of delivery performance and quick response. The approximation of VAT on footwear will not now take place until at least 1997, at which time Member States which currently have low VAT on footwear - Ireland, Spain, Italy and Luxembourg - will experience price increases.

Imports of footwear to the EC originate mainly from the low labour cost countries, most notably China, South Korea, Indonesia, Thailand and Taiwan, although imports from other developing countries, such as India and Brazil, are growing.

Extra-EC exports are generally high quality leather footwear to developed countries such as the USA, Canada, Switzerland, Austria and other EFTA countries. The volume of exports to destinations such as the USA and Canada has fallen, partially explained by the depreciation of the dollar during the latter half of the 1980s. The long run competitiveness of the EC footwear industry will depend on its ability to continue to supply high quality products to high income markets. In common with the leather industry upstream, expansion into some extra-EC markets is blocked by high duties and tariff barriers (particularly Japan), while restricted access to some of raw materials necessary for higher-value added European production is also a problem.

To help improve the prospects of EC footwear firms, there is a budget for export promotion voted by the European Parliament with the aim of improving access to markets of non-EC countries and to reduce high levels of duty imposed on extra-EC exports by many countries. The on-going Uruguay round of the General Agreement on Tariffs and Trade (GATT) negotiations may also yield some benefits in this regard.

The fragmented nature of the footwear industry makes it difficult for manufacturers to benefit from economies of scale. Pressure from cheap imports coupled with increases in the cost of labour has led to a decline in profitability in the sector. European manufactures trying to compete with cheap imports have tried to maintain market share by expanding their existing line of products, while companies responsive to changing fashions are producing smaller production lots and recouping increased product costs through higher prices.

Production process

The traditional production process for footwear is a relatively simple labour intensive manufacturing process, which can be divided into a number of stages. The first stage, called "clicking", involves the cutting out and preparation of components for the upper and the sole. This is followed by "closing", when the components are stitched together to produce an "upper". The upper is then shaped and an insole and a sole are affixed. Finally, the shoe is finished by cleaning, inspecting and boxing.

Footwear production is still mainly based around a stack of foot-shaped formers, the last, over which the upper is draped and constructed and to which the sole is joined. Mechanised footwear production has usually been organised in a track system along which progressively assembled shoes are carried and are lifted from the track by operatives to perform the next stage. The introduction of the "rink" system has increased productivity and has led to a significant reduction in the volume of rejects. The "rink" system involves arranging the various steps in the shoe-making process in sequence, generally in the shape of a horseshoe. Each function is the responsibility of an operator, although each operator should have the flexibility to perform a number of tasks. Work is passed from one operator to the next, one pair at a time. The team is responsible for quality control and inspects its own work.

Production of footwear within the EC is becoming more mechanised and specialised. The introduction of computer-aided design (CAD), which allows a shoe to be designed on computer and the details to be downloaded to production machines, has been one of the most important developments. CAD reduces the time span between design and production to a few hours enabling quick response to style changes for fashion footwear. The use of CAD systems has been accompanied by computer aided manufacture (CAM) and computer integrated manufacture (CIM). CAD systems are increasingly being linked with computer aided cutting systems using waterjet, laser or die cutters. Operators can view a piece of leather with the use of video and computers and create shoe patterns, having taken account of any blemishes on the raw material.

Unit labour costs in current prices in the EC footwear industry increased continuously over the last ten years, registering an overall increase of 56% over the 1983-92 period. In recent years, these unit cost increases have been relatively sharp, rising by 22% between 1989 and 1992. However, labour productivity has risen very slowly, by just 8% between 1983 and 1992. The need to rationalise costs to maintain competitiveness with developing countries has led larger companies in some Member States to transfer production facilities to lower labour cost countries within the EC, including Portugal.

INDUSTRY STRUCTURE

Companies

The footwear industry within the Community is highly fragmented, characterised by a large number of small business. According to the CEC, there were about 14 730 footwear firms in the EC in 1992, employing an average of 21 workers, compared to 15 396 firms in 1991. More than half of these firms, 55%, were in Italy. Major EC footwear manufacturers include Salamander AG (D), Romika & Co. KG (D), Eccolet Sko (DK), Eram (F), André (F), Clarks (UK), Church & Co (UK), Simod SpA (I) and Filanto SpA (I).

Strategies

Available investment data on the EC footwear industry is dated, with 1989 the latest year for which information is available for most Member States. In 1989, the value of investment in current prices for all Member States, except the Netherlands, was 295 million ECU, roughly equivalent to levels in 1985 and 1986 in nominal terms. This is less than 2% of the value of production and indicated little confidence in the future of footwear manufacturing in the EC during the second half of the 1980s.

The nature of the production process makes automation of the shoe-manufacturing difficult, although a number of state-of-the-art plants in northern Europe are using robotics to reduce labour content. For example, Bata Holland's "precision manufacturing unit" assembly line features computerised robots for the automatic roughing, control, loading and unloading. However, the low level of major investment in plant and machinery, which might result in substitution of capital for labour, has not helped maintain employment. Rather, employment in the EC footwear industry fell by 13% over the five years to 1992 and by 25% since 1983. Only in Portugal has employment increased over the last ten years, although along with stagnation in production volumes employment growth in Portugal ceased in 1988 and fell slightly during 1991 and 1992. This reflected the sourcing strategies of major EC producers who sought to take advantage of lower labour costs in Portugal in the early and mid-1980s. The creation of clusters of foreign footwear firms in Portugal also helped stimulate indigenous Portuguese manufacturers leading to rapid growth in that country. The fall-off in production and employment in Portugal in recent years is partially due to economic conditions in general but also reflects rising labour costs, which increased by almost 90% per person employed in the footwear industry in Portugal between 1987 and 1992.

Companies which have transferred production to lower-cost countries within the EC such as Spain and Portugal include the French company, Charles Jourdan, that transferred production from the Rhône valley to Spain. Some French manufacturers now sub-contract to Portugal as well as to extra-EC countries such as Tunisia, Morocco and China. Eram, one of France's largest producers and distributors of footwear operates ten plants within France along with one in Portugal and one in Spain. Many German producers have transferred their production to Portugal and many also operate plants in Austria, while United Kingdom manufacturer, Clarks, have two plants in Portugal. The Danish footwear manufacturer, Eccolet, operates plants in Portugal and former Czechoslovakia as well as in Denmark. Bata, the world's largest footwear organisation is to modernise a manufacturing facility in former Czechoslovakia.

Many EC producers have also shifted operations to low labour cost developing countries outside of the EC. The German company, Wortmann, has factories which manufacture inputs in Taiwan, Hong Kong, China, Thailand, Brazil as well as in different EC countries. Europe's leading sports footwear manufacturers such as Adidas and Puma also transferred substantial proportions of their production facilities to the Far East during the second half of the 1980s. This was done in order to remain competitive with their main competitors who already manufacture the majority of their footwear in the Far East. Puma closed its last German manufacturing facility during 1993. South Korea, Taiwan and Thailand are the most popular countries for sourcing as some of the lower cost countries are not yet as well organised or as reliable. The importation of uppers and other labour-intensive parts from low labour cost countries for assembly is also common, although this is less popular in Italy and most popular in Germany, which pioneered such outward processing in Eastern Europe. However, the trend of locating production facilities in Eastern Europe is likely to slow. Labour costs in these countries have been increasing implying that any benefit to footwear manufacturers will only exist in the short term.

Some quality and image conscious footwear companies almost completely refrain from sourcing production in low-cost locations. While Bally's in-house production contracted rapidly during the 1980s, most of the subsequent subcontract work is in high-cost locations with the major portion of the company's sub-contractors located in Italy. Bally's fashion studios in Milan, Paris and London co-operate closely with these sub-contractors. Some leading German retailers also source production of their private label shoes with Italian sub-contractors.

Some EC footwear firms, particularly sports footwear firms, are adopting global strategies, acquiring manufacturing and retail outlets or franchises outside the EC, as part of their expansion strategies. However, this process is also working in reverse with Japanese and South Korean companies such as Asics and Kukje each establishing a strong presence in

Europe. This trend is not confined to sports footwear - the acquisition of part of Charles Jourdan by Dickson Concepts, a Hong Kong retailing group in early 1992 indicates a similar trend in the classic footwear market.

Integration of retailing and manufacturing has been an important feature of the footwear sector over the last decade. Reflecting the greater importance of the EC as a market for footwear rather than as a manufacturing base, many footwear companies now place greater emphasis on retailing aspects of their operations than on manufacturing - France's Groupe Andre, for example, which has been increasing its retail presence in France and other EC markets sold Jallate, a world leader in safety shoes, in early 1993. In addition, strategies both in terms of capital investment and new organisational structures place increasing emphasis on quick response, flexibility and other aspects of delivery performance. In France, Bata's computerised manufacturing system can provide customers with a coated sample in real time, and can achieve a three day turnaround for urgent repeat orders. Similarly, Bally recently introduced a computerised merchandise information system aimed at minimising stocks, shortening order delays and improving cooperation between Bally's production units, its sub-contractors and retailers.

REGIONAL DISTRIBUTION

Much of the EC's footwear industry is concentrated in particular countries and within regions in these countries. These regions are often areas with little alternative employment to the footwear industry. The industry is most regionally concentrated in Iberian Peninsula. In Portugal, Averio accounts for over half of footwear production while Porto and Braga account for a further 31% and 11%, respectively, while in Spain 62% of footwear firms were located in the Valencia region in 1991. Three Italian regions the Marches, Tuscany and Veneto account for almost two-thirds of footwear employment in Italy, and hence a fifth of footwear employment in the EC. Similarly over 60% of shoes produced in France in 1991 came from the Pays de Loire and Aquitaine regions. In addition, the industry often tends to be even more concentrated in towns and areas within regions such as Herzogenaurach and Pirmasens in Germany, and Northamptonshire in the United Kingdom. The impact of any adverse developments for the industry are therefore particularly concentrated within specific areas of the EC.

ENVIRONMENT

Environmental issues are more important in industries supplying the footwear industry than in the industry itself. The leather and tanning industry is a major source of raw materials to European producers. Suppliers in this sector are under pressure to use water and chemicals more carefully to reduce effluent. The need to install water effluent treatment equipment to meet increasing environmental standards will lead to increased tanning costs and an increase in costs of the raw material for the footwear industry, although there is already sourcing of materials outside the EC. Further problems for the industry are caused by divergence between existing national legislation and the EC Directive on PCP (pentachlorophenol), with the maximum permitted limit set at very low levels in some Member States. The lack of standard testing procedures also exacerbates the situation.

Suppliers of raw materials for non-leather footwear production are likely to face increasing constraints from regulations on usage of polyurethane and polyvinyl chloride (PVC).

REGULATIONS

With the arrival of the single market the national quotas for footwear imports from some low cost producers which many Member States had established have become somewhat redundant as a result of the dismantling of border protection. Previously, national quotas could be protected through Article 115 of the Rome Treaty. This Article helped preclude extra-EC footwear imports from circumventing Member State level import controls by routing goods through another Member State. With no physical internal border controls since January 1993, the use of this Article has become very problematic and it is now being phased out.

EC authorities are currently working on the development of a global proposal in relation to imports from low-cost countries which would cover a range of product areas, including footwear. For example a series of quotas would be set at EC level for nine different categories of footwear. The quota levels are still under discussion but would be set in value terms and would significantly reduce EC imports of footwear in the categories concerned.

Following concerns about the impact that national legislation on footwear labelling in France and Spain would have on intra-EC trade, a proposal for an EC Directive has been forwarded concerning the labelling of the materials used in the main components of footwear for sale to the final consumer. The Directive deals primarily with indicating the composition of footwear by means of either "pictograms" or text and should be soon adopted by the Council.

OUTLOOK

The EC footwear industry faces a difficult future, although there are some encouraging factors. These include the possibility that a GATT agreement may ease some of the trade restrictions which EC manufacturers face on some lucrative extra-EC markets, recovery in the key extra-EC markets of Japan and the USA and better prospects for Member State economies from 1994. A stronger Yen and a stronger USD will also improve competitiveness of extra-EC exports.

However, recovery in the EC will also lead to resumed growth of extra-EC imports of footwear from low-cost competitors. The rate of growth of sourcing of production in lower-cost countries slowed in recent years, but the shifting of manufacturing facilities outside the EC is unlikely to halt. The industry's fundamental difficulty is that it is caught in a wider global shift of comparative advantage in labour intensive industries. In the case of footwear, this shift is accentuated by the fact that it is a basic commodity for which there is tra-

ditionally strong local demand and also is a producing sector in developing countries at early stages of industrialisation. Thus, as labour costs in countries such as Taiwan and South Korea climbed as a result of ongoing economic development, new and additional locations such as China and Indonesia have come on-line. In addition, technology is relatively basic and non-proprietary.

The full impact of the Single Market has thus far been blunted by the impact of the recession on consumer demand. However, it can be expected to increase competition within the EC and is likely to cause a further squeeze on the margins of European manufacturers. How competitive the internal market becomes will also depend on the evolution of EC trade policies, not only in the context of the GATT but also with regard to arrangements vis-a-vis East Europe. In addition to improved ease of access for East European footwear, easier access to East Europe will facilitate EC manufacturers in locating production facilities in these countries. Provided political stability is maintained, the volume of extra-EC footwear imports from Eastern Europe seems likely to increase as does the volume of imports of uppers or partially assembled inputs.

Consumption of footwear can be expected to fall in the short-term as major EC markets remain in recession, but is expected to pick up in the medium term. Growth in consumption is, however, expected to lag behind overall economic growth both in time and in magnitude. With increasing import penetration, both employment and production by EC firms are expected to fall in the medium term. While the increasing use of technology by footwear companies will assist the industry in regaining competitiveness, it will not provide the complete solution. Increased cost effectiveness will also be needed along with greater emphasis on marketing and satisfying the changing demands of the consumer.

Table 7: Footwear

Growth in exports to extra-EC markets is expected to offset some of the impact of contracting sales in the internal EC market. A more rapid return to growth in the USA and Japan than in Europe, facilitated by recent (and likely future) exchange rate movements, will boost EC exports of high value-added quality footwear to these markets. New markets are also likely to appear in the increasingly prosperous Asian NICs with a positive outcome to the GATT negotiations and, although uncertainty in this regard complicates any forecast, growth is likely in any case.

Leather tanning and finishing

NACE 441

Tanning and finishing is a traditional sector of EC industry. Despite its exposure to increased and often unfair foreign competition, the EC leather sector remains at the forefront of the world industry representing about half of total world trade. Against a background of a shrinking domestic market, EC tanners have concentrated in smaller but lucrative market niches, placing emphasis on quality and fashion while consolidating their competitive advantages of flexibility in production and quicker delivery times and improving their environmental performance.

INDUSTRY PROFILE

Description of the sector

The NACE 441 (tanning and dressing of leather) includes: tanning and dressing (NACE 441.1); manufacture of imitation leather based on natural leather (NACE 441.2); and currying, dyeing and finishing of leather (at independent workshops) (NACE 441.3).

The NACE nomenclature includes (under position 441.2) activities which can not be classified as genuine leather according to the definition set by the International Council of Tanners (ICT).

Tanning and finishing consists of converting raw hides and skins into leather which serves for the production of footwear, clothing, furniture, and other consumer goods. Leather is thus an intermediate product used as an essential raw material in downstream industrial processes or crafts. Only "chamois" is sold directly to consumers as a cloth able to absorb four times its weight in water and therefore ideally suited for drying cars and kitchenware. The tanning industry depends upstream on the agricultural sector and on the availability of animal hides and skins obtained as a by-product in abattoirs.

The economic weight of the single tanning sector is with an added value of nearly 1 300 million ECU relatively small compared to other industries, but considered as a whole, the leather, footwear and other leather articles industry induced by the tanning industry accounts for over 10 000 million ECU competing in importance with consumer electronics or clothing.

Italy is by far the most important Member State in terms of leather production with output valued at 4.6 billion ECU in 1992, nearly 60% of total EC output, ranking among the world's leading tanning industries. Italy accounts for 72% of establishments in the sector, a total of 2 200. Next comes Spain with only 278 tanneries (9% of the total) but about 928 million ECU and 13% of the production value. France, Germany and United Kingdom each produce about 500 million ECU. However, in terms of companies, they represent, respectively, 5%, 1.8% and 2%. Portugal's importance in the sector has grown in recent years due to the boost in demand derived from the relocation of downstream industries to that country. There are now 115 tanning establishments located in Portugal. The production value in other Member States is relatively small and their tanning sector minimal.

Recent trends

Leather production in the EC has experienced a severe downturn since 1989 when it reached record levels of over 8 000 million ECU. Since the beginning of the decade, the industry's turnover has fallen sharply, coming close to the figures of the early 1980s and reflecting the general economic crisis. Consumption of leather is dropping rapidly in the EC as more and more downstream industries disappear, either relocating their factories in low cost countries or closing down their business because of the fierce and often unfair competition from extra-EC producers.

As a consequence, EC tanners have been forced to look for alternative foreign markets which could make up for the loss in the domestic one. In value terms, extra-EC exports progressed significantly until 1989. Since then, they have slightly decreased, but they stabilised at about 1 200 million ECU in 1992. Intra-EC trade experienced the same trend, while the value of extra-EC imports remained relatively stable at a high level over the past decade.

All EC Member States' leather industries continued to loose ground during 1992 in terms of production and market share, with Italy and the Netherlands faring best with decreases of 2% and 5%, respectively. The EC sector's turnover (in current prices) declined by 9% compared to 1991 and EC tanners faced difficulties in maintaining a reasonable share of the

shrinking EC market. The instability of the EMS had detrimental consequences on leather trade with the devaluation of several European currencies conferring more damage on the industry than advantages, particularly for operators relying on imports for their raw material supply. Uncertainties in the outcome of the Uruguay Round continue to erode EC tanners confidence in a somewhat brighter future. Preliminary 1993 data for the main indicators show no signs of recovery in the short term.

International comparison

The EC tanning sector remains at the forefront of the world leather industry well ahead of the USA and Japan. Its well established image of quality and reliability combined with its leadership in terms of fashion and design still secure EC tanners a privileged position with regard to other competitors. Despite recent contractions, the EC leather market remains with a value of nearly 6 500 million ECU, one of the world's largest trade areas for this industry.

Behind a wall of protection, Japan's tanning industry continues to enjoy a significant and lucrative captive market while distorting international trade.

The USA, the world's largest supplier of cattle hides, takes advantage of its large, guaranteed and concentrated supply of raw materials and maintains a profitable leather industry, particularly up to the wet blue stage.

However, as consumption of leather is shifting to other markets in developing countries and newly industrialised countries (NICs), especially in Far East Asia and Latin America, it is the leather industry in those countries that experiences the fastest growth. In this respect, China represents both an enormous market opportunity and a tremendous threat to competitors.

Foreign trade

While EC tanneries still account for about half of world trade in leather, developing countries and East Asian NICs are pro-

gressively increasing their share as they develop their domestic tanning industries and adopt strong export oriented strategies. In this respect, the EC offers them, at a cost to its own tanning industry, easy access to its internal market through the Generalised System of Preferences (GSP). As a result, India and Pakistan have managed to become the largest single suppliers of finished leather to the EC accounting for 18% and 12%, respectively, of all extra EC imports in 1992. Argentina's share represents 6%.

Unfair trade practices and protectionist measures proliferate in a number of the EC's trading partners in the leather area. Japan's leather market for instance is virtually closed. Leather exports to that country are heavily discouraged by a penalising tariff-quota system established in 1986 and recently renewed until at least 1996. EFTA countries and the USA remain the most important export markets for the EC tanning industry with a share of 13% and 11%, respectively, of all exports of finished leather in 1992.

MARKET FORCES

Demand

As an intermediate product, leather is normally sold to industrial customers for the manufacture of a wide range of consumer goods and some technical applications. Demand for leather depends, therefore, on sourcing decisions of client sectors which in turn try to fulfil the needs of the general public. Footwear, garments, leather goods upholstered furniture and cars constitute the most typical outlets for leather. Among the factors which influence demand for these products, and thus for leather, per capita income, consumer spending, fashion considerations and lifestyle rank as the most important. EC tanners have so far been reasonably successful in providing fashion services to their clients and anticipating colour trends and consumer preferences, taking advantage of their proximity to the major fashion centres.

The footwear industry remains the most important market for EC leather consuming 49.3% of total production in 1992. The clothing industry accounted for 20.5%, while leather upholstered furniture and cars absorbed 16.8% in 1992. Leather for leather goods and other uses was the least important end use, accounting for the remaining 13.4%. The importance of the different downstream uses varies across Member States according to their particular patterns of specialisation. In Germany, for instance, upholstery leather represents 48% of the total leather production.

Reduction of consumer spending has been evident in most consumer good markets over the last three years but has been a particular problem for the EC leather industry for whom luxury products are a major target market segment. Similarly, the present recession is seriously affecting demand in key extra-EC markets. Demand for quality leather from the EC is, however, increasing in the fast growing economies of the Pacific Rim with the emergence of a relatively wealthy middle class.

Supply and competition

The move of the EC tanning industry towards the supply of more qualitative but smaller market niches as a result of the fierce competition from developing countries in the standard and bulk leather segments has led to a loss of significant production capacities in most Member States. The United Kingdom, for instance, lost 75% of its output capacity over the last decade. The lack of early structural adjustment, combined with the persistence of the recession, has resulted in substantial and costly unused capacities for some tanneries in other Member States. In southern France, a number of tanneries, mainly supplying the clothing market, are running at about 30% of capacity. Flexibility and adaptability in the supply of industrial customers has been a major theme in the restructuring of the EC leather sector, but shorter and more diversified runs also entails additional unit costs and precludes the development of economies of scale.

Reflecting the openness of the EC internal market, EC tanners do not benefit from a dominant position. They do, however, have some non-price advantages such as quick response and just-in-time (JIT) techniques that are becoming more important as EC producers attempt to maximise the advantage of market proximity.

The EC leather industry is increasingly threatened by an often unfair foreign competition in its domestic and export markets exerted by extra-EC tanners with protected access to raw materials and governmental support in the development of their trade. As hides and skins typically represent 50% of the production cost of leather, tanners are very vulnerable to fluctuations in raw material prices on world markets. Export restrictions on raw hides and skins create an artificial oversupply in the captive market distorting the competition to the advantage of domestic manufacturers. These unfair trade practices have indeed been implemented by a number of developing countries in order to boost the growth of their domestic tanning industry. Price advantages of up to 20% due to the lower cost of raw materials have been recorded in finished leather imports from Argentina, India and other countries.

Social dumping has a less important impact on the EC leather industry as tanning is a capital intensive industry where labour costs do not account for a significant part of production costs. Environmental dumping, however, is putting additional threats on the competitiveness of the EC tanning industry. Whereas European tanners have to contend with a competitive disadvantage estimated at 2% to 4% of turnover for environmental protection, their counterparts in developing countries face virtually no environmental cost because of the lack of regulations or of their effective enforcement.

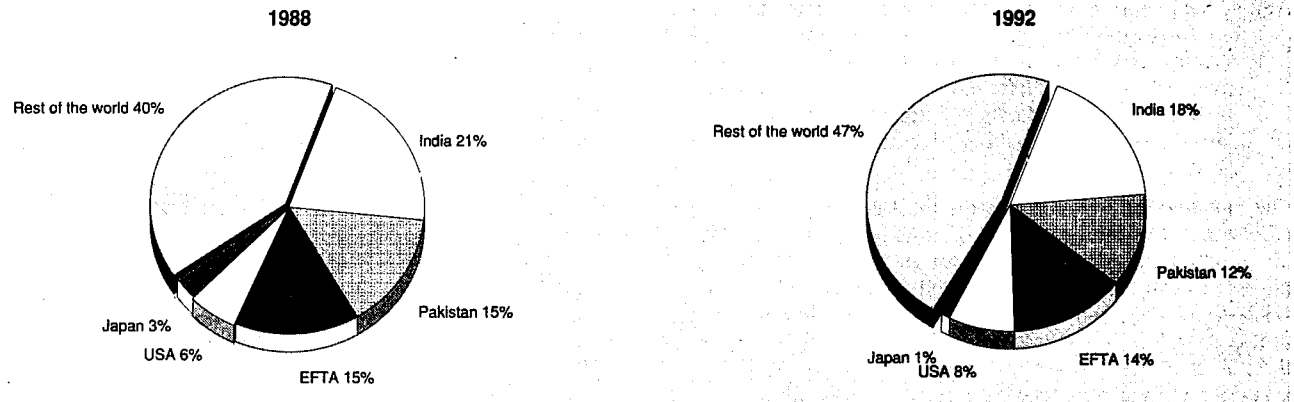
The world hides and skins market appear to be turning around after several years of increased supplies and lower prices. Hide prices began dropping in 1990 remaining low through 1991 and early 1992 due primarily to increased slaughter in the EC, the former Soviet Union and Australia. However, lower slaughter rates reduced world supplies in the latter half of 1992 and early 1993. With this, and continued high utilisation in the USA market, early 1993 world hide prices have shown a significant improvement compared with a year ago. Improvement in prices should continue through 1993, but only gradually as continued sluggishness in the world economy, particularly outside the USA, dampens growth in world leather demand.

The EC tanning industry's supply capacity also varies according to the different subsectors and the developments in the different user industries. Between 1980 and 1990, bovine leather consumption and production grew in the EC due to an increased demand in the footwear and upholstery markets but EC production failed to keep pace with the growth in EC consumption in the second half of the decade. In the sheep and goat leather sector, lower priced imports of garment leather and leather clothing from developing countries and NICs have contributed to the increasing overcapacity in EC tanneries.

By providing a more competitive service to manufacturers, EC tanners may find themselves in a position either to charge a higher price and/or to attract a more consistent level of orders.

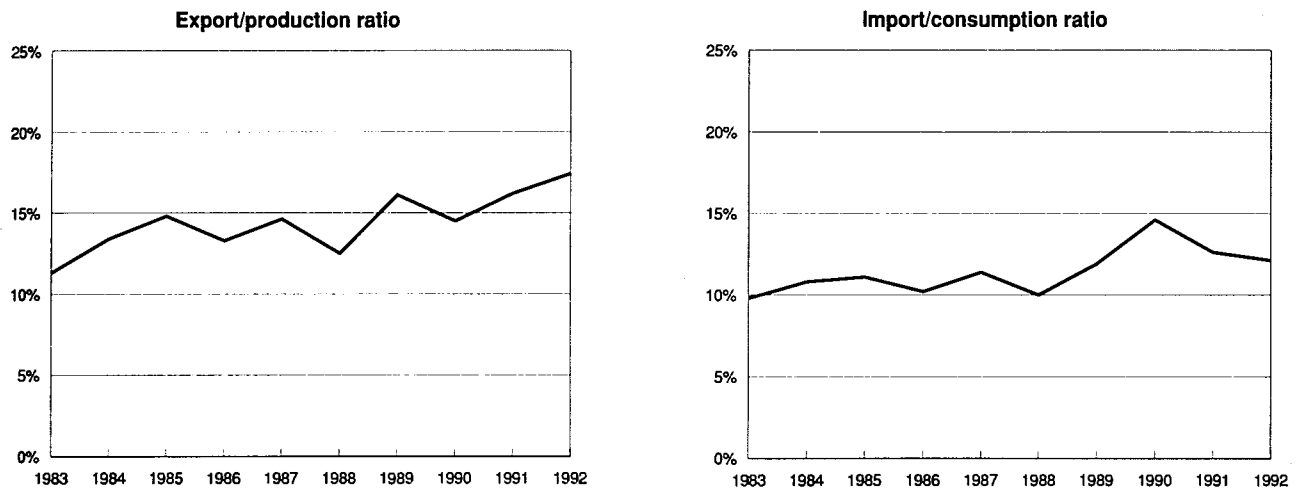
The completion of the internal market has not had a significant effect on the EC tanning industry as intra-EC barriers to trade in leather were non-existent. The progressive erosion of the EC market for leather due to relocation of client industries to low wage countries has a more important impact on competition among EC tanners.

Figure 7: Leather tanning and finishing
Origin of EC imports



Source: Eurostat

Figure 8: Leather tanning and finishing
Trade intensities



Source: Cotance, Eurostat

The EC tanning industry is increasingly being put under pressure by lower priced imports, particularly from lower cost producers in South America and Asia with protected access to raw materials. Export restrictions on raw hides and skins have been implemented by a number of developing countries to accelerate the growth of their domestic tanning industry. These trade restrictions give companies located in those countries a considerable price advantage.

Additional threats to the EC tanning industry are caused by relatively high wages and increasingly stringent environmental regulations. The latter factor is the more potent threat. Lower labour costs in many non-EC countries, while a direct competitive threat, is relatively less important. Tanning is a capital intensive industry where labour costs do not account for a significant proportion of production costs.

The competitiveness of the EC leather industry depends on its ability to secure reasonable access to potentially profitable export markets for its high quality output and so achieve economies of scale in production. Among OECD countries, which are target export markets for the leather sector due to their high level of discretionary consumer expenditure, Japan is the only one that EC tanners have not managed to penetrate significantly. The principal reason for this is restricted access due to a tariff-quota system which effectively limits imports to 1% to 2% of Japanese production. It is estimated by some European producers that exports to Japan could increase six fold if that market were free. The present round of multilateral trade negotiations in the context of the General Agreement on Tariffs and Trade (GATT) discussions may somewhat ease the level of Japanese protection.

Production process

The EC leather industry is well endowed with tanning machinery and chemical producers placing EC tanners at the forefront of leather technology in the design and production of leather for the most demanding outlets. Many EC leather producers cooperate with upstream raw material suppliers for the improvement of the quality of hides and skins and with downstream manufacturers in the development of new products, but vertical integration is not a common feature in the sector. Close cooperation also occurs with machinery producers and specialist chemical suppliers particularly for improving existing tanning techniques and environmental performance.

INDUSTRY STRUCTURE

Companies

The number of tanneries operating in the EC continued to decline in 1992, falling to 3 071 companies. This is a decrease of 10% compared to 1991 and 23% compared to 1983.

The EC's tanning industry is mainly composed of small and medium sized enterprises. With a total workforce of 54 574 people in 1992, the average number of workers per plant was 18. North European tanneries tend to be larger than their southern counterparts. Italy in particular has the lowest ratio of workers per plant with an average of 10, reflecting cluster development and a successful blend of competition and co-operation where producing units specialise in only a limited number of operations and rely on the activities of neighbouring units for other aspects of the production process. In Germany, the average number of workers per plant is over 90, and is about 60 in both Belgium and the United Kingdom. In Portugal, Spain and France, the average ranges from 20 to 50 people per tannery, while the Netherlands is an exception among northern Member States with an average of only 28 workers per plant.

The leading tanneries in the EC include: Gruppo Mastrotto (I), Industria Conciaria Europa S.p.A. (I), Motta Alfredo S.p.A. (I), Grupo Colomer (E), Grupo Lederval (E), Costil Tanneries de France S.A. (F), Tanneries du Puy (F), Freudenberg (D), Lederfabrik Louis Schweizer GmbH & Co. (D), Roser (D), Conolly (UK) and Pittards (UK).

Strategies

The EC tanning industry is undergoing a continuous process of structural adjustment in order to face the challenges of the present and forthcoming business environment. EC tanneries have to excel in quality or fashion succeeding in market segments where price considerations are not the most important factor. Investments in quality assurance systems of the ISO 9000 series, research and development in product innovation and improving skills of the workforce appear to be the main strategies of EC tanners for strengthening their competitiveness. Export orientation and building strategic alliances in key foreign markets are also important.

REGIONAL DISTRIBUTION

For historical reasons, tanneries are regionally and/or locally concentrated. The centres of Santa Croce sull'Arno, San Miniato, Castelfranco, Montopoli and Fucecchio produce about 90% of all Italian sole leathers and some 35% of that Member State's soft leathers. The centres of Vic and Igualada in the Spanish region of Catalonia have a long established tradition in the leather business, while Alcanena in southern Portugal, Graulhet and Mazamet in southern France and Backnang in Germany are other examples of areas with a high concentration of tanneries, often playing an essential role in the local and/or regional socio-economic life.

ENVIRONMENT

The tanning industry has historically been regarded as a polluting activity. However, many of these potentially negative environmental impacts are either innocuous or have been successfully tackled by EC tanners. Few modern tanneries in the EC, for example, now have the characteristic odour of ammonia released in the early stages of raw material conditioning for tanning.

In profitably recovering a by-product of the meat industry, which would otherwise be landfilled, the tanning industry helps to maximise use of a renewable natural resource and relieves abattoirs of disposal problems. It is worth noting that a large part of the waste is inherited from operations upstream of the tanning process, deriving from improper hygienic conditions of animals when presented to the abattoir and salting and other chemical preserving operations after skinning. The later washout of salt, pesticides or fungicides as well as the removal of dung and animal hair require particular attention in tannery effluent treatment plants. Treatment plants, however, generate another form of residue (generally sludge) which carries the organic and inorganic matter collected after filtration, cleaning and sedimentation of the effluent before it is released ieither to a municipal plant for further treatment or directly to the environment if quality standards are met. Sewage sludge has been successfully used in agriculture in replacement of chemical fertilisers or as a soil conditioner. Recent research developments have scientifically proven that there is no observable effect of chromium containing sewage sludge when disposed on agricultural land. Trivalent chromium salts are now the most widely used tanning agents in industrial leather production. Contrary to the toxic hexavelant form, which is not used in tanning, trivalent chromium does not represent a threat to the environment.

However, leather tanning can be a source of environmental impact if basic precautions are not taken in the factory. The concept of environmental protection is being integrated into the management strategies of EC tanneries. Recognising that pollution prevention is often easier to apply than "end of pipe" solutions, the industry is developing cleaner production technologies in experimental projects, often in cooperation with other EC tanners. Joining efforts to tackle commonly specific problems as well as cooperative research in cleaner technologies have already brought positive results in the field of recovery of by-products such as glue, gelatine or leatherboard or in the recycling of tannery liquors for reuse.

REGULATIONS

At the EC level, it is possible to distinguish three main areas where the leather industry is particularly addressed. These are trade related, technical and ecological regulations.

Trade regulations

The EC common customs tariff in chapter 41 provides for import duties on leather. These range from 3% to 7% and are among the lowest in the world. As far as GSP rules are concerned, the European leather industry seeks the immediate re-imposition by the EC of customs tariffs for hides and tanned skins and for manufactured leather goods as soon as the ceilings set within this system are reached. According to COTANCE, anti-dumping and anti-subsidy regulations and other trade "weapons" have been largely unsuccessful, mainly due to excessively bureaucratic procedures.

Technical regulations

The Commission has issued a proposal for a footwear labelling directive, laying down the means to be used for footwear labelling referring also to the constituent materials of it and thus defining leather. This Directive, however, remains unadopted by the Council even though it would sensibly improve consumer information on shoes and leather.

Environmental regulations

EC environmental instruments of a specific importance include the European Waste Catalogue and the VOC (volatile organic chemical) Directive, which lays down standards in relation to atmospheric emissions. These may have negative consequences on the EC tanning industry if measures are set without consideration of the capability of industry to assume ever increasing standards. The EC Commission's move in the field of environmental liability may also have a negative impact on financially weak small to medium sized enterprises (SMEs), a description which aptly fits many tanneries.

OUTLOOK

Overall, despite prospects of a modest upturn in demand for leather, a substantial increase of production in the EC seems unlikely in the short term. The non-completion of the Uruguay Round and the general economic recession has worsened the situation. Leather consumption also reflects the effects of recession for the third consecutive year, and demand remains flat. Against this background, the outlook for the EC leather industry is bleak.

Overview
NACE 46

In 1992, the wood processing industry reached a production value in current prices of 35.6 billion ECU. The sector is still characterised by a number of barriers to trade between Member States. However, the completion of the EC single market and the progressive removal of barriers to trade should result in an increase of intra-EC trade, which represented 34% of total trade in 1992. From 1993-1997, demand for products of the wood industry is expected to grow by 1.9% per year.

INDUSTRY PROFILE

Description of the sector

According to the NACE definition of sector 46, woodworking can be divided into :

- sawmills and plane mills (NACE 461);
- semi-finished wood products, such as particleboard, fibreboard, plywood, etc. (NACE 462);
- wooden building components, such as carpentry, joinery and parquet flooring (NACE 463);
- wooden containers and pallets (NACE 464);
- other wood manufactures (NACE 465); and
- cork, basketware, wickerwork, brushes and brooms (NACE 466).

In view of the typical small and medium sized enterprise (SME) character of these activities in all the EC countries, the output of these groups is considerably underestimated by the majority of statistical analyses since the latter generally ignore smaller businesses (less than 20 people employed).

Recent trends

In 1992, consumption in current prices in the EC amounted to 43.7 billion ECU, an increase of 1.5% compared to 1991.

Production amounted to 35.6 billion ECU in 1992, an increase of 1.1% compared to 1991. Sawing and planing of wood accounted for 16% of total production, the semi-finished wood products for 23%, the wooden building components for 36% and the other wood products for 25%.

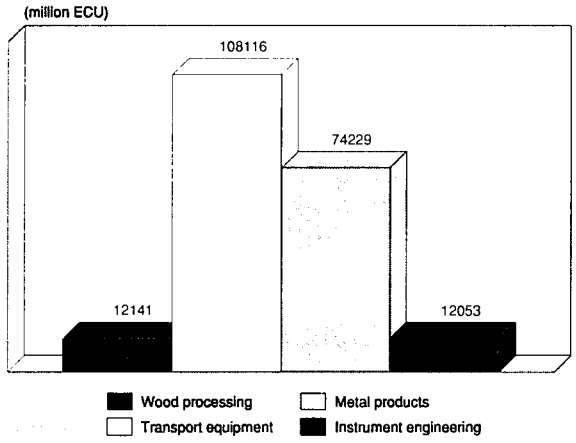
The trade balance deteriorated in 1992 due to trade evolution in the wooden building components and the other wood products. The woodworking industry employed about 424 000 people in 1992, a decrease of 2.6% compared to 1991.

Between 1983 and 1992, apparent consumption increased by an average real growth rate of 2.5% per year. Production in constant prices increased by 27.2% compared to 1985 while during the same period the manufacturing industry as a whole grew by 20.3%. Extra-EC exports have remained stable since the 1989 jump, albeit with a very slight decline. Employment since 1985 has fluctuated around 430 000 people, although in 1992 employment dropped to 424 000.

Foreign trade

Extra-EC imports, after rising continually from 1985 to 1990, declined by 5% in 1991 but increased again by 2.6% in 1992. The ratio of extra-EC exports/extra-EC imports, after having reached a level of about 23% in 1985, remained stable at a level of roughly 20%. Intra-EC trade increased constantly during the period 1983-1992, amounting to 5.2 billion ECU in 1992 and representing 34% of total imports.

Figure 1: Wood processing
Value added in comparison with other industries, 1992



Source: DEBA

The import penetration rate progressively declined, from 26% in 1983 to 23% in 1992.

MARKET FORCES

Demand

Since the products of the woodworking industry are very heterogeneous, these products have different types of buyers, i.e. industrial or final consumers.

Demand for the products of the woodworking industry largely depends on two sectors: the building or construction industry on the one hand and the furniture industry on the other hand. Since these two sectors are highly cyclical, demand for the products of the woodworking industry is largely influenced by the evolution of general income and interest rates.

In 1993, the building industry in Western Europe will experience a further decline. It is estimated that total building

output will be reduced by more than 1%. This stands in contrast to a general GDP growth of 0.75% which is forecasted for 1993. The European construction industry continues its downward trend for the second year and no longer follows the general economic development. The main reasons for the negative trend are the high level of interest rates, a surplus of buildings in some countries, large public budget deficits and the widespread uncertainty about the development of the individual economies. The decline in European building volume is slightly curbed by the comparatively positive trends in Germany, Portugal and the United Kingdom, where a certain increase in construction activity is expected.

Depending on the country, 1992 was either a year of stagnation or a year of deep recession for the furniture manufacturers in Europe. Actually, if Denmark and Germany among others succeeded in maintaining their production at 1991 levels (the growth of turnover was just sufficient to offset price increases), furniture industries of countries such as France, Italy, the UK and some other countries continued to sink deep into recession, reaching negative, double-digit real growth rates. Only Portugal showed an important positive real growth rate. Generally, all national furniture markets are suffering from a weakened demand which affected the production of the domestic manufacturers as well as imports. While 1993 should confirm these trends, a slight recovery is expected for 1994.

Supply and competition

The deficit in the EC trade balance can be explained by the dependence of important subsectors on tropical hardwood (and on sawn timber), imports of plywood from South East Asia (especially from Indonesia), hardboard from South America (especially Brazil), and imports of wood products from the countries of central and Eastern Europe at extremely low prices.

The political and economic developments in the countries of central and Eastern Europe will continue to have important implications since these countries have very large wood re-

serves and a very low wage labour force as compared to the EC-countries.

Although imports of raw materials like tropical hardwood are likely to continue, an improvement in the trade balance of the sector could be achieved depending on the EC's forestry policy. An increase in the domestic supply of wood could be achieved through the use of marginal land. As there are important surpluses of agricultural products within the EC, there is a tendency to convert agricultural land into forestry areas. This could possibly lead to an improvement of the trade balance of the EC woodworking industry and would also have a positive ecological impact.

Trade flows among Member States are more significant than extra-EC exports. This may partly be explained by the importance of transport costs which affect trade in wood and wood products. During the period 1988-1992, the value of intra-EC trade increased by a nominal average rate of 6.6% per year.

In the past, competition has been affected by a large number of technical barriers to trade between Member States (nationally oriented standards that have already been in existence for a long time, major differences in the procedures for technical approval, etc.). In light of the European integration, the sector will be influenced by the results of discussions on the short term implementation of European standards and technical reference documents. This technical integration is expected to result in increased trade between Member States. Thus, it is of crucial importance for the industry to follow up on the activities in the regulatory and technical fields. Within the European Committee for Standardisation (CEN), 7 technical committees were created to work out standards for products in the woodworking field: CEN/TC 33 for doors, windows, shutters and building hardware; CEN/TC 38 for durability of wood and derived products; CEN/TC 112 for wood based panels; CEN/TC 124 for timber structures; CEN/TC 175 for round and sawn timber; CEN/TC 207 for furniture; and CEN/TC 261 for packaging.

INDUSTRY STRUCTURE

Companies

The woodworking industry, including the manufacture of wooden furniture, has about 242 000 companies, 94.2% thereof being enterprises with less than 20 employees, representing 46% of employment and 34% of turnover. Companies

with more than 99 employees represent 0.6% of the enterprises but they realise 36% of turnover and account for 25% of total employment in the wood processing industry.

Strategies

Since woodworking started as an artisanal activity, the family structure of its SMEs is still very important. The industry enjoyed rapid growth between 1960 and 1974.

Like most sectors of European industry, the woodworking industry went through a major crisis during the second half of the 1970's until the beginning of the 1980's. Due to substantial investment efforts since 1983, the EC woodworking industry is heading for overcapacity problems in the beginning of the 1990's, despite achieving a balance in the late 1980's. This balance, in part, was due to a significant increase in the demand for products of the wood processing industry. In order to respond to this increased demand, the enterprises of the woodworking industry made substantial investments. Since new machines normally outperform older ones, new investments resulted in a rationalisation of the production process and an improvement of efficiency and productivity.

As demand slowed down in the beginning of the 1990's, investments were focused on the introduction of new products (e.g. oriented strand board, medium density fibreboard, etc.) and new production technologies.

In order to cope with extra-EC competition, many small and medium sized enterprises have adopted a strategy of diversification and specialisation.

Skill shortages

Due to the very fast evolution in production techniques, the sector is experiencing increasing difficulties in finding properly trained staff. This implies that considerable attention will have to be paid to higher training standards in this field, as qualified executives are certainly needed, as well as skilled workers. In the context of the Eurofortech/EC-Comett programme, a training and education programme in the area of timber engineering and design has been worked out, known as STEP (Structural Timber Education Programme). STEP aims at organising more than 100 Euro-wide courses, seminars and workshops on the structural use of timber. STEP has a budget of almost 1.5 million ECU.

ENVIRONMENT

Wood is a renewable raw material. Its transformation into finished products requires a minimum of energy and, depending on the subsector, it results in minimal to no pollution to air, water or soil. Some discussions have, however, arisen on the use of tropical timber, the recycling and disposal of packaging waste and the tax related to CO_2-emission. This evolution is certainly not unique to this sector, but has to be seen in a much broader context.

The protection of tropical forest

The deforestation of the tropics is an alarming situation that gives rise to general concern. The most important reason for this deforestation is the circle of poverty, population pressure, over-indebtedness and economic underdevelopment that results in an increasing demand of land for farming, industrial purposes and infrastructure at the expense of forests.

Unqualified and destructive timber exploitation only accounts for a minor portion of the deforestation (approximately 6%). Nevertheless, it is an ecologically irresponsible action. In order to preserve the biological variety and protect endangered animal and plant species as well as to prevent erosion, it is necessary to turn large areas of forest into nature reserves where any kind of commercial exploitation is prohibited. The tropical forests must be protected, but adequate account has to be taken of their economic and social functions. This requires a land planning that designates protected forests, commercially exploited forests and areas for agricultural, industrial and infrastructure purposes.

Environmentally sound and sustainable forest management schemes can contribute, to a large extent, to the preservation of forests. The European woodworking industry fully supports the introduction of these schemes. Generalised bans and boycotts do not contribute to the preservation of tropical forests. On the contrary, they are likely to accelerate the deforestation of tropical areas due to the increase of poverty that would result from them. The International Tropical Timber Organisation's (ITTO) guidelines for sustainable forestry, which have been adopted by all producer and consumer countries, constitute the first internationally recognised criteria for an environmentally sound, sustainable forest management. It is essential to achieve the implementation of these guidelines before the target date 2000 agreed upon within ITTO.

The measures agreed upon in this context should be implemented in collaboration with competent environmental organisations. An important incentive for the realisation of sustainable forestry is the introduction of an attestation of origin. An attestation scheme can be established on a country basis or on a case by case basis. The interests of the wood producing countries of the Third World have to be considered appropriately when coordinating international measures for the protection of tropical forests. Even in the problem zone of the tropical forests, ecology and economy are not irreconcilable contrasts.

In the same context, some "green parties" even contest the use of wood from temperate forests! Although the European woodworking industry is in favour of a generalised labelling-scheme in which temperate forests have to be submitted to the same criteria of sustainability, there is no fear for deforestation in this area.

On the contrary, studies and EC-figures show that there has been an enormous increase in wood potential in the EC and in the EFTA countries. The data indicate that there is a potential increase of annual removal of 105 million m^3 in the EC alone in 1992. It should be clear that these enormous wood reserves are bringing the prices down very rapidly. This should be taken into consideration by the woodworking industry as well as national and international authorities. EFTA, the EC and its Member States should strengthen the market for wood products through promotional activities.

The tremendous potential is likely to increase even more when 16 million hectares of agricultural land within the EC will be available for alternate uses due to agricultural policies requiring a percentage of farmed land to be taken out of food crop production. A majority of this land is expected to be used for reforestation.

Recycling and disposal

During recent years, national as well as European authorities have begun to focus on packaging and packaging waste. Within the range of packaging materials, wood takes a specific place. As already stated, wood is a renewable raw material. Compared to other materials, wood needs a small amount of energy for processing and therefore helps to reduce the use of valuable energy resources.

Wood waste cannot be considered as real waste, since it can be and is used to manufacture other materials such as particleboard, fibreboard, laminated wood, etc. If this use of wood waste is not possible, it can also be used for energy production. Many woodworking companies heat their workplaces mainly with bark and wood waste from their operations. Modern firing installations have reached a very high technical standard and, from an environmental point of view, have to be regarded as being highly efficient.

Based on the arguments above, wood is a very suitable packaging material. It can be recycled to produce other materials or can be used to produce energy. Treated or coated wood packaging can be burned in suitable firing installations together with household wastes.

The woodworking industry continues to defend the re-use of timber packaging materials for energy production as one of the solutions for recycling.

CO_2 reduction policy

In the past, after considerable effort, the woodworking industries have managed to achieve quite good results in the reduction of energy consumption. This branch of industry is well aware of the necessity to reduce the emissions of CO_2 to protect the atmosphere. Therefore, it will aim at further CO_2 reductions and will support political concepts consistent with that purpose if they can be realised in an economic way and be combined with the necessary political measures.

Wood as a raw material should be promoted more extensively. This includes an increase of the forest area as this leads to an increased CO_2 absorption and helps to redress the balance against the disappearing of tropical rain forests.

Product promotion could include, for example, specific orders from public authorities for anti-noise barriers made from wood or wood based materials to be placed along roads and railway

tracks as part of a positive attitude towards the use of wood construction.

One should also remember that about 30% of the CO_2 emissions are caused by private households, mainly for heating purposes. It is therefore necessary to try to reduce energy consumption for the heating of houses. Wooden constructions, which account for a very low average energy consumption, could very well contribute to this.

Finally, one should point out the positive and expandable role of the thermal use of wood waste. This would restrict the use of other non-renewable energy sources, that are less "CO_2 friendly".

REGULATIONS

There are relatively few technical regulations in the woodworking industry, so one can state that the "single European market" is practically realised. The "construction products directive" and the related European standardisation activities certainly helped a lot in this respect. A similar effort is being made regarding the placement of biocidal products on the market (including wood preservatives), where an EC-directive is being prepared and should allow the removal of barriers to trade in this field. Finally, a lot of discussions are going on related to the "phyto-sanitary" field and plant protection.

The following items are of specific concern for the woodworking industries.

German "Gefahrstoffverordnung"

In 1986, Germany notified a "decree on dangerous substances", introducing, among other things, a requirement that wood based materials and furniture made thereof should not provoke a concentration of more than 0.1 parts per million (ppm) of formaldehyde in a "testing chamber". This gave rise to detailed opinions/observations from different Member States. Between 1986 and 1991 the subject remained under discussion.

On 12 February 1991, the German government notified its "Prüfverfahren für Holzwerkstoffe" (test methods for wood based panels) that these can be considered the implementing orders of the formaldehyde section in the "Gefahrstoffverordnung". Again six Member States and the EFTA Secretariat as well as the Commission itself introduced detailed opinions/observations.

In spite of this, a final decision on the implementing orders was taken when, at the end of October 1991, the German government published the test methods for wood based panels in the "Bundesgesundheitsblatt".

Compared to the initial proposal of the German authorities, some beneficial changes were introduced. The main request of industry, that the results of the "derived test methods" (such as perforator and gas analysis values) should be considered as equivalent to the tests in "large chambers", was met.

In principle, however, this industry remains opposed to this regulation and believes it requires a lot more clarification.

Regulations related to wood dust

In some countries, there are very stringent regulations on the exposure to wood dust on the workplace, due to its presumed risks for workers.

For the time being, wood dust does not appear on the EC-list of carcinogenic substances at work places, because no direct relationship between exposure to pure wood dust and certain types of cancers of the higher respiratory system have been proven. Research continues, however. The industry launched a research programme to be performed at the Cancer Research Centre in Heidelberg. The programme, which will be co-financed by the EC, will take approximately 3 years. It is expected to provide vital scientific evidence in the wood dust discussion.

German "Verpackungsverordnung"

The German "Verpackungsverordnung" (regulation on packaging waste) came into force on 1 August 1991. The main implications of this regulation are: from 1 December 1991, all transport packaging such as pallets and crates have to be taken back and recycled; from 1 April 1992, it must be possible for a consumer to return the "Umverpackungen", i.e. the packing material meant to avoid theft or used for publicity; from 1 January 1993 on, used sales packaging has to be taken back by commerce and industry to be recycled and there is an obligation for deposit on certain one way packing.

According to this "Töpfer-law", recycling is equivalent to "material recovery". This poses specific problems for wood material as "material recovery" is not always possible. The German law does not allow energy recovery.

As a consequence, recycling systems for wooden packaging in Germany had to be developed in a very short period of time. The "Grow" label is already used for vegetable and fruit crates. It still is difficult and costly to find industrial consumers of recycled wood.

As other countries, like France, already have a national law concerning packaging wastes or are developing one, the problem is also being dealt with on the European level. The actual version of the proposal for an European Directive does authorise energy recovery. This clearly is the best solution for certain wood wastes.

Volatile organic compounds

The Commission of the EC has developed a proposal for a Council Directive concerning the limitation of the emissions of VOCs from certain activities and industrial installations. The aim of this directive is to reduce the emissions of VOCs from certain industrial installations and processes. It is part of a strategy for an overall reduction of the emission of VOCs in the EC.

The proposal covers two activities of the woodworking sector, namely coating of wooden surfaces and wood impregnation. It is based on the principle that all enterprises, using more than two tonnes of organic solvents per year and with a nominal capacity of more than 10 kg per hour, should apply a strict management plan and emission limits for organic compounds. Those using more than 25 tonnes per year and with a nominal capacity of more than 25 kg per hour should apply even stricter emission limits.

It could therefore have important implications on a lot of SMEs in the subsectors of the woodworking industries, such as furniture, joinery, parqueting, etc. Actually, the discussions on this subject continue.

Import arrangements concerning the countries of central and Eastern Europe

In December 1991, interim or European agreements were signed between the EC and Poland, Hungary and the former Czechoslovakia. These interim agreements stipulate that certain products originating in these countries may benefit from a suspension of customs duties on imports into the EC within the limits of annual tariff quotas or ceilings. They further stipulate that the volumes or values of the tariff quotas or ceilings shall be increased progressively to arrive at a complete abolition of customs duties on imports by the end of the twentieth century.

An interim agreement has also been signed with Romania, so that import arrangements for certain industrial products have been worked out for this country as well. The agreement aims at creating a free trade area with Romania within ten years.

For most of the products of the woodworking industry, duties on imports into the EC originating from the above mentioned countries have beeп abolished. However, there still exist some quotas or ceilings for products such as particleboard, fibreboard, plywood, windows, doors, parquet panels, shuttering, etc.

The republics of the former Soviet Union have been included in the 1993 EC Generalised System of Preferences (GSP). In this context, fixed duty-free amounts are applicable to imports into the EC of some products, such as fibreboard and plywood.

OUTLOOK

Average real annual growth for the period 1993-97 is estimated at 1.9% for consumption and 1.8% for production. This picture is strongly influenced by the sectors of semi-finished wood products and the wooden building components. Extra-EC exports are expected to decrease by 0.3% annually until 1997.

The increasingly stringent requirements with respect to health and environment will increase the costs of the industry. Furthermore, the industry is facing increasing social and environmental dumping, especially from countries of central and Eastern Europe. The implementation of European standards, however, will have a beneficial impact on trade between Member States. The agreement signed in May 1992 between the EC and EFTA substantially increases the market potential by creating a European Economic Area of 400 million consumers.

Sawing and first processing of wood
NACE 461

Though half of EC consumption of sawn, planed and dried timber is met by imports, the restructuring of the industry that took place in the early 1980's had a favourable impact on EC production, and could even lead to a decrease in extra-EC imports in the 1990's. Structural changes have taken the form of increased vertical integration and/or the merging of small production units. The average annual real growth rate for the period 1993 to 1997 is estimated at 0.6% for consumption and 1.1% for production.

INDUSTRY PROFILE

Description of the sector

The first stage in the processing of wood falls under NACE code 461. The companies engaged in the following activities are grouped into this code:

- saw milling,
- planing of wood and
- drying and seasoning of wood.

Recent trends

The further improvement of the trade balance in 1992, for the second consecutive year, is explained by a slight reduction in consumption (-0.3%) while production stagnated.

Production in 1992 amounted to 5.8 billion ECU and represents 16% of total production of the wood industry.

Sawing and the first processing of wood had a value added of 1.8 billion ECU in 1992. This is more than the European leather articles industry and represents 13% of the value added of the European consumer electronics industry. Sawing and the first processing of wood represents about 15% of the value added of the wood processing sector (12.1 billion ECU).

In 1992, the most important producers in the EC were Germany (representing about 27% of value added), Spain (representing 21% of value added) and the United Kingdom (accounting for about 20% of value added).

Employment in 1992 decreased by 4% to 72 000 people, reaching its lowest level in ten years. Employment in the sector represents 17% of total employment in the wood industry.

Apparent consumption, after a constant rise from 1986 to 1990, decreased in the beginning of the 1990's and stagnated in 1992. Production rose sharply in 1988 (17%). Afterwards, production growth slowed down considerably. The beginning of the 1990's correspond to a deceleration or stagnation in economic activity.

Production in constant prices increased by 27.8% compared to 1985, outperforming the manufacturing industry average (20.3%).

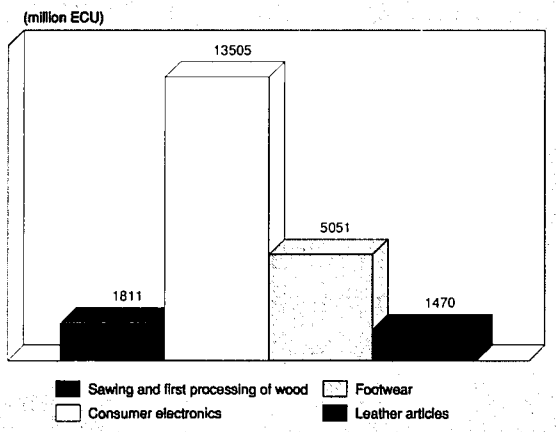
Foreign trade

The negative picture of the trade balance is reflected in the very low extra-EC exports/extra-EC imports ratio averaging 5% for the last decade. The share of intra-EC trade in total imports remains low, averaging 13% in the 1980s, but slightly increased in the beginning of the 1990s to 14%.

The import penetration rate declined by about 7% in the period 1983-92, reaching 50.6% in 1992. Although the import penetration rate remains very high, European producers have been successful in substituting extra-EC imports since 1984.

In 1992, extra-EC imports mainly came from the EFTA countries (49%) and the USA (11%). Extra-EC exports are mainly destined for the EFTA countries (66%).

Figure 1: Sawing and first processing of wood Value added in comparison with other industries, 1992



Source: DEBA

MARKET FORCES

Demand

Only 5% of EC production is exported while 8% of EC production is directed to the final consumer. The large majority of EC production goes to industry, more specifically to the pallets, carpentry and furniture industries. This situation is not expected to change in the near future.

New products are emerging based on new techniques, such as gluing, in order to increase value added. There is an important automation process taking place in the large sawmills, more specifically in the softwood sector.

Supply and competition

The EC saw milling market has been hurt by massive imports coming mainly from Sweden and Finland. The devaluation

of the currencies of these countries led to a huge increase of exports to the Community. This created high tensions on the European market while domestic production in most of the importing countries dropped by approximately 15 to 25%.

There are also serious problems in the pallets industry where very cheap products are entering the EC market, coming from Central and Eastern European countries, but from mainly Poland.

INDUSTRY STRUCTURE

Companies

Some 3 700 enterprises, employing more than 20 persons each, operate in the first processing of wood in the EC. Altogether, about 72 000 persons were working in this sector in 1992. The sector is dominated by small and medium sized enterprises so that total employment is likely to be considerably larger than the official figures.

Strategies

The investments that took place in the course of the 1980's contributed to the reorganisation of the industry, a necessity caused by the strong competition from non-EC producers. There were three main types of structural changes: the closure of non-profitable enterprises, the merging of small production units, and an increased tendency towards vertical integration. Moreover, there is a growing need for highly qualified personnel.

Investments focused on plant modernisation and existing projects. Investments are principally taking place inside the EC. There is a tendency for large companies to disinvest, mainly because of cash problems. Furthermore, there are a lot of mergers and acquisitions taking place in the sector.

Source: DEBA

The main strategy for the enterprises of the first processing of wood is to produce goods with a higher value added. They tend to become subcontractors for the second processing, instead of remaining simple raw material suppliers. By producing more custom-made goods for the second processing of wood, the EC enterprises can improve their competitiveness vis-à-vis extra-EC competitors.

Due to their geographical proximity, the enterprises of the first processing of wood can also respond in a more flexible way to the needs of enterprises of the second processing of wood (e.g. just-in-time delivery).

OUTLOOK

Consumption which stagnated in 1992 (-0.3% compared to 1991) is expected to increase slightly in 1994. For the period 1993-1997, a real annual growth rate of 0.6% is expected. Production, which also stagnated in 1992 (in current prices), is expected to increase in the period 1993-97 by a real average growth rate of 1.1% per year. This means that EC production will continue to substitute for extra-EC imports. Extra-EC exports are expected to decrease by an estimated annual rate of 3.8% in the period 1993-97 as attention will be focused on the EC market.

Semi-finished wood products
NACE 462

The manufacture of semi-finished wood products is the second largest woodworking sector, representing 23% of the total value of production of wood. Approximately 1 600 firms are involved in the manufacture of semi-finished wood products, employing about 67 000 people. The average annual growth rate for the period 1993 to 1997 is estimated at 1.8% for consumption and 2.2% for production.

INDUSTRY PROFILE

Description of the sector

This group mainly covers wooden board material (particleboard, fibreboard and plywood), which is in turn used as an intermediate product in either the furniture or construction industries (the 'industry' circuit), or as a finished product (the 'do-it-yourself' circuit). Besides raw boards, there are also surface improved panels (boards covered with veneer, PVC or melamine resin impregnated paper).

NACE 462 also includes enterprises who deal with the impregnation of wood with chemical preservatives.

Recent trends

Apparent consumption in current prices amounted to 9.7 billion ECU in 1992, approximately the same level as in 1991. Of the total value of consumption of raw wooden board material, particleboard represents 45%, fibreboard 32% and plywood an estimated 23%. In volume, consumption of particleboard accounts for 71% of total consumption of wood based panels.

Production of semi-finished wood products represents 23% of total production of the wood industry. Particleboard production in volume represents about 80% of the wood based panels industry in the EC.

The sector of the semi-finished wood products employed about 67 000 people in 1992, representing 16% of total employment in the wood processing industry.

In 1992, semi-finished wood products reached a value added of approximately 2.5 billion ECU, representing 18% of the EC consumer electronics industry. Germany is the most important producer, accounting for 34% of total value added.

Apparent consumption increased constantly since 1983, except in 1986. In 1992, consumption was 28% higher than in 1987. Production has followed the same pattern, as have extra-EC exports (except for 1990 to 1992 when there was a slight decrease in exports). Production in constant prices increased by 26.3% as compared to 1985, showing a better performance than the manufacturing industry average (+20.3%). Employment, however, decreased from 1983 to 1986 and stabilised afterwards at a level of about 68 000 people.

Foreign trade

The trade balance, after constant deterioration since 1982, improved in 1991. In 1992, there was again a slight deterioration explained by a small reduction in production (-0.4%) and higher extra-EC imports (+1.3%). The negative trade balance is mainly due to massive imports of plywood. The share of intra-EC trade in total imports reached 45% in 1992, showing an increasing trend during the past ten years.

The ratio of extra-EC exports/extra-EC imports remained stable during the past several years, exports representing about 23% of imports. The import penetration rate also remained stable during the same period at about 21-22%.

The EFTA countries are the major trading partners for the subsector of the semi-finished wood products, representing 54% of EC exports and 35% of EC imports in 1992.

MARKET FORCES

Demand

The important gap in the particleboard market between production capacity and demand has made it very difficult for manufacturers to recover the heavy investment costs. Chipboard production is almost fully automated and the investment threshold, especially for the continuous lines, is high. Important modernisation and concentration took place during recent years and the industry has reached a very high level of technology and efficiency. This ensures that the industry can match high quality standards in the near future.

The trend in buyer's preferences has been to replace solid wood, tropical wood, plastics and other wood based panels by MDF (medium density fibreboard), especially for furniture manufacturing. MDF acts as a good substitute material for more expensive types of solid wood. Thin MDF is a strong

competitor and a potential substitution product for thin plywood and hardboard. As thin plywood is mainly produced in Indonesia, European competition is not affected by it.

The development of new applications will continue to gather momentum and, hence, influence demand. The range of speciality boards is being extended constantly. Specialities like moisture resistant boards, fire retarding panels, bendable, lacquered, printed and melamine faced boards have joined other specialities like very thin as well as very thick boards.

Apart from the traditional customer branches of MDF, (i.e. the furniture industry, the production of furniture parts and the production of profiles and skirtings), MDF becomes more and more attractive for interior design, exhibition stands, the production of window frames and door skins, the manufacture of TV and radio cabinets and for architects and designers.

For plywood, one of the tendencies relating to the world market is the reinforcement of export limitations of wood due to international environmental pressures (such as the reduction of trade in logs in Malaysia, the limitation of log exports from the USA, etc.).

Oriented Strand Board (OSB) is a relatively recent type of wooden board material, at least in Europe. It is mainly used in the construction industry because of its mechanical properties. OSB is also a substitution product for plywood.

Supply and competition

Overcapacity puts supplementary pressure on the market and leads, in many cases, to increased risks of mill failures. The EC industry has signalled its willingness to maintain its competitiveness. The necessary condition, however, is that extra-EC competitors respect the prevailing rules for international trade and competition. Large imports into the EC at very low prices, from East European countries and countries benefiting from the Generalised System of Preferences (GSP), are a real threat for the industry. The completion of the single European market will be very difficult for the industry if imports from East European countries are not controlled fairly, especially

Figure 4: Semi-finished wood products

in the light of the European or interim agreements signed with these countries aiming at a complete abolition of customs duties on imports by the end of the twentieth century.

Pressure from foreign competition also results from exchange rate variations as well as less environmental friendly log harvesting methods. Pressure by foreign competition is also the result of low labour costs, better availability of raw materials and trade practices and policies, such as dumping from countries of Central and Eastern Europe and the GSP countries or the United States' request in the context of GATT to reduce import duties on wood to 0%. Technological advantages are not considered as a factor affecting competition in EC and extra-EC markets.

The deficit in the EC trade balance for semi-finished wood products is the consequence of large inexpensive wood reserves outside the EC (North America, Scandinavia and Eastern Europe) and the huge import of plywood from North America and South East Asia as well as hardboard from South America and Eastern Europe. For the plywood sector, the most important competitive advantage of the EC plywood manufacturers over the large single-product manufacturers in the USA and Indonesia is that European industry is specialised in the manufacture of small series of special, custom-made goods from very different types of wood.

For particleboard and MDF, competition is mainly taking place within the EC. For plywood and hardboard, there is a strong competition from outside the EC.

In the fibreboard sector, the number of companies switching from the so-called wet to the dry process is expected to increase further due to strict regulations regarding environmental protection. Currently, replacement investments required to meet these regulations automatically result in an expansion of capacity that contributes to overcapacity on the European market. This situation is aggravated by strong pressure from imports from Central and Eastern Europe and the persisting weak demand in the construction activity in most of the EC and EFTA countries.

Competition is also distorted by the fact that producers in Eastern Europe can continue to use the wet process because of a lack of environmental regulations, whereas producers in the EC are forced to switch to the more ecological, but also more expensive dry process.

OSB is mainly produced in the United Kingdom and France and the product has reached a high standard of acceptability

in these and several other European countries. During this decade it is expected to become a major product in the European panel industry.

The completion of the single European market offers a lot of opportunities to the sector, as normally all barriers to trade will be removed. The creation of a European economic space could also contribute to the development of a flourishing market. Furthermore, economic reforms in the countries of Central and Eastern Europe offer some good prospects for increased trade with the industrialised countries.

INDUSTRY STRUCTURE

Companies

According to estimates, about 1 600 firms are involved in the manufacture of semi-finished wood products. The particleboard industry consists of approximately 120 companies, employing 20 000 people. Total employment in the industry is about 68 000 persons, which means that the average number of employees per firm is about 40. This is relatively high compared to other subsectors of the woodworking industry.

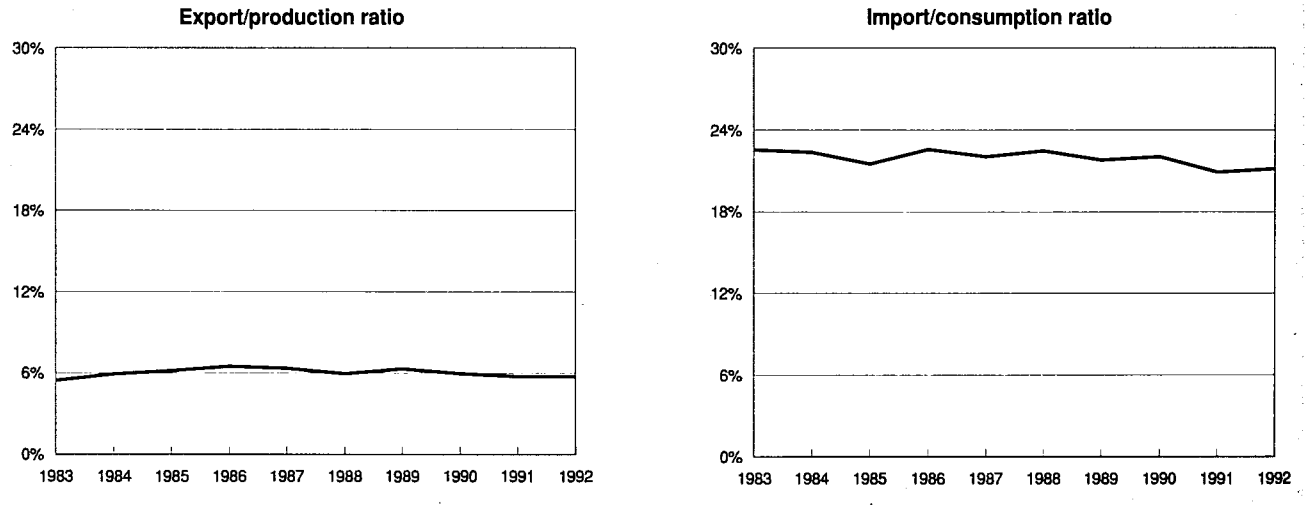
Strategies

The chipboard industry is a capital-intensive sector. Production is virtually fully automated, requiring huge research and development efforts; the investment threshold, especially for the continuous production lines, is high. These circumstances imply that an average chipboard firm exceeds the small to medium size enterprise (SME) dimension of the sector and that the added value in the case of this activity is lower than in the rest of the woodworking industry where the high percentage of labour costs raises the value added. In recent years, the sector has gone through a major restructuring and an apparent concentration has taken place. Large competitors have begun to expand their market share by investing in larger plants and by investing across Europe.

In the fibreboard sector, investments are focused on the development of new products, the modernisation of existing products, the increase of capacity and the switching to eco-friendly production methods (as converting from the wet process in the hardboard industry to the dry process in the MDF industry). In order to reduce overcapacity, diversification of products is taking place aiming at the development of structural boards, for example. As far as firm structures are concerned, there are several new joint investments by board manufacturers concerning MDF, but there are as yet no major changes in hardboard.

Until recently, the plywood sector was rather labour-intensive. Technological development and computer applications in production control and the operation of machinery have, however, lowered production costs to a great extent, and have at the same time enabled a substantial reduction in the percentage of wood waste. The sector is still highly suited to product

Figure 8: Semi-finished wood products
Trade intensities



Source: DEBA

diversification (with a greater utilisation of European wood species), especially when production methods allow the manufacture of small series of special, custom-made goods. The nature of investments, carried out by the European companies themselves, is to modernise and to find new product developments.

REGULATIONS

The common external tariff on imports coming from outside the EC is the same for particleboard, fibreboard and plywood, and has been maintained for some time now at 10%.

The interim, or European, agreements signed between the EC and Hungary, Poland, the former Czechoslovakia and Romania changed the regulations formerly applicable to these countries.

Customs duties on imports applicable in the EC to particleboard and plywood coming from Poland, Hungary, the former Czechoslovakia and Romania were abolished since the European agreements became effective. Fibreboard from Hungary, Poland, the former Czechoslovakia and Romania will benefit from the suspension of customs duties on imports within the limits of annual EC tariff quotas or ceilings amounting to 5.6 million ECU for fibreboard from Poland and the former Czechoslovakia, 6.3 million ECU for fibreboard originating in Romania and 9.1 million ECU for fibreboard from Hungary.

As far as the republics of the former Soviet Union are concerned, since their inclusion in the 1993 EC GSP, a fixed duty-free quota of 4.2 million ECU applies on imports of fibreboard into the EC originating in Russia, Ukraine and Belarus. As far as plywood is concerned, there is a fixed duty-free quota of 90 300 m^3 for plywood from Russia, Ukraine and Belarus.

Annual import quotas on imports of particleboard and plywood originating in the Republics of Croatia, Slovenia, Bosnia-Herzegovina and Macedonia have been fixed for 1993. The annual ceiling for particleboard is 41 523 tonnes, while for plywood, the annual ceiling reaches 161 162 m^3. As soon as these ceilings have been reached, the levying of a customs tariff of 10% may be reintroduced by the Commission, by means of a regulation.

OUTLOOK

Consumption as well as production of semi-finished wood products is expected to grow in the coming years. The average growth rate for the period 1993 to 1997 is estimated at 1.8% for consumption and 2.2% for production. Extra-EC exports are expected to grow by 1% annually from 1993-1997.

In the particleboard industry, it seems that the countries of Northern Europe will see a slow recovery in 1993 after many years of recession. Countries in Central Europe suffered badly from the downturn of the German economy. Their recovery will, among other factors, depend on western world support to Russia and the other East European countries to help them to rebuild their economies. The industry in the countries of Southern Europe is heading for a period of restructuring which has already started in some countries. All these developments will take some time to materialise. Therefore, one should not expect any significant recovery before 1994.

In the fibreboard sector, the MDF industry represents a European production capacity of more than 4 million m^3. Compared to particleboard (30.7 million m^3) and sawn timber (68 million m^3), the share of MDF in the market of wood and wood products still appears quite moderate. The relative success of MDF compared with the stagnation of the traditional woodworking sectors can be attributed to the innovative power of the industry making efforts to upgrade its products to meet specific requirements for special applications which are increasingly in demand. The European MDF industry will, furthermore, increasingly open up export markets for its products outside the EC and EFTA for special MDF boards.

The sector of semi-finished wood products is facing a number of risks, including the additional costs associated with the increasingly stringent health and environmental requirements, competition with imports and the persistence of overcapacity. However, political reforms in the countries of Central and Eastern Europe offer a potential for exports and possibly joint-ventures.

Wooden building components
NACE 463

The manufacture of wooden building components accounts for 36% of the production value of the woodworking industries, making it the main subsector in the European Community's wood processing industry. It depends largely on trends in the building industry. The sector of wooden building components is highly involved in renovation work, making the sector less dependent on cyclical new building construction.

INDUSTRY PROFILE

Description of the sector

The NACE definition of this subsector bears the title 'Manufacture of carpentry and joinery components and of parquet flooring'. The subsector produces a wide variety of wooden building components: doors, window frames, shutters, partitioning and other walls, staircases, constructions of glued and laminated wood, prefabricated buildings of wood, etc. This subsector of the woodworking industry distinguishes itself from the carpentry subsector of the construction industry by its industrial scale and production methods.

In 1992, production in current prices reached a value of 12.6 billion ECU, which was 35.5% of the total production of the woodworking industries (excluding wooden furniture). This makes the manufacture of wooden building components the most important subsector of the woodworking industries.

Apparent consumption amounted to 13.2 billion ECU. This means that the trade balance is slightly negative.

The industry employs approximately 160 000 people, representing 37.6% of the total employment in the woodworking industries.

In 1992 the wooden building components industry created a value added of 4.5 million ECU. This is roughly the same as the footwear industry or one third of the consumer electronics industry.

In absolute value, Germany is the biggest producer. In relative terms, the proportionally high share of Spain in the total EC production of wooden building components is evident.

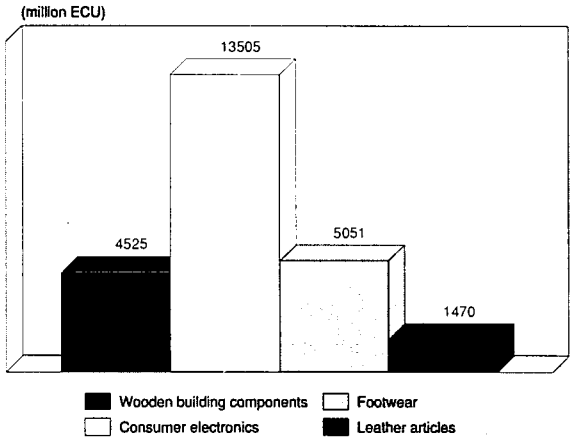
Recent trends

Throughout the eighties, apparent consumption of wooden building components has increased steadily at an average real growth rate of 2.6%. Unfortunately, production within the EC was not able to keep pace with the rapidly growing demand, despite the decrease in extra-EC exports. This resulted in a steep rise in extra-EC imports, especially between 1988 and 1992 (+17.7% average real annual growth), and a negative trade balance from 1987 on.

Nevertheless, production in constant prices grew at a rate of 30% between 1985 and 1992, which is 10% more than the EC manufacturing industry average. This rapid growth was mainly realised between 1987 and 1989, the years in which economic growth and construction activity recovered after a period of recession.

Employment declined in the first half of the eighties. Thanks to increasing demand, employment started to grow again in 1987 to reach a peak of 163 000 people in 1990. Since then, employment has remained relatively stable at approximately 160 000. Compared to 1985, the wooden building components

Figure 1: Wooden building components Value added in comparison with other industries, 1992



Source: DEBA

industry has increased its share in total EC industrial employment.

The beginning of the nineties saw a slowdown of economic growth that was also felt in the wooden building components industry. In 1992, production in constant prices grew only by 0.2%. Extra-EC exports even declined in current prices, causing a further deterioration of the trade balance. Employment decreased by 1.1% in 1992.

International comparison

In the USA, the wooden building components industry is significantly larger than in the EC. In 1983, the difference was more than 36%. This is undoubtedly due to the higher popularity of wood as a construction material in the USA. Nevertheless, the sector is growing more rapidly in the EC (+30% between 1985 and 1990) than in the USA (+17% in the same period). This is not only due to cyclical factors, but also to the fact that wood is enjoying an increase in popularity as a construction material in the EC, too.

Foreign trade

Between 1983 and 1992, extra-EC exports have declined at an average real annual rate of -6.0%. However, extra-EC imports have grown by an average rate of more than 10% during

Source: DEBA

the same period. The trade balance has deteriorated continuously during the observation period and became negative in 1987.

This is not as dramatic as it may sound. After all, extra-EC trade in wooden building components remains rather limited. Extra-EC exports represent only 3.2% of production, while extra-EC imports only cover 7.4% of consumption.

The largest part of the wooden building components sector works closely together with the local construction industry. Extra-EC trade remains limited to a few highly standardised products that can be transported at relatively low costs (e.g. plane doors).

Nevertheless, intra-EC trade is increasing rapidly. This is undoubtedly due to the process of European integration that has brought about a harmonisation of technical standards and a broadening of the "local" market horizon.

Extra-EC exports are still mainly oriented towards the EFTA countries (53.8%), because of the geographical proximity and the partial similarity in building traditions. However, the EFTA countries are no longer the main origin of extra EC-imports (44.8%). Imports of cheap standardised products are now coming from low wage countries in Eastern Europe and South East Asia.

MARKET FORCES

Demand

Demand in the sector depends heavily on the trends in the building sector. The recent trend in buyer's preferences, in a market not confronted with saturation, is to use more softwood. During the past decade, renovation has expanded significantly. Thus, the demand for wooden building components for this purpose increased as well. This development has made the subsector less dependent on cyclical new building construction. In the private housing construction market, the single

Figure 4: Wooden building components

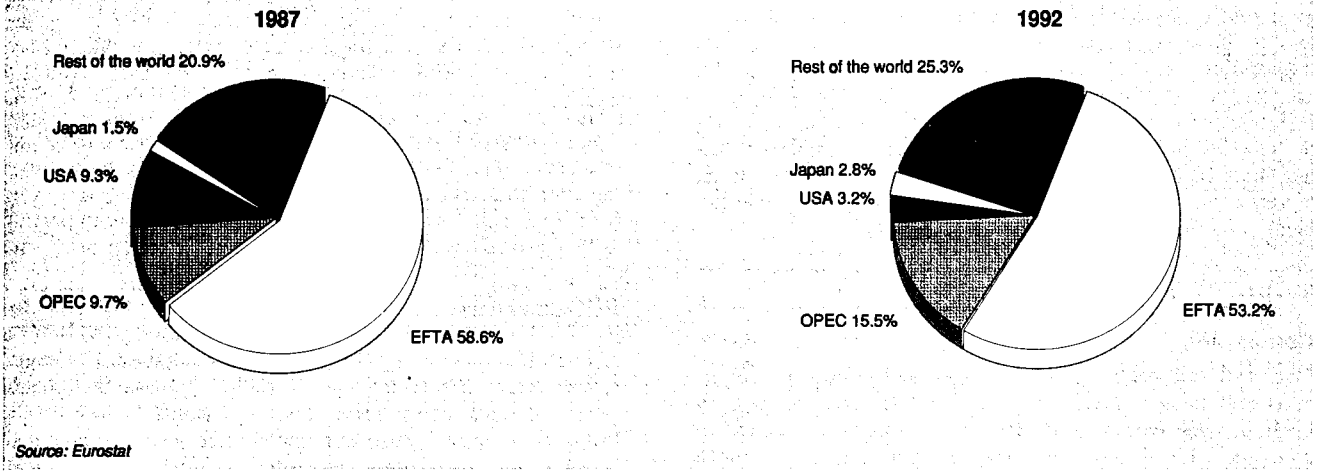
Figure 6: Wooden building components
Destination of EC exports



Source: Eurostat

EC market will not significantly impact the demand for building components since well-defined regional markets will continue to exist within Europe. This is largely due to the specific climatic conditions and local building traditions and styles, rather than any specific standards laid down by the various local authorities.

Wooden joinery and parquet flooring in private housing has benefited from growing consumer preference in recent years.

The demand for wooden building components is becoming more dependent on characteristics such as thermal and acoustic insulation, rather than the more traditional properties associated with wood, particularly in the non-residential building sector.

Supply and competition

International competition remains rather limited because of existing differences in climatic conditions and building traditions. Transport costs are also a limiting factor for international trade since most products are heavy and voluminous.

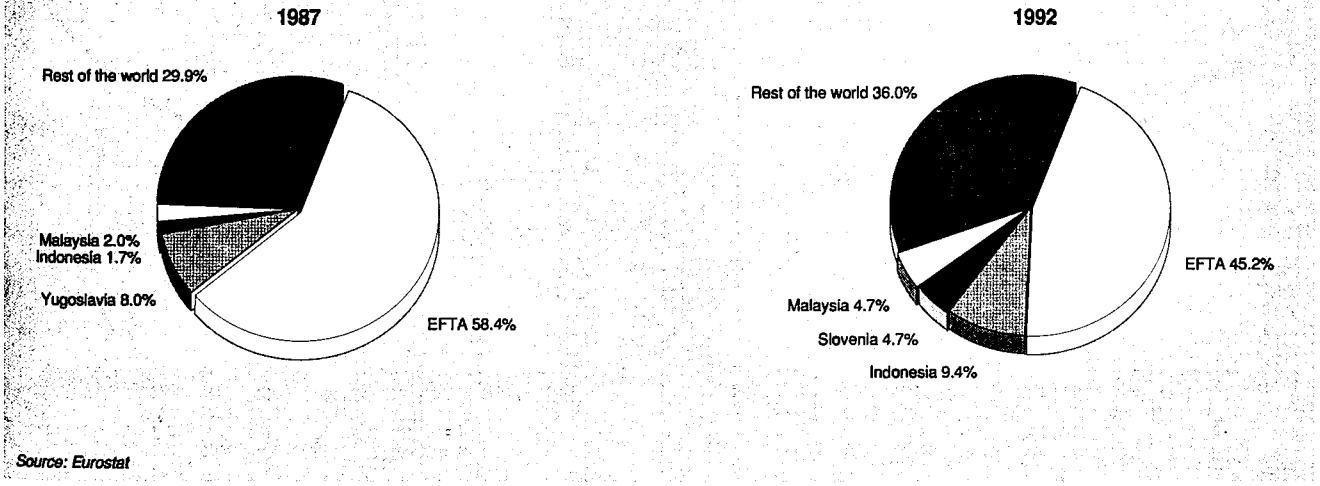
Nevertheless, pressure from foreign competition does exist, mainly due to lower labour costs. Factors such as better availability of raw materials or technological advantages are less important.

The significance of wood treatment for the wooden building components industry is apparent, since this process has enabled the use of wood in applications where previously rapid biological attacks would have excluded its use. Thus, wood is gaining market share from alternative building materials in non-traditional markets. Treated wood is now used in relatively new applications such as agriculture, vineyards and horticulture, fruit-growing, enclosures, playgrounds, hydraulic engineering, etc.

Products such as fire-resistant wooden doors may, initially, appear unusual. However, the high degree of dimensional stability of wood provides these doors with a competitive advantage over metal or synthetic products, since the latter deform more rapidly at high temperatures.

Producers of wooden window frames experience competition from substitution products made from other raw materials such as aluminium and polyvinyl chloride (PVC). However, wooden frames still have the largest market share in the EC with 40%, well ahead of aluminium and PVC.

Figure 7: Wooden building components
Origin of EC imports



Source: Eurostat

Production process

It is mainly the production process that distinguishes the industrial manufacturer of wooden building components from the local carpenter. The machinery and production techniques used in a factory producing doors or window frames, for example, are more similar to those in the furniture industry than to those of the individual carpenter. Computer aided design-computer aided manufacturing (CAD-CAM), state of the art computerised numeric control (CNC) machinery and automated coating installations have already found their way into the wooden building components industry. The industry has thus become the supplier of the individual carpenter who integrates the prefabricated components into the building at the local construction site.

INDUSTRY STRUCTURE

Companies

The ideal enterprise for coping with specific climatic conditions and local building traditions and styles is a small to medium-sized enterprise (SME) that optimises its size in accordance with clearly determined geographical limits and a technical specialisation. Indeed, it is the SMEs that make up the vast majority of this industry.

Strategies

Recent investments concentrated on plant modernisation and increasing capacity (e.g. in Germany due to the five new Länder). Investment is being predominantly undertaken by the European producers themselves, so foreign investment is not important.

Producers tend to specialise considerably and the sector is characterised by a lot of acquisitions, particularly in Germany.

Most manufacturers of wooden building components work on a local or regional scale because of the differences in climatic conditions and building traditions. However, by conforming to the European construction products directive, many enterprises will be able to expand their potential market to the EC.

Shortly stated, there are three possible strategies for the enterprises in this sector. The first strategy is to specialise and focus on the local market, by taking the specific preferences and requirements of local consumers and building companies into account. Aspects such as service and flexibility are very important within this strategy, which is followed by many of the SMEs in the sector.

The second strategy involves concentration and mass production of highly standardised building components. The market for these products is the EC. Economies of scale and price leadership are the keys to success. Large companies who follow this strategy have to reckon with competition from extra-EC imports.

A third strategy is to focus on a product with specific technical properties. This is also a specialisation strategy but, unlike the first strategy, it allows operation on an EC level, even for SMEs. This strategy will probably become more important as the harmonisation of standards for these products proceeds.

REGULATIONS

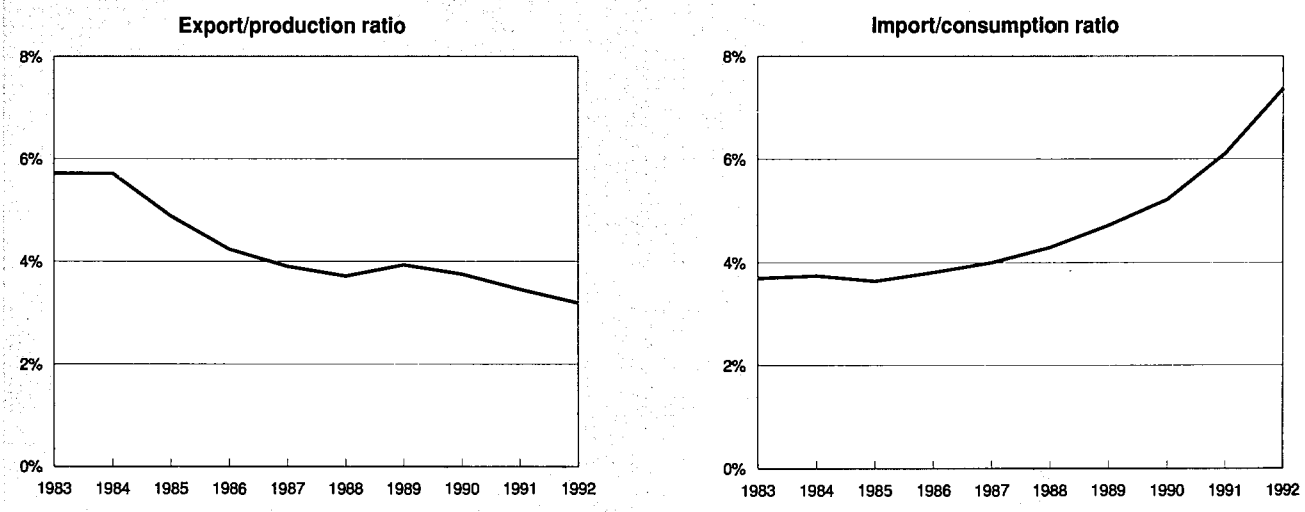
Council Directive 89/106 on the approximation of laws, regulations and administrative provisions of the Member States related to Construction Products, (the so-called "Construction Products Directive") still can not be applied despite its adoption in 1988 and its entering into force in 1991. The reason is that the "Standing Committee on Construction", responsible for its application, has not formally adopted the so-called interpretative documents yet. These interpretative documents define in more detail the six essential requirements for a construction, as listed in the Directive.

Construction products fulfilling all essential requirements can obtain the CE-mark, enabling free trade and use of the product in all Member States.

Meanwhile, the preparation of European standards concerning product specifications for products wishing to obtain the CE-mark is progressing steadily. Five technical committees of CEN, the European Committee for Standardisation, are preparing standards for wooden construction products. New or innovative products, not covered by a European Standard, could obtain the CE-mark via a "European Technical Approval", issued by EOTA, the European Organisation for Technical Approvals.

It is hoped that the interpretative documents will be adopted by the end of 1993, which could imply that, 5 years after its adoption, the Construction Products Directive would be fully operational.

Figure 8: Wooden building components
Trade intensities



Source: DEBA

OUTLOOK

Apparent consumption of wooden building components is expected to grow by 1.6% in 1994, thanks to the fall of interest rates, the revival of construction activity in the United Kingdom and the important structural needs in the five new German Länder. The average real annual growth rate of consumption from 1993 to 1997 is estimated at 2.0%. As in the past, extra-EC imports are expected to increase further. As a result, the average growth rate of production (1.3%) will be lower than that of consumption. This may be partially explained by standardisation at the European level which leads to uniform products and hence, increases in extra-EC imports.

Extra-EC exports are expected to decrease by an estimated 1.1% in 1994 and by 1.9% in the following years.

In the future, European standardisation and the single market should give producers the opportunity to expand within the European market instead of depending on the local market. Activity in the renovation market will make the sector less dependent on the cyclical new construction industry.

Other wood products
NACE 464, 465, 466

Production and consumption in this industry have improved consistently since 1982 despite increasing competition from low wage countries in Eastern Europe and the Far East. The industry is characterised by a large number of small to medium sized enterprises (SMEs) with relatively stable employment. Significant investments have taken place in recent years to automate the production process as much as possible in order to compete more effectively with imports. However, the trade balance has continued to deteriorate.

INDUSTRY PROFILE

Description of the sector

This chapter covers several smaller and very heterogeneous subsectors of the woodworking industry. The most important is wooden containers (NACE 464), which comprises boxes, crates, pallets, barrels, cable drums, etc.

NACE 465 groups together miscellaneous wood manufactures. The most important products are wooden frames for paintings, photographs, mirrors and similar objects.

NACE 466 includes the manufacture of articles of cork, basket ware, wickerwork and other articles of plaiting materials (except case and wicker furniture) and the manufacture of brushes and brooms.

In 1992, the current value of production of these subsectors added up to 9.1 billion ECU representing 25.3% of the total production of the woodworking industries (except wooden furniture).

Employment amounted to 125 700 or 29.6% of the total employment in the woodworking industries, proportionally more than its 25.3% share in the total production of the woodworking industries. This shows that these subsectors are very labour intensive.

Wooden containers and pallets account for 3.2 billion ECU or 35.4% of the production of the "other wood products". Brushes and brooms represent a current production value of 1.2 billion ECU (13.3% of "other wood products). Extra-EC exports of wooden containers remain limited.

The value added of these subsectors adds up to 3.3 billion ECU, roughly one quarter of the consumer electronics industry.

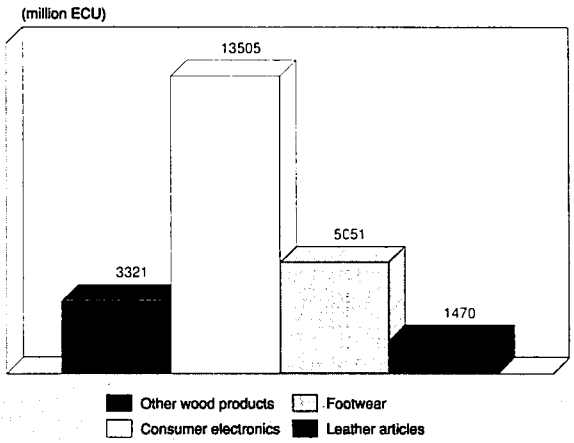
Germany is by far the most important producer of "other wood products", and not only in absolute value. The per capita production is also much higher in Germany than in other EC countries, like France, Italy or the United Kingdom.

Recent trends

Apparent consumption grew constantly from 1983 to 1992. Until 1986, however, this growth was rather limited. From 1987 until 1989, there was an important increase in the level of consumption, followed by a moderate growth in 1990-1991 and a stagnation in 1992.

EC producers were initially slow to react to the upswing in consumption, however, and there was a remarkable rise in extra-EC imports in 1987. EC production responded to strong demand at home with big increases in 1988 and 1989. In fact, extra-EC imports have been increasing steadily since 1987, taking a continuously higher share of EC consumption. On the other hand, extra EC-exports only grew by a real annual rate of 0.6% between 1988 and 1992.

Figure 1: Other wood products
Value added in comparison with other industries, 1992



Source: DEBA

Employment declined steadily from 131 900 in 1984 to 122 800 in 1988. There was an important rise in employment in 1989, again followed by a decrease in the years 1990-1993. In 1993, employment is estimated at 124 100.

Because of the slowdown in economic growth and international trade, demand for "other wood products" stagnated in 1993 at an estimated 9 462 million ECU. Production even decreased in current prices to an estimated 8 911 million ECU. Despite the slowdown in demand, the trade balance further deteriorated due to an increase in extra-EC imports.

Foreign trade

Although most of the subsectors dealt with in this chapter are exposed to strong competition from extra-EC low wage countries, the import penetration ratio remains relatively low at about 13.7% in 1992 up from 11.2% in 1983. The share of production exported to non-EC markets has averaged a steady 10 % throughout the eighties up to 1992.

External trade in wooden containers and pallets is of limited importance but has nevertheless increased noticeably since 1989. Extra-EC imports now cover 1.8% of the consumption of wooden containers and pallets. These increased imports

mainly consist of cheep pallets made in East European countries like Poland, Hungary and former Czechoslovakia.

The trade balance for wooden containers and pallets, which was still largely positive at the beginning of the survey period, has gradually worsened and showed only a very small surplus in 1992. Most of the trade takes place within the EC. This figure might be overstated, however, as some international movements of pallets are "invisible" since consignments of empty pallets are included in the customs statistics, whereas loaded pallets are not.

Although the EC brushes and brooms industry experiences severe competition from China and Eastern Europe, the external trade balance remains positive. Differentiating with regard to product lines, there is a positive trade balance for industrial brushes, paint brushes and rollers and domestic brushes. The trade balance is negative for toilet brushes, fine hair brushes and, since 1992, also for brooms.

Articles of plaiting materials are mainly imported from countries in the Far East, such as South Korea, Taiwan and the Philippines.

MARKET FORCES

Demand

Since the products dealt with in this chapter are very heterogeneous, these products also have different types of buyers, i.e. industry or final consumers.

Wooden containers are mainly bought by industry. In fact, demand for these products has an indirect character and relies on demand for other products which are transported and stored in containers or on pallets. Since most products can be transported either in a wooden container or on a pallet, demand for these packaging materials depends largely on the general macroeconomic situation.

Figure 4: Other wood products

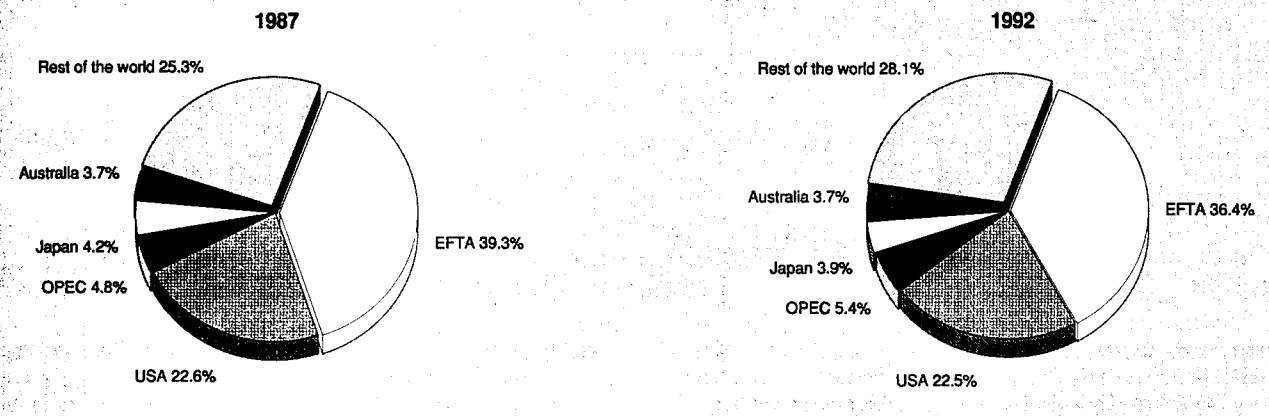
Figure 6: Other wood products
Destination of EC exports



Source: Eurostat

Since trade, intra-EC as well as extra-EC, is intensifying, there is a potential stimulus for sustained growth for the sector of transport-related packaging like wooden containers and pallets. For the moment, however, demand for wooden containers is rather weak due to the slowdown in economic growth and international trade.

Wooden containers are used during the transportation or storage of products in order to improve their manoeuvrability. This requires light structures that are able to withstand rough handling. Standardisation of pallet dimensions makes them highly suitable for repeated and different uses.

With the exception of industrial brushes, most brushes and brooms are bought by final consumers. Industrial brushes are sold by direct sales contact between the industrial client and the supplier. Personal hygiene products (tooth-brushes, hair-brushes, make-up brushes) are distributed by specialist chains, pharmacies and supermarkets. Household brushes are offered to individuals by supermarkets; the same applies to paint brushes and rollers. It is worth noting that large distribution centres also import products directly from outside the EC.

Wooden frames for photographs, paintings, mirrors, etc., are also mainly destined for final consumers. These products are distributed by large distribution centres as well as by small specialised businesses, like photographers, art galleries and gift shops.

Demand for bottle corks comes from the wine, champagne and beer producers. Cork is also used for insulation and, recently for flooring with increasing success.

Supply and competition

Since 1990 demand for wooden containers has weakened due to the general slowdown in economic growth and international trade, putting pressure on the supply side to lower profit margins.

For all the subsectors under observation, internal EC competition remains rather limited. Foreign competition from extra-EC countries, however, is fierce in all product lines. The major extra-EC competitors are not the other industrialised countries like USA and Japan, but low wage countries in the Far East and Eastern Europe.

It is clear that lower labour costs are the main competitive advantage of these extra-EC competitors. They also have a lower regulative burden (lower social and environmental costs).

Source: DEBA

Because of the relatively low degree of complexity of the production process, it is difficult for EC producers to realise technological advantages. Even with the highest possible level of automation, the lower labour costs of the extra-EC competitors is often of overriding importance, especially when combined with dumping practices. The EC brushes and brooms sector has already been involved several times in anti-dumping procedures regarding Chinese brushes.

Since 1990, there has been a sharp rise in the imports of pallets from Eastern Europe (especially Poland, Hungary and former Czechoslovakia) at extremely low prices that barely cover transportation costs. These imports are a serious threat for the survival of the EC pallets producers. In the case of pallets, it is clear that European standardisation of pallet dimensions has led to increasing extra-EC imports.

Most of the extra-EC imports of brushes and brooms come from China and Eastern Europe. China has a quasi-monopoly where imports of paint brushes are concerned. Imports of brushes from China and Eastern Europe have disrupted EC production on more than one occasion. Products from these countries are often offered at dumping prices. The EC industry hopes that trade agreements with these countries, as well as certain structural changes in their markets, will rectify the situation.

Availability of raw materials often plays an important role, too. China has a quasi-monopoly for pig hairs, used in paint brushes. Articles of straw, cork and other plaiting materials are mainly imported from South East Asia. Eastern Europe has large reserves of wood that are suitable for the production of pallets.

Since 1985, production and employment in the "other wood products" sector have grown more rapidly (23.6%) than the EC manufacturing industry average (20.3%).

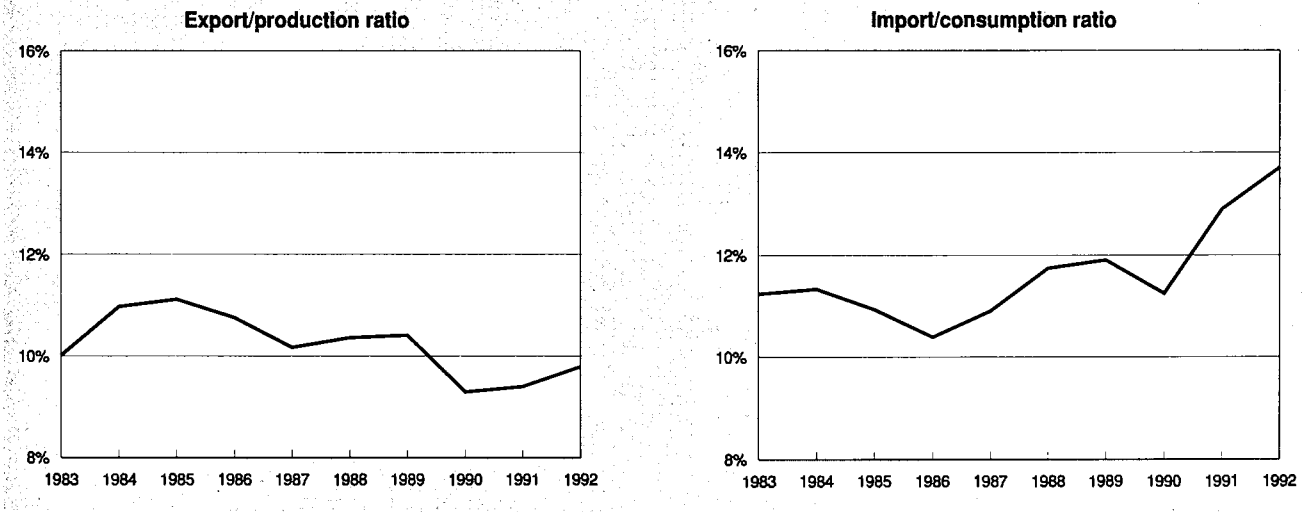
Production process

The raw materials used for the production of wooden containers and pallets are mostly local types of wood, such as poplar and pine. Pallet dimensions have, to a large extent, been standardised. The handles of brushes and brooms are mostly made of wood or plastic. The hairs can be synthetic fibre, animal (pig hair) or vegetable (coconut fibre).

Although the degree of complexity of the production process is relatively low, automation is possible. During the second half of the 1980's, the wooden containers sector has realised important automation and rationalisation investments.

Because of external competition, EC producers of brushes and brooms need to acquire high-performance machines that introduce the fibres, attach them to the frame and adjust the packing material all in one cycle. In this way, toothbrushes and nail brushes, etc. can be produced in very large quantities. The packaging and labelling operations are also performed automatically. The manufacture of paint brushes, particularly

Figure 8: Other wood products
Trade intensities



Source: DEBA

fine brushes, is less automated, although here too, significant progress has been made.

The workforce still has an important role to play in the case of certain operations (for example, the manufacture of paint brushes). In addition, automation has generated an increasing need for people with technical knowledge of machines and tools.

INDUSTRY STRUCTURE

Companies

Most of the enterprises in these subsectors are SMEs. The number of enterprises employing more than 20 people is estimated at 5 200, of which 1 400 are in the wooden containers sector.

Among the subsectors dealt with in this chapter, the wooden container subsector is the most capital-intensive. The size of the enterprises is also relatively larger.

Strategies

The major strategy for all the enterprises of these subsectors is to rationalise and automate the production process as much as possible to face the competition from extra-EC, low wage countries.

For the producers of wooden containers, specialisation in custom-made packaging helps to minimise competition from low wage countries which mainly produce standardised products. Because of geographical proximity, EC producers can respond in a more flexible way to the needs of their customers (e.g., special dimensions, just-in-time delivery).

Producers of wooden containers and especially pallets are working out systems for recycling (see the environmental section in the Overview to wood processing at the beginning of this chapter). This should provide them with a competitive advantage over the producers of plastic and metal pallets.

REGIONAL DISTRIBUTION

The firms in the wooden containers industry are mostly located in the vicinity of the available raw materials and/or major transport centres, such as harbours and airports. The brushes and brooms industry is mainly concentrated in Germany (33%), United Kingdom (23%), Italy (17.5%) and France (16.5%). Portugal is the most important producer of cork.

Table 6: Other wood products
Expected real annual growth rates

(%)	1993-94	1993-97
Apparent consumption	2.8	3.3
Production	2.3	2.6
Extra-EC exports	1.0	0.8

Source: Cei-Bois

OUTLOOK

After a slowdown in 1991-1993, production and consumption will grow again at a steady pace. It is expected that consumption will grow faster (at an average real annual growth rate of 3.3% between 1993 and 1997) than production (2.6%). This means that extra-EC imports will increase their market share. Extra-EC exports, however, will probably slow down.

The risks for these subsectors come from increasing imports from low wage countries in the Far East and Eastern Europe, and from European standardisation which may lead to increasing extra-EC imports (e.g., pallets).

Opportunities for EC producers will come from specialisation in custom-made packaging and from working out systems for recovery (energy recovery, production of particleboard, repeated use, etc.).

Written by: Cei-Bois

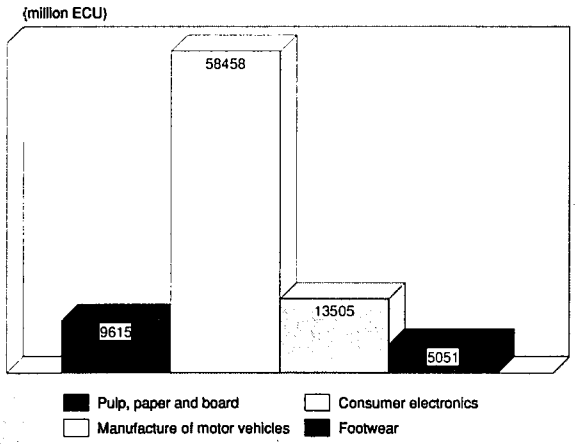
Pulp, paper and board
NACE 471

The pulp, paper and board industry recorded a new record production of 49.2 million tonnes in 1992, and was the tenth consecutive year of volume growth in the industry. Although this performance compares positively with other industries, it doesn't provide a clear picture of the industry in 1992. Since 1990, the growth in demand slowed down, and growth rates of exports have also fallen as well as their prices, operating rates and profit margins. In 1992, the pulp, paper and board industry experienced a tough year: production value dropped 3%. The pulp portion of the industry experienced a year worse than the paper and board portion with a decrease in pulp production volume. The increase in consumption of pulp was met by increased imports.
The industry was hit hard by the general economic slowdown, currency movements, political uncertainty related to the Maastricht ratification and the General Agreement on Tariffs and Trade (GATT). The industry experienced clear symptoms of overcapacity. All these factors pushed prices down, in some cases dramatically, eroding the profitability of the companies. A tough, and in some cases dramatic, restructuring process was undertaken.
Environmental legislation and public action of pressure groups are becoming the main concerns for the industry. The future performance of the pulp, paper and board industry will depend on its ability to address these concerns.

Figure 1: Pulp, paper and board
Value added in comparison with other industries, 1992



Source: DEBA

INDUSTRY PROFILE

Description of the sector

The products of the industry are divided in three categories: pulp, paper and board.

Market pulp is wood pulp for paper making, produced for sale in competition with similar pulp from other producers. It excludes pulp for use by the producing mill or other mills which it owns or controls in the same country. However, it does includes pulp shipped to affiliated firms in other countries.

Paper and board comprises products such as printing and writing paper, sanitary and household paper, wrapping and packaging paper and board, and various sorts of specific quality paper.

There are three main final uses of these products: in communications, for printing, writing and drawing; in the packaging industry, for transportation, storage and presentation of traded goods; and in a variety of special applications such as hygienic paper, nappies, fiduciary paper (money or cheques) or technical uses (filters and insulation).

Within the EC, market pulp production is concentrated in Germany, France Portugal, Spain. Newsprint is produced mainly in Germany, the United Kingdom and France. Most of the EC kraftliner production is in France and most uncoated graphic paper is produced in Germany, the United Kingdom, Italy and Spain.

In this monograph, paper and board together will always be referred to as "paper".

Recent trends

Volume production in the industry increased by 2.4% in 1992, reaching 49 240 tonnes. Nevertheless, as a result of the lower prices caused by overcapacity, currency movements, etc., the overall production of the industry dropped 3% in current value terms. The evolution of pulp (19% of total industry production) and paper (81% of total industry production) followed different directions in 1992. Pulp production, measured in tonnes, dropped 0.1% in 1992, while paper production, measured in tonnes, increased by 2.5% in 1992.

The pulp, paper and board industry is significant in terms of value added when compared to other industries; it represents 16% of the value added of the motor vehicle manufacturing industry and 71% of that of the consumer electronics industry.

The breakdown by country shows that Germany is the main producer in the industry, followed by France (the EC's top pulp producer), the United Kingdom and Italy.

Waste paper was a major element of the industry. The industry consumption of waste paper in 1992 represented 52.9% of total paper production. In 1992, chemical pulp production continued to increase while mechanical production continued its decline. On the paper side, graphic grades grew in 1992 faster than other grades; coated woodfree grades are rapidly gaining market share.

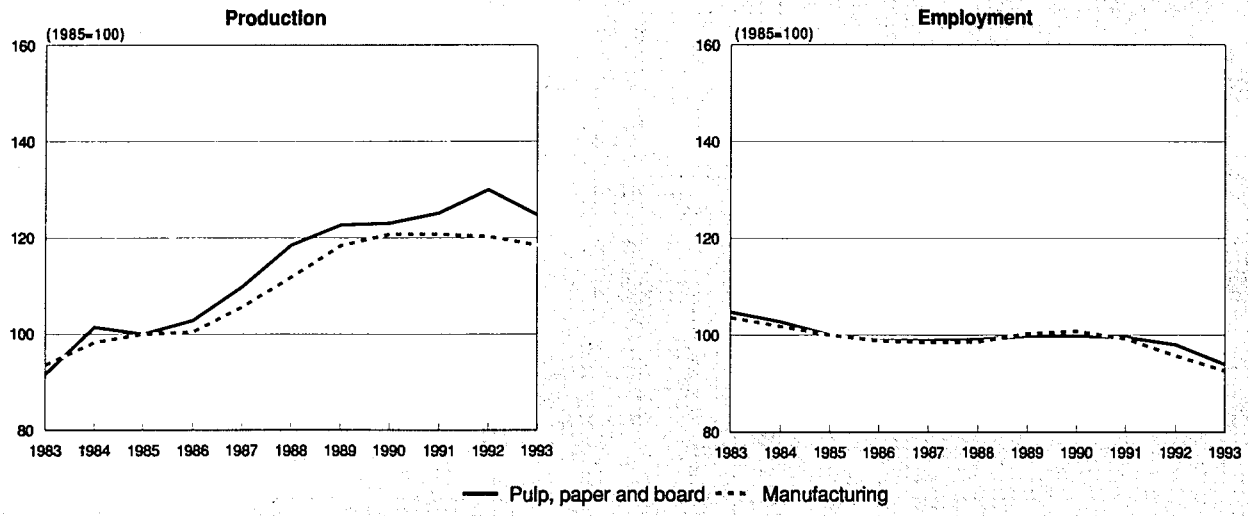
Production in constant prices and employment compared to EC manufacturing



1993 are Eurostat estimates.
Source: DEBA

Employment in the industry suffered a reduction of 2 900 jobs (15%) in 1992 as a result of the restructuring process companies undertook. Spain, Greece and the Netherlands were the only countries with positive employment growth in 1992 with 3%, 0.6% and 0.2%, respectively.

Real production in the pulp and paper sector experienced a 4% rate of growth from 1983-1992. This growth rate was higher in the mid 1980's, reaching 5.2% from 1983-1988, compared to 2.4% from 1988-1992. Between 1983 and 1993, total output in the pulp and paper industry rose faster than EC manufacturing as a whole.

The trend of employment contrasted with that of production. The number of jobs in the pulp and paper sector decreased steadily since the first half of the 1980's (except in 1988 and 1989 as a result of the upward phase of the business cycle), from 197 300 in 1983 to 184 700 in 1992. This plummeting of employment in the first few years of the 1980's illustrates the deep restructuring process which occurred in the industry.

International comparison

In 1992, total EC pulp production stood at around 9.4 million tonnes, while paper production reached 39.8 million tonnes.

With 49.2 million tonnes in 1992, the EC was the world's second larger producer of pulp and paper, after the USA, with an output of 133.7 million tonnes. Japan and Canada followed with around 39 million tonnes each. As far as pulp is concerned, the EC is only the fifth largest producer in the world. The EC was the second largest producer of paper after the USA, and was followed by Japan, Canada, Finland and Sweden.

Foreign trade

Despite the international economic slowdown, EC exports of pulp and paper rose by 5.4% to 2.6 billion ECU in 1992. EC imports in 1992 decreased by 5.2% to 14.5 billion ECU. EC Trade balance in the sector has traditionally had a negative evolution; nevertheless, in 1992, it improved by 7.3% (11.875 million ECU).

(2) Exports to the world for the EC
Source: CEPI

Intra-EC trade grew rapidly in the second part of the 1980's and, in 1991, was double that of the 1983 value, although in 1992 it decreased by 2.8%. The exports/production ratio rose to 8.7% in 1992 from 6.2% in 1983. The import/consumption ratio remained relatively constant throughout the decade, reaching 34.3% in 1992.

The EFTA countries (especially Sweden and Finland) are the main trading partners of the EC, receiving 27.9% of EC exports in 1992 and originating 70.9% of EC imports in 1992.

Globally, USA is the EC's second largest trading partner, absorbing 12.5% of EC exports and originating 10.8% of EC imports in 1992. Canada continues to be the second largest exporter to the EC, taking, at the same time, a minimum percentage of EC exports. Japanese imports into the EC represented 0.1% of total EC exports, while Japan absorbed 1.9% of EC exports.

MARKET FORCES

Demand

The principal customers of the paper and board production industry are the paper and board converting industry, the printing industry and final consumers. The market power of these three groups in influencing prices has inevitably grown with the current oversupply on the market. In particular, the market power of the printing industry and final consumers is increasingly demonstrated in the field of environmental issues. Effective campaigns by green pressure groups are forcing the paper and board production industry to adapt to new standards.

Despite the boom in German demand of pulp and paper due to the unification process, consumption in the EC slackened in 1992 by 3% in line with the general slowdown in economic activity. The German market continued to be the largest European market, and the fact that no kraft pulp production is allowed in Germany still generates considerable imports of these raw materials. The EC is the largest single importer of

Figure 7: Pulp and paper
Destination of EC exports

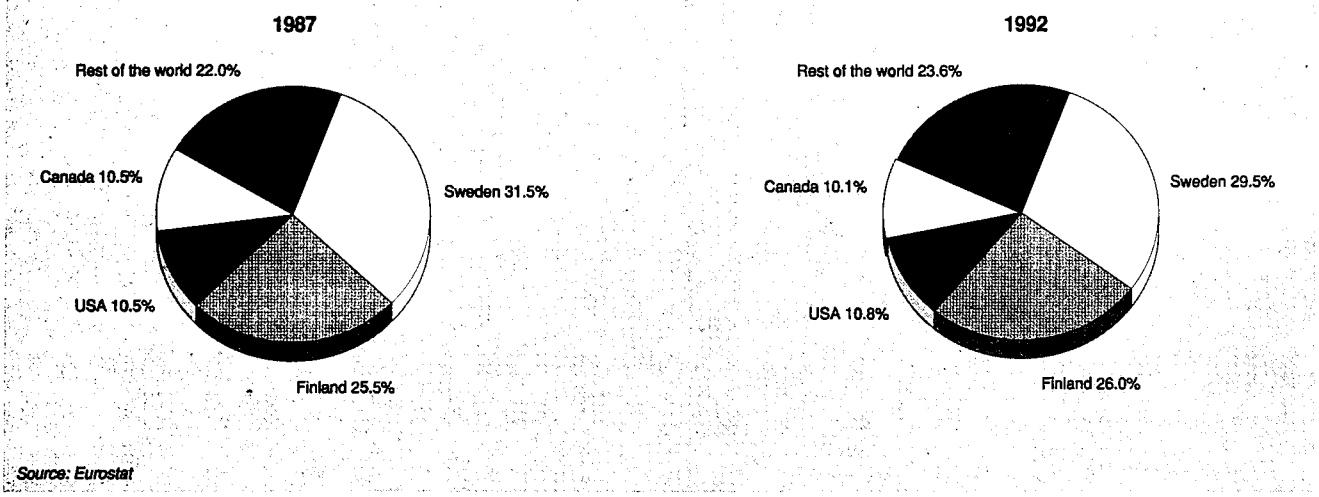
Figure 8: Pulp, paper and board
Origin of EC imports



Source: Eurostat

pulp in the world. A short description of the activity for each subsector is given below.

Newsprint

Newsprint is largely made from waste paper and mechanical pulp. Although belonging to the category of uncoated graphic papers, newsprint can be lightly calendered, to facilitate the increasing use of colour in newspaper advertising. Newsprint is used in letterpress, flexographic or offset printing. Newsprint consumption is directly related to the revenues of printed advertising. In this respect, depressed spending on advertising in 1992 led to lower demand for newsprint. In the EC, apparent consumption of newsprint in 1992 went down by 0.2, although production volume increased by 3.2%.

Uncoated graphic paper

These grades include directory, heavily filled and super-calendered paper. They are used in rotogravure and offset. A distinction is made between uncoated mechanical and uncoated woodfree graphic paper. Production and consumption of uncoated mechanical in the EC and EFTA in 1992 slightly decreased. In 1992, production of uncoated woodfree grade in the EC and EFTA increased by approximately 1%, while consumption rose by 2.1% and exports by 8.3%. Overall 1992 production of uncoated graphic papers in the EC decreased by less than 0.1%.

Coated graphic paper

A distinction is made between coated mechanical printing paper and coated woodfree printing paper. The coated mechanical grade is made with a mixture of mechanical and chemical pulp and used to print catalogues, magazines and advertising material. The coated woodfree grade is made almost exclusively of chemical pulp and it is used for high-quality "glossy" printed products. The coated graphic paper grades did well in 1992 experiencing rising production (+ 5.5%) and consumption (+5.3%). Production of coated woodfree grew at a faster rate than coated mechanical. Coated woodfree has gained market share over coated mechanical, accounting in 1992 for 48% of total coated paper output, compared with 43% in 1983. Growth in imports of coated graphic paper outstripped growth in exports.

Non-graphic grades

Non graphic grades include kraftliner paper, corrugated board materials, packaging paper, folding boxboard and greyboard. Kraftliner is used for the outer lining of corrugated board. This product is mainly produced in France, Spain and Portugal. Most of these non-graphic grades experienced slight increases in production and consumption in 1992. Folding boxboard and other boards experienced a 1.5% rise in production and a 1.2% increase in consumption in 1992.

Hygienic and sanitary products

The main final products of this grade are hygienic paper and napkins and industrial wipes. Production and consumption of these grades grew by 3.3% and 5%, respectively, in 1992 but exports fell sharply reaching a net exports deficit a 309 000 tonnes.

Supply and competition

Paper and board

Overcapacity is the industry's current biggest problem and it is particularly acute in the printing paper segment. In 1992, the average overcapacity rate reached 87.9%.

The present situation is directly related to the outstanding growth of the 1980s. Confident with double-digit growth figures and cheap loans in those years, many companies in the EC, Scandinavia and North America decided to build new, larger and more efficient paper mills. These machines are now a source of huge capacities in a market which, although growing, can not absorb all the new supplies. Recent and planned capacity increases have consistently exceeded the growth in European market demand.

Steeply increased interest rates and a general economic slowdown have now created a bad situation for many of the world's larger, and often heavily indebted, companies. Smaller manufacturers, who have been more cautious in the past, are in a slightly better position.

The gradual abolition of EC frontiers, both in legal as well as in practical terms, has a further impact on internal EC competition. In this process, access to the German market remains crucial. Although this market is well served by German based, and partly Scandinavian owned production facilities, the country's high labour costs encourage strong competition from efficient French and Dutch producers.

The international competitiveness of the EC paper and board industry is generally good. Its productivity stands out positively against competitors in North America and Scandinavia. EC industries have invested less in super-capacity and more in strategically flexible production techniques. At the moment, this strategy is proving to be vital to overcome rapidly changing market conditions for the various grades of paper products. Otherwise, the competitiveness of EC paper industries is a relative concept since many outside competitors moved into Europe. Some 50-60% of the EC production capacity is foreign owned with Swedish and Finnish companies as the main shareholders.

The EC paper industry is also gradually adapting to Community-wide economies of scale. National EC producers previously concentrated on the manufacturing of all paper and board grades for the national market. This resulted in rather small nationally oriented production facilities having a high degree of product diversification. Through a series of mergers and acquisitions, these producers are now seeking economies of scale comparable to those of their main competitors in the world. Many EC manufacturers have focused on niche markets, specialising in higher value added products, such as carbonless paper, thermal paper and watermarked paper. Most of them have no integrated links with wood processing plants, and buy pulp on the world market.

The US paper industry remained badly affected by the persisting economic recession. Much of US paper production is volume oriented which makes it less easy to adapt to changing market conditions. In 1992, USA production of paper and board reached 74.5 million tonnes. However, general economic conditions are currently better than in Europe, therefore USA has better medium term expectations.

The Canadian pulp and paper industry was hit by legislative developments in its main market, the USA. An increasing number of American states demand by law that newsprint, for example, be made partly from recycled wastepaper instead of virgin fibres. Canada therefore is searching out new outlets for its virgin-based pulp products, notably in Europe. In 1992, Canadian paper and board production reached 8.4 million tonnes.

The Finnish pulp and paper industry was drawn into that country's deep economic recession and, although Finnish machines are among the world's most advanced,. the large investments in them resulted in most companies becoming heavily indebted. The Finnish industry also suffered from disruption in its former annual imports of 5 million m^3 of wood from the former Soviet Union. Furthermore, Finland also lost the large Russian export market for their paper products. Finnish paper and board production reached 9.1 million tonnes in 1992.

As for the Scandinavian countries in general, the EEA treaty between the EC and EFTA that took effect in 1993 will not cause much change the trading conditions in the paper industry. Under existing trade agreements, EFTA countries already enjoy a zero tariff for paper imports into the EC.

The Japanese market, although important, is largely self-contained and of limited direct relevance to European producers. Japan produced 28.3 million tonnes of paper and board in 1992. The Far East paper market is the fastest growing in the world, notably in the ASEAN (Association of South East Asian Nations) countries and South Korea. One of the potential main suppliers in that area will be Indonesia. Indonesian government policy is actively aiming to become a world leader in paper and pulp production. It is not yet fully clear how European producers are situated to compete on the Asian market.

Pulp

The prices of various grades of pulp were subject to highly cyclical changes after 1986, the year when steep prices rises began. In the peak year of 1989, prices for Northern Bleached Softwood Kraft (NBSK - the prime grade) had risen between 44 and 75%. By 1990, these prices had dropped again by 35%. In 1992, they varied widely throughout the year, but at the and of the year remained close to their lowest levels of the past several years.

Analysts mainly attribute these large fluctuations to an initially tight market in the latter part of the 1980s and a subsequent overshoot in pulp capacity development. In response to a booming demand for paper in most parts of the world, many pulp mills were delivering pulp not only to their regular customers and integrated paper production units but also to many outsiders who increased capacity. Most pulp mills were running at full capacity.

A logical reaction to these developments was to increase pulp producing capacity by building larger and more efficient pulp mills, often accompanied by restructuring of the industry at large. Some of these new production capacities have now been established. They are often so big that the opening of one mill (with an average annual capacity of 400 000 tonnes) has an immediate effect on world market prices. In 1991 and 1992, it became clear that a number of planned new production units were no longer economically justified.

Production of chemical pulp has grown since 1983 at slower rates than mechanical pulp. This is a result of the substitution of chemical pulp for mechanical pulp as well as by other materials such as recycled fibres, mineral fillings and coating pigments.

Production process

The pulp, paper and board manufacturing industry is traditionally linked to the forestry and wood processing industry. due to lower costs of transport and the main raw material (cellulose), dependence on the supplying industries is decreasing. The original vertical integration of forestry, pulp mills and paper manufacturers is gradually replaced by more horizontal integration: big conglomerates in Europe and elsewhere are shaping up to produce every conceivable paper-related product from a variety of raw materials. This increasingly includes recycled paper.

The EC pulp and paper sector is highly innovative, modernising its machine park at a fairly rapid rate. Scale advantages and efficiency gains still continue to increase productivity. But despite this trend, the unit labour costs and the total unit costs continue to rise. Labour costs rise slightly because the industry workforce needs continuous training and ever higher technical education. Total unit costs increase even faster because of the high levels of investments needed to stay competitive. The level of indebtedness of many major EC producers is significant.

INDUSTRY STRUCTURE

Companies

The number of paper and pulp companies is still gradually decreasing and their average size is getting bigger. Nevertheless, the level of concentration within the EC is still low compared to the situation in Scandinavia and the USA. The

five largest companies in the EC are: KNP BT (NL), Arjo Wiggins Appleton (UK), PWA (D), Jefferson Smurfit (IRL) and Jamont (B). Most of the largest companies are integrated, participating in the pulp, paper and board industry as well as in the paper and board converting industry.

The major events in recent years were the 1990 takeover of the EC's largest firm, Feldmuehle Nobel (D), by the Swedish giant, Stora, and the merger of Arjomari (F), Appleton (USA) and Wiggins (UK) in the same year.

The years 1989-1990 were marked by increased acquisitions by Scandinavian and American companies within the EC and some regrouping among EC companies. The USA's largest paper company, International Paper, bought Zanders (D), Cookson Graphics (UK) and Laurent-Espaly (F). In 1989, the Swedish firm, SCA, bought Reedpack (UK). Kymmene of Finland bought Chapelle Darblay (F). The Irish based Jefferson-Smurfit internally restructured its US operations and acquired some smaller mills in the USA as well as in Europe.

The year 1992 was a quiet one as far as mergers and acquisitions were concerned. During 1992, firms have been developing minor operations to strengthen their markets and to step into new ones. USA and Scandinavian companies have acquired some small mills in the EC, while the process of regrouping among EC firms has continued. The main operation among EC firms was the KNP (NL), Bührmann-Tetterode (D) and VRG merger which created KNP-BT. This consolidation began in 1992 and was completed in early 1993. Other operations undertaken in 1992 were: Jamont (B) acquiring Dancrepe (D), Metsa-Serla (SF) expanding its position in Finland by buying Kotka Tissue mill, Bührmann-Tetterode (D) buying 49% of Hartmann & Flinsh (D) making its share of Hartmann & Flinsh now 75% and Saffa (I) acquiring 76% of the Kolicevu Board Mill in Slovenia

Late in 1993, KNP-BT (NL) and Leykam Mürztaler (A) announced plans to form a new company, KNP Leykam, which will be Europe's largest coated paper producer.

Strategies

Practically all top European (EC and EFTA) paper manufacturers have been involved in major restructuring activities in the past years. Because of the overcapacity, industries are now less convinced that bigger is better. The financial world is also less keen to finance the mergers and takeovers of already firmly indebted companies.

The average production per American mill is much higher than in the EC; 75% of EC mills, mostly non-integrated, have an annual capacity of less than 50 000 tonnes. By contrast, 60% of the EFTA mills, mostly integrated, have a capacity of more than 50 000 tonnes. However, further restructuring should not necessarily entail expansion of scale. In many market niches, the industry needs smaller and more flexible production units which are increasingly closer to their markets. The recent rate of structural change was greater in Europe than in North America and Japan, this may have contributed to increased uncertainty in the industry.

ENVIRONMENT

Although the industry was among the first to acknowledge the importance of monitoring the "eco-balance" in its production processes and actively recycles a large proportion of paper, it has become the target of several hard hitting protest campaigns.

Protest campaigns of international environmental organisations focused on four main issues: the bleaching method using chlorine and chlorine compounds necessary to obtain a flawless white colour in quality paper; the quantity of forest wood used in paper production; the degree of recycled paper to be used in the production process; and the high and growing per capita consumption of paper in the Western world.

In response to these pressures and a growing consumer awareness, the industry has a strong case to present. Firstly, the pulp and paper industry is one of the few which actually regenerates its raw materials. Sustainable forestry is employed in Europe where at least two trees are planted for every one that is harvested, with the result that forests in Europe are actually increasing. Secondly, the industry has switched largely from the use of pure chlorine gas to the much less harmful chlorine-dioxide as the main active ingredient in the bleaching process. Thirdly, the industry already recycles almost half of the paper consumed in Europe and is still stepping up this activity. In 1992 the European paper industry used 25 million tonnes of recovered fibre, equal to the use of chemical pulp. There are, however, other effective methods of waste disposal besides recycling, such as energy recovery in state-of-the-art incineration plants.

REGULATIONS

The European Community is presently developing a regulation which will affect the pulp and paper industry. The industry fully supports this pan-European of harmonisation, rather than the development of national legislation, because the latter risks hampering international trade without actually improving the environmental impact of global pulp and paper activities.

A proposal for a packaging waste directive that aims to increase the amount of waste to be recovered places increased responsibility on manufacturers to assist in waste disposal. In Germany, legislators have already set very high recovery standards and forbid incineration for packaging waste. The impact of this policy in this crucial market may influence pending EC legislation.

One major effect of the German legislation which has already been demonstrated is its important effect on the waste paper market. Waste paper prices have become so low that collection by private enterprises is not attractive. In certain cases, prices have even become negative because municipalities no longer knew what to do with their growing stocks. All these direct and indirect market developments will have to be carefully considered in the development of waste management policy, integrated prevention and pollution control, eco-labelling, eco-audits, etc.

OUTLOOK

General macroeconomic variables such as reduced consumption, unstable currencies, excess productive capacity, together with a significant political uncertainty, do not point out to a rapid recovery in demand or profitability. Also, USA and Japanese economic recoveries seem to be too slow to boost the world economy.

The European market, mainly driven by slowdown forces, is rapidly changing its conditions. The industry must be very flexible to adapt to these new conditions. Unstable supply and demand developments among the different paper grades make it crucial that modern facilities flexibly produce the kind and quantity of paper which the market is willing to absorb. The industry will undertake further restructuring activities in next few years.

Demand may pick up by mid or late 1994. This will release the pressure on prices, nevertheless overcapacity will still remain since considerable capacity increases have been recently developed and some are still planned.

The Eastern markets will have positive impact in the EC pulp and paper industry but only in the medium or long-term outlook. In the short run, it is likely that demand in Eastern Europe will grow particularly for lower grades of paper such

Table 7: Pulp, paper and board

as newsprint. In the long run, new production facilities in these countries might serve other European consumers.

Paper and board converting

NACE 472

The paper and board industry is strongly influenced by the activity of the general economy. Since the beginning of general economic slowdown in 1990, the industry has nearly come to a standstill. Its production increased slightly in 1992, nevertheless it reached a new record high of 44.4 billion ECU. The best performance of the industry indicators was achieved by its trade balance, with a strong improvement due to very significant export increases. Although production experienced a slowdown in some products in the industry, packaging products which make up the main proportion of the industry production value experienced a large growth, fuelled by increasing demand as a result of Germany's unification. Overcapacity in the paper production industry continued to spill over to the paper converters, pushing their prices down as well. Nevertheless, the paper and board converting industry has carried out a significant restructuring process, in which integrating and collaborating forces have been displayed. This leaves the industry in a much more solid position for the coming years, and facing a new set of challenges.

INDUSTRY PROFILE

Description of the sector

The paper and board converting industry covers all processing of paper and board into final applications in packaging, communications and other special uses. The industry manufactures a wide variety of products in packaging, often in combination with plastics and metal foils, in stationery and office supplies, wallpaper, labels, hygienic material, etc.

The distinction between the paper and board manufacturing and the paper and board converting industry is not easy to make. Increasingly, the major European paper producing manufacturers integrate forward into the production chain. As such they become active in both production and converting markets.

Recent trends

The size of manufactured goods made of paper and board increased steadily in the EC during the 1983-1992 period. The trade balance has always been of small proportion, although positive. In 1992, the trade balance experienced a significant improvement which contrasts with the reduction of previous years due to the increase in imports. In 1992, EC exports rose 6.2% and imports fell by 0.5%. The main trade flow, approximately 75%, takes place within the EC.

The paper and board converting industry is a major contributor to overall industrial activity. Its value added in 1992 reached 25% of that of the motor vehicles manufacturing industry and was 10% higher than the consumer electronic industry. The breakdown by country shows that the largest producer within the EC is Germany, with 30% of total value added in 1992 followed by the United Kingdom (23.1%), France (20.2%) and Italy (10.1%). At the same time, production and employment, measured in constant prices (1985), grew faster than those in the average EC manufacturing industry.

The breakdown by country shows that the largest producer within the EC is Germany, with 30% of total value added in 1992, followed by the United Kingdom (23.1%), France (20.2%) and Italy (10.1%).

Average growth rates during the 1983-1992 period were 3.5% and 3.4% in consumption and production, respectively. Both production and consumption grew much faster in the first half of the period, 4.5% and 4.4%, respectively. Extra-EC exports grew at an average annual rate of 5.5% in the period 1983-1992, the rate being higher in the latter half of the 1980's and first years of the 1990's (5.8%). From 1983-1992, extra-EC imports grew at an average annual rate of 7.2%, although the rate was higher during the first half of the period: 7.9% from 1983 to 1988.

Source: DEBA

International comparison

The EC paper and board converting industry is widely diverging in its activities. Thus, it is difficult to make clear comparisons between Scandinavia, North America and Asia. The EC is the second largest producer of paper and board after the USA. In 1992, EC production was about 60% of that of the USA. Nevertheless EC production compared with the USA accomplished a higher growth rate during the 1985-1992 period. Japan's production, nevertheless, experienced the highest growth rate: approximately 27% from 1985-1992.

As in Europe, the prosperity of the paper-derived products industry in other regions is closely related to the health of the economy at large. Thus, the persistent recession in North America has had a negative impact on the sales of packaging products in the last few years.

Foreign trade

Trade in most goods of the paper converting industry is limited. In packaging products, the volume/weight (i.e. corrugated board/containers) ratio makes transporting over longer distances particularly uneconomical. For other packaging materials, i.e. bags, sacks, folding boxes, this is no longer valid due to container transport systems. For hygienic products, office products, labels, envelopes, the volume/weight ratio is less relevant, and they are exported to distant markets in Asia and South America. Most production is organised as close as possible to the market to keep costs low. Both ratios of exports/production and imports/consumption reached a level of 7.5% and 6.5% in 1992.

Given the importance of geographical proximity for trade of paper and board, the main trading partners are the EFTA countries, which account for a share of about 40% of extra-EC exports and 68% of extra-EC imports in 1992, the USA takes only about 7% of total extra-EC exports and originates 13% of total extra-EC imports.

MARKET FORCES

Demand

The 1992 market situation for the different product groups of the industry was as follows.

Packaging products represented approximately 60% of the industry's production. It includes corrugated and solid fibre board, folding and rigid board boxes and containers, paper packs and carrier bags and other wrappings of consumable items. Demand for packaging products continued to grow at high levels in the EC. The industry received an extra impulse by the unification of Germany, which already was the most important market. It was a particularly welcome boost since most EC Member States experienced lagging demand. Uncertainty arose out of the different environmental legislation in the EC Member States.

Household and hygienic paper goods represented the second largest segment of production in the industry. It includes high

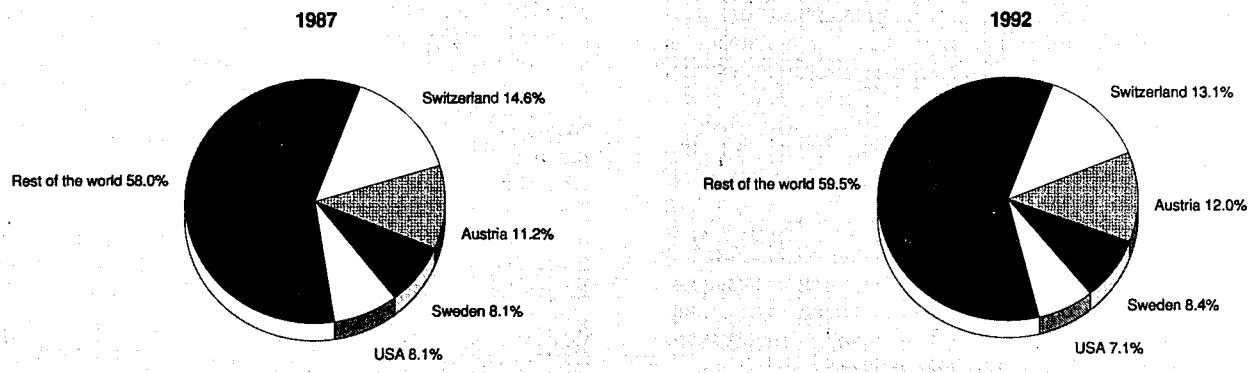
Destination of EC exports



Source: Eurostat

quality products containing cellulose, cotton tissue and crepe paper, which are used in nursing, baby care and feminine hygiene. Demand for these products has grown exceptionally in the past two decades. Demand for products of slightly less added value, such as travelling items, kitchen towels and toilet paper has grown rapidly as well. It seems that after this period of strong growth, the market for these products has reached certain saturation levels in the EC, although consumption per capita of various goods still lies below the US average. Some growth of demand may still be possible in southern EC Member States.

Stationery and office supplies was the third largest segment of production in this industry. It includes envelopes, labels, printing and copying paper, and products for special applications such as fax paper. Shifts in consumer patterns and the emergence of new technologies has taken away demand from mail-related stationery such as envelopes to electronic transmission-oriented stationery such as fax-paper and computer printing paper. Overall demand for office supplies is still gradually rising. Although some long term effects are expected of a transition to an electronic "paperless office", most analysts believe that stationery consumption in the EC will still expand.

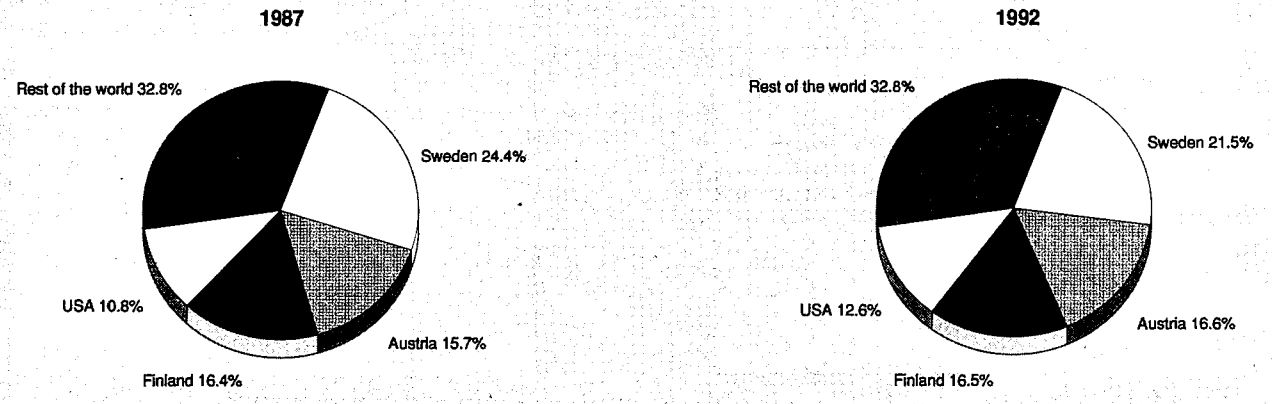
The fourth and last segment of production, miscellaneous, includes a wide variety of products such as core and tubes, wall paper, metallised paper, etc. This segment, because of the different nature of its products, exhibited a variety of tendencies during the last few years. Nevertheless, it generally showed a steady production increase.

Supply and competition

Overcapacity and the resulting pressure on prices in the paper and board manufacturing industry had an impact on the market for paper converting goods. But lower costs for the converting industry's raw materials have not led to higher profit margins as labour costs, transport and energy costs increased dramatically. The converting industry's customers have been able to negotiate lower prices for the end products. These customers include increasingly integrated retail trade chains which have considerable market power. Moreover, the industry is faced with steeply rising operating costs as a result of higher costs of labour and the financing of large capital investments.

The principal customers of the packaging industry are distributors, retailers and food processors. These customers are shaping up for the European single market and have much to gain with increased scale advantages and integration of

Figure 7: Paper and board converting
Origin of EC imports



Source: Eurostat

international operations. There are indications of heightened levels of cooperation among the principal players in this field. In the process, they become more powerful negotiating partners for their suppliers in the packaging industry. A similar trend takes place in the hygienic and stationery products sector.

The EC paper converting industry is gradually adapting to EC-wide economies of scale. The pace of restructuring is largely determined by the activities of non-EC manufacturers in the EC market. Major Scandinavian groups such as Stora (S), SCA Packaging (S), MoDo (S) and Iggesund (S) have been very active acquiring both paper mills and paper converting production units throughout the EC. The advent of the Scandinavians in the EC market had an important positive impact on the productivity of the EC-based industry as a whole. Their introduction of new production techniques and process innovations has been quickly followed by a substantial part of the EC industry. Labour costs and general productivity now compare positively against Scandinavian and perhaps even better against North American industry.

At the same time, some USA firms have enlarged their activities in the EC paper and board manufacturing and converting industries.

Production process

In some of its branches, the paper and board converting industry is integrated with the paper and board production industry. But as a whole it still remains essentially a separate and moderately fragmented industry of small and medium-sized firms. Originally, these two sides of the branch were clearly separated in an upstream side closely related to forestry and bulk paper production and a downstream side related to packaging and other applications, often of smaller scale. Today, bulk paper producers are integrating forward into the production chain. In competition with their Scandinavian counterparts, the large EC paper manufacturers acquire smaller converting production units. In doing so they gain efficiency, secure market shares and guarantee a steady demand for the raw materials.

These integrating forces led to synergies in new capital investments and a reorganisation of labour. As one notable result, the productivity index went up almost 20% from 1985 to 1992.

INDUSTRY STRUCTURE

Companies

Major EC, Scandinavian and North American companies in the paper and board converting industry are integrated: they produce paper and board as well as developed converting production. Together with further integration, companies in the industry have experienced a rapid rate of mergers and acquisitions.

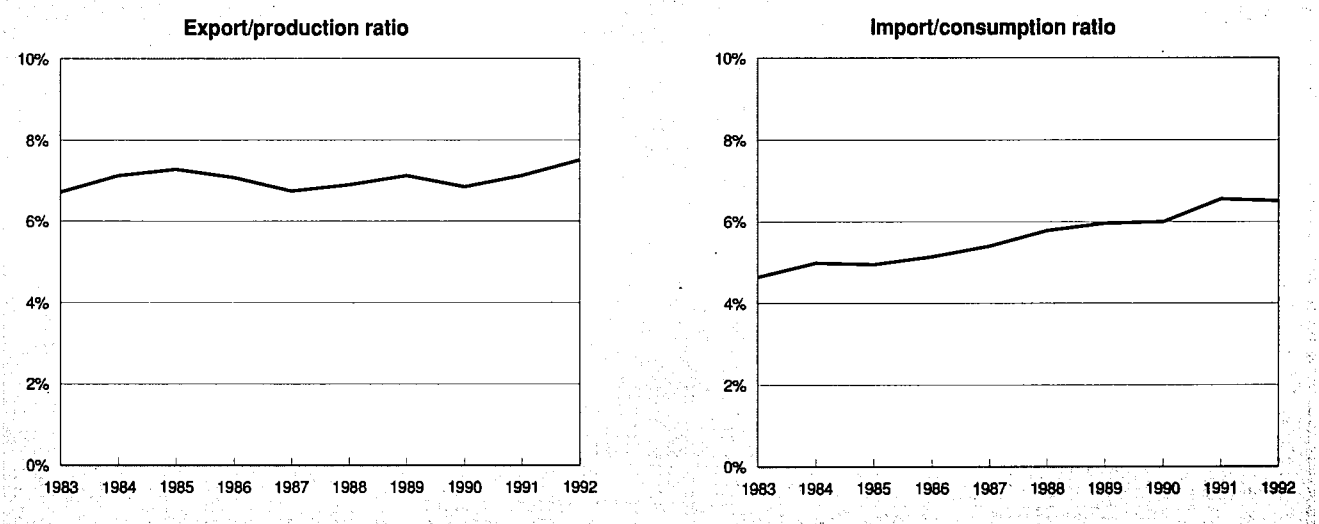
Major EC companies are: KNP BT (NL), Arjo Wiggins Appleton (UK), PWA (D), Jefferson Smurfit Group (IRL), Jamont (B), Saint-Gobain Paper Wood (F), David S. Smith (UK), Torras (E), La Rochette (F) and MD Papier (D). Scandinavian and North American firms are of a larger size than EC firms. Stora (S), Svenska (S) and United Paper (SF) are among the largest Scandinavian firms. The larger North American companies are International Paper (USA), Kimberly-Clark (USA), and Georgia Pacific (USA). Japan has some companies that are among the world's largest in the industry (integrated): Nippon Paper Industries, Oil Paper and Honshu Paper. Similar to the EC, most of the world largest above mentioned firms are integrated.

In 1992, there was a reduction in the number of enterprises. Following CITPA estimations, there were around 4 900 in 1992 compared to approximately 5 300 in the previous year. Most of existing companies are small and medium-sized. This large reduction has been caused by integration of companies as well as by multiple acquisitions carried out by extra-EC companies.

Strategies

The strategies of the EC paper converting industries are guided by the integrating forces from mergers and acquisitions which thrived in the late 1980s but which have been temporarily slowed down. Continued inward investments of Scandinavian and North American producers within the EC are forcing EC producers either to join them or to cooperate among themselves. The general expectation is that when business picks up again somewhere in 1994, the concentration of the industry will receive a new boost.

Figure 8: Paper and board converting Trade intensities



Source: DEBA

REGIONAL DISTRIBUTION

As with the bulk of EC paper production, most EC paper converting is concentrated in the United Kingdom, Germany and France. Some of the specialised packaging industries have settled close to foodstuffs production areas in Southern Europe and smaller countries in the North such as Denmark and the Netherlands. The biggest market, both for packaging stationery and hygienic products is Germany. This market has become even more crucial for EC producers after the reunification in 1990. Further details on regional distribution will be available in 1995 in PRODCOM.

ENVIRONMENT

The paper and board converting industry is directly related to environmental issues since society takes special concern with its raw material, trees. At the same time, the industry is related with general environmental issues such as energy efficient processes, solvent emissions, solid waste, etc.

The paper and board converting industry, mainly the corrugated board producers, are manufacturing products that meet modern environmental demands, following society's increasing demands for environmentally friendly products. As an example, no material comes from endangered tropical rain forest and there is an increasing replacement of primary fibres by recycled fibres. Waste paper and board is the most recycled material in the EC: 50% of municipal solid waste paper and board is recycled. Technological improvements in manufacturing and recycling processes have encouraged the use of recycled fibres. The percentage of recycled fibres in the total fibres used in the production processes varies depending on the products as follows: 80% in corrugated board containers, 70 to 100% in solid board containers, 50 to 70% in folding boxes, 60 to 100% in household or toilet paper and 60 to 100% in office products and stationary.

The packaging industry is most concerned with legislative developments in several EC Member States. Early in 1992, Denmark, the Netherlands, Germany and France implemented legislation to set minimum amounts of packaging waste which are to be recovered by manufacturers. The other main element of these new laws are minimum amounts of packaging waste which need to be recycled into the production process.

REGULATIONS

The EC is developing a waste packaging directive which will directly affect the paper and board converting industry as well as the pulp, paper and board industry. Through this directive, the EC is trying to increase the amount of material to be recycled and to create a harmonised legislative framework for all EC Member States.

Germany already has legislation with quite high packaging recovery standards. Other Member States are starting to consider similar legislative measures as a consequence of the recycling directive. In the case of Germany, the effects of legislation have already highlighted the problems related to the fact of not having a developed market for recycled materials. Waste paper prices have recently become so low that collection by private enterprises is no longer economically attractive.

OUTLOOK

The paper and board converting industry will face a negative growth in production in 1993 (measured in ECU): the first year with a negative growth after a decade of continued growth. The coming years, will experience slow growth as a result of general consumption slowdown. Most experts think that overcapacity in bulk production could be reduced by 1994. This fact, together with the restructuring process undertaken by the industry and new technical developments introduced, would allow some restoration of prices and profits.

New opportunities could be offered by the opening of new markets in East European countries. Tied closely to the transport and trading of consumable items, the demand for packaging products seems set to grow with increasing competition and consumer choice. The spending power of consumers in East European countries, however, will take several years to grow significantly. The new trading accords with some of the East European countries allow increased exports of certain goods to the EC. Since local production of EC-standard packaging material is hardly available in those markets, this might also trigger additional demand for the EC packaging industry. Stationery and hygienic products will probably profit less from these market openings.

The industry is represented at the EC level by: International Confederation of Paper and Board Converters in the EC (CITPA). Address: Arndtstrasse 47, D-6000 Frankfurt am Main 1; tel: (49 69) 746 070; fax: (49 69) 746 499.

Printing and publishing
NACE 473, 474

Printing and publishing, with all its historical and cultural importance, is a mature sector of moderate and steady growth which benefits from a reduced susceptibility to movements in the economy by comparison with other media. Nevertheless, the industry is currently undergoing a technological revolution which could bring the whole of paper-based production into question.

INDUSTRY PROFILE

Description of the sector

The printing and publishing sector comprises all the stages necessary to transform a piece of creative work into a manufactured product available for distribution to the public.

The finished products of the printing and publishing sector are diverse and include books, encyclopaedias, daily and periodical press, maps, and musical scores.

Recent trends

In most EC countries, consumption and production doubled between 1983 and 1992. Since 1991, however, overall EC consumption growth has slowed down, reflecting the recession in the United Kingdom, the largest printing and publishing producer in the EC. Growth in consumption in South European countries such as Italy, Spain and Portugal, on the other hand, held steady.

As shown in Figure 2, the United Kingdom, France and Italy together account for over 50% of the value added of the sector in Europe, with the United Kingdom dominating with more than 20%. Data on Germany are not available.

The EC trade balance with the rest of the world remains in surplus both in value and volume terms. Following a period of marked volume growth, the balance has stabilised since 1985 as exports performed less well.

Figure 3 shows the remarkable growth of production for the printing and publishing sector during the 1983-1992 period. Employment in the sector has been rapidly growing after a temporary slump in 1986, and stabilised since 1990.

International comparison

With a population slightly higher than that of the USA and a diversity of languages and cultures, Europe publishes five times as many titles, 250 000 a year. From 1982 to 1986, the number of titles published rose in Europe by 10%, while production over the same period fell in the USA and Japan.

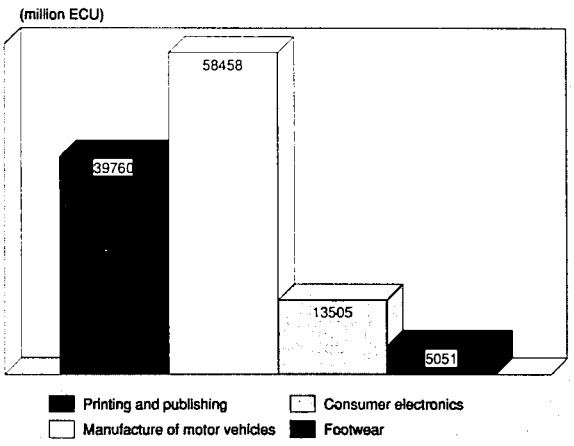
The USA remains the world leader in printing and publishing. In 1991 US production was worth 36% more than that of the EC and nearly double that of Japan, which had the fastest growth during the 1982-1991 period.

Foreign trade

EFTA is the EC's main partner in the printing and publishing sector for both imports and exports, surpassing trade with USA.

In fact, although language considerations do predominate in matters of trade, new markets are developing as economic frontiers expand. Within the EC, the wide use of the English language has allowed the United Kingdom to benefit the most from the single European market, closely followed by the Netherlands. The United Kingdom is becoming a crucial centre for European publishers, as well as an important entry point

Figure 1: Printing and publishing
Value added in comparison with other industries, 1992



Source: DEBA

for American printers and publishers wishing to establish themselves in the European market.

Intra-EC trade is growing at the expense of commerce with the rest of the world. Trade intensities are very low in the printing and publishing industry: the export/production ratio is about 4 to 5% and the import/consumption ratio is around 2%. This is related to the fact that major national markets are dominated by large domestic business groups.

MARKET FORCES

Demand

Developments in the book, magazine and newspaper trade depend on a complex variety of factors, including economic and social aspects such as demographics, education, leisure trends, number of public libraries, buying power and financing possibilities ranging from sponsoring to advertising.

Books do not follow the rules which generally dictate the economic performance of other products. The book, in fact, is one of those basic products whose evolution takes place over the long term in keeping with the demographic circumstances. And every European country has seen a reduction in its birthrate.

Stagnancy in new school entries intensifies this trend, as a reduction in the number of children has not been offset by a wider provision of education.

The situation appears most favourable in the United Kingdom and France, where a slight rise in population is forecast. Meanwhile, the average birth rate in Europe has stabilised at around 1.9 children per couple; the corresponding figure for the rest of the world is 3.6.

Analysis of consumption trends for books reveals a marked difference between the South and the North, with the Southern Europe characterised by relatively weak reading habits. The same considerations apply to newspaper reading and, to a much lesser extent, magazine reading.

Books represent 27.5% of leisure spending in Italy, compared with 18.7% in 1981, but only 46% of the population can be described as "readers", among whom 70% read less than five books a year. In Spain 63% of the population does not read for leisure.

There is a strong correlation between the level of education attaincd and the tendency to read. On average, 93% of graduate Italians read regularly, compared to a figure of 26% for those less qualified.

While reading ranks behind television and radio, nearly 50% of Britons read one book per month. Despite such a high consumption rate, the level of buying is very low: of the 56% of regular readers, only 60% actually purchase their books. This situation is due to the importance of public libraries - seven times more numerous in the United Kingdom than, for example, in France.

Overall, Europe is a mosaic of contrasts. In addition to major cultural differences, we can highlight:

- the ageing of the readership in Northern Europe linked to demographic factors, as well as regular consumption of books, magazines and newspapers due to improvements in living standards and the cultural importance of reading in these regions.

- increased importance given to reading in the cultural habits of Southern Europe due to improved education. This now means that the most committed readership is among the young.

Despite national disparities throughout Europe, it would appear that two sectors of editorial are emerging to cater to the interests of the main groups and the upper segment of small and medium-sized businesses - youth and educational publishing.

For a long time, children have been considered prime consumers; seen as the readers of tomorrow, they have spearheaded the youth sector as a major arena for socio-cultural activity. Educational success is a key factor for professional development and one of the main sources of parental concern. Encyclopaedias and dictionaries, as part of the educational publishing sector, also represent a rapidly expanding-market.

Supply and competition

Two separate phenomena have given rise to talk of a "publishing crisis" in Europe. On the one hand, stagnant sales have held down the number of titles published. On the other, the titles that have been published testify to editorial dynamism and healthy competition.

In the book publishing in particular, the apparent contradiction between these two phenomena has led to what some see as a crisis of over-production, resulting in a reduction in the size of average print runs. Stagnation or even reduction in the number of copies published emerges as a widespread phenomenon.

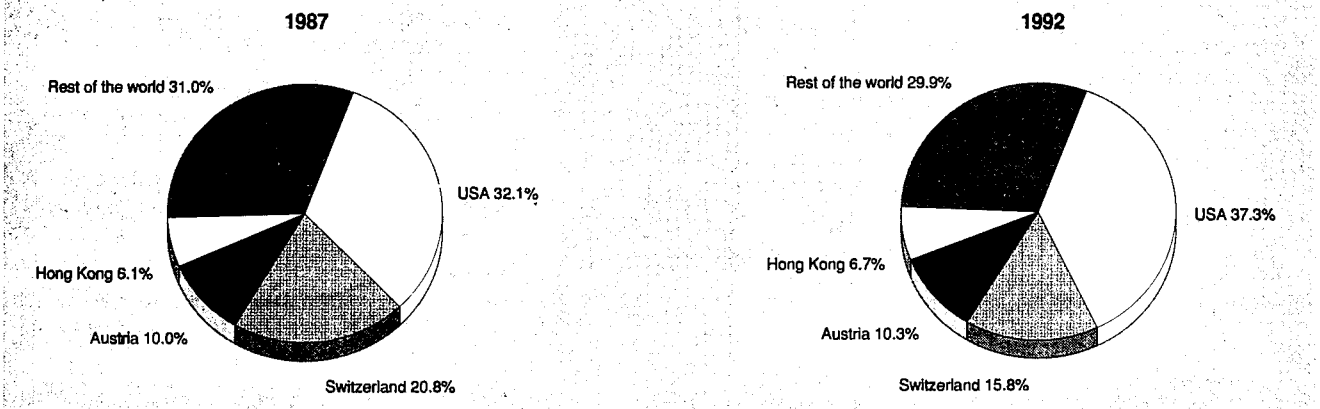
In Germany, the average print run for a contemporary novel never exceeds 5 000 copies. Those countries with the most vigorous publishing sector are the ones most hurt by cutbacks in average print runs.

The countries where production has grown most are the United Kingdom (with 68% growth between 1976 to 1986) and Spain, with a growth rate of 50% over the same period.

The number of titles published gives some indication of the expansion of the market; the percentage of new titles gives a further indication of market health.

Accordingly, Germany exhibits a high number of published titles, but a low ratio of new titles (27% of the total in 1989). France and Italy come in the middle, with the ratio of new titles to overall published output roughly balanced. Finally, the Netherlands, Spain and the United Kingdom exhibit strong

Figure 7: Printing and publishing
Origin of EC imports



Source: Eurostat

market vitality, with new titles accounting for some two-thirds of total published output.

Commercially speaking, new titles are high-risk area for publishers, whereas reprints reduce uncertainty and hold down fixed costs on a larger number of units over a longer period. The strategy of differentiation practised by the major publishing groups can be seen, to some extent, as "competition by attrition", with each publishing house attempting to secure maximum shelf space in retail bookseller outlets and, by definition, crowding out its competitors.

The reduction in average print runs and price rises are related. In practise, the average production cost of a book falls in relation to the number of copies published. Lower print runs therefore push up average unit costs.

Book prices do not obey the laws of supply and demand. In fact, eleven EC countries have adopted different forms of single-price arrangements. Only in Portugal is there a system of free pricing for books. On the other hand, books benefit in general from lower value-added tax rates. These range from zero in Italy, Portugal, the United Kingdom and Ireland to 22% in Denmark.

Book publishing has been affected by developments in audio-visual media, but the press has been affected even more. Advertising revenue, the principal source of finance for the press, has fallen dramatically over the last ten years, with advertising spending in the press dropping from 77% of total revenues in 1980 to 41,6% in 1990. Over the same period the corresponding figures for TV advertising revenues rose from 15,8% to 25,1%.

Nevertheless, despite forecasts that dailies, weeklies and periodicals would disappear as a result of the rise of audio-visual media, the principal newspapers have maintained their profit level over the last ten years.

The market for the press in southern European countries is relatively underdeveloped. Huge disparities are shown by the following figures on the ratio between daily newspaper circulation and population: Germans are top ranking in the EC as 426 copies are sold daily per 1 000 inhabitants against 157 in France, 81 in Spain and only 39 in Portugal.

In addition, the press is highly competitive. In European countries on average, ten daily titles together account for more than 50% of national circulation. This situation is most pronounced in the United Kingdom, where that percentage is reached by combined circulation of only four titles.

The 1990s will be witness to a major upheaval in printing and publishing as the very notion of paper-based media is progressively challenged. A CD-ROM (Compact Disc - Read Only Memory) is capable of storing up to 550 million characters - the equivalent of about 25 000 printed pages - and has become a vital storage medium for activities such as archiving, data banks and directories.

Meanwhile, the CD-I (Compact Disk Interactive) has a storage capacity capable of storing and reproducing sound and images as well as text. The CD-I also permits interactive audio-visual applications via a simple remote control device. Units are already on sale in the USA, and the launch of CD-I on the UK market was planned for June 1992.

Given this enormous text and image data storage capacity and know-how, CD-I publishers will play a major role in these markets: when it comes to targeting the public at large, the industry will be critically dependent on publishers.

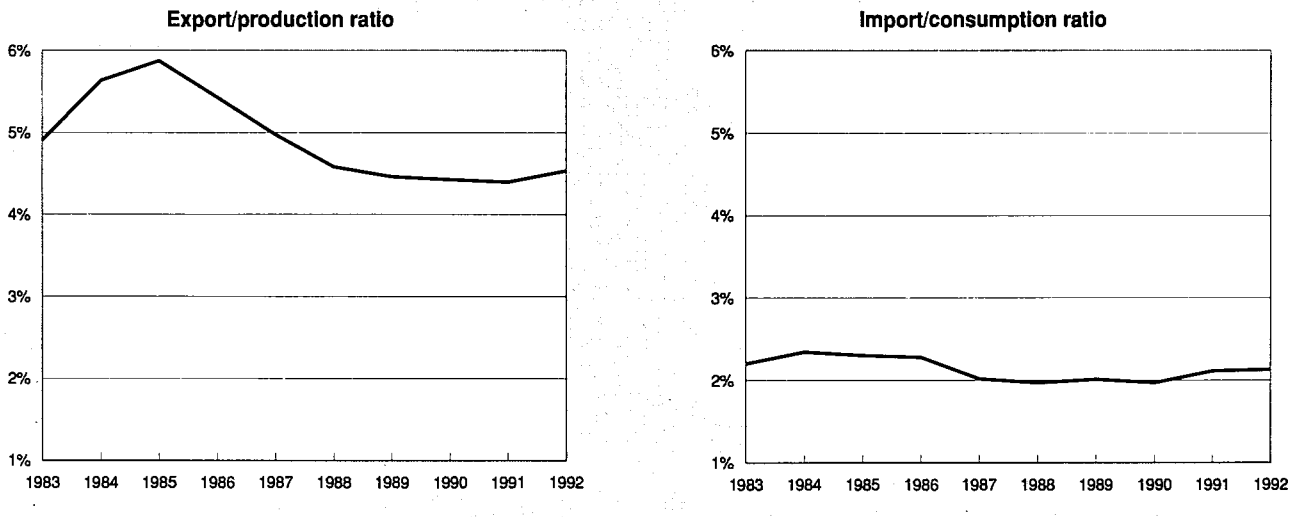
Production process

The printing and publishing sector is characterised by strong value added and a high dependence on skilled personnel. In Germany, where manpower is particularly expensive, printing labour costs can represent 36% of total costs in Germany.

The main stages in the manufacture of a book are: editing the work following acceptance of the author's manuscripts; a technical stage where typesetting and pagination allow a calculation of the costs of production and the raw materials needed; return of the composed text to the publisher in proof form; initial correction; layout and illustration with preparation of a "dummy" copy for the printer; checking printer's final proofs; printing a determined number of copies; distribution of the requisite number of copies to points of sale; and acceptance of returns or unsold copies at the publisher's expense.

In the course of the last few years, computer-assisted publication (CAP) and desk-top publishing (DTP) have generated professional interests. Computerisation of design and manufacture has allowed considerable gains in time and cost, but CAP will add to salary costs in the short term, since the process requires new skills from the workforce. CAP seems to be better adapted to limited print runs and, as a result, is more cost-advantageous to smaller publishers than to the major groups.

Figure 8: Printing and publishing
Trade intensities



Source: DEBA

In hardware terms, computerisation opens up the possibility of creating new forms of published product such as CD-ROM and CD-I. For example, a 9-volume dictionary weighing 50 kg can now be captured on 6 cm disc weighing a few grams and the entirety of its information accessed in a matter of seconds.

In the printing sector, most films now use electronic systems for composition and image processing. Photo composition has now replaced hot metal as the main technology. Micro-publishing (desk-top publishing) has also brought about considerable changes in the sector by facilitating PC-driven integrated text and image processing.

These technological innovations imply improved qualifications for staff and increases in productivity. Output per employee has thus risen from ECU 59 000 in 1980 to ECU 73 000 in 1989 (at constant 1985 ECU values).

A special feature of publishing is the cost burden of "returns", i.e., unsold copies. This burden is all the more difficult to bear in a period of recession. Books which are not sold are returned and destroyed/recycled.

Part of the problem is that available sales space tends to remain constant, whereas the number of titles on the market continues to grow. Inevitably, this disparity leads to a reduction of the time a book is on display, and its overall life-span. Volume and speed of returns has affected some publishers disproportionately, with several experiencing rates of return of over 60%.

Both the printing and the publishing industries require an increasing level of capitalisation. the best-known example is in dictionaries and encyclopaedias, where long production and commercialisation lead times presuppose financial resources to absorb heavy cost burdens both during the period of investment and to cover the costs of promotion and publicity to launch the title on the market.

INDUSTRY STRUCTURE

Companies

Europe's publishing sector is highly fragmented. Most groups have activities beyond merely publishing, covering a wider range of economic activities such as printing, press and publishing, bringing together a range of activities of creation and manufacture of paper-based media. Fewer than 10% of all printers operate independently of a publisher.

The main groups such as Bertelsmann (D) and Hachette (F) range even further afield, and are involved in multi-media activity.

The trend towards concentration by acquisition and merger is not equally marked in every country, but it is growing everywhere.

In Italy, the three main groups are Mondadori (30% of the market), Rizzoli (12%) and Fabbri (10.5%).

In the United Kingdom, the two publishing giants are Pearson and Reed which, between them, have 31% of the domestic market.

In the Netherlands, where 500 publishers serve a population of 15 million, three houses dominate: Elsevier, Wolters-Kluwer and VNU, which together control two third of the nation's publishing activities.

In Spain, five groups - Planeta, Anaya, Plaza y Janes, Circulo Lectores and Salvat - represented 38% of the market in 1983.

In France, five main groups, control three-quarters of the market. Groupe de la Cité and Hachette hold two-thirds of the national market between them - a situation without parallel elsewhere in Europe. Having said that, French publishing as a whole is characterised by modest levels of globalisation and poor sales of French language books on international markets (as compared with the performance of Anglo-Saxon publishers).

Strategies

The two main aspects of strategy are concentration and globalisation. Publishing groups are developing both vertical (publishing and distribution) and editorial (diversification) strategies in these new areas as well as in traditionally profitable areas, the net result being to favour economies of scale. However small publishing houses have a capacity for creativity and flexibility which allows them to stay in the market.

Publishers, in the strict sense of the word, tend on the whole to be medium-sized in Europe, with the exception of the major Dutch groups Elsevier and Wolters-Kluwer. The latter has recently purchased Liber, the second largest publisher of Sweden, as part of its strategy of expansion in the Scandinavian markets.

Mixed books/press houses are becoming more numerous, as a result of a growing synergy between the two activities: newspapers and magazines remain the most reliable media for book promotion. Thus, Mondadori acquired control of L'Espresso, a famous Italian weekly magazine, in 1989.

The most prestigious names belong to the multi-media groups: Bertelsmann (D), Time-Warner (USA), Paramount (USA), News Corporation (AUS) and Hachette (F). These groups have a presence in all the main mass media markets - books, cinema, television, press - and all have extensive international connections.

Globalisation strategies are pursued in general by way of subsidiaries or by acquisitions. In practise, publishing groups - acknowledging their limited knowledge of international markets and the cultural differences implicit in language and business practices - are more likely to expand by acquisitions rather than industrial or commercial means.

Bertelsmann and Hachette are the most international of the major global groups. Between now and the mid-1990s, however, they will in all probability be joined by groups like Pearson and Reed, which have made no secret of their intention to diversify away from their pronounced Anglo-Saxon orientation.

Meanwhile, the Single European market is obliging publishers to consolidate their position in Europe: what is at stake is not so much Europe itself, but the principal European languages which predominate on world markets: English, Spanish, and, to a lesser extent, French.

Expansion both in Europe and throughout the world is nevertheless limited by the national character of information. None of the multi-media groups has a major position across Europe in the three main media - press, TV and radio.

ENVIRONMENT

Paper consumption in developed countries is of the order of 120 kg a year per inhabitant. Demand in the OECD countries for wood pulp, paper and cardboard is projected to grow substantially in volume, from 150 million tonnes today to some 200 million tonnes by 2010.

Western Europe uses a total of 27.5 million tonnes a year of graphical paper. Books consume 1.5 million tonnes, magazines 4.6 and newspapers 6.8. The remaining 14.7 million tonnes go to advertising, free sheets, directories and catalogues. The use of recycled paper is increasing.

The publishing industry is itself involved in the debate about collection and recycling. Research is being carried out, not merely on how to increase paper recycling, but to analyse the overall environmental economics of the paper chain. New areas of interest include the valorisation of the energy content

of paper fibres that underwent different life cycles and have lost their useful mechanical properties.

REGULATIONS

As a cultural product, books ought to remain affordable to consumers. For this reason, most European countries apply conservative measures on pricing, Portugal being a notable exception. These measures would appear to be crucial to the continued existence and development of the distribution networks needed to keep books available to the public and, by extension, for the survival of literary creativity in all its diversity.

In the United Kingdom, the Net Book Agreement governs the fixing of book prices. It is for the publisher to decide whether his books should be sold at a free or an imposed price. In practice, only textbooks tend to be sold at free market prices.

In Germany, publishers themselves operate the rules on price fixing. In Germany, bookshops are bound by collective contract with 1 700 affiliated publishers to respect the fixed cover price. A similar arrangement operates in Italy. In France and Spain, legal provisions exist to enforce the obligation to sell at the published cover price.

One way out of the problem is to purchase and sell rights on a pan-European level; this, of course, would entail larger investment on part of publishers.

It will be difficult, especially in the case of more internationally-oriented publications such as English-language encyclopaedias and technical and scientific literature, to maintain an imposed price which differs according to the country concerned. The logic of the Single Market calls for application of a European price in the country with the lowest applicable value-added tax.

The book publishers' concern on VAT is echoed in the daily and periodical publishing business. The present differences in taxation policy with some zero-rate strongholds may come to an end if the EC were to decide to harmonise the rates applicable to publications. The industry is running massive lobby efforts to safeguard the possibility of having zero VAT on print.

OUTLOOK

The publishing sector is best described as a mature sector posting regular if moderate year-on-year growth. Because of its peculiar mix of historical and cultural factors, the publishing market is relatively immune from economic swings.

The cultural habits of consumers are the key to future development in the sector. Its evolution depends on socio-economic factors such as demographic trends, education, industrialisation, political trends (as in Spain, Greece and Portugal) and, not least, tradition.

Table 5: Printing and publishing

Production	0.0	2.0
Extra-EC exports	0.0	1.5

Source: LEK Partnership

New technologies now seem to be complementing rather than substituting for the written word: in fact, those countries which have emerged as the prime consumers of images are also those which remain most attached to the written word.

The most promising sub-sectors of the publishing industry are those connected with knowledge, teaching and professional training - such as dictionaries, encyclopaedias, textbooks, practical guides and books aimed at the youth market.

The application of new technologies in publishing - either as production aids or as new media per se - is still at an embryonic stage. New products derived from books or developed from synergy between different media - sound, images, text and data - can be expected to multiply and stimulate global markets.

The development of EC regulation on media concentration as well as EC research programmes may influence the way the European media houses will adapt to the technological change and become competitive multi-media operators.

Printing
NACE 473

Comprising more than 60 000 firms and employing some 670 000 people, the Community's graphic industry handles a turnover of over 50 billion ECU. The industry is mainly made of small enterprises, as 85% of the companies of the industry employ less than 20 persons. The graphic industry is a modern, high-technology industry which, by keeping up with the latest manufacturing processes and investing heavily in new machinery over the last few years, has placed itself at the forefront of technical progress. Image processing in modern printing is now carried out by computer or computer assisted equipment. This technology requires highly-skilled workers.

INDUSTRY PROFILE

Description of the sector

Printing firms produce a wide variety of products ranging from simple visiting cards printed in one colour, to bulky, four-colour, direct mail catalogues. The smaller firms work mainly with local clients, for whom they produce personal or commercial printed documents, whereas bigger firms often deal with clients further afield and supply, for example, printed advertising material, books or continuous stationery. Some large firms run both a printing and a publishing house, and specialise in newspapers and magazines.

Larger firms, doing gravure printing, often print and/or publish magazines, catalogues and long-run advertising material for the international market.

Of course, this variety of markets goes together with a variety of results; the economic health and vitality of local markets can vary substantially because of their economic, cultural and social situation.

Recent trends

Despite the economic growth of the last few years and the positive effect on employment and production, the graphic industry in Europe is now developing differently from country to country. Germany, for example, benefited from a continuation of its economic growth, partly because of the increase in demand after the unification of Germany, but the situation has declined considerably since then. On the whole, though, in 1992 the growth of the graphic industry somewhat exceeded that of the community's economy. In 1992 exports to non-EC-countries amounted to 1 500 million ECU, whereas imports amounted to 718 million ECU.

Foreign trade

No detailed figures on trade in graphic products (or trade structure) are available because external trade statistics do not distinguish between the trade of printing firms and that of publishing houses.

The production of graphic products in EC Member States is mainly determined by internal demand. The export rate is in general below 10%. This relatively low figure is due to several characteristics of the industry, such as the need for frequent contacts with the client, the great need for communication during the work, linguistic barriers or the relatively high costs of transport. Exports concern mainly large runs or special contracts, such as catalogues or other printed advertising, books or newspapers. Exports are in general done by a small number of large firms working in gravure or web-offset.

Most of the external trade with non-EC countries is done with other Western European countries. The amount of printed work done by EC-printers for outside clients has increased considerably in recent years. Trade with Eastern countries remains low but is expected to develop in the near future. Exports to non-EC countries are about twice as important as imports.

MARKET FORCES

Demand

In the graphic industry there is a direct link between demand and production because this sector supplies mainly to order. Printing firms are rarely able to manufacture for stock as other industrial sectors can.

Demand for printed products is influenced by a number of demographic and economic factors such as population growth, composition of households, training and education as well as economic growth. The graphic industry, just like the publishing sector, is above all a supplier of products which disseminate information and knowledge and cater for leisure activities. Its role stems from its cultural, intellectual and educational vocation within the context of the exchange of ideas and information found in democratic societies. Despite the low growth of population, the number of households and managerial jobs continues to grow as does the proportion of income available for education and information. All this continues

to stimulate the demand for newspapers, magazines, periodicals and books. Consequently, the number of books printed has never been so high. New technologies have opened up new and ever growing markets, such as for computer manuals and educational material. On the other hand, private demand represents only a small part of the graphic market.

The advertising expenditures of the economy as a whole is one of the most important factors influencing demand and production in the graphic industry. Almost two thirds of the industry's turnover depend directly or indirectly on advertising. Any political decision affecting advertising, in general or in particular also affects the graphic industry and consequently can jeopardise employment. The printing of catalogues, advertising brochures, pamphlets and company reports is ever increasing as are advertising inserts in newspapers.

General commercial printing is an important part of graphic production. Individuals, municipalities, industry, commerce and insurance companies are now big clients for printed products of all kinds, including stationery, visiting cards etc.

These products, printed on separate sheets remain one of the main activities of the small printer who is often limited to local custom. Larger printers will deal with continuous forms and customers further afield. The demand for continuous business forms is constantly increasing, mainly due to the growth in electronic data processing used for example in electricity bills and insurance certificates. The continuous forms market is expanding substantially in some countries, partly because of increasing electronic processing of information, whilst the market is suffering from a harsh crisis in other countries, such as Italy.

Labels, packaging products, wall calendars, illustrations and postcards form yet another sector of the graphic industry. These products are often printed by specialised firms.

The upward trend in overall demand has been stimulated by the development of new and existing products. At the same time, printers are now trying to cater for special requests. Quality standards are rising visibly, particularly in creativity and design by electronic means and improved equipment for colour printing. Multicolored pictorial information is increasing for advertisements, magazines and company reports, and newspapers are also now making use of colour.

Progress in technology has also led to a number of electronic data processing functions being carried out at the client's office, for example, articles are often now drafted on the client's computer. The printer then has to transfer the information - off-line and on-line - to and from the client.

Information needs are satisfied by an increasing variety of electronic means and communication devices. Nevertheless, the permanence and high degree of information stored in the printed product have enabled it to retain its position as a simple, easy, accessible and efficient means of communication. A number of printed products are complemented by electronic media and vice versa (for example, specialised magazines). It is clear that the necessity to process and exchange information efficiently will continue to increase.

Supply and competition

The publisher remains one of the printer's main clients, and accounts for about 40 to 50% of production. The printing of newspapers is almost exclusively carried out for publishing firms. Furthermore, in this area, publishing houses and printing houses often form a legal entity and belong to one owner.

The printing of newspapers accounts for roughly one-fifth of the total printing production.

Publishing houses are also important clients of the magazine printer. In countries such as Germany, widely circulated magazines are invariably produced by printing houses which are owned by publishing houses. In other countries like Great Britain and France such a situation is rare: printing and publishing represent two distinct and different activities. These publishing houses are dealing increasingly on the international markets. Other types of publications, such as specialised magazines, religious, scientific or professional are printed for independent publishers or for publishing houses linked to printing houses. The production of periodicals accounts for about one-fifth of the total print production. Book printing follows a similar pattern to that of periodicals. Book publishers - independent or linked to printing houses - are not the only ones to order the printing of books, paperbacks or hardbacks; industry, public authorities and other organisations are also ready clients. Book printing accounts for about one-tenth of the total printing production.

The market for printed advertising material consists of a wide range of goods, such as direct mail catalogues, prospectuses, advertising inserts, posters or leaflets. The structure of this market is as diversified as its products as a large proportion of the clients are made up of direct mail companies, commerce and industry. Political parties and other organisations are also big consumers of printed advertising material. This sector has grown considerably over the last few years, stimulated mainly by the development of new forms of advertising, such as direct mail. The production of printed advertising material accounts for a quarter of the total printing production.

Printed matter for individuals and professionals is often taken on by the small printing firms. These cater for the municipalities, various organisations, industry, commerce and local individuals to whom they supply visiting cards, business forms, headed paper, invoices, transport tickets and cheques. These small firms often print in single sheets, whereas the larger or more specialised firms deal with continuous printing and produce different types of continuous forms, completed on computer by the clients themselves. The production of this printed matter accounts for about one-fifth of the total printing production.

The tenth of the printing production which has not been attributed to any of the above categories accounts for various products such as calendars, fine-art prints, postcards and greetings cards, cartographic products etc. Alongside these printed

products the sector also produces rubber or polymer stamps, reprographic products such as photocopies, overhead foils and microfilms.

Alongside these printing firms can be found suppliers of services who often take the place of printers when these cannot cater for exact needs. This is why composition and word-processing are sometimes carried out by trade typesetters; the same applies to reproduction (image processing) and to finishing. Services such as the design of printed matter and the production of layouts and dummies are also offered to the client. In the future, firms who will offer new services through desk-top-publishing processes will complete the existing structure of the graphic industry.

Production process

Current developments in the industry indicate a close link between the printing sector and the development in communication and information technology. Innovations in equipment and graphic machinery have taken the industry to the forefront of technological progress, an industry where equipment has a major impact on the type, the quantity and the flexibility of the work carried out as well as on the professional skills and the organisation of the work in general. Many aspects of the print production process are now commonly automated, measured and controlled by computers. In the last few years, there has been a substantial increase in investment in new printing machinery in several Community countries.

There have been particularly fast changes in the sectors of pre-press and reproduction. Even small printing and reproduction firms now use totally electronic pre-press systems with word and image processors. Photo-composition is the dominating technology and is progressively taking over the old system of hot-metal composition. The latter is still used, however, in certain specialised jobs.

Desk-top-publishing has also brought about a number of changes. Generally speaking, desk-top-publishing allows combined processing of both text and image; in other words, one can not only capture, process and display text but also capture line illustrations from files as well as read and modify simple illustrations with the help of scanners.

This new development means that a number of customers are now able to do their own keying work which in turn has led to ever greater demands in photo-setting especially in capturing, processing and converting the very varied information found in printed matter. A number of customers have tried to accomplish these operations themselves but have had to face the fact that such systems require the experience of a professional typesetter and that the cost is often underestimated.

Upstream of the printing process, reproduction has also undergone a number of important changes due to the rapid developments in micro-electronics. Photomechanical reproduction by camera which was once quite common has already been widely replaced by electronic image processing. Such systems process and convert image-data through electronic whole-page transmission; after the lay-out of the page with the text, the illustrations are mounted electronically. These very expensive systems are installed in the large printing firms and in reproduction firms dealing with colour magazine and catalogue printing. Other less expensive systems, such as powerful personal computers are now being used for colour separation. In this area, technological progress is comparable to that found in composition. In fact, there are now very definite signs that the two areas of composition and reproduction will eventually merge.

Equipment and production techniques now used in printing and in finishing have also been influenced by the arrival of the micro-processor. The latter is being increasingly used to control such functions as tension of the paper web, ink flow, machine control, labelling and despatching. To a great extent these two areas also show signs of merging. Certain printed products, such as books, are already being produced by what is known as on-line finishing, in other words the printing and binding are carried out on the same production line.

The use of electronics in information and communication now play a significant role in printing as a whole. The effect is quite obvious in the transmission of information from client to printer as this is now, more often than not, carried out through electronic media. The transmission of information within a printing house - for example, in newspaper printing, from the editing department to the printing floor or in the case of magazine printing, from one printing department to another - is becoming quite common.

On the other hand, publishing firms have tried to evaluate the impact of this new technology in communication on printed products and are looking into ways of becoming more involved in these areas. Publishers and printer-publishers have often invested in such areas as data-processing units, data banks, videotext and even local radio stations, whereas the printers tend to remain faithful to purely technical operations.

Bearing in mind that most equipment manufacturers now offer similar techniques and know-how in all European countries,

if not world-wide, the technological progress of the graphic industry can be considered to be similar in all the Community countries.

INDUSTRY STRUCTURE

Companies

The graphic industry in the Community, is made of small and medium-sized companies. A typical printing firm employs fewer than 20 employees, as some 85% of all the firms belong to this category. The remaining 15% are nearly all firms employing between 20 and 500 workers. Only a very small number of printing firms employ over 500 workers; in Germany this category stands for 0.3% of all the firms and this percentage is even lower in a number of other countries.

Labour and training

Printing has traditionally been a high wage industry, reflecting the above-average levels of skill required from its labour force. Printers have also often been among the first to benefit from improved working conditions - shorter hours, longer holidays and other advantages. In half the Community countries the working week is 37.5 hours or less. In most others it is not more than 40. Only Portugal still has a basic week of 45 hours. German printers already enjoy 6 weeks annual holiday and in five other countries they have at least 5 weeks.

At the same time, wage costs have a considerable impact on total production costs and have even increased in the last few years. Furthermore, important investment costs need to be made to ensure that the necessary qualified personnel is available. Despite all this and the swift technological developments of recent years, which have enabled new markets to be won, employment has remained relatively stable in the graphic industry.

Training goals have been adapted everywhere over recent years to attract trainees with the necessary qualities to the industry, to give them broad- based knowledge of the various stages of print production and of the different processes like offset lithography and photogravure. Printing technology, which has undergone great changes in the last quarter of a century, is still evolving to become faster, more automated and better controlled with the help of electronics, leading finally to more attractive print products of higher and more constant quality.

The industry's labour force has to be receptive to continuous training to adapt to the changing and improved techniques. The trend throughout the Community has been to move away from a situation in which the labour force had 30, 40 or more different craft skills towards one of greater flexibility, in which print workers are not limited to a single speciality.

ENVIRONMENT

The European graphic industry is an industrial branch which has only a marginal impact on the environment. Nevertheless, the industry is devoting increased resources to meeting the stricter environmental requirements. For example, it has invested large amounts of money to limit emissions caused by web-offset printing, to improve the quality of water and to encourage the recycling of waste.

In some EC-countries the graphic industries federations collaborate closely with government departments to agree on the best measures for environmental protection. At international level, the international association for the graphic industry, Intergraf, is co-operating with the EC-Commission to define appropriate directives in this area. To maintain fair competition, the Single Market requires the harmonisation of laws and directives in all EC-Member States, and this also in the field of the environment. The graphic industry considers it has a responsible role to play in safeguarding the environment and therefore our living space.

OUTLOOK

New changes will take place in the future. The main changing factor will be electronics and the automatization that goes along with it. Pre-press (composition/reproduction) will be the branch mostly affected 'by these changes. Electronics will also have a significant impact on printing and finishing machinery. Technical developments imply that customers can carry out simple pre-press operations at the printing plant. On top of this, new communication techniques are reducing the distance between the printer and his customer, facilitating and intensifying all data transfer.

Rubber products
NACE 481, 482

The rubber products industry consists of two main subsectors: the manufacture of tyres and the manufacture of industrial rubber products. EC and Japanese-owned manufacturers are dominating the industry, but the US market is the largest in the world. After a slow but positive production growth in the 1980s, the industry is now for several years in a period of stagnation. To adjust to this situation, firms are restructuring and investing in cost-reducing automation. Prospects are for slow recovery after 1993.

INDUSTRY PROFILE

Description of the sector

The rubber industry comprises two main subsectors, the tyre and inner tube industry and the manufacture of industrial rubber products (which include some products for consumers).

The tyre and inner tube industry includes the manufacture of tyres and tubes for passenger cars, trucks and buses, agricultural vehicles, earth moving and mining machinery, bicycles and motorbikes, and other applications.

Industrial rubber products are pipes, hoses, sealings, belts, profiles, foam, soles, adhesives, etc. which are manufactured for such end markets as vehicles, machinery, electrical engineering, construction, the chemical industry, the food and drink industry, the medical sector and sporting goods.

The rubber industry is to some extent connected with the plastics processing industry (NACE 483); both process polymeric material based on hydrocarbons. The bigger enterprises in the sector of rubber products are often active in the plastics processing industry too. The processing machinery for both branches is similar; the rubber industry uses mixing equipment in addition because the raw material is mixed by the manufacturers themselves.

Germany is by far the largest producer of rubber products in the EC, accounting for about a third of total value added in 1992. France is the next largest producer, with about one fifth of total value added, followed by the United Kingdom and Italy, both of which account for about 15% of total value added.

Recent trends

In the 1980s the market for rubber products was effected by the pressure of competition, technological progress and environmental concerns. EC production in current prices grew by 4.5% during the 1983-1992 period. In constant prices however, total production has increased with a meagre 1.2% in the same period. Demand has increased at a slightly higher rate than production, with the result that the positive trade balance has become smaller and smaller. Due to sluggish growth and rationalisation efforts of the industry, employment in the rubber products sector has declined from 1989 onwards.

The sustained recession in most European countries, and not only in Europe, continued to depress the rubber products sector in 1993. Low growth rates in the end markets, especially the automotive markets, created a tough economic climate for the rubber products sector. The car manufacturing sector accounts for more than two thirds of the demand for rubber products.

International comparison

Data from the International Rubber Study Group show that the USA have the largest tyre-production in the world. EC-owned tyre manufacturers however, are the world leaders. The same situation also holds for industrial rubber products. As far as tyre production is concerned, Japan experienced the largest percentage growth over the 1983 and 1992 period with 27%, followed by the USA and the EC, both with a percentage growth of 23%. The ranking changes however, when only the period 1985-1992 is considered: then the EC has the largest growth.

The developments in tyre production are mimicked in the real growth figures for the whole rubber products sector. During the 1985-1992 period only the EC shows an overall positive growth, whereas Japan and the USA had a production level in 1992 which was below that of 1985. All three markets however are declining since 1989.

Foreign trade

Extra-EC exports show a much more cyclical pattern than extra-EC imports. In 1984 and 1985 as well as in 1988 and 1989 there were upswings in extra-EC exports, followed by downswings and recovery. Extra-EC imports, however, steadily increased every year from 1982 to 1992 by more than 10% on average. As a result the trade balance decreased. At the beginning of the 1990s the share of intra-EC trade in total imports declined a few percentage-points, whereas during the 1980s the share remained fairly constant.

Among the export markets of EC rubber products, the EFTA countries account for roughly one third of total extra-EC exports, followed by the USA and the OPEC countries. The share taken by Japan is small.

As for extra-EC imports, Japan has become the largest supplier of rubber products, as a result of a growing import share during the last 5 years. The share of the EFTA countries decreased significantly from 1987 to 1992 and became eventually lower than Japan's. The importance of Malaysia as a world rubber producer is confirmed by the fact that this country more than doubled its share of total extra-EC imports during the 1987-1992 period.

MARKET FORCES

Demand

The tyre market for original equipment (OE) is highly competitive with a limited number of customers who exert a strong market pressure on the suppliers. The replacement market is entirely different with a huge number of customers. Most of them are individual car owners, some are commercial organisations like rent-a-car firms or transport enterprises.

The ratio between OE tyres and replacement tyres depends on the development of car production and on the total fleet of vehicles. In periods of overall economic growth, for ex-

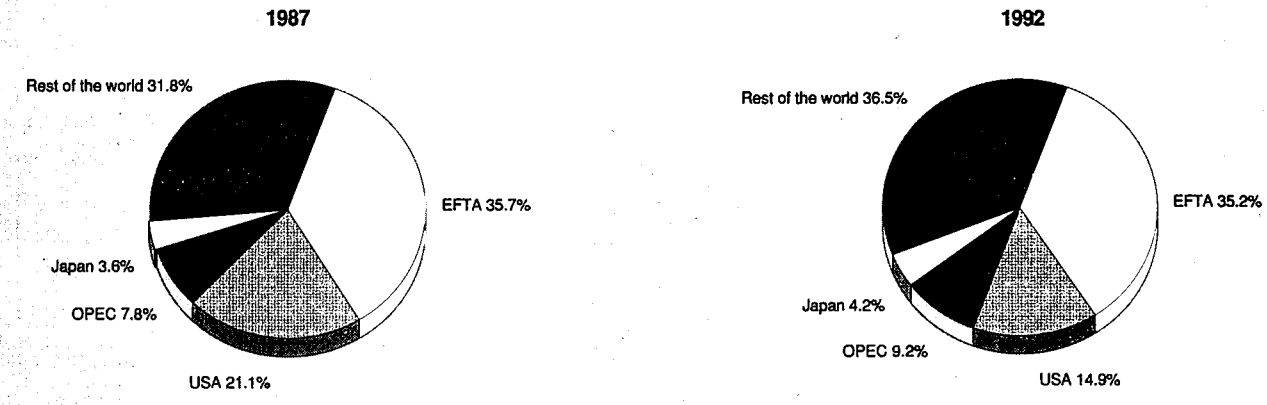
Destination of EC exports



Source: Eurostat

ample, high car sales may boost the share of original equipment up to about one half of the total tyre sales; during periods of recession or stagnation, the ratio is about 40:60.

The problems on the car market have forced the car manufacturers, customers of the rubber products sector, to rationalise production and lower costs. Moreover, cars are more and more tailored to the wants of the end-user. The result is a production of many different types of tyres, which also last longer. Due to technological progress in materials the production of radial tyres with warranties of 80 000 miles become possible, whereas 40 000 miles was customary a few years ago.

Industrial products account for almost 40% of the volume of total EC production of rubber products, while tyres account for about 60%. Sales values are about the same for both sectors due to a higher specific value of industrial products.

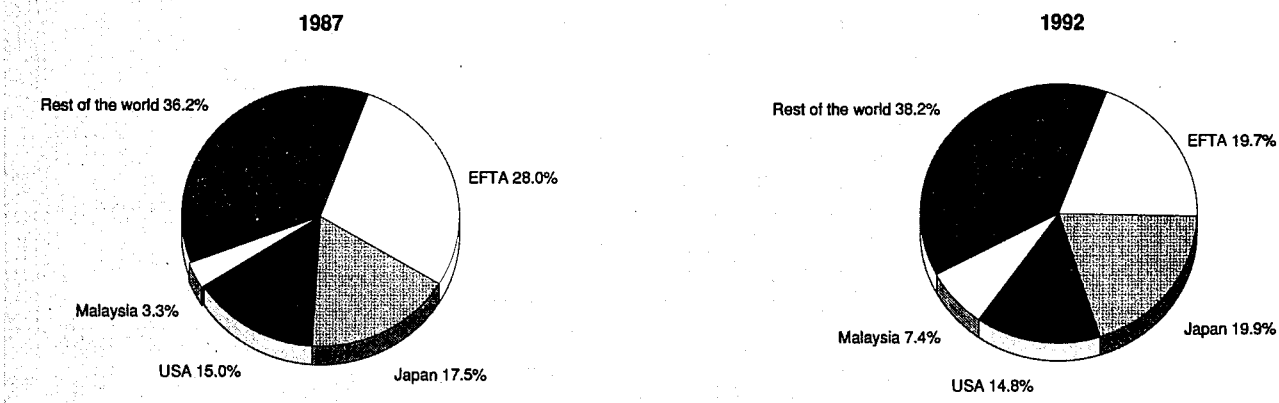
Taking tyres, tubes, and industrial products for motor vehicles together, the automotive sector covers about 70% of the rubber products market. Although tyre replacement demand is not as closely connected with income developments as the demand for new cars, in periods of recession there is a tendency to reduce the driven distance per vehicle, privately and commercially.

The rubber products industry profited from the boom in the late 1980s, but also suffered heavily from the stagnation and recession afterwards. Large companies made losses during the beginning of the 1990s. Recovery is likely to begin only in 1994/95, and at a low growth rate.

Substitution processes have taken place in some areas of industrial rubber products in the last decade. Rubber has been substituted by plastics especially in the profile, hoses, pipes, and sealings sector or in the production of toys or soles. Presently, the situation has in some cases reversed and substitution has taken place. The plastic tyre which was introduced some years ago did not achieve a breakthrough. Its application is, according to experts, limited to very specific purposes. Rubber has replaced metal in some hoses and window frames in cars.

To promote the use of rubber, intensive research and development activity was undertaken partly on raw material and partly on rubber products. Composites of rubber and metal, rubber and glass, rubber and plastic were developed and pro-

Figure 7: Rubber products
Origin of EC imports



Source: Eurostat

duced. New tyre elastomer blends make the production possible of tyres with warranties of 80 000 miles. Under pressure of car makers specialty heat tolerant elastomers are being produced.

Supply and competition

Tyres form a highly competitive market. Production capacity often exceeds demand and there is a constant pressure on prices. This is particularly true for OE tyres. Car manufacturers accept the cheapest offer under certain quality and specification conditions to reduce their own costs. Worldwide procurement of tyres is possible and acts as a permanent market discipline for the suppliers. The price-setting margins are restricted and the tyre industry complains all over the world of low prices and low profits. The replacement market does not face such stiff competition, but wholesalers and retailers also take advantage of the competitive situation as long as the demand by car owners is not restricted to specific brands.

The industrial rubber sector is a much more specialised branch with less opportunity to take advantage of economies of scale than the tyre sector. Even the supply of parts to the automobile sector involves a high degree of specialisation and differentiation. The consequence is that competition among suppliers is less strong than in the tyre sector and the globalisation of procurement is limited because of the necessary consultations between customer and supplier.

Production process

The rubber industry processes natural and synthetic rubber.

Natural rubber is imported mainly from South-East Asia, while synthetic rubber is supplied by the chemical industry. Natural rubber is especially used in truck and bus tyres because of its low heat build-up. For technical rubber products a much higher fraction of synthetic rubber is used, depending on the specifications of the product. An important raw material for the rubber industry is carbon black, besides other textile and metal components.

The unfavourable price and profit situation in the market for OE tyres leads to constant efforts to bring down costs, especially labour costs, by automation. But not only cost-reduction is a target of automation, but also better repeatability, shorter downtimes during size-changes and more flexibility.

If these technical developments can be implemented successfully and labour will be needed more and more only in controlling and supervising tasks, then a major change in productivity would follow. Currently, labour costs represent 25 to 40% of a tyre firm's turnover, depending on the data used.

INDUSTRY STRUCTURE

Companies

The tyre industry is highly concentrated. The three largest tyre companies in the world account for more than 50% of all sales. Japanese and European companies have a large portion of the market; the five largest Japanese firms account for 31% of all sales, the five largest European firms for 33%. Independent US tyre makers do not have such a position; in the top 50 only two are listed, and they account for 17% of all sales. This, together with the US market being the largest in the world, indeed reflects the fact that many US tyre manufacturers are foreign subsidiaries. All European tyre manufacturers account for 36-40% of the world market. The three largest European tyre manufacturers are Michelin (F), Pirelli (I) and Continental (D).

The largest tyre manufacturers normally produce industrial rubber products as well. However, small and medium-sized enterprises which produce technical products or products for end-consumers only, dominate in this part of the market.

Strategies

There are at least three ways to react to the challenges resulting from intense competition. First, higher investment in cost-reducing processes; second, increased research and development activity; third, mergers and acquisitions and/or alliances.

Investment activity in Europe is concentrated towards cost-reduction and productivity-increases, not to new capacity, whereas in Asia new plants dominate the investments. In Europe capacity has been cut in the past years in answer to slow growing, or even declining demand and to reduced expectations. New investments encompass the application of new technologies in new products and/or new processes. Diversification can be part of the strategy that a company follows; among the active tyre producers worldwide none restricts itself to making tyres.

As the car market became increasingly international, tyre manufacturers have had no choice but to adopt a worldwide strategy. The concept of dominant position at both national and EC level has disappeared. Several structural changes have taken place in the recent past that have reshaped the structure of the world tyre industry, aimed at increasing the size of the largest groups. Bridgestone (JPN) took over Firestone (USA), Michelin took over Uniroyal Goodrich (USA), Pirelli acquired Armstrong (USA) and Metzeler (D). Continental took over Semperit (A), General Tire (USA), and Uniroyal-Englebert (USA). Fulda (D) was acquired by Goodyear (USA) and Dunlop (UK) by Sumitomo (JPN). Besides acquisitions firms engage in strategic alliances. Michelin is seeking influence in Asia through this strategy. Continental focuses on East Europe, as well as Mexico and South Africa.

The industrial rubber industry supplies a large number of sectors, and some rubber producers are now tailoring their production to the needs of the main local client industries. The Italian industry, for example, tends to specialise in sole components for footwear, while the German rubber industry tends to specialise in conveyor belts for the mining industry.

ENVIRONMENT

The main environmental issue for the rubber industry is the recycling, incineration or disposal of scrap tyres and rubber products. Retreading used tyres is a widespread recycling method which has many positive aspects from the ecological point of view. Also, the longer life of tyres in comparison with the past put a downward pressure on the amount of disposal. But this does not solve the problem of disposal; at the end every tyre and rubber article has to be incinerated or disposed at dumps. There have been attempts to make chemical recycling by pyrolysis in order to get hydrocarbons but so far it turned out to be too expensive and generated itself air pollution.

The EC is in a leading position worldwide in research on and development of ecological techniques. In the long run this could lead to export opportunities either in the form of machinery and plants, or in the form of licenses for ecological incineration technology. The United Kingdom has recently inaugurated a power plant fuelled by used tyres.

The recession in the European economies has a large impact on cyclical industries like car and truck manufacturers, and as a result on the rubber products industry. However, the replacement tyre market acts as a stabilising element; there is always some growth as long as the number of registered cars is increasing. Industrial rubber products grow more or less in line with general industrial growth and slightly faster than tyres. All this means that growth will be slow in the recent future, likely to be followed by a period of moderate recovery.

Written by: Netherlands Economic Institute, on the basis of the Panorama 1992 report
The industry is represented at the EC level by: Bureau de Liaison des Industries du Caoutchouc de la CEE (BLIC). Address: Avenue des Arts, Bte 12, B-1040 Brussels; tel. (32 2) 218 4940; fax: (32 2) 218 6162.

Plastics processing
NACE 483

The world wide economic recession has affected the plastics industry as a whole. Production and consumption of plastics have dropped to some extent in the EC. Traditionally extensive deliveries into the countries of Eastern Europe have almost completely failed to take place since the end of 1991. The decrease in sales has been accompanied by a dramatic drop in prices both of standard plastics and technical plastics which were relatively stable before. Faced with losses, the European plastics processors reduced their development activities giving up unprofitable business ventures and postponing capital projects.

INDUSTRY PROFILE

Description of the sector

Consumption of plastics material in the EC plastics processing industry was in 1992 approximately 28 million tonnes. The main plastics materials processed for the different plastic markets are the following: polyvinylchloride (PVC 5.0 million tonnes), High and low density polyethylene (HDPE 3.0 million tonnes/LDPE 4.7 million tonnes), polypropylene (PP 3.9 million tonnes), polystyrene (PS 1.5 million tonnes), polyurethanes (PUR 1.4 million tonnes) and fibre reinforced plastics/composites (FRP/C 0.9 million tonnes).

The industry employs around 850 000 persons and counts 20 000 companies. Sales in the plastics converting industry represented a total of 95 billion ECU in 1992. Its main business is to convert plastic resins and compounds into products. The sector operates a range of different technologies, such as injection moulding, compression and blow moulding extrusion, hand lay-up of fibre reinforced plastics and coating. It also carries out ancillary operations such as decoration by silk printing, hot stamping and a variety of subassembly operations.

Plastics converters may produce finished articles which are used by other industries like food packaging and building articles, or distributed to consumers. They may also be custom processors who produce components on a subcontract basis for other manufacturers, or inhouse operations integrated into the manufacturing process. The major markets for plastics are packaging, building materials, electrical goods and electronics, automotive components, furniture, and agriculture.

Recent trends

A growth rate of just 1.5% was forecasted for 1993 which will lead to a total processed volume of 28.5 million tonnes in Europe.

Polymer producers suffered losses as depressed general demand conditions, destocking by processors, some overcapacity in polymer production and increasing imports, particularly from Southeast Asia and Latin America (once traditional targets for European exports) combined to lower prices and margins. However, plastics processors did not reap much benefit from these low input prices. Their customers expected a supply of higher quality products at prices remaining low.

Both consumption and production strongly increased during the 1983-1992 period, respectively by 7.3% and 6.8% per year. Extra-EC imports grew at a spectacular annual rate of 10.5% during the 1983-1992, that is two times more than extra-EC exports. The trade balance remained more or less stable during the 1983-1992 period at a level of around 1.9 to 1.7 billion ECU. During the same period, employment in the plastics processing industry grew by 34.7%.

International comparison

The USA, EC, and Japan remain the largest producers and consumers of plastic materials. In 1992 production and consumption (in million tonnes) amounted to: USA (30.1 and 27.7); EC (29.5 and 27.9); Japan (12.6 and 10.8).

The chemical industry and the plastics converting industries are the only technology-intensive sectors in which Europe is leading in front of Japan and the United States although a lot of Japanese firms operate in Europe or have set up joint ventures with European manufacturers. The existing capacity of polymer production incorporated in large chemical units corresponds to the demand for raw materials from processors.

USA

In 1992 the recovery of plastics processors was stronger than that of the US economy as a whole, and contrasted with the condition of its supplying industries (polymer production and the manufacture of plastics processing machinery). Developments in the sector largely depend on other industries, and the competition between plastics being intense, the situation is not expected to improve in the short term.

The American processors met the increasing quality requirements of their customers with statistical process control, total quality management and advanced technology.

Japan and Asia

The Asian economies are becoming more integrated and less dependent on the US and Europe.

Japan, Korea, Taiwan, China and Singapore are the main plastics processing countries with a production of about 25 million tonnes i.e. 25% of the world production. In terms of end-use applications market opportunities for plastics products in Asia include: blow moulded bottles for liquid detergent, milk and water, industrial drums, pharmaceutical bottles, injection moulded consumer items, packaging films, gas and water pipes; mono-layer and multi-layer insulation and packaging in wire and cable applications, and agricultural film, automotive applications, textiles for reducing soil erosion, competing closures, consumer items and packaging. China's output of plastics products has been growing at an annual rate of more than 20% during the 1990s. In 1992 plastics processors in China numbered about 17 000 and employed about 1.6 million people.

Foreign trade

The value of the plastic products exported from the EC increased less rapidly than what was imported. From 1983 to 1992 the value of the exports has been multiplied by 1.98 and the value of the imports by 3.12.

During the 1987-1992 period there has been a decrease in trade between the EC and the USA as well as a reduction of imports from EFTA countries. This was balanced by an increase of the imports from south-east Asian countries (Taiwan, Singapore) and especially from China which is becoming an important supplier of the EC. The EC imported less from USA, Japan and EFTA in 1992 than in 1987.

Trade with extra-EC countries grew more slowly than the production. On the contrary intra-EC trade increased faster than production. For the same period the share of EC imports from the rest of the world increased by approximately 10%.

MARKET FORCES

Demand

In 1992 thermoplastics consumption grew approximately 3.5% over 1991 whereas the general economic growth for Europe was only 0.5% last year. However, even this growth of demand is threatened by the economic downturn and environmental pressures.

Products made by plastic processors range from such massproduced items as small injection mouldings and continuously produced low density polyethylene packaging film to such specialised ones as composites used in spaceshuttle components. In short, virtually every product manufacturer uses, or can use, plastic components.

There is an extensive and diversified demand for plastics goods. Consumer goods and technical applications are characterised by continuous developments. Demand for plastics can be subdivided in six important markets: packaging (food,

Figure 4: Plastics processing

Source: DEBA, Census of Manufacturers, Nikkei

beverages, etc.); building (window frames, insulation, etc.); electrical/electronics (office automation, telecommunications, etc.); automotive; other transports (railways, shipping, aircraft, etc.); other markets (agriculture, leisure, toys, household, garden, furniture etc.). The first five sectors mentioned deliver to other industries, while the last one deliver directly to consumers via distribution outlets such as department stores.

Many industries use components made of numerous types of polymers. About 5 000 types of polymers, alloys and combinations enhance the design and manufacturing of various applications (from compact disc to medical instruments). The energy crisis increased the need for low-weight materials. For example, in the automotive industry plastics have been replacing several parts previously made out of metal.

Packaging

In the packaging sector plastics have been replacing glass for bottles (mineral water, soft drink, milk) and jars (yoghurts). The food industry constitutes the major end-user followed by the distribution and beverage industries. Despite environmental concerns, the European market for plastics packaging is forecast to rise from 10.5 million ECU in 1992 to over 13.67 million ECU by the end of 1995. Nevertheless, the growth should be lower than in the 1980s reflecting the trend towards reduced packaging and refillable containers. In spite of economic downturns in the EC and the burst of legislation which could impose severe pressure, pharmaceuticals, toiletries and cosmetics are large users of packaging. Cleaning powders are starting to move away from cartons to blow-moulding plastics while cleaning fluids change blow-moulding containers to bag-in-box packaging. The motor oil business is still moving away from metal cans to plastics containers.

The greatest growth rate is expected for PET particularly in the carbonated drinks market (from 512.8 million ECU in 1992 to 940.2 million ECU by 1995).

Film should remain the most common polymer grade used in packaging (and the largest sub-sector of plastics processing industry, although losing to blow- moulding and injection moulding) until 1995.

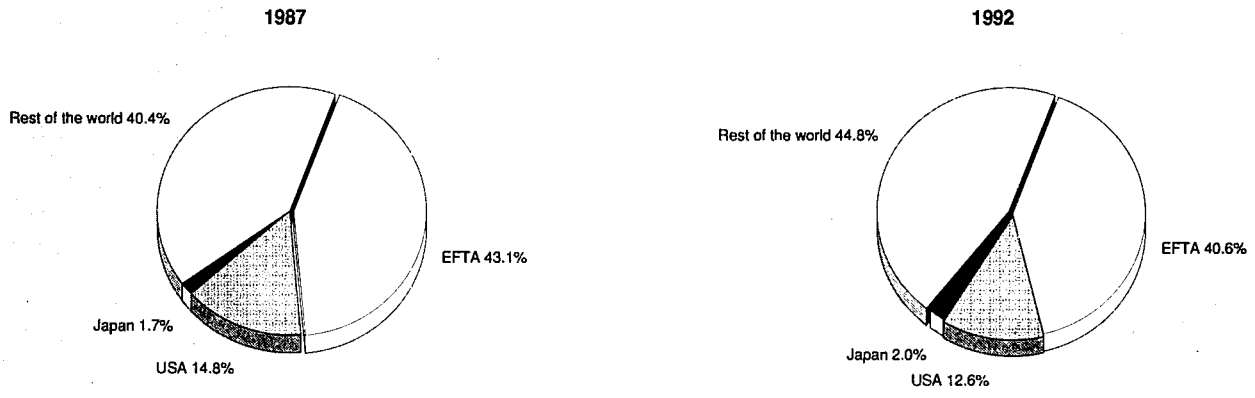
Plastic films

Production of plastic films, the largest subsector of the plastics processing industry, reached 6.2 million tonnes in 1992 in western Europe with a small decrease expected for 1993. Plastic films are mostly based on polyethylenes but also on polypropylene, PVC, PET or coextruded resins (polymides, ethylene-vinyl acetate etc.). The major end uses of plastic films are printed films for automatic packaging, shrink and stretch film for overpacking films for agriculture and horticulture (greenhouses, mulching), films for construction, for shoppers, carrier bags, refuse bags, heavy duty sacs and films for a wide range of technical applications as magnetic tapes, credit cards, hot foil stamping, cables, motor insulation, furniture films, office films, etc. A high percentage of plastic films are printed (especially in the field of packaging) or further converted to bags, laminations, metallized films and thermoformed to blisters, cups, trays, etc. PET, PP, PVC in particular can be converted to films by extruding or calandering.

Building

In the building sector, plastic window frames have a good market share in the countries of Central Europe whereas in South and Northern Europe other materials prevail. The other main applications of plastics in building are insulation materials, floor and wall coverings, roof applications and pipes.

Figure 6: Plastics processing
Destination of EC exports



Source: Eurostat

Electrical appliances

The consumption of plastics in the western European household electrical appliances sectors reached in 1992 a global tonnage of 530 000. The major polymers processed in the household electrical appliance are polystyrene (197 000 tons), polypropylene (175 000 tons) and ABS (75 000 tons). An annual growth rate in this sector is predicted of 3.5% with an exception for ABS -4% and polypropylene +6% . The main household electrical appliances are: refrigerators and freezers, washing machines/dishwashers, ovens, food processors, coffee makers and vacuum cleaners.

Automotive sector

The West European average for plastics in vehicles is 11% of total weight. In 1992, 1.35 million tonnes of plastics were used in car applications, of which 0.37 million tonnes of PP, 0.32 million tonnes of PUR and 0.16 million tonnes of PVC. PP consumption in cars is predicted to augment almost by 40% by the year 2002; at the same time, PUR consumption is set to grow by about 10%, while PVC consumption should remain stable.

Agriculture

Agriculture accounts for 3% of total plastics consumption in Europe. Plastic films for covering greenhouses have enjoyed spectacular growth over the last twenty years: from their original use a simple tunnels, they have evolved to the present sophisticated multi-span structures which offer the same advantages of traditional glass-covered structures.

The consumption of plastics materials for 1992 in the EC was about 28 million tons. Although the global increase of overall market for thermoplastic polymers, demand varied differently by individual polymers and markets. The following breakdown by material illustrates the growth rates for the total consumption in Western Europe

Consumption of plastics materials

PP (Polypropylene)

Despite the recession, polypropylene demand across Europe in 1992 grew from 3.73 million tonnes in 1991 to 4 million tonnes in 1992, a 7.5% increase. Some believe that higher growth rates will be seen in 1993 and demand will rise by about 10% during the year because the market from recycled material is less than had been expected (it is hard to find many applications for recycled polypropylene). The extrusion applications have been particularly successful (as with HDPE) with film and fibre products performing very strongly. The trend was the replacement of PVC by cast PP films especially in Germany. 1992 was the year when rigid containers in polypropylene, especially for bottle applications made advances particularly in the Italian market. The increased use of polypropylene in electrical automotive and technical applications, has also contributed to this demand growth and PP is increasingly substituting ABS in different fields.

HDPE (High Density Polyethylene)

In 1992, the most successful polymer in terms of growth of demand was high density polyethylene (HDPE): from 3.1 million tonnes to 3.365 million tonnes e.g. 8.5%. It occurred in all HDPE markets although the HDPE pipe market has been particularly strong in Germany. With film, HDPE has found favour over LDPE and PVC in certain packaging uses, and injection moulding, especially for wheeled refuse bins. Blow moulded containers also hold up better than expected. The increased demand in HDPE has also occurred across nearly all European markets with Germany and Italy having a particularly good year. It is estimated that HDPE consumption will grow by 5% in 1993 rising from 3.25 to 3.34 million tonnes. Virgin products will be increasingly vulnerable to substitution by recycled material (100 000 tonnes of recycled HDPE will most probably replace virgin material in 1993).

PVC (Polyvinylchloride)

This polymer continues to show modest growth despite environmental pressure. In 1992 demand increased from 5.1 million tonnes to 5.19 million tonnes, a 1.8% increase. There was some shift in the origin of the product used. Manufacturers in Western Europe lost about 2% of their market to imports, which rose by 100 000 tonnes to some 700 000 tonnes. PVC prices rose in 1993 because increased chlorine and ethylene costs were passed onto consumers. The main application area which has helped the increase in demand for PVC was building products. The window profile market has also been particularly strong in Germany while demand for pipes has been less marked. The use of PVC in packaging applications, particularly films, tended to decline partly because of substitution by PP and PET films. In 1993, demand for PVC grew by 1-1.5% after remaining static in 1992.

LDPE (Low Density Polyethylene)

The increase in demand for low density and linear polypropylenes was 0.5%, more in line with economic activity. This can partly be explained by the fact that the markets for LDPE are more mature than other polymer markets and suffer from competition from polymers such as HDPE in bottle and film

applications. For the LDPE market, recycling is also a key issue and the increasing use of recycled material will continue to limit growth for virgin polymers. Although in terms of square metre the market continues to advance rapidly, the use of LDPE will also depress overall growth in demand for resin.

PS (Polystyrene)

PS experienced a downturn in demand over 1992 when consumption has fallen from 1.75 million tonnes to 1.71 million tonnes. The polystyrene market is struggling to find any new growth applications. The traditional markets of packaging, domestic and electrical appliances are well developed and therefore offer limited growth prospects. Under unjustified threat from the environmentalists PS like PVC declined in its use for packaging. The use of OPS sheet in transparent packaging applications has increased but this growth area has not achieved the speedy success its supporters expected. Prices fell to their lowest point ever in real terms whereas serious structural problems of the market intensified (export potential slip and import penetration increase). The demand of PS is declining because of the competition from producers in South-east Asia (for teletronic products) and because of the substitution of PS by PP in some domestic and packaging applications. The future holds little prospect for growth.

PUR (Polyurethane)

In 1992 the production in western Europe reached 1.6 million tonnes, of which rigid foams accounted for 450 000 tonnes. The key end markets for polyurethane are furniture, transport and construction which together account for two-thirds of polyurethane consumption.

FRP/C (Fibre Reinforced Plastics / Composites)

The main constituents of fibre reinforced plastics/composites (FRP/C) are reinforcing fibres dispersed or imbedded in a continuous matrix (polymer). Glass fibres represent over 98% of the total tonnage of reinforcing fibres used. The remaining 2% is shared between carbon and aramid fibres. The total EC glass reinforced plastics (GRP) production in 1991 reached about 990 000 tonnes. The main resins converted are Unsaturated Polyester Resins (UP), Epoxy Resins (EP), Phenolic Resins (PF) and Melamine Resins. The most important markets are electrical engineering (wiring devices, electronics), domestic appliances (pot and pan handles, control butter, table ware), automotive industry (brake parts and other car parts), sanitary section (toilet seats, bathroom equipment), closures (caps for pharmaceutical and cosmetic use) and other markets (sliding elements, sealings).

EPS (Expanded Polystyrene)

Expanded polystyrene represented an output of 535 000 tonnes in 1991 in western Europe.

Other plastics

Demand for the other polymers, particularly some of the engineering thermoplastics, has not been as strong as for some of the commodity polymers.

From a global point of view, the remainder of the thermoplastic polymer market grew by 4.8% in 1992 which is less than had been traditionally achieved. Most polymer markets were in a similar and precarious state in the beginning of 1993 as they were in 1992. Industry observers are more cautious in predicting a brighter future after seeing last years predictions proved hopelessly optimistic. A definite credibility gap has emerged for many plastics producers.

Supply and competition

The existing capacity of polymer production, mostly in the hands of the main petrochemical groups, is in general in accordance with the demand of raw materials by processors.

The plastic processing industry is mainly composed of small and medium-sized companies. On one hand for the procurement of raw material, the medium-sized plastics processor has to deal with strong polymer producing companies, and on the other hand it has to sell his plastic products through large scale industries like carmakers, manufacturers of electrical and electronic equipment and department store chains.

The highly advanced technology in the European processing companies enables them to export 9.3% of their total production in spite of the high transportation costs for plastics products. The same happens to the imported goods where extra-EC imports account only for 7.28% of the total EC consumption.

Polymer producers need higher prices if they are to achieve decent margins. The plastics industry cannot continue to produce at a loss even though plastics converters will be hurt if it reduces output substantially. For European plastics markets, some products still experience price erosions due to overcapacity and the pursuit of market share over margins. In certain cases, costs were not being covered because of the enormous decrease of the margins. The current low price level for plastics with tonnage prices today comparable with those of 15 years ago may partly explain the situation. These low prices are encouraging processors to build up stocks and the increase in consumption is apparently being driven by genuine market demand.

Nevertheless, it is worth noting that it is increasingly difficult to assess the size and development of the European market because of the emergence of a world-wide market for polymers. In 1992, the imports came from Eastern Europe and the Middle East but resin sourced from Latin America and Southern east Asia also increased dramatically in volume.

Production process

The plastic processing industry utilises a variety of production methods and plastic materials. For every production method, a skilled labour force and important investments in numerically controlled machines are necessary. Professional training is very important for the plastics processors in the EC.

Different technologies are operated such as injection moulding, compression, extrusion, blow moulding extrusion, calandering, thermoforming, film extrusion blowing, blow moulding, hand lay up of fibre reinforced plastics and coating. Decoration by printing, hot stamping and other subassembly operations are also carried out.

During its early years in the 1950s the only technologies known for the FRP/C were manual hand lay-up and spray lay-up. The first mechanisation appeared only in the 1960s, while pultrusion and winding were introduced only in the 1970s. The breakdown of EC production of thermoset GRP by manufacturing technique shows that manual techniques still account for about 35%, followed by automated techniques

like SMC and BMC. Semi-finished products in SMC (Sheet Moulding Compound) / BMC (Bulk Moulding Compound) and finished parts (118 000 tonnes) are at the centre of new technological developments mainly linked to the requirements of the automotive industry and transport sector in general.

INDUSTRY STRUCTURE

Companies

Statistics received from the national plastics federations in EC countries show that the number of plastics converting companies in Europe adds up to 20 000 mostly small and medium sized companies. Only a dozen companies employ more than a thousand persons.

Altogether this industry employs around 850 000 persons in EC. The sector experienced a consistent growth during recent years. This was not only achieved by an extension of the sales of the existing companies, but mainly of new companies joining the sector.

In spite of being a sector of small and medium sized companies, the plastics processing industry in Europe has also large companies such as: Plastic Omnium (F); Wavin (NL); Alphacan (F); Rehau (D); CMB Packaging (F); BPI (UK); Schöller (D); Autobar (UK); Allibert (D); Klockner (D); PEGUFORM (D); Freudenberg (D); subsidiaries of Hoechst (D) and Solvay (B); Fardem (NL) and Nyborg (DK).

Strategies

The best growth opportunities may come from new markets in Eastern Europe, and new applications in leisure and health care. Plastics lead to many new applications in consumer products as well as in high tech applications. This is why the sector experienced a consistent growth during recent years.

Concentrations are expected in different fields such as subcontracting for the automotive sector and consumer electronics. The biggest companies in the field are establishing links within the EC and eastern Europe and are looking for partners.

ENVIRONMENT

The gloomy economic situation in the entire European plastics industry is related to the extensive recycling discussions. Recycling quotas imposed by national and European authorities in the packaging sector, the pending EC and national legislation for automotive waste, teletronic waste, building waste and others, are impeding new growth and are creating uncertainty in the user sectors. The plastics industry has to take up this challenge. However, there remains the question of when the necessary economic recovery will start and when will the investments required for the recycling measures be made available.

In general the plastics industry is prepared to accept its fair share of responsibility for the environmental impact of plastics but other essential partners in the process are: supply and user industries, retailers, consumers, governments, and waste disposal authorities. The plastics converters industry is very conscious that plastics have become increasingly popular because of the immense social benefits they have brought and that therefore they now constitute a prominent and durable component in the waste stream.

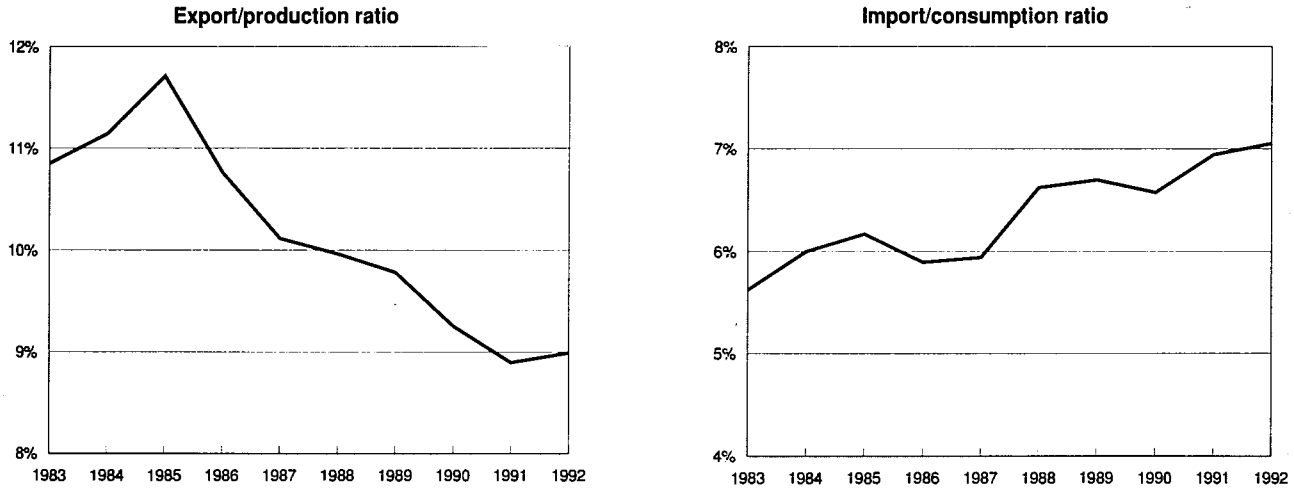
The industry wants to see common environmental policies for the EC. Unilateral legislation by individual Member States can lead to undesirable distortions in the market causing trade barriers which will delay the creation of a truly single European market. Converters wish to play a constructive role in the preparation of these policies and believe that the ensuing legislation must be objective and based on science and not on irrational reactions to imaginary situations. Such legislation must give due weight to the full 'cradle to grave' environmental impact of plastics.

The industry fully supports the preparation of eco-balance studies for both plastics materials and plastics products. Full consideration must be given to the entire life span of plastic materials and products. Recognition must be accorded to the environmental benefits they can impart from their initial conception through their service life, for example by saving energy, and to their ultimate manifestation as waste ensuring that their full potential for re-use is exploited.

There is no single solution to the problems of plastics: waste management and recycling, incineration and landfill all have their part to play to different extents and according to particular local circumstances. Possible waste management options, all of equal validity, include:

- Resource efficiency and waste avoidance;
- Material recycling/feedstock recycling;

Figure 8: Plastics processing
Trade intensities



Source: DEBA

- Energy recovery/recycling;
- Incineration;
- Landfill.

The plastics converters stand resolutely against limiting the use of any plastics material as this would constitute an unacceptable barrier to trade. To encourage the development of plastics recycling, plastics converters wish to encourage the adoption of an industry agreed, EC-wide product marking system in order to facilitate the easy identification and encourage the appropriate standards in those applications in which recycled products fulfil 'suitability for purpose' criteria.

No plastic products are made with the intention that they should be disposed of as litter. Nevertheless part of litter is plastics. The industry itself can assist by avoiding overpackaging but public discipline and education has a major part to play. Degradable plastics are for many reasons not a solution to litter problems, or indeed to plastics waste management questions in general. The products of the plastics industry should be promoted on there own technical merits. If the replacement of materials by plastics has proven advantages to the environment, the announcement of these advantages in advertising is acceptable.

REGULATIONS

The EC Commission is designing and has designed directives, decisions or regulations which are affecting the industry of plastics converters. Concerning food contact applications, the Commission is specifying positive lists for monomer, additives, colorants, etc. used in plastic products. The building sector is awaiting the pending directive for building products.

One of the major concerns in the plastic industry is the management of waste. The EC Commission developed legislation - based on the framework set by the Directive on waste (91/156/EEC) - which covers different fields touching the industry. Directives on packaging and packaging waste and other waste streams (e.g. automotive, building, hospital, teletronic) should be finalised in 1994 and are of major concern to the plastics converters industry.

OUTLOOK

The consumption of plastics will further increase in the next years. The existing production capacities can accommodate additional consumption of most product classes. At present it is still difficult to judge to which extent recycled products can decrease the future consumption of new plastics. However it is expected that the consumption of plastics in the EC will grow by an average of 3-4% per year for the end of the decade. The best growth opportunities will come from new markets in Eastern Europe and new leisure and health care applications. The plastics industry is working at heightening public awareness of its many initiatives to contribute to a cleaner environment. Taking into consideration the efforts in developing recycled plastic products, the plastic processing industry looks to a bright future.

Furniture

NACE 316.6, 467

The furniture industry is fragmented and dominated by small and medium sized firms. Concentration, however, is increasing because of stiffer competition by foreign suppliers on the EC market and the increasing concentration of the retail business. Major suppliers in the EC are Germany, France, Italy and the United Kingdom.
Demand for furniture is cyclical being dependent on the general economic climate. The present economic recession in Europe is the main cause for the slowdown in the furniture industry. In the medium term, however, the economic recovery will allow growth rates to improve substantially.

INDUSTRY PROFILE

Description of the sector

Products of the furniture industry are classified according to the main composing material, with metal furniture classified under NACE 316.6 and wooden furniture under NACE 467. This last category makes up some 75% of total furniture production in the EC. However, since most products are made up of different materials, the classification according to the composing material is rather out-dated. A market-oriented classification is more appropriate.

According to such a classification, furniture for the dining and living room is the most important group in this sector. Office and shop furniture makes up some 20% of total production (wooden and metal furniture). The main product groups in office furniture are seatings, desks, tables, cupboards and cabinets.

Germany is by far the most important producer in terms of value added. Other important Member States in this sector are Italy, France and the United Kingdom. Together, these four Member States are responsible for about 80% of the total value added in the EC. Germany is more specialised in kitchen furniture, while the main product group in Italy is lounge and dining room furniture.

Recent trends

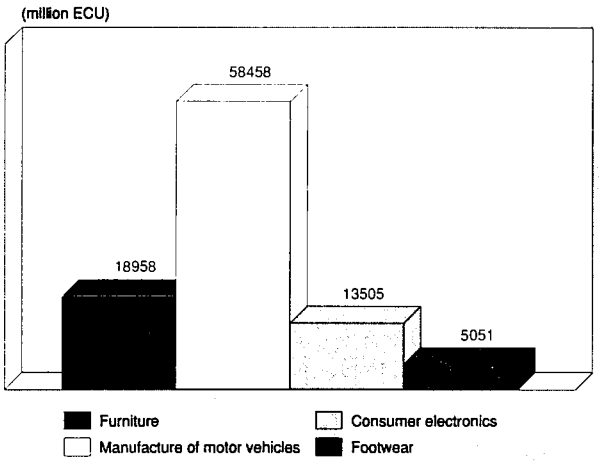
After a slowdown in the early 1980s (except for office furniture), production of furniture grew sharply, especially after 1985, with growth rates averaging 10% per annum over 1885-90. In the 1990s however, production in the EC decreased due to the economic recession, and has remained flat since.

Export growth has generally lagged behind production, particularly since 1990 when it started to register negative figures.

Apparent consumption showed even higher growth figures than production, with especially a strong increase in office and shop furniture. Another important observation is that imports account for a consistently larger part of apparent consumption every year. The combination of decreasing exports and increasing imports led to the worsening of the trade balance for the EC.

Compared with overall EC manufacturing, the furniture industry showed above average growth figures in production and employment after 1985. Fluctuations in consumer spending are exaggerated in furniture demand both during upswings and downswings. In times of economic recession like in the early 1980s and 1990s, purchases of furniture are postponed, while the reverse holds for periods of economic growth.

Figure 1: Furniture
Value added in comparison with other industries, 1992



Source: DEBA

International comparison

Production growth in the USA principally took place in the period before 1989. After this year, the furniture industry was hurt by the economic recession which showed up earlier in the USA than in the EC. Also before 1989 consumption in the USA had grown considerably, spurring exports from the EC to the USA since US producers did not have enough capacity to satisfy the growing demand.

Although in Japan production of furniture has grown significantly as well, both the USA and Japan are in the red as imports of furniture still exceed exports in both countries.

Foreign trade

Although the trade balance of the EC remains positive, extra-EC imports grew faster than exports since the late 1980s. A higher proportion of EC demand is satisfied by foreign imports, while EC Member States are facing stronger competition for their exports.

Source: DEBA

The EFTA countries account for a large part of the external trade of furniture in the EC, both for exports and imports. Eastern Europe is also a major supplier.

Italy, Denmark and Belgium are net exporters in the EC, with Italy and Denmark mainly exporting dining/living room furniture. Germany was a net exporter until the 1990s. However, the unification caused a strong increase in exports to Germany since many foreign (EC and non-EC) producers were attracted by the large business opportunities in the former East Germany. France and the United Kingdom are net importers.

Intra-EC trade makes up some 75% of total imports, a figure which has remained fairly constant. Demand for furniture in the EC is mostly satisfied by EC production (low import/consumption ratio), although this ratio has been steadily increasing in the last years. Exports account for a larger part of EC production (high export/production ratio). However, this ratio is decreasing during the last years, which may indicate that EC producers are loosing competitiveness vis-à-vis foreign producers.

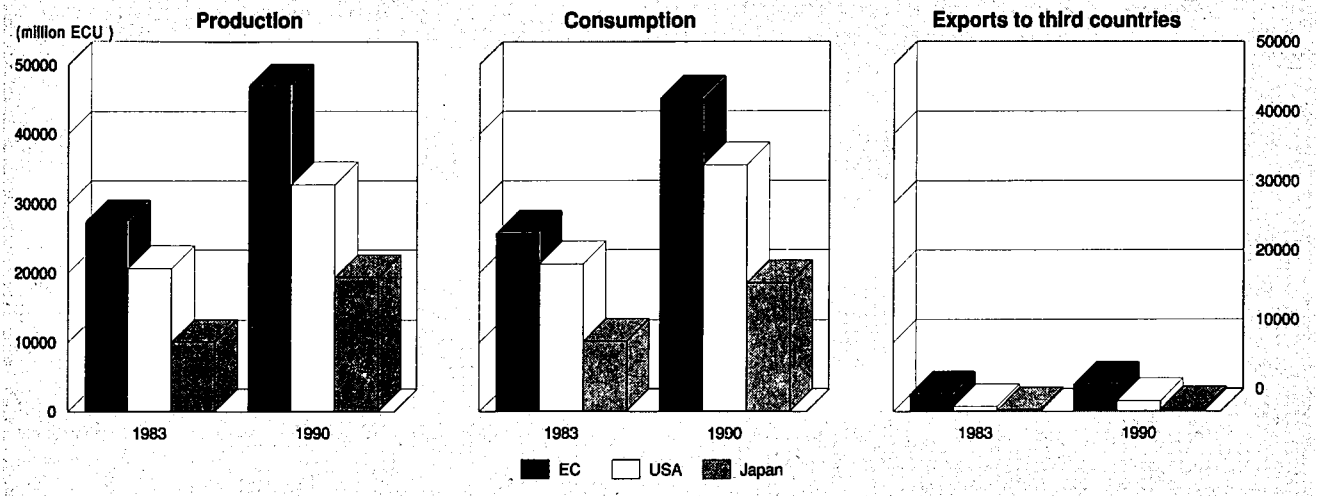
MARKET FORCES

Demand

The furniture industry is highly susceptible to cyclical fluctuations in demand. Further, demand for household furniture has a high income elasticity. The implication is that furniture demand tends to overshoot cyclical fluctuations in the economy in either directions.

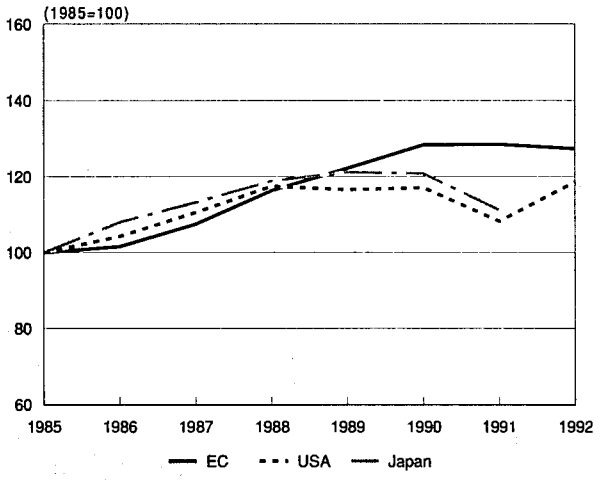
About two thirds of total demand refers to replacement. It is estimated that about one third of total demand is permanent due to births, the formation of new households and the breakdown of existing furniture.

Figure 4: Furniture
International comparison of main indicators in current prices



Source: DEBA, Eurostat, OECD

Figure 5: Furniture
International comparison of production in constant prices



Source: DEBA, Bureau of Economic Analysis (USA), Statistics Bureau (Japan)

Other factors influencing the household furniture industry relate to the demographic situation, the housing market (which, in turn, is highly influenced by the interest rate level), changing of life styles, the renewal rate of furniture and advertisement expenditures by furniture producers.

The combined negative effect of high interest rates (affecting negatively the housing market) and the economic recession has been far greater than the positive effect of the growing number of households (due to the baby boom in the 1950s and 1960s). This resulted in a slowdown in the early 1990s.

The economic recession is also the main reason for the slowdown of growth in the office furniture industry. Companies are not investing large amounts in the purchase of furniture preferring to wait for better times.

Supply and competition

The furniture industry in the EC consists primarily of relatively small companies, although differences between Member States exist. In the southern Member States, the manufacturing process is still artisan, with a subsequently high presence of small firms especially in Greece, Portugal and Spain. Also, in Italy the average company size is relatively small. However, a large number of these companies are working together under co-operation agreements. In the northern Member States, although smaller companies exist alongside larger establishments there is a trend towards denser concentration in production.

In contrast, the retail business is strongly concentrated, resulting in a strong bargaining position for the retailers vis-à-vis producers. The latter face large chains, large department stores or smaller retailers grouped together in co-operatives. In Germany retail groups and chains are responsible for more than 80% of national sales.

Internationalisation is expected to increase in the retail business because of the internationalisation of department stores and the companies divided into branches, although only one company can be said to be really international, the Swedish group IKEA.

Another trend in the retail business is the increasing importance of large superstores which are usually located in the outskirts of large urban areas. IKEA and national chains secure a larger share of the market by setting up such stores. Besides that, the success of IKEA is also due to the focus on the self-assembly part of the furniture market, which has gained importance over recent years. Furthermore, self-assembly products are more suitable for the import/export strategy of IKEA.

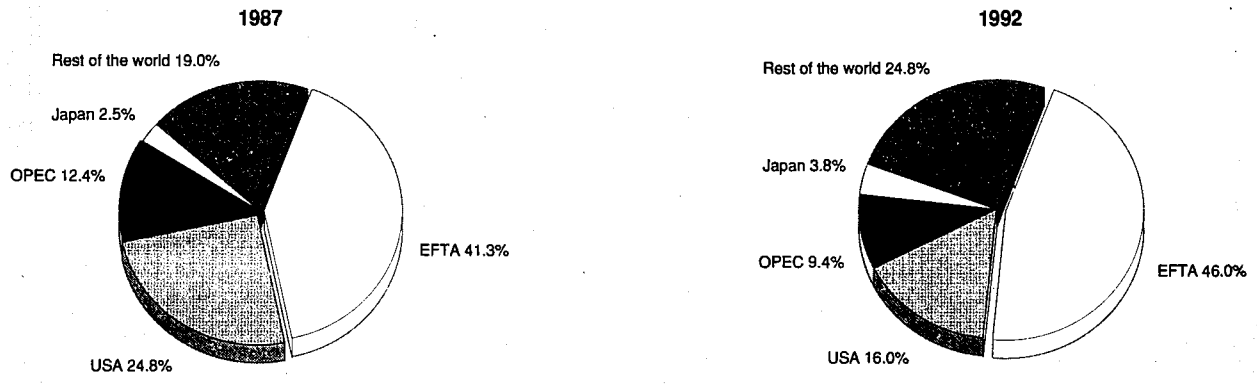
The increasing competition in the export market comes especially from Asian and East European producers. Asian producers like Taiwan and Singapore are competitive vis-à-vis EC producers because of lower wages combined with modern technology. These countries, however, are faced with an insufficient supply of wood. East European producers are (temporarily) relying on low labour costs. Their products are more focused to the cheaper end of the market.

Competition from the USA and Japan is only minor in the furniture industry. Furthermore it is expected that US exports will decrease in the longer term because the conclusion of the NAFTA agreement will divert the attention of US producers away from the EC market.

Production process

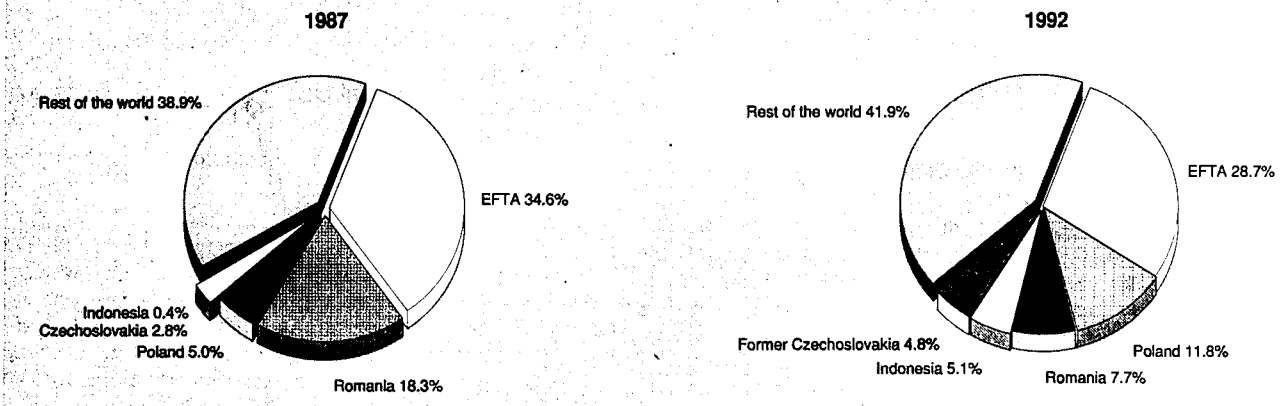
Until a decade ago the furniture industry was very labour intensive with labour productivity and unit labour cost being the most critical factors for competitiveness. Over the last decade greater capital investment in machinery and equipment has resulted in steady productivity gains. Unit labour costs,

Figure 6: Wooden furniture
Destination of EC exports



Source: Eurostat

Figure 7: Wooden furniture
Origin of EC imports



Source: Eurostat

which represents now about 30% of total unit cost, has grown at the same rate as total unit costs.

Most impressive technological improvements have taken place in the production and assembly of rectilinear furniture and coated panel boards.

INDUSTRY STRUCTURE

Companies

Technical and market related reasons force furniture producers to specialise in a limited range of products. Given this high degree of specialisation, companies in the furniture industry have a relatively small scale. However, over the years, the average size of companies has increased because of several reasons: the formation of the Single Market, the increasing market power of the retail business and the potential for economies of scale embedded in new production technology.

The number of firms varies regionally. In Spain, where the production process is largely artisan, the number of manufacturers is around 12 000 whereas in Germany the number is around 1 500.

Strategies

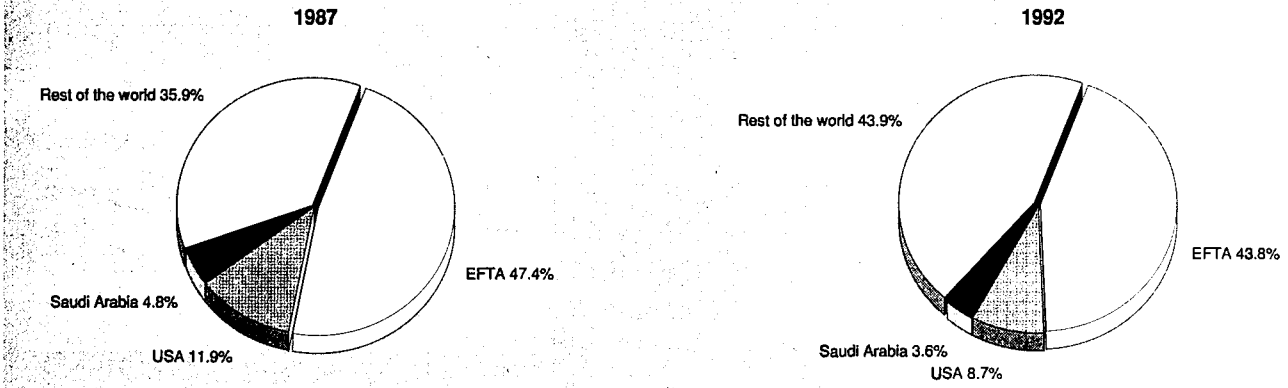
Producers are faced with a variety of risks over the coming years. On the one hand, there is the firm position of the retail business which forces downward pressure on producer prices and profit margins. Furthermore, some retailers are trying to pursue a strategy of vertical integration by becoming also producers (MFI in the United Kingdom, and IKEA in the whole EC). At the other hand, there is growing competition from foreign producers in the EC market.

The above developments are aggravated by the economic recession, which has been resulting in closures for many smaller firms (especially in former East Germany).

The strategies of furniture producers can be grouped in three broad categories. First, investment strategies where producers are spending large amounts in the purchase of modern machinery and equipment, in order to increase their competitiveness by introducing more advanced production technology.

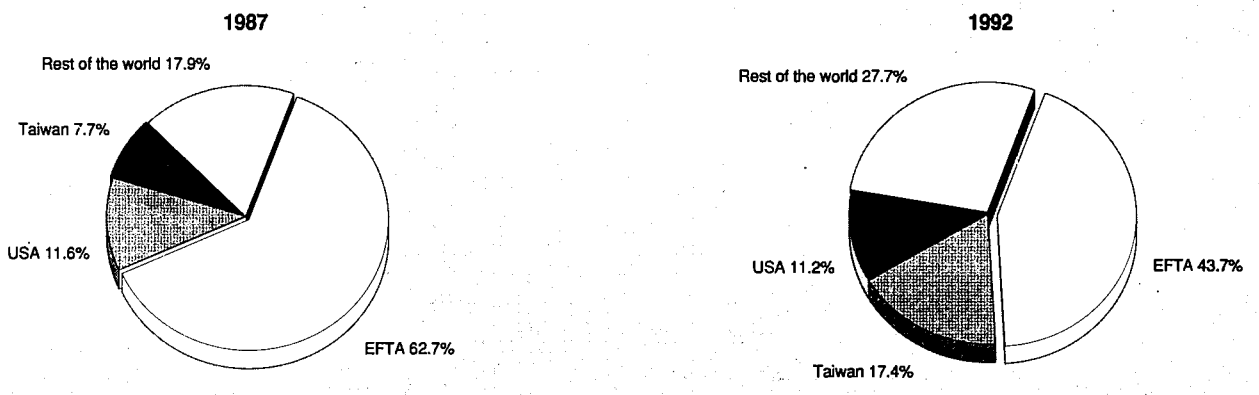
A second strategy is one of concentration in order to gain market power against the retail business. In some Member States like France and the United Kingdom this happens through mergers and take-overs. In Denmark and Italy independent companies have set up co-operation agreements in

Figure 8: Metal furniture
Destination of EC exports



Source: Eurostat

Figure 9: Metal furniture
Origin of EC imports



Source: Eurostat

order to exploit economies of scale and to acquire a stronger position vis-à-vis the retail business. In other Member States, smaller firms seek protection with larger companies, which are better armed against the economic recession because of their financial backlog, their stronger position in export markets and their large investments in technology.

Third, there is a brand strategy where furniture producers try to differentiate their brand by product development and market position, in order to strengthen their position vis-a-vis retailers.

REGIONAL DISTRIBUTION

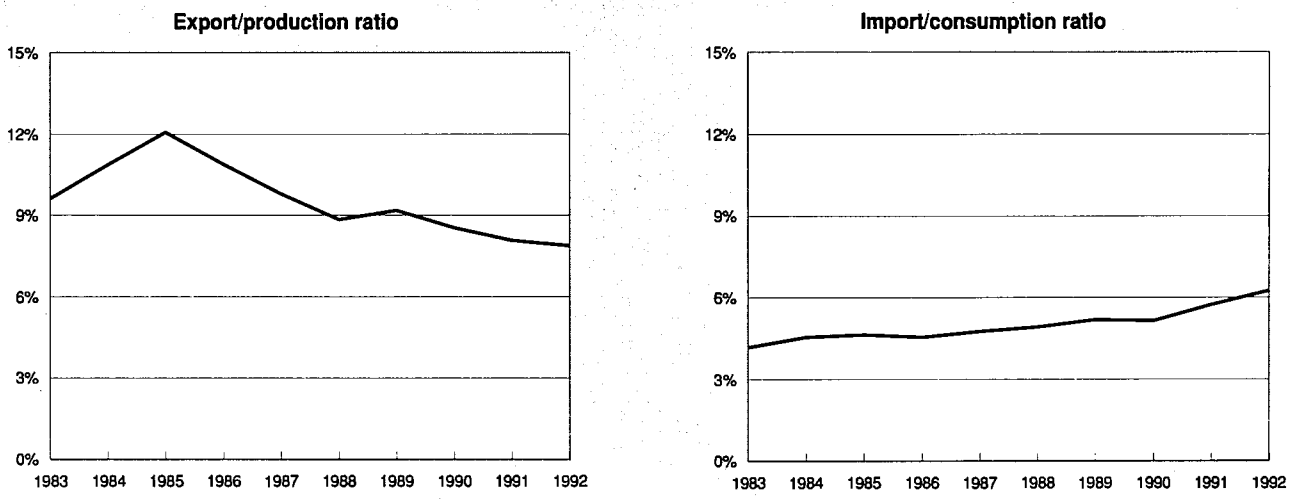
Although the furniture industry is present in every Member State, its distribution is not evenly spread over all Member States. The northern Member States account for the largest part of the production and value added. This distribution of production and value added however, is not reflected in the distribution of companies over the Member States. Because the furniture industry has a quite artisan character in the southern members states, these Member States have relatively more companies active in the furniture industry. In the northern Member States, the furniture industry is more concentrated.

ENVIRONMENT

Ecological issues for the furniture industry concern the use of specific materials and emissions in the production process. The use of some materials like plastics and polyurethane may be subject to regulations. Emissions from some materials in the production process may be affected by government directives, in the light of the increased concern for the environment and work safety.

Another concern affecting the furniture industry is the continued erosion of woodland and forested areas. Although no specific regulations are yet taken in this field, voluntary actions in some Member States are underway, which focus on management of forested areas.

Figure 10: Furniture
Trade intensities



Source: DEBA, Eurostat

REGULATIONS

The EC Commission has given a mandate to CEN organisation to develop standards concerning the fire safety of upholstered furniture. The CEN committee on Furniture (Committee 207) has two standards ready while it is working on seven others. The two standards concern upholstered furniture to be set on fire by a burning match or cigarette.

Another aspect is the protection of design and models. The services of EC Commission are working on legislation which will safeguard the interests of the industry without hampering innovation.

OUTLOOK

The outlook for the household furniture industry looks rather unfavourable in the short term. Several forces are responsible for this: the weak economic recovery over 1993-1994, the rising unemployment rates, the high interest rates which affect negatively the housing market and the saturated furniture market. After 1994, however, economic recovery will lead to increasing consumer confidence and consumer spending, and this together with the growing number of households will result in a significant recovery in production and consumption.

The office furniture industry is also negatively affected in the short term by the economic recession, with a decline of investment in office buildings. In the long term however, the investment in office automation and the growth in the service sector will result in an increasing demand for office furniture.

Table 5: Furniture
Expected real annual growth rates

(%)	1993-94	1993-97
Apparent consumption	-3.0	6.0
Production	-4.0	5.0
Extra-EC exports	-4.0	3.0

Source: NEI

The furniture industry in the EC is faced with major challenges in the near future. While increasing competition from foreign suppliers and retail business forces individual companies to become more competitive, the industry as a whole is confronted with decreasing sales. These developments will make it harder for the less competitive producers to stay in business. Strategies like co-operation, subcontracting, restructuring of production by investing in new production technologies, reorganisation of distribution facilities should therefore be considered.

Jewellery
NACE 491

The jewellery sector recovered somewhat in 1992 after the difficulties it encountered in 1991. In nominal terms production was stagnant, but the volume has increased. Prices, however, continued to decrease implying increased purchases of lower valued jewellery. The outlook for 1993 and 1994 remains pessimistic in view of the economic slowdown. After 1994, however, prospects are more promising, as it is expected that general economic growth will increase again.

INDUSTRY PROFILE

Description of the sector

The jewellery sector is divided into six subgroups:

- precious metal or precious plated ware;
- goldsmiths' and silversmiths' wares;
- costume (or "fancy") jewellery;
- diamond cutting;
- precious and semi-precious stones;
- coins and medals.

The difference between precious jewellery and costume jewellery is sometimes difficult to determine. An article made of base metal and coated with precious metal set with imitation stones would be regarded as costume jewellery, but high-quality plated metals may be set with natural stones, and the designation of costume versus precious jewellery is unclear. The industry includes articles made of precious metals (particularly silver) that are not worn on the person.

At the retail level, it is customary for the industry to have close ties with the clocks and watches industry as well as with antiques not necessarily made of precious metals.

It should be noted that Eurostat data on production and employment show the relative volume of the industry in each country and the trends in production and employment. However, the absolute figures are underestimating the importance of the industry, as units employing less than 20 people are not taken into account by official statistics. Small firms can account for more than 40% of production for a country.

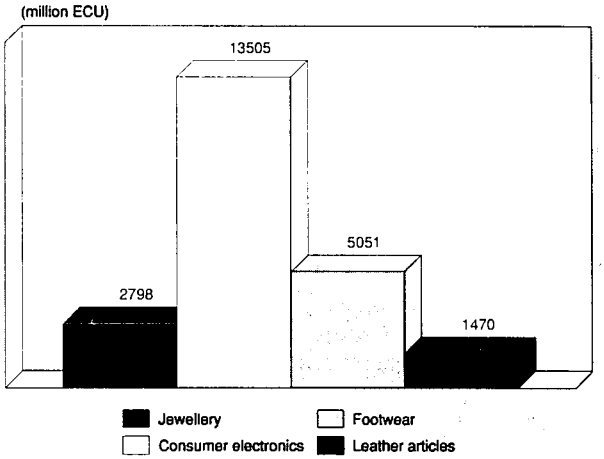
Recent trends

Production at current prices was stagnant in 1992 after the decline in 1991. In real terms production has grown by 2.8%

The demand for gold for the purpose of jewellery fabrication rose markedly, from 54% of total gold production in 1980 to 87% in 1990, which had a notable effect on the price of gold. The market for costume jewellery in particular expanded during the 1980s. On the basis of estimates at the retail level for the EC (Euromonitor) and for Japan (Japan External Trade Organisation) and at the industry level for the United States (Department of Commerce) the total value of the market for jewellery in the late 1980s was roughly divided into 80% precious jewellery and 20% costume jewellery. There are indications that the share of costume jewellery is gaining.

Gold jewellery fabrication recovered substantially in 1992. World production grew by 16.5% to 2662 million tonnes after a relatively low 7.4% growth in 1991. This recovery was especially due to the very high production growth in the Middle East, the Indian Subcontinent and the Far East. The EC benefited only marginally as production increased by only 6.5% in 1992.

Figure 1: Jewellery
Value added in comparison with other industries, 1992



Source: DEBA

Italy, being the largest gold jewellery manufacturer in the EC, benefited to some extent: its production increased by 11.1% reaching 461 tonnes in 1992. Other EC countries of some importance are Germany, France and Spain. Germany and Spain, however, encountered a reduction, whereas France was able to increase production by only 3.5%.

Gold and silver traded at stable price levels in the beginning of the 1990s compared to more buoyant price fluctuation in the 1980s. The price of gold went down from 392 USD per ounce to about 370 USD. Silver prices fluctuate around 4.85 USD per ounce. Traditionally, instability raises gold and silver prices, but neither the Gulf war nor the attempted Soviet coup affected prices. Diamond prices, which are strongly influenced by the De Beers Central Selling Organisation (South Africa), remained fairly stable.

Apparent consumption is likely to be underestimated because the interval between production and sale is often long and stock levels fluctuate significantly. Moreover, production figures are underestimated by the exclusion of firms with less than 20 employees. Apparent consumption is derived by sub-

Source: DEBA

tracting exports and adding imports to production, so apparent consumption figures are highly dependant on production figures. Import and export figures, however, will cover most trade because the high value of the products involved is well above the minimum for statistical declaration.

As a result, apparent consumption for even the largest producing countries, such as Italy, could be negative. This is readily understood when one considers that the enterprises included in the production figures employed in 1988 some 12 000 people, whereas it is estimated that total industry employment in Italy is actually around 40 000.

With this in mind, the figures on apparent consumption indicate the following trend. At current prices it continued to decrease in 1992. The decrease, however, was much lower than in 1991: the decline amounted to 2.7%, whereas in 1991 consumption encountered a reduction of 13.7%.

An indication of the market can be found when looking at retail figures. Euromonitor estimates for 1991 showed a market of 6.6 billion ECU (8.2 billion USD) for diamond jewellery for the EC as a whole. Using the retail sector margins, the comparable consumption figure calculated equals 4 billion ECU, about 1 billion ECU more than was indicated for apparent consumption.

France and the United Kingdom are traditionally the major markets for costume jewellery in the EC. Germany has recently witnessed an upsurge in demand for costume jewellery which places the German market alongside the United Kingdom and French markets in importance. German consumers, more than other Europeans, had a bias towards real jewellery during the 1960s and 1970s. Costume jewellery became more fashionable at the end of the 1970s. This trend continued in the 1980s and the 1990s.

Employment figures show very little change in the numbers employed between 1985 and 1992. There was a peak in 1990 after which employment reduced again due to the economic situation.

International comparison

According to the World Gold Council, in 1988 around 38% of Italian adults bought at least one article of gold jewellery, compared to 34% in the United Kingdom, 18% in Germany, 14% in France and 15% in other EC countries. In Japan, a comparable figure was 33% of all female adults. In the 1980s these figures showed a rise in almost all countries, but the growth has been especially strong in Japan, where in 1986 this figure stood at 21%. In the USA, sales are under pressure, due to a 10% luxury excise tax applied on the portion of

retail sales over 10 000 USD, effective on January 1, 1991, that especially affected high end products.

US demand stagnated in 1992. Total turnover in 1992 had been estimated between 15 billion to 18 billion USD in retail prices. At the industry level, the market for precious jewellery in 1992 was estimated at 6.2 billion USD and for costume jewellery at 1.7 billion USD.

Japan is still considered a growth market. The total market in Japan has been estimated at 2 500 billion Yen at the retail level (13.7 billion ECU). Japan itself is facing competition from East Asian countries in the costume jewellery market. Japanese manufacturers are increasingly using the workforce in those areas; bullion and diamond materials are being shipped to East Asia, from which finished or semi-finished products in turn are imported.

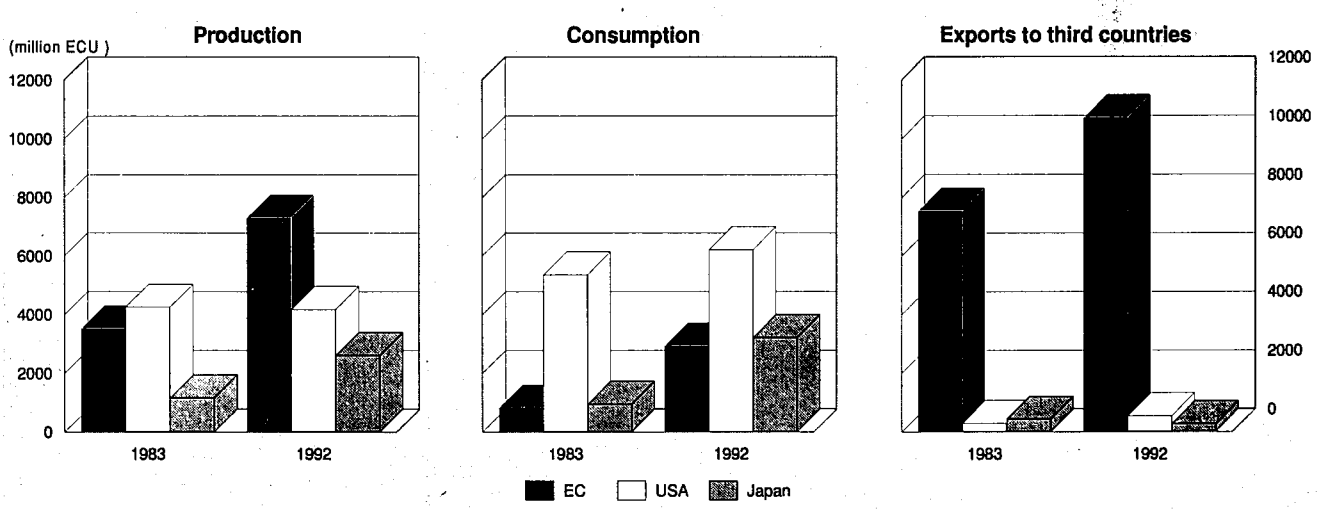
According to De Beers, world retail sales of diamonds reached 39 billion USD in 1991.

Foreign trade

The most significant general feature of the trade figures is the volatility of the figures over the years. It should be noted that all values are in ECU. As most international trade takes place in dollars, the ECU values are influenced by fluctuations in the dollar rate. The appreciation of the yen during the 1980s had an overwhelming impact on EC exports to Japan: by 1990, exports to Japan in ECU value were well over nine and a half times the 1980 figure in ECU.

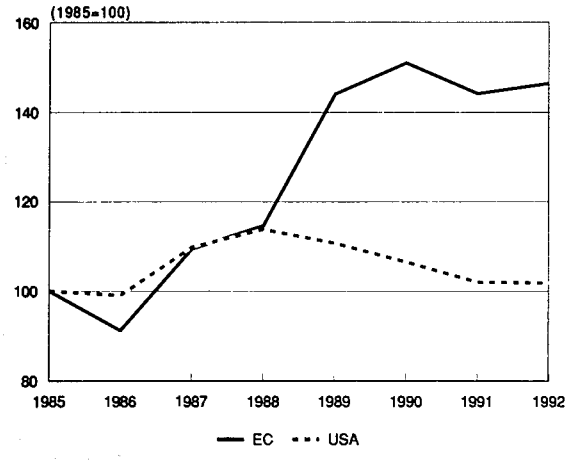
With 6.4 billion ECU in 1992 extra-EC imports were of considerable size in comparison with the 7.3 billion ECU of production. There is a declining trend in imports: since 1989 imports have decreased by 4.3% on average. Italy is a large importer of raw materials and semi-finished products, which are exported after further processing. In 1992, extra-EC suppliers were by far the developing countries.

Figure 4: Jewellery
International comparison of main indicators in current prices



Source: DEBA, Census of Manufacturers

Figure 5: Jewellery
International comparison of production in constant prices



Source: DEBA, Census of Manufacturers, Nikkei

Extra-EC exports totalled 10.7 billion ECU in 1992. The same figure was shown for 1990 and 1991 implying stagnating export markets at current prices.

Extra-EC exports are substantially larger than extra-EC imports. The trade surplus amounted to 4.4 billion ECU in 1992, which was more or less the same as in 1991. Compared to 1990 however, imports decreased, causing the surplus to improve. The breakdown of EC imports by country of destination emphasises the importance of Italy as a producer of jewellery. For Italy itself, exports are very important, accounting for 70% of production. Italian exports mainly involve high priced products.

Exports from Thailand have been accelerating over the past ten years, placing it in the position of second largest exporter of jewellery in the world after Italy, with the potential to become the largest. Exports of polished diamonds look particularly promising for Thailand.

For intra-EC trade, the Single European Market will mean that national tariff and quota restrictions will disappear, restrictions mainly found in trade with Spain, Portugal and Greece. EC import tariffs for jewellery range from 3% of CIF (Cost, Insurance and Freight) value for types of precious jewellery to 8.5% for costume jewellery. For countries falling under the GSP (Generalised System of Preferences) of the Lomé convention there are no tariffs.

France and the United Kingdom are the most important consumers of EC exports in Europe. France is the most important intra-EC importer of costume jewellery, followed by Germany, the United Kingdom and Belgium.

MARKET FORCES

Demand

In 1992, as in previous years, demand for heavier, bulky items increased; ethnic jewellery also grew in popularity, particularly gold mixed with coloured enamel. In the EC, polished gold remains the most popular choice for general jewellery, although textured gold is gaining popularity for more 'avant garde' designs. Earrings are the most frequently bought item.

Diamond rings continued to dominate the retail sales of diamond jewellery throughout the world. This domination is pronounced especially in those countries where diamond engagement rings are traditional. For instance, in the United Kingdom, where 70% of brides receive a diamond engagement ring before their marriage, rings account for 83% of the total value of the market. In the USA, however, despite its strong tradition of diamond engagement rings, rings account for only 61% of total value. This is a result of the increasing popularity of men's diamond jewellery and of high priced diamond bracelets. In Germany and Spain, where engagement rings are not

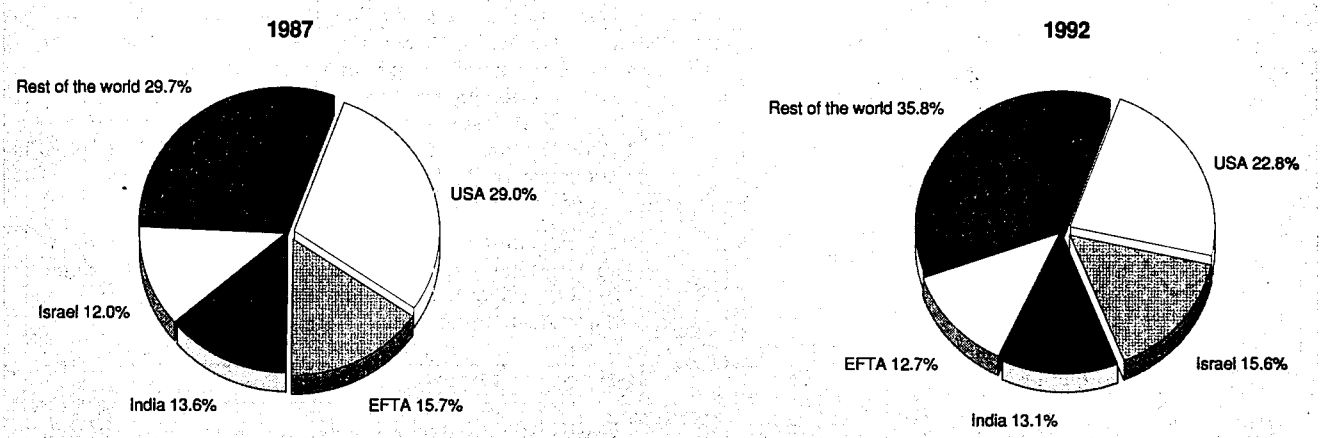
Destination of EC exports



Source: Eurostat

a tradition, rings account for only 52% and 41% of total value, respectively. In Germany, high-value necklaces form a very important category. In Spain, earrings are particularly popular. Sales promotion by the De Beers Corporation in Japan has been very effective, firmly establishing the position of diamond jewellery in the engagement ring market. In Japan, 77% of brides receive a diamond engagement ring. As a result, rings account for approximately 76% of total value in that country.

Purchasing of jewellery is highly seasonal with one-third of diamond jewellery being bought in December. The rising demand for precious jewellery is a result of growth in the standard of living and personal disposable incomes. National differences can also be quite large. These are influenced by the amount of disposable income people are prepared to pay for luxury items. For instance, Dutch consumers' spending on precious jewellery is relatively low, whereas Italian consumers' spending is high.

The majority of purchasers are women, but the percentage of men buying jewellery is rising. Much of this is for gifts, but there is also an increasing portion of men wearing jewellery. Younger groups in the population are the leading purchasers.

The ageing population and demand for unusual and natural materials stimulate demand for more costly jewellery. The percentage of people between 30 and 40 years old will rise in the 1990s. These are the people who buy costly jewellery: younger people tend to buy less expensive fashion accessories.

Among the discernible trends for more ornate and luxurious fashion items some interesting developments can be distinguished. There is an increased attention for Far East, Indian and African styles, for folklore, heraldic and Art Deco themes, for use of natural raw materials, and for floral and animal motifs. The last two trends emerge out of a general concern for ecology and nature.

Supply and competition

There is little or no branding in the precious jewellery sector, which makes analysing competition at an industry level irrelevant. It is more significant to determine competition at the retail level. Manufacturing for costume jewellery as well as precious jewellery is highly fragmented, with many small, handicraft companies. At the retail level there is also fragmentation, but in the 1980s some retail chains gained importance: including Ratners (parent company of Ratners and H. Samuel) in the United Kingdom, Magic Moment and Gold Market in Italy.

Precious jewellery is sold mainly through specialist jewellers, whereas costume jewellery is sold through a variety of outlets: department stores, chemists, clothing shops, jewellers.

Competition in the costume jewellery industry is coming mainly from East Asian countries, especially Hong Kong, South Korea, Taiwan and Thailand. Usually these countries operate at the less expensive end-market, but product quality is improving. Competition from East Asia takes place mainly through price.

Since 1990 the industry's employment in the EC decreased from 62 600 to 58 500 in 1992. This implies however, that productivity in the industry is increasing.

Production process

Most of the enterprises in the precious jewellery industry are handicraft in character. Therefore it is difficult for the industry to keep up with fast growing demand, as was the case in the 1980s. In comparison with costume jewellery, however, the precious jewellery industry has the advantage of not being under the influence of fashion trends: designs last much longer.

The manufacture of costume jewellery includes a broad variety of products: brooches, earrings, necklaces, bracelets, rings, hair ornaments, hat ornaments, shoe ornaments, cuff-links, tie-clips, etc. To maintain market position, manufacturers of fashion jewellery are urged to produce up-to-date designs. In theory, new collections are introduced 2 to 4 times per year, but in practice new ranges appear much more frequently. This makes short distribution lines necessary, giving local EC producers an advantage over overseas manufacturers. Much costume jewellery is shipped by air because of the need for quick delivery. In view of the high frequency in new collections high mark-ups are necessary to compensate for the risk of goods becoming not saleable.

INDUSTRY STRUCTURE

Companies

Jewellery manufacture, for both precious and costume jewellery, is highly fragmented. For example, Italy's industry has 6 500 businesses, employing 40 000 people (estimated). The largest are all privately, generally family, owned and managed.

Primary precious jewellery firms include Lyon Alemand Louyet (France), Engelhard (France), Trattamenti Ceneri Auroargentari (Italy), Uno a Erre Italia (Italy), Rosy Blue (Belgium), Lens Diamond (Belgium), Franz Golz (Germany) and Guthmann & Wittenauer (Germany). Among the costume jewellery companies with the highest sales are Bijoux GL (France), Moranduzzo Dario (Italy), Modern Creation Muenchen Reisegepack (Germany), and Rudolf Zenner (Germany), among others.

Strategies

The use of brands is rare in the jewellery industry. The few existing brands tend to be active in the costume jewellery sector, mainly originating from enterprises with well known brand names in other industries such as cosmetics or clothing (Kenzo (F), Moschino (I), Fiorucci (I) which branch out into jewellery. Distribution, therefore, plays an important role in competition and strategy.

Precious jewellery is mainly sold through speciality jewellers, but there are a growing number of multiple and non-specialist outlets. For costume jewellery sales outlets are much more diverse, with special emphasis on the tax and duty free shops. With the Single European Market, this type of outlet will disappear for intra-EC travel, but the European Commission has given the duty free stores until the year 2000.

Most of the enterprises of the industry are too small to activate rigid strategies other than following the market. As competition with foreign industries increases, however, more emphasis could be placed on quality.

REGIONAL DISTRIBUTION

The industry has a great need for specialists and therefore remains concentrated in places where the infrastructure has

been built over many years. By further specialised aggregation, some locations lend themselves to higher-quality jewellery, some to quantity production, and some to production of larger silver articles.

The main manufacturing centres in Italy are Arezzo, Vicenza and Piedmont. In Germany about 75% of the trade is based in Pforzheim, with Idar-Oberstein being an important centre of the gemstone industry. Other centres are Schwabisch Gmund, Hanau and Kaufbeuren. In France, Paris and Lyon account for a major part of the industry, as does St. Amand. In the United Kingdom the main centres are London, Hatton Garden, Birmingham and Sheffield (the centre for cutlery and a large portion of the table-silver industry). In Belgium, Antwerp is the centre of the jewellery industry. Belgium ranks among the major diamond cutting centres in the world, along with India, Israel and the United States.

REGULATIONS

Regulations in this industry refer only to the precious jewellery, as there are generally no specific standards or restrictions for fancy jewellery.

Currently, four systems of grading polished diamonds are in use. They are associated with the Gemological Institute of America (GIA), the International Diamond Council (IDC), the Scandinavian Diamond Nomenclature Committee (ScanDN) and the International Confederation for Jewellery, Silverware, Diamonds, Pearls and Stones (CIBJO). Proposals have been made to arrive at one international standard. Although the organisations are confident of reaching a successful solution, an agreement has still not been reached.

On October 8, 1990 the European Commission accepted the Green Paper on standardisation (published on January, 28, 1991). Early in 1992, the Commission gave a communiqué summarising the reactions on the Green Paper. All this has to lead to directives in the spirit of the "new approach" (the

Source: Dun & Bradstreet

Commission only providing general guidelines and prescriptions for a product).

Probably the most significant matter happening in the EC jewellery industry is the progress towards a Directive for Precious Metal Articles.

OUTLOOK

Demographic changes will affect the market. The proportion of persons 45 to 65 years old in the population is forecasted to grow 4% by 1995, that should stimulate demand for higher priced items. The proportion of people aged 15 to 24 years is forecasted to fall 12%, that will lead to more competition in the lower-priced end-market.

Along with the expected moderate economic growth, the gold price may move upwards. But several scenarios are possible here, including a further decline in price should the mining industry not decrease production.

The costume jewellery industry is very sensitive to developments in the world economy. As the prospects for general economic developments are for slow growth, the outlook for the costume jewellery industry is also moderate.

Furthermore, competition is expected to intensify as a result of the advent of the Single European Market and of production in East Asia. Another threat to domestic EC manufacturers is the assembly of imported pieces into products by importers. Subcontracting with manufacturers in the Far East is also growing. These developments put pressure on prices.

One possible response of manufacturers is the development of brand names. At the moment, brands are mostly absent in the sector, which increases vulnerability to imports. Developing brands could offer significant opportunities, although more for distributors than producers, due to the higher level of concentration among distributors. Brands could also differentiate between East Asian and European manufacture on the basis of quality; East Asian imports compete on a price basis, and with the demographic changes expected in the near future, price will be less important than quality.

Table 8: Jewellery
Expected real annual growth rates

(%)	1993-94	1993-97
Apparent consumption	-1.5	2.0
Production	-1.5	2.0
Extra-EC exports	1.0	4.0

Source: NEI

All in all, after the active years of 1988 to 1990 and the successive slowdown in 1991 and 1992, it is expected that production and consumption will continue to decline by -1.5% in 1993 and 1994. Afterwards growth will recover to about 2% on average for the 1993-1997 period.

Musical instruments
NACE 492

There has been an increasing demand for musical instruments in the 1980s as a result of changing life styles and the development of musical culture among the general public. The market for musical instruments, however, shows signs of saturation. Asian imports account for a large portion of the supply of electronic instruments. Japan also supplies up-market, sophisticated instruments. It is expected that the decline in production and demand in the 1992-1993 period will be temporary. The growth in the years after will be moderate, fuelling competition in this market.

INDUSTRY PROFILE

Description of the sector

Musical instruments are highly diversified and can be summarised in the following groups:

- pianos (upright and grand pianos) and digital pianos;
- organs and electronic organs;
- woodwind instruments (saxophones, oboes, flutes and clarinets);
- brass wind instruments (trumpets, trombones);
- stringed instruments (violins, cellos, violas and double basses);
- fretted instruments (non-electric guitars, mandolins, banjos);
- percussion instruments (drums, cymbals);
- electric pianos, electric guitars, electric basses, portable keyboards;
- synthesisers;
- other instruments (accordions, rhythm machines, mouth organs, harpsichords, pipe organs); and
- accessories and parts (bows, strings, bridges, components for electronic music).

Musical instruments include both traditional instruments, whether early or modern, and electronic instruments. Demand for pianos, keyboards and related instruments accounts for two-third of the market.

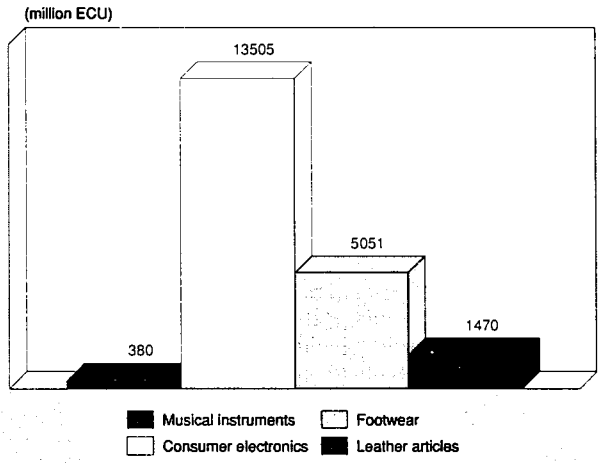
The situation varies greatly according to the type of musical instrument and the country concerned. The country with the largest production is Germany (West), accounting for almost 50% of the EC production. When taken together with Italy and France, 84% of the EC production is accounted for.

Recent trends

EC production at current prices grew by roughly 28% between 1983 and 1991. At constant prices however, total production declined by almost 9% in the same period. Germany (West) suffered a decrease in production at constant prices from 1980 onwards and experienced a temporary increase in 1989. Italian production figures are somewhat difficult to interpret due to a large difference between the figures before and after 1989. Nevertheless, Italian production at constant prices in 1992 seems to be back on the level of 1984. The same can be said for the French production, whereas British production has declined overall during the 1983-1992 period.

Consumption expenditure on musical instruments, at current prices has, on average, risen during the last ten years. This trend can be found in most EC countries. The United Kingdom,

Figure 1: Musical instruments
Value added in comparison with other industries, 1992



Source: DEBA

however, experienced first an increase, then a decline in the expenditure. In real terms, the growth in consumption expenditure has been modest in the EC. However that trend does not necessarily reflect a trend in private music-making, as purchasing an instrument and actually playing it are two different things. The resale of instruments and the rental market, that are significant in all European countries, must also be taken into account.

The EC is a net importer of musical instruments. Moreover, the gap between exports and imports has been widening during the last ten years. Since 1989 the trade deficit seems to be stabilising. This is due to the levelling off of exports as well as imports.

The number of people working had been rapidly declining in the first half of the 1980s, but since 1986, this trend slowed down. In 1992, employment stood at 12 800 million ECU but decreased again in 1993. The evolution varies from country to country. Reflecting the geographical location of production, employment is mainly concentrated in the Federal Republic

of Germany (48% of the total), Italy (18%), the United Kingdom (13%) and France (11%). The greatest job losses since 1980 occurred in Italy, the United Kingdom and Spain. The decreasing trend was slower in Germany and France.

Many countries, however, only report employment for firms with 20 employees or more. In Germany alone, 30% of the workforce is employed in firms with less than 20 employees. When taking into account that labour force reduction is more difficult in small companies than in large ones, the decline in employment in recent years is likely to be insignificant.

In 1992, production at current prices of musical instruments was considerably larger than in the previous year, reflecting growing consumer demand and an ameliorating trade balance. However, recent figures show that production during 1992 has begun to decline. A decline that continued in 1993. It is estimated that in 1993 production as well as consumption will be lower than in 1992.

Production growth in 1992 mainly took place in Italy, whereas in the other large countries production, at current and at constant prices has declined. The pattern of consumption expenditure on musical instruments varies also among countries. British and French expenditure declined during the 1991 and 1992 period, German and Italian expenditure, on the other hand, increased. In 1992, the trade balance ameliorated due to declining imports. The smaller trade deficit in musical instruments originates mainly from Italy, the United Kingdom and France, Germany however, experienced a larger deficit.

International comparison

With production at 797 million ECU, the EC was among the largest world producers in 1992. The USA production recovered in 1992 after several years of decline. Most of the US demand is for acoustic guitars, grand pianos, digital pianos and school band instruments. In the US and Japan, sales of digital pianos outweigh those of acoustic uprights and grands,

Figure 4: Musical instruments

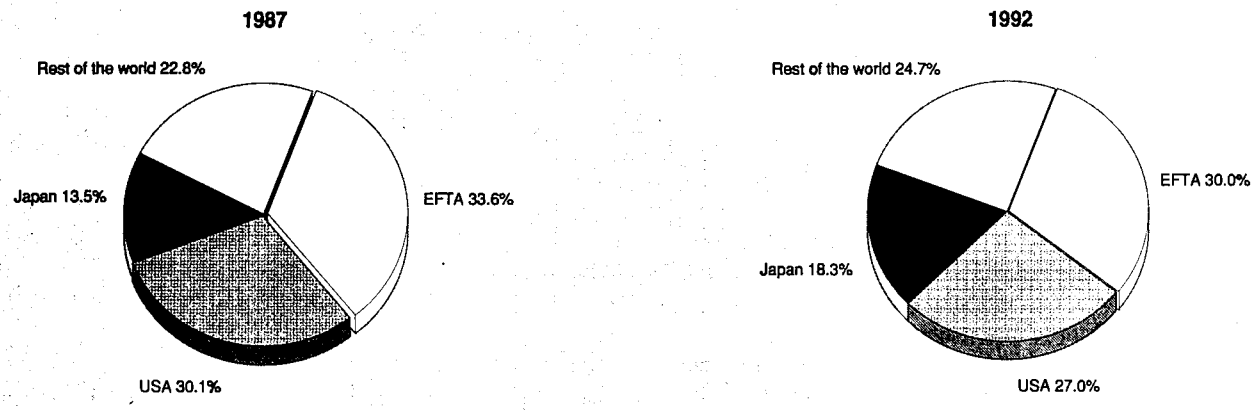
Figure 6: Musical instruments
Destination of EC exports



Source: Eurostat

while in the rest of the world the opposite holds true. Worldwide, digital pianos account for 35% of the piano market.

Foreign trade

The EC faces stiff competition from Japan when it comes to up-market, sophisticated instruments and from other Asian countries as South-Korea, China and Taiwan. Japan's share in EC imports has declined, while that of other Asian countries, as well as that of the USA, has risen since 1987. In the field of traditional instruments, competition is also present from other European countries like those in Eastern Europe, Austria and Finland.

In previous years, there has been a substantial growth of imports; they are mainly composed of electronic instruments, pianos, wind instruments, and accessories and parts. EC producers are faced with an absolute decline in market share. The share of the EC market being supplied by non-EC producers has grown from 40% in 1980 to 56% in 1992.

Exports of musical instrument accounted for 36% of total production in 1992, which is more than this ratio had been during the 1980s and the beginning of the 1990s. The EC balance-of-trade figures showed an ever increasing deficit throughout the 1980s. This trend, however, has come to a halt in the beginning of the 1990s. Exports consist mainly of string instruments, accordions, organs, and accessories and parts. In 1992, extra-EC exports declined slightly in current and in constant prices. In 1992, intra-EC trade decreased at the same rate as extra-EC imports. As a result, the 1989 rising share of intra EC imports in view of total imports levelled off.

MARKET FORCES

Demand

The EC industry had a large market in 1992 and was estimated at 1 151 million ECU. The consumption of musical instruments in the EC, however, remains low compared to the United States. This is due to the fact that the market is made up of individual national markets with specific characteristics that are still very noticeable. There is, however, a trend towards greater uniformity in electronic instruments.

Demographic developments have opposing effects on the musical instrument market. The decreasing number of 5 to 20 year old people will, in the longer term, lower total demand for musical instruments and in the shorter term lower growth of demand for electronic instruments like portable keyboards.

Source: DEBA

The increasing number of 30 to 40 year old people means more purchasing power and more interest in acoustic instruments in the future.

The rise in purchasing power and changing life styles have revived interest in music-making. But this trend is counteracted by the attraction of other leisure activities. The decreasing time that people can devote to music leads to an upward pressure on the demand for electronic instruments that have the reputation to be easier to learn.

According to some market reports on Germany and the United Kingdom, there is a trend to use more traditional acoustic instruments. The renewed interest in jazz that has been seen in some countries also leads to more demand for stringed, fretted and wind instruments. However, the overall market seems saturated.

Supply and competition

Despite its large home market and its increasing productivity, the EC musical instruments industry has been losing ground during the 1980s in the competition with instrument makers abroad. Increasing labour costs had a negative impact on EC competitiveness. Moreover, the depreciation of the yen during the second half of the 1980s made Japanese products relatively cheaper in the EC.

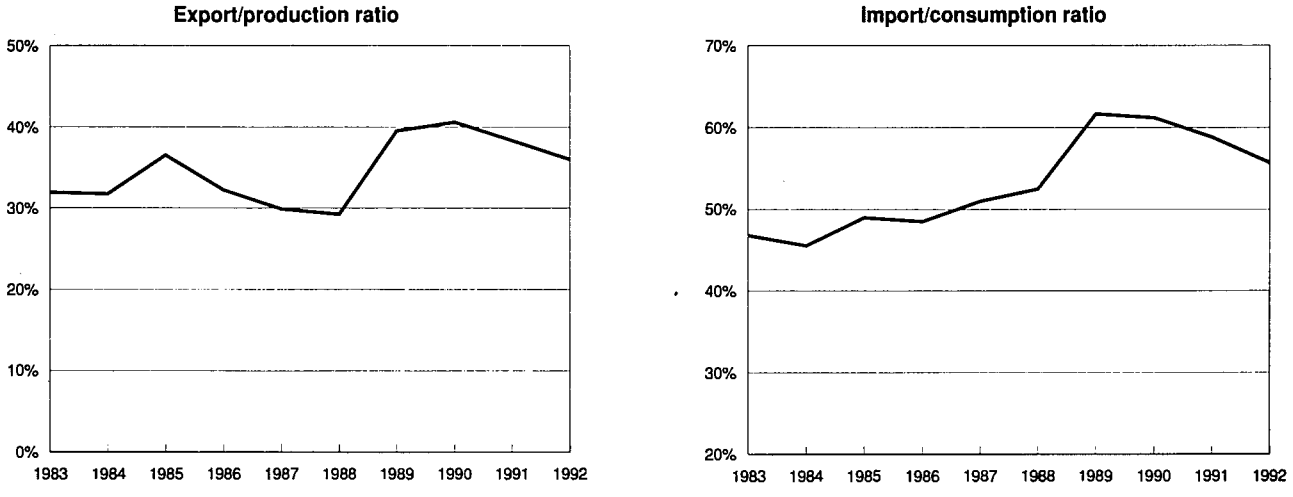
Competition in this market is stiff. EC demand in real terms has shown only a modest increase, while supply and competition from Asia, Eastern Europe and the USA has increased. Moreover, due to the differing composition of EC demand and EC supply, competition among European suppliers is also high.

Production process

European firms concentrate on products in the top of the market range. High-quality production implies smaller production runs or even single instruments being made to order, and is geared to an experienced clientele rather than the general public. The EC industry, with its specific national features, also plays an important role in transmitting European musical culture through the instruments it manufactures: all kinds of instruments in Germany, with emphasis on pianos, wind instruments and violins; woodwind instruments in France; guitars in Spain; and some piano and brass wind instrument manufacturing in Britain.

However, concentrating on top of the line products can be a dangerous game in an economy in recession and in a more or less saturated market. On the other hand, growing interest in classical music could be a countervailing power. Nonetheless, Steinway (D) has for instance introduced a piano for a lower segment of the piano market so that the gap between the low end of the market for pianos and the top is filled. Pianos are also being built by the Japanese company Kawai.

Figure 8: Musical instruments
Trade intensities



Source: DEBA

The development of electronic musical instruments has led to a wider range of products. These electronic instruments, an easier way of making music and more accessible for non-professional music makers, have the advantage over traditional musical instruments. This has not just created a larger market: a part of the market for traditional instruments has been lost, mostly in the segment of musical instruments which were designed to be played at home. In the professional market, the trend in live music towards more sophisticated shows and video clips has led to a demand for easy compatibility of instruments.

INDUSTRY STRUCTURE

Companies

The EC musical instrument industry suffers from two major structural handicaps: the industry is fragmented, with many small and medium-sized firms; the EC lacks multinational firms similar to those of the United States and Japan. That situation has led to restructuring and mergers in all EC countries.

The world leader, Yamaha, faces stiff competition from Asian rivals. It has been losing market share to its competitors in recent years. This competition is depressing operating margins. Yamaha set up localised production plants in the EC and took over several other companies during the 1980s. Overall, it strengthened its presence in the EC.

Other Asian producers are also spreading their wings over Europe. The South Korean company Daewoo is a case in point: it is operating piano assembly plants in Germany.

The shift in markets and the development of new markets has led a number of companies, mostly Japanese and South Korean ones whose core activity is outside the market for musical instruments, to enter this market. An increasing use of computers in synthesisers and public address (PA) systems facilitated the entry of computer manufacturers in this market.

The development of new electronic instruments has mostly hit the lower quality market, EC companies still having an outstanding name for the higher quality products. Steinway piano's and Selmer saxophones are still regarded as the absolute best, as well as Buffet-Crampon clarinets and Hohner accordions and mouth organs.

There are only a few large companies in the EC musical instrument industry. They include: Schreiber, Sonor, Höfner, Miraphone and VMI in Germany; GEM in Italy; Van doren in France; Marshall and Kemble in the United Kingdom.

Strategies

Several structural factors influence the industry's operations. Firstly, high and increasing labour costs are a major handicap for an industry that has to compete with foreign companies that are sometimes larger, and use more efficient and more flexible production methods. Especially the most important competitors (Japan, Korea, Taiwan and other Far East countries) produce more efficiently and/or have lower labour costs. Moreover, Asian companies, notably Yamaha, sometimes take care of their own needs for (rain forest) wood and other natural materials that gives them a competitive edge. Within the EC, however, the value added per employee increased in real terms from about 25 100 ECU in 1983 to 29 500 ECU in 1992. This is a result of increasing production and a decreasing workforce with EC manufacturers.

Secondly, with the small size of the European firms and a tendency toward national specialisation, manufacturers of musical instruments tend to be individualistic and highly independent. Therefore, investments in production and marketing are low for the sector as a whole, except for one or two larger companies that have achieved reasonable profitability levels. The case of electronic musical instruments is an illustration: investments in the EC grew initially but are still not sufficient to match the sums laid out by Japanese, Korean and American firms.

Thirdly, because of poor financial resources and of the predominantly manual production process, production automation has developed only slowly, in contrast to the persistent streamlining efforts made in Japan, South-Korea and the United States. These countries have achieved large production runs by using computer-aided design and micro-computer and software developments to produce musical instruments at lower costs. In addition, American and Japanese firms have introduced greater manufacturing flexibility by subcontracting the manufacture of electronic components. This has given them a further advantage over their European counterparts, to whom this type of flexibility is virtually unheard of.

The EC industry however, still has a few dynamic firms with good technical and human potential that is beginning to be exploited once again. The concentration on products in the top of the market range exemplifies this.

REGIONAL DISTRIBUTION

Some local regions have gained worldwide reputations. These include Paris and Mirecourt in the Vosges in France, Berlin, Bayern, Hessen, Sachsen (Vogtland) and Baden-Württemberg in Germany, and London in the United Kingdom.

ENVIRONMENT

The musical instruments industry is relatively non-polluting, when compared with the chemical industry or the transport sector. There are however a few remarks that could be made concerning the environment.

Firstly, the use of endangered materials in instruments is a case in point. For instance, guitar sound boards are made of ebony and encased in rosewood from the forests of India and Brazil, or pine and spruce from the Alps.

Secondly, modern electronic musical instruments use plastics. But this is of greater concern to the plastics processing and plastics producing industries. Given the long life of instruments, the problems are negligible. All in all, the musical instruments sector could be called a clean industry.

OUTLOOK

It is estimated that the production of musical instruments in the EC declined in 1993. This decline reflects a saturated market in recession. The recession is likely to be temporary and in the medium term a return to moderate growth rates is expected. Furthermore, demand is likely to reflect a gradual return to acoustic music and a steady development of electronic music through new applications.

In spite of certain advantages, the EC musical-instrument industry is likely to face a number of difficulties in the next few years, owing to the nature of its professional structure and its lack of flexibility in responding to the latest consumer

trends, which favour high-quality, reasonably-priced, all-electronic products. Parallel markets, such as the second-hand piano market, which often distort competition, may also cause problems.

Toys
NACE 494

The market for toys has grown significantly in the last years, mainly because of the strong growth recorded by video games. The European toy industry, in spite of a particularly lively international competition, is fairing relatively well and is increasing its investments in Europe, on the basis of its own main competitive advantages: quality, safety and innovation. The industry has to cope both with increasing imports from the Far East (China in particular), and unfair competition practices (imitations, price dumping, imports which do not comply with established rules, etc.) which penalise its activities.
The Internal Market is providing the opportunity for the EC toy industry to restructure further and develop companies with the appropriate size and marketing skills to compete at world level.

INDUSTRY PROFILE

Description of the sector

The industry is divided into ten subcategories as follows:

- Infant and pre-school toys;
- Dolls of all types made of plastic or other material, accessories and spare parts for dolls;
- Plush toys;
- Action toys;
- Vehicles (this includes radio controlled toys, electric trains);
- Ride-ons, such as tricycles, pedal cycles and cars, battery operated ride-ons, spring-horses, roller-skates, etc.;
- Games/Puzzles (this includes cards, non-electronic family board games, dice games, etc.)
- Activity toys (model kits, construction sets, powered appliances, die cast miniature toys, etc.);
- All other toys (including musical toys, guns, weapons, construction games).

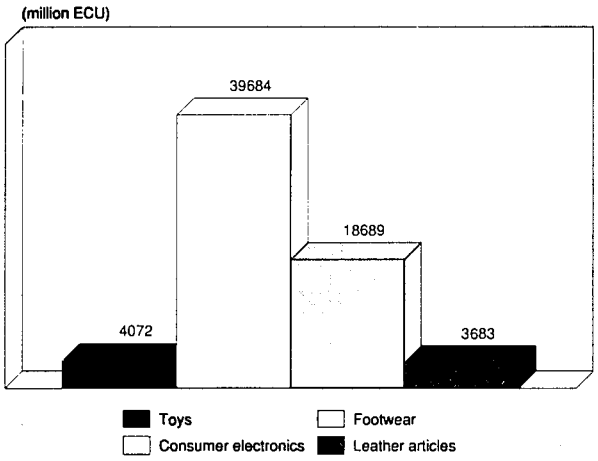
It is important to note that video games are just marketed, and not produced, in Europe. Sports equipment, playing cards, Christmas decorations or gambling machines are not included in this report.

Recent trends

Over the last five years, the toy market increased by 10% on average at current prices. Especially in 1991 and 1992, the market grew significantly. In real terms, the market growth was only 7.8% on average. This growth is not reflected in production, which in real terms has been stagnant since 1989.

The very high growth rates of the toy market in 1991 and 1992 are a result of video games' very strong increase in these years. It is estimated that the size of the video games market in 1992 was around ECU 3.5 billion at retail price, which corresponds to approximately 20-25% of the total market, according to the various countries. The rapid development of the video games market had only a minor influence on other toy sectors, without however, replacing the market for "traditional" toys. It is estimated that of the total growth of the video games market, between 50% and 70% of the volume has been incremental and between 30% and 50% has been at the expense of traditional toys, in particular higher prices games for older children but also different products targeted at similar segments in the market.

Figure 1: Toys
Production in comparison with other industries, 1992



Source: TME, DEBA

The four main categories after video games in market share terms are non-electronic family board games and puzzles, dolls, activity toys and toys which reproduce objects commonly used by adults ("sit and ride" and "supershop/superstore" range). However, these are not necessarily the sectors which have showed the highest growth figures in recent years. Beyond video games, the progression has been most important for dolls, pre-school and infant toys, as well as electronic games. The growth of video games has in fact highlighted the importance of the trend to "compression" in toys whereby children move towards more sophisticated products at an earlier age. However, the slow saturation of the market is putting this trend towards video games at risk in 1993.

The effect of this "compression"-trend and the increase in the child population 0-5 years (which is due to peak in 1995) explain the growing importance of the "pre-school" market in the demand for toys.

The EC toy market is characterised by the fact that five countries account for 86% of the market (on the basis of 1991 retail price figures). In order of importance, these are: France,

Figure 2: Toys

Source: TME

the United Kingdom, Italy, Germany and Spain. The remaining EC countries only account for between 1 and 4% each of the total EC toy sales.

These five markets are also the largest toy manufacturers. Their total production accounts for 95% of the toys produced in the EC. Germany appears to be the main EC producer with 27% of the EC production, followed by Spain (20%), Italy (19%), France (17%) and the United Kingdom (12%). There are some discrepancies among Member States: whereas the share in EC production of Germany, France, Italy have increased, the share of EC production of the United Kingdom decreased from 17% in 1988 to 12% in 1991. This may reflect the more rapid transfer of United Kingdom manufacturing to offshore production than in other countries.

The stagnation of production of toys in the EC contrasted to the growing consumption caused by video games, of which the majority comes from Far East countries, which increased steadily over the last few years.

Due to the highly competitive nature of the toy industry, there is a trend towards consolidation with major companies making international acquisitions. An inevitable consequence of these acquisitions is a reduction in employment, often due to partial or total delocalisations of production.

In fact, some EC toy manufacturers, who have the sufficient critical size to do it, have moved part of their own production facilities to the Far East, where the manufacturing activity can be achieved at a lower cost. Other European producers partially subcontract to Far East producers parts and pieces of toys, components and other finished products, which are imported to complement the range of products.

However, the production of bulky toys is generally kept within the EC, as transport from non-EC countries would be expensive. Production also takes place in the EC when a high level of automation and/or high precision manufacturing is necessary, notably in the sector of plastic toys, where important investments have been undertaken (Jura in France and Alicante in Spain).

International comparison

At retail prices, apparent consumption of toys in the EC is only slightly lower than in the US. However, per capita expenditure on toys is higher in the US, if one considers that there are less children in the US than in the EC. Furthermore, prices of toys in the US are on average lower than in the EC. In Japan, the consumption reaches a level of ECU 4.9 billion, i.e. more than one third of the EC's consumption, for a third of its children population.

The EC is the third largest producer of games and toys in the world after Japan and the United States. At the same time it has to be noted that the EC producers are acquiring stronger positions vis-à-vis the USA but loosing to Japan (only in the video segment). But it should be noted, that much of the fluctuations in the positions is due to the fluctuations of the exchange rates. The figures in real terms, however, indicate a relatively more flourishing toy manufacturing industry in the EC than in the USA.

There is an increasing convergence in terms of product requirements between these three markets. This reflects the growing internationalisation of the industry and its dominance by a relatively small number of multinational companies, essentially American and Japanese ones.

Foreign trade

During the 1989-1992 period, the import/consumption ratio of toys has increased from 42% to 59%, with imports particularly contributing to market growth. These imports are increasingly coming from the Far East: in 1988 they accounted for 49% of extra EC imports in 1988, in 1992 they accounted 63%. This big increase in imports is largely due to the boom of video games, whereas imports of traditional toys from the Far East has remained stable since 1988, apart from the case of direct imports of low-range plastic toys.

Imports from the Far East mainly come from China, via the intermediation of US and Japanese multinationals, of European manufacturers in the framework of the complementation of their range of products, and of direct imports from retailers. Here, two strategies are opposed and/or complement each other: the first one is that of the multinationals, which provokes a reduction in manufacturing employment in the toy industry which has been partly offset by job creation in sales and marketing, distribution, product design and advertising functions, as international companies have built up their organisation's capacity to handle the EC market. On the other side one finds the strategy of European manufacturers which, besides sales and marketing personnel, employs many subcontractors and skilled workers.

The four biggest toy markets, France, the United Kingdom Italy and Germany account for 75% of imports into the EC,

Table 2: Toys

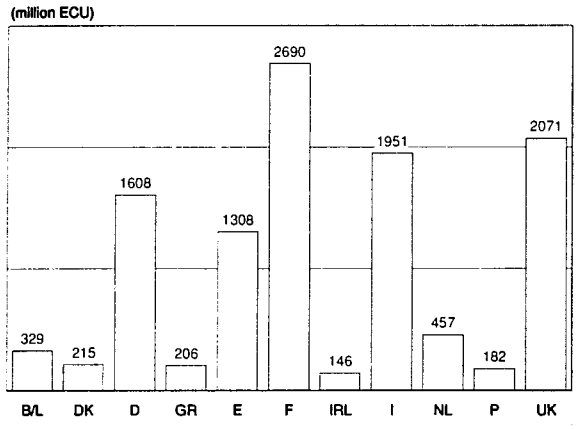
Figure 3: Toys
National toy markets at retail prices by Member State, 1991



Source: TME

which corresponds to their total market share of 78%. Spain, the fifth biggest market, imports to a lesser extent than the other four. The fact that The Netherlands and Belgium receive a larger share of imports than their relative market share is due to the role of these countries as distribution centres for many major toy suppliers, combined with their very small production level.

Extra-EC exports have been increasing since 1988, but the rate of increase is diminishing, unlike extra-EC imports, for which the rate of increase has accelerated. The import-export ratio shows that imports into the EC are considerably higher than exports from the EC and this negative trade balance is aggravating.

Again, the same pattern described for imports might be applied for exports: the five largest markets in the EC account for 80% of exports, i.e. slightly more than their market share. In addition and as already mentioned, The Netherlands and Belgium account for a relatively large part of exports, this being easily attributed to their role as distributors of toys.

EFTA countries appear to be the main destination for 32.7% of toys manufactured in the EC, before the USA for 17.8% of extra-EC exports.

MARKET FORCES

Demand

Disposable income is one factor for determining the level of spending on toys per child in the EC: children in the EC receive on average toys valued at approximately ECU 190 per year, but there are discrepancies among EC countries, the GDP being the determining criteria. Children from former West Germany receive the highest amount of toys, but French children receive more toys than the re-united Germany. Spanish and Italian children receive less toys than any other EC country with an amount of ECU 160 per year. Germany, Denmark, France and the United Kingdom are the leading EC countries in terms of toy spending per child. The number of toys received per child per year and the amount spent on these toys has been increasing, as a result of the higher average age on which parents have their first child. On average, these parents have a larger disposable income than in their early twenties.

Another factor is the demographic development: the number of children in the EC has been decreasing since 1985 and this decrease is expected to continue in the future. This decline

will be moderate due to the counter force of people in the baby boom generation who become parents in the 1990s.

TV advertising is an important factor which affects demand: quantitatively, it is particularly important for a company wishing to penetrate a market. However, only large multinationals can afford to pay the high fees necessary to buy advertising spaces to promote their products. Furthermore differences among Member States exist in access to commercial TV-time. Demand is particularly influenced by TV-advertising in the United Kingdom and Italy, and less so in Germany.

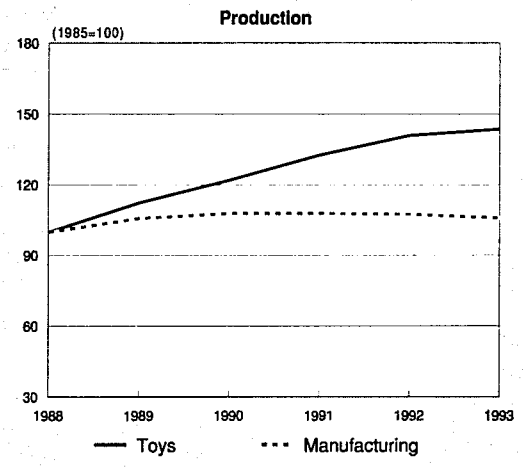
Fashion and promotional type hit products, often supported by a heavy TV campaign, also play an important role in demand. New toys can create entirely new categories resulting incremental sales for the industry as a whole. Demand however, can switch from a hit product to another one over a short period of time.

Finally, seasonality is an important characteristic of the demand for toys. The toy industry is, above all, an industry which responds to a highly cyclical demand pattern. Some 60% of the total volume of toys is sold to consumers in the last two months of the year, i.e. around the St Nicholas, Christmas period. Outside the Christmas peak season, toys are more particularly sold at Easter and similar occasions, as well as for birthdays. Finally, it is worth to note the strong development of summer toys (notably sporting toys) and open-air toys.

Supply and competition

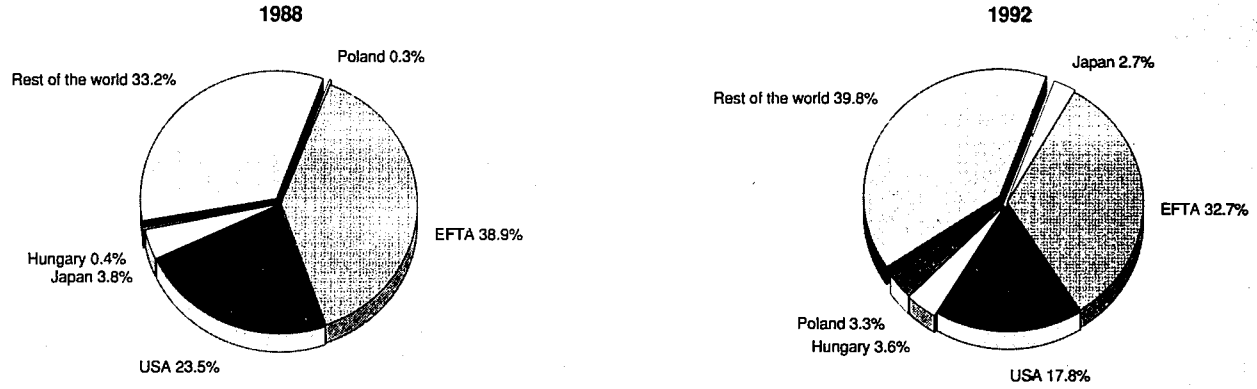
The high wage costs in Europe are a major handicap for the EC toy industry in relation to foreign competitors, with respect to products manufactured in the Far East. China has become the hub of international subcontracting because of the low

Figure 4: Toys
Production in constant prices compared to EC manufacturing



1993 are Eurostat estimates.
Source: TME, DEBA

Figure 5: Toys
Destination of EC exports



Source: Eurostat

labour cost. The handicap of high labour costs is particularly penalising in a sector where assembly operations are numerous and difficult to automate for small production runs.

The increasing sourcing of toys in the Far East, and especially in China by American multinationals have lead some EC toy manufacturers to follow the same pattern, to the extent of their ability to do it.

Smaller manufacturers tend to meet local market requirements and can not penetrate international trade markets. However, it becomes increasingly necessary to operate at an international level (e.g. by cooperation) in order to absorb the high development costs and investments required for new products. Owing to their small size, smaller EC companies have a low investment capacity. Lack of financial resources is a basic handicap in the bid to compete with other producers.

In addition, because of insufficient production runs due to the patchwork nature of the EC market and the small size of firms, no benefits can be achieved from economies of scale comparable to those made by American multinationals. The latter companies offer a single worldwide range.

Production flexibility is a major advantage for toy multinationals, who have to deal with a cyclical market influenced by fashion trends and who often have more than 50% of their products manufactured in Taiwan and Hong Kong, and particularly in China.

The retail business is highly competitive with a strong emphasis on improved margins. At the same time, the retail market is increasingly concentrating. In the last five years the American chain Toys'R'Us has become the largest single retailer of toys within Europe and it has developed this unique position by offering a very large assortment of toys and other child related products at very competitive prices. Hypermarkets and supermarkets also have a major impact on the sales of toys but mostly during the Christmas season. Their usual strategy is to market the products themselves, using the combination of low price/limited assortment, as well as special offers which attract customers to the shops.

In certain markets such as France, hypermarkets and supermarkets control up to 65% of the market, discounting toys marginally above their cost price.

As a consequence of these developments, the number of toy retailers decreased significantly the last ten years, with many small retail shops losing market share and finally closing down. The outcome is a concentration on the supply side of toys

into the hands of fewer, more professional, internationally operating companies.

The weak industrial structure has led to a fall in profitability levels in EC companies since 1980. This is mainly due to rising costs of production, marketing and advertising, which are difficult to pass on to the consumer because of the strong competitive pressure in the sector.

Toy manufacturers in Europe are also facing unfair competition, which in particular takes the form of:

- dumping practices on the prices of low-range toys, and the so-called "social" dumping due to the exploitation of workforce;
- piracy and imitation of design, trade marks and models.

Production process

Companies operate more and more on a global scale, leading to relocations of manufacturing plants from the EC to the Far East because of cost conditions. However, some successful companies still manufacture in Europe, e.g. Lego (DK), Playmobil (D), Monneret (F), Smoby (F), Berchet (F), Milton Bradley (US), Hasbro (US), Fisher Price (US), Meccano (F), Parker (US), Chicco (I), Spears (UK), Waddington (UK), Mattel (US), Majorette (F), Ravensburger (D), Steiff (D), Jeux Nathan (F), Clementoni (I), Burago (I), Märklin (D), Trudi (I), Jumbo (NL). For some of these, the European share in the production is sometimes up to 100%.

Apart from the development of manufacturing in Europe or in the Far East, the concession of licensing is also a key elements to the success of EC companies. However, only international companies, armed with appropriate distribution networks, are able to make good use of licences, with the support of important TV advertising campaigns, whereas the majority of EC firms lack a proper international system of distribution.

INDUSTRY STRUCTURE

Companies

In general, the European companies specialise in traditional toys. On the other hand, companies located outside the EC prefer to produce fashion toys, which remain however very aleatory and which require high publicity costs and have a short economic life cycle.

The EC toy industry consists of a wide spectrum of companies of different sizes: from small privately owned domestic manufacturers to large international toy companies. The top ten toy companies in terms of market shares in the EC are: Nintendo (J), Hasbro (US), Sega (J), Lego (DK), Mattel (US), Idéal Loisirs (F), Playmobil (D), Fisher-Price (US), Tomy (J), Ravensburger (D).

Other important European firms are Clementoni (I), Burago (I), Jumbo (NL), Märklin (D), Bluebird (UK), Jeux Nathan (F), Brio (S), Berchet (F), Famosa (E), Smoby (F), Chicco (I), Spears (UK), Hornsby (UK), Britains Petite (UK), Waddingtons (UK).

The EC toy industry suffers from two main structural handicaps. The first is the high fragmentation of firms in the sector, because of the vast spread of different products. It is estimated that 80% of the firms operating in the sector on a full-time basis (excluding seasonal activity) employ fewer than 20 salaried workers.

The second problem is the absence of multinational firms comparable to American and Japanese groups, with the exception of Lego. This explains also why production is so dispersed.

In the EC toy industry a concentration of resources into fewer and larger international companies has taken place, reflecting the need to meet the European consumers' demands for new products through greater investment and manufacturing skills. Furthermore, there appears a process of polarisation. At the one side, large companies gain increasing market shares mainly at the expense of the effective middle sized domestic manufacturers who are unable, because of their structure, to respond quickly to changes in the market place. At the other side smaller, niche manufacturers acquire strong positions by focusing on a particular segment of the market.

Strategies

The internationalisation on the world market has also major effects for the EC toy industry with national companies devoting more efforts towards international expansion. The European Single Market has only reinforced this process.

The EC toy industry has undergone a restructuring phase over the last decade, mainly through mergers and acquisitions, in order to face-up to international competition. An example of this process concerns the French firm Idéal Loisirs, which is now one of the big international companies in the EC, due to its alliance with the Hong Kong based Playmates company and its acquisition of the French firm Majorette.

In order to stay competitive vis-à-vis international competitors, a global manufacturing strategy is necessary in order to exploit substantial economies of scale.

With respect to labour costs, the Lego company has a somewhat exceptional position inasmuch as it produces in Denmark and Switzerland, which have especially high labour costs. The explanation is the high level of automation and the need for high precision manufacturing.

In order to create a brand image, marketing efforts have proved to be rewarding. With respect to this, it is necessary for toy companies to make use of the whole range of the marketing mix. Within this marketing mix, a good media programme is crucial, but it must rely on all forms of promotion rather than on solely TV advertising.

REGIONAL DISTRIBUTION

The industry is highly concentrated geographically. Some 95% of the firms, accounting for approximately 90% of EC production, are situated in Germany, Italy, France, the United Kingdom and Spain. Within those five countries, firms are often located in a particular region: Bavaria and Baden-Württemberg in Germany, Lombardy in Italy, the Jura and Rhône-Alps (Ain) in France, and the Alicante and Barcelona provinces in Spain. Each country has its own specialisation:

- Germany: plastic toys, model trains and board games;
- Italy: bicycles and dolls;
- France: plastic toys, board games, plush toys and small scale cars;
- United Kingdom: metal and plastic miniatures, table and board games and die-cast;
- Netherlands: board games.

Each country has a production advantage. Germany is known for technical know-how; Italy's structure allows great flexibility and high product quality; France has particular knowledge in plastics transformation.

ENVIRONMENT

The toy industry is not regarded as a polluting industry, but has proved to be pro-active in the face of the increasing environmental consciousness among consumers. There are three areas in which environmental protection is relevant to it, i.e. packaging waste, environmentally friendly production, and removal of used products.

The "Green Movement" has led national governments, followed by the EC, to prepare rules designed to ensure the reduction of packaging waste. The toy industry has taken an active part in these debates and favours a single EC system aimed at reducing packaging waste.

In terms of the products themselves, wooden toys, considered by consumers as environmentally friendly, have benefited the most from the increased public ecological awareness. However, it is difficult to assess objectively which toys are most friendly to the environment.

REGULATIONS

The first and most important EC regulatory step was taken with the adoption of the "EC Toy Safety Directive" on 3 May 1988. The Toy Safety Directive contains essential physical, mechanical, chemical, electrical and flammability requirements, which, if fulfilled by toy manufacturers, allow them to affix on their products (or packaging) the "CE" mark. This sign is designed to indicate to surveillance officers that the product conforms to relevant EC safety regulations and can therefore freely circulate within the Internal Market. The Toy Safety Directive refers to a set of harmonised standards (elaborated by CEN and CENELEC), which are being constantly revised and extended.

Advertising regulations also affect the toy industry. The 1984 Misleading Directive and the 1989 Broadcasting Directive, although not designed primarily for the toy industry, encompass within their scope advertisement to children.

Creativity is the essence of the dynamism of the toy industry, and regulations relating to intellectual property, in particular trademark protection, design protection, as well as anti-counterfeiting measures are also of great interest to toy manufacturers, who devote a lot of time and effort to the development of new designs to satisfy the rapid evolution of children's tastes.

Trade measures, either included in GATT rules, or in specific EC regulations, affect greatly the European toy industry, which, as explained above, operates more and more on a global scale.

OUTLOOK

Prospects for the demand for toys in the short-term are only moderately optimistic. The economic recession, with a decrease in disposable income as a consequence, will result in a stagnation of the EC market for toys. In the longer term the economic recovery will lead to relative higher growth figures, however at a lower level than the growth figures of the 1980s.

EC manufacturers continue to be faced with stiff competition from suppliers in the Far East, and from China in particular, which risks to penalise European production in the medium term. Also EC-exports will be hurt by this fierce competition.

Electronic toys, which recorded strong growth for a few years, might undergo a slowdown in the short term, due both to the possible development of a bad reputation for these games with parents, and to saturation.

Sporting goods
NACE 494.2, part of 451, 453

The EC market for sporting goods expanded significantly in the 1980s. Several factors were responsible for this evolution, under which the increased interest for sports because of health reasons and the increased leisure time of people. Moreover, the more fashion-led consumption has stimulated the industry. Demographic changes with a growing proportion of the population over 25 years old have resulted in a changing pattern in demand: year-round recreation activities, higher quality products and more individualistic sports are becoming more attractive.
Competition has become very fierce in the EC market due to the rising imports of particularly Asian products. New strategies concentrating on key products, more outsourcing, centralisation of functions and improved logistics and distribution have been applied by EC manufacturers.

INDUSTRY PROFILE

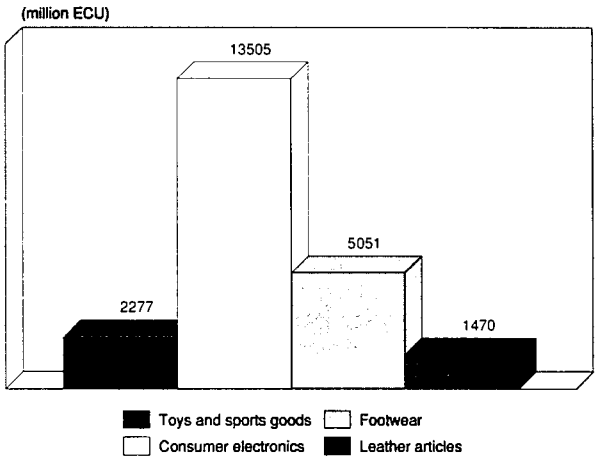
Description of the sector

Sporting goods are covered by NACE 494.2 and by parts of NACE 451 and 453 for sports footwear and sports clothing, respectively. The sporting goods sector is very heterogeneous and detailed statistics except for trade are not available. Moreover, it is difficult to give a precise definition of sporting goods because many products originally marketed as sporting goods are used only partly for sporting activities. Sports clothing and sports footwear are also worn by people in spare time or even at work. Furthermore, manufacturers of sporting goods also produce other goods such as toys and camping equipment. Most of the tables and figures in this chapter refer thus to NACE 494, toys and sporting goods.

The chief countries of origin for the main product groups are as follows (main non-European origin countries);

- gymnastic and athletic equipment: United Kingdom, France, Germany, Finland, Norway (USA, China);
- tennis rackets: Belgium, Austria, France, Germany (Taiwan, USA);
- golf equipment: United Kingdom, France, Germany (Taiwan, Japan, USA);
- table-tennis equipment: France, Germany, Sweden, United Kingdom (China, Japan);
- leather balls: Italy, United Kingdom, France, Germany (Pakistan, China);
- roller and ice skates: Austria, Switzerland (Canada, China);
- cross-country skis: Austria, Finland, Italy (Commonwealth Independent States: CIS);
- alpine skis: France, Austria, Finland, Italy, Switzerland, former Yugoslavia (USA);
- aquatic sports equipment (incl. windsurfing): France, Austria, Switzerland, Italy, Germany (USA, China);
- leather sports gloves: Italy, France, Germany, Netherlands, Hungary (Pakistan, South Korea, USA);
- track suits: Italy, France, Germany, Portugal, Turkey, former Yugoslavia, Denmark, UK, Switzerland, Poland (China, Pakistan, India);
- ski-suits (woven): Italy, France, Germany, Austria, Greece, Portugal, former Yugoslavia (China);

Figure 1: Toys and sports goods
Value added in comparison with other industries, 1992



Source: DEBA

- ski-boots: Austria, Italy, Germany, France, Switzerland, former Yugoslavia (South Korea);
- sports footwear: Italy, France, Germany, United Kingdom, Austria, Portugal, Switzerland, former Yugoslavia (China, Indonesia, South Korea, Taiwan).

The largest markets for sporting goods are Germany, France and the United Kingdom, although these markets show little potential for further substantial growth. The levels of participation in sports is not as high in the south Member States. Nevertheless, these countries offer good prospects for increasing consumer expenditure on sporting goods. The reason is that the larger markets and the Member States with high purchasing power (Belgium, the Netherlands, Denmark) are highly saturated.

In 1992, Germany had the largest value added, closely followed by France.

Recent trends

Several key trends have prompted increased participation in sport and hence huge growth in consumer expenditure on sporting goods.

Furthermore, sportswear has become ordinary casual wear during the 1980s and as such it has become a fashion product. The use of sports clothing and sports footwear as fashion goods, whereby people incorporate sports clothing and sports footwear in their outfit, has positively influenced the demand for sporting goods. In the 1990s however, consumption of sporting goods in the EC stagnated partly because of the economic recession.

Production has not grown at the same rate as consumption because an increasing part of production is done by outsourcing. Exports from especially East and South-East Asia have grown significantly the latest years, as low labour costs attracted production of sporting goods to these countries.

Moreover, Germany, Italy, France and the United Kingdom have sizeable manufacturing industries, but all are net importers and the share of Asian suppliers has increased steadily. This may explain the worsening of the already negative trade balance.

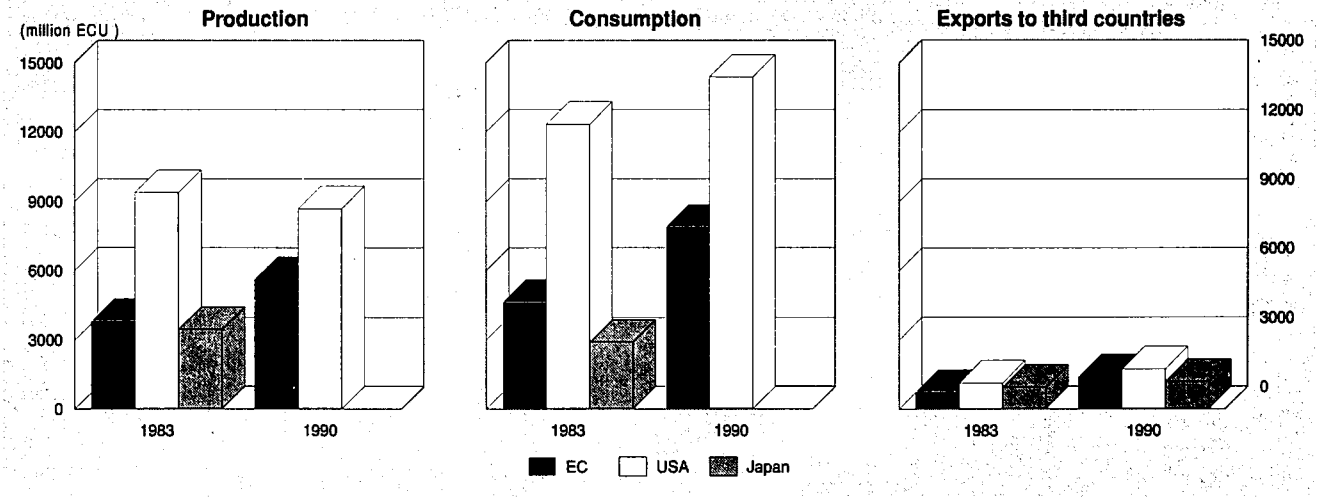
Since 1990, employment fell continuously due to high EC labour costs. This may explain the increase of productivity.

International comparison

Helped by the low value of the US Dollar in the 1986-1990 period, exports of sporting goods from the USA have risen tremendously. In line with the increasing exports, USA manufacturers expanded their production capacity in the US itself. In order to benefit from lower wages , output shifted from the US to lower labour cost markets (Asia) since 1990.

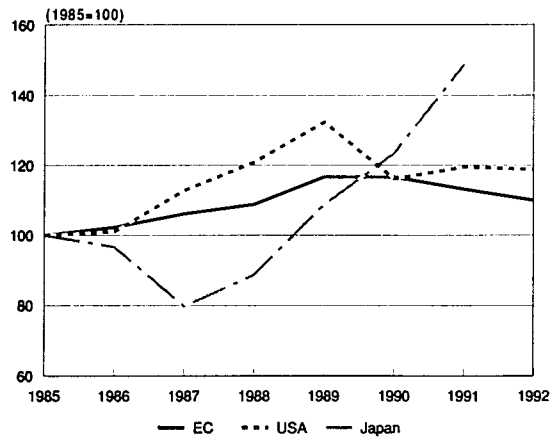
Aiming at increasing consumption, the Japanese government has taken several actions among which shortening of working

Figure 4: Toys and sports goods
International comparison of main indicators in current prices



Source: DEBA, Census of Manufacturers, Nikkei

Figure 5: Toys and sports goods
International comparison of production in constant prices



Source: DEBA, Census of Manufacturers, Nikkei

hours is one. The increase in leisure time resulted in higher consumer expenditures of sporting goods. Japanese manufacturers have benefited from this evolution in order to gain a foothold on foreign market for sporting goods.

Foreign trade

The trade deficit has been consistently growing during the 1980s, due to stagnating exports and increasing imports. Extra-EC imports rose by 20% in 1992 and tripled if compared to 1983. As a result, in 1992, extra-EC imports accounted for an increasing share of consumption: 60% of the demand in the EC was satisfied by foreign imports.

EC imports from the USA accounted for about 14% with the USA consolidating its position as a major importer of sporting goods in the EC. The shift of production to lower labour cost countries, has led to the huge growth of imports from East and South-East Asia. Another observation is that the composition of these imports is changing. In earlier years these imports mainly originated in countries like South Korea and Hong Kong, the increasing wage level in these countries however, has moved production of sporting goods to countries like Indonesia, Thailand, and China.

Because of the increasing competition from low labour cost countries, EC exports are stagnating during the last few years. Although the huge growth in the Japanese market for sporting goods resulted in growth figures in EC exports to Japan, overall EC exports have not grown significantly in the last years. The main exporters in the EC are France, Germany, Italy and the United Kingdom. These countries however are net importers, since they are also the main importers in the EC.

Intra-EC trade occurs mainly among Member States where most of sporting goods manufacturers are established and where the population has high purchasing power. These are the large countries already mentioned as the largest extra-EC importers and exporters.

MARKET FORCES

Demand

Factors affecting demand are:

- participation in sports: overall there was an increased interest and participation in sports, with especially an increasing popularity for 'new' sports like windsurfing, squash, golf and snooker;
- sporting activities are increasingly evolving from competitive team sports into recreational activities for the individual;
- demographic factors will be important: the proportion of people more than 25 years old will increase in the coming decade;
- importance of lifestyle: fashion and leisure usage of sports clothing and sports footwear.

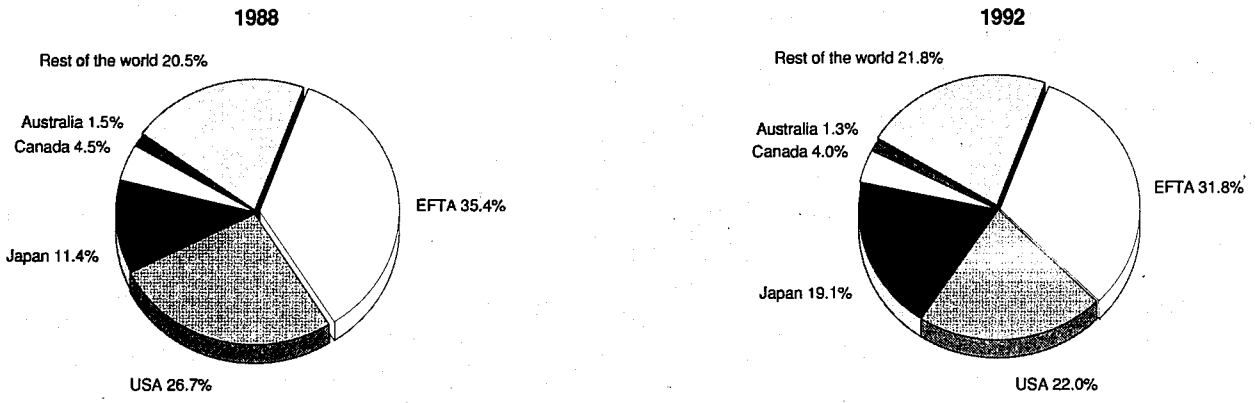
The increased interest for sports due to health reasons, the use of sports clothing and sports footwear for fashion clothing and the increased leisure time, all were positive factors in the development of the sporting goods industry in the 1980s.

The demand for sporting goods however is a discretionary demand. Therefore it is a cyclical demand because purchases of sporting goods are postponed in the recessionary period. The economic recession and the high saturation levels were the main reasons for the slowdown of the sporting goods industry in the early 1990s.

Supply and competition

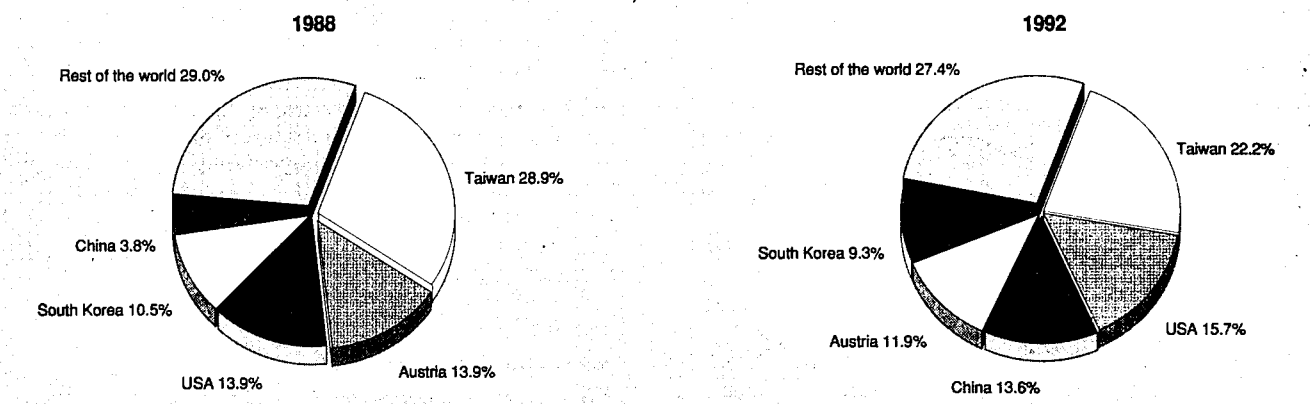
The European sporting goods industry has until now been characterised by a large number of small and medium sized

Figure 6: Sports goods
Destination of EC exports



Source: Eurostat

Figure 7: Sports goods
Origin of EC imports



Source: Eurostat

enterprises. There is however a growing concentration resulting in an increasing market power for a few multinationals. In response to the growing concentration of large companies, the smaller firms are cooperating together throughout the EC.

Furthermore, in the light of the Single Market and the abolition of the frontiers, a well developed distribution-network is a crucial factor in this highly competitive sector. In respect to this, the power of the retail business has significantly increased.

Apart from the competition of the US production, there is strong competition from manufacturers in the Far East. These suppliers can deliver large orders because of the size of their production capacity. Moreover new production technologies make it possible for them to offer relatively good quality at low prices because of the low labour cost in these countries. In order to strengthen their competitiveness, the large EC manufacturers have set up plants in this region. A lot of the smaller manufacturers have contracted out orders to suppliers in these countries. They have also expanded their buying teams in these countries in order to guarantee adequate supply.

Production process

The largest manufacturers of sporting goods in the EC rank among the world leaders in product and production technology. Through constant R&D expenditure these manufacturers endeavour to use state-of-the-art materials and technologies.

The manufacturing is usually carried out by independent companies while design, quality, control, distribution and marketing are controlled and carried out by the respective brand companies

A distinction can be made between different groupings of products, in terms of differences in positioning in the market, advertising and promotion. At the one end, there are the top international brands: they are very exclusive, have superior quality and are highly priced. Generally, they are only sold through specialist stores, mostly clothing stores.

A second group are the more mass market brands that are also heavily promoted, but are less exclusive while still fashionable. They have a high quality and are distributed through specialised independents and specialised chains.

At the other end, there are the brands of middle quality with competitive prices. Advertising and promotion is far more limited and competition is directly with 'private label' merchandise offered by large retailers and department stores.

INDUSTRY STRUCTURE

Companies

The major product groups and brands-manufacturers in the EC are:

- Adidas/Puma (D) and Nike/Reebok (US): sports clothing and footwear
- Rossignol, Salomon:(F), Fisher (D): skiing and tennis equipment, golf clubs and equipment;
- Lacoste:(F): sport and leisure clothes,
- Bogner: (D): leisure clothing;
- Kettler:(D): sports and fitness equipment;
- Dunlop/Slazenger (UK), Donnay (B): tennis equipment and clothing.

Strategies

The increasing competition from Asian suppliers and the growing market power of the retail business make it necessary for the sporting goods industry to become more competitive. The European Single Market is only reinforcing this process.

Larger companies are mainly rationalising their activities. In the 1980s, numerous manufacturers pursued a policy of diversification and produced not only their core products but also sports and leisure clothing and footwear for highly varied activities. As such they competed directly with clothing and footwear manufacturers, who expanded their product ranges by including more sports items. Because of the competitive advantages of these clothing and footwear manufacturers, mainly in distribution and advertising, profits of the sporting goods manufacturers went down. This resulted in streamlining of the product ranges, focusing on the companies' strengths and disposing of loss-making divisions. An example is Adidas that abandoned the Adidas branded leisure wear sector and concentrated on key products.

Smaller companies are setting up cooperation agreements in order to work together in the fields of distribution, marketing and R&D. The financial resources of these smaller companies are most of the time too small to set up a European-wide distribution network or to spend large budgets on R&D for product development.

Moreover, smaller companies are focusing and specialising on segments of the market for sporting goods, thereby pursuing a niche-strategy.

Instead of diversifying into totally new product lines (such as leisure footwear or clothing), sporting goods manufacturers are nowadays diversifying into related product lines (e.g. a manufacturer of running shoes also produces golf shoes). This makes it possible to diversify away from the crowded, highly competitive markets into new less competitive areas. The recognition of higher rewards of more highly distinctive product sales and the all too high dependence on a specific part of the market, are the main drivers behind this process.

Finally, the recognition of demographic changes by manufacturers has made them consider sports where consumers other than the young (male) adults are active. This increase of the older population sections with high purchasing power and a strong interest in sport has, for example, led to a growing interest in golf. Manufacturers take into account these demographic changes in their advertising and promotion strategy by more focusing on the 'new' consumers in sports. In par-

ticular submarkets of sporting goods, advertising represents a key barrier to entry, but it also enables the major manufacturers to maintain their position and dominance within the industry.

REGIONAL DISTRIBUTION

The major producers in the EC are Germany, France, Italy and the United Kingdom. Figures about the number of manufacturers in these countries can only be indicative, since the sporting goods industry is very heterogeneous, and it depends on small differences in interpretation if a company is considered to be in the sporting goods industry or not. This is especially relevant to the clothing sportswear sector. However, most companies seem to be engaged in the sports clothing sector, and the least in the sports footwear.

Within countries the geographical pattern can be very different. In Italy, most of the manufacturers are based in Lombardy and in Spain a majority of manufacturers are located in Catalonia and in the region around Madrid. France and Germany, by contrast, have companies widely spread throughout the country.

ENVIRONMENT

Some of the outdoor activities are being opposed by environmental movements. The arguments are that some outdoor activities could have a direct effect on the environment of the sport area. Two remarks should be made relating to this observation.

First, a distinction should be made between the environmental hazards caused directly by the sporting goods industry and those hazards that tourist services are responsible for. Second, recent efforts have been made to protect the environment in the concerned areas. National sporting associations and local and/or regional authorities are involved to protect the environment by local regulations for doing sports (e.g. minimum of snow for skiing, special routes for cross-country skiing).

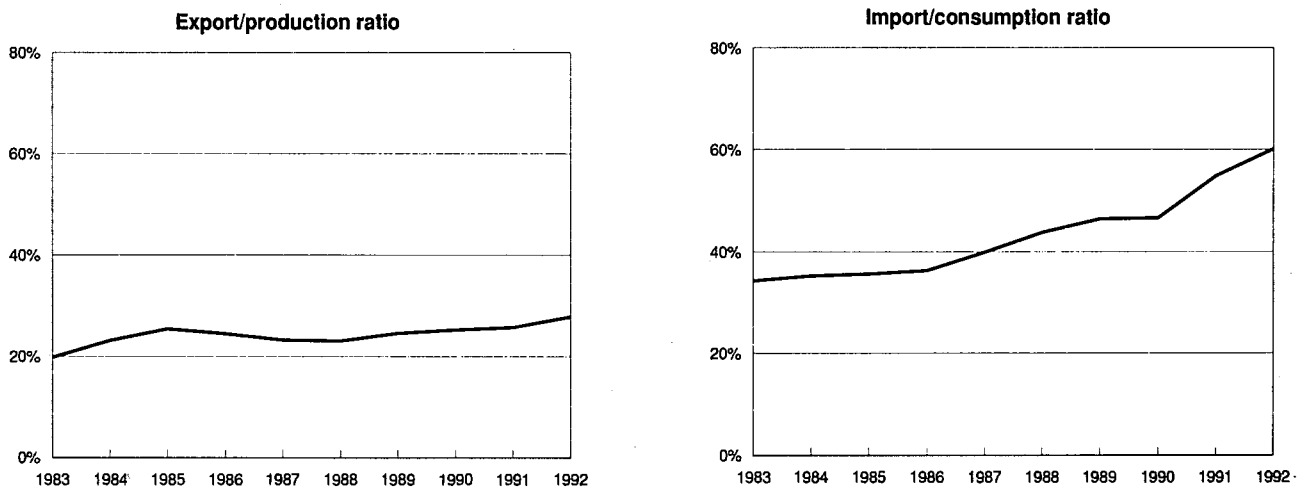
Moreover, other sports benefit from the heightened ecological awareness and to compensate for stress of overcrowded and polluted cities. Cycling, windsurfing, and trekking are just a few examples.

REGULATIONS

Under the GSP (Generalised System of Preferences) scheme of the EC, imports of sporting goods from a number of developing countries are admitted duty free within an overall ceiling. The EC can reintroduce normal customs duties when the ceiling has been reached.

The new product liability laws increase the responsibility of the producers but also the importers who introduce products in the EC market. Products can be held to be faulty because

Figure 10: Toys and sports goods
Trade intensities



Source: DEBA

of design and construction faults, production or assembly faults, presentation (strongly tied in GATT policy, e.g. packaging or advertising producing over high expectations) and misleading or in adequate instructions. The manufacturer/importer must ensure that full advice is given to the consumer regarding 'expected reasonable use of the product' through instructions for use, labelling and appropriate safety warnings.

Other fields of importance for sporting goods are the harmonisation of standards (e.g. gymnastic equipment), intellectual property rights (e.g. product-patenting in order to protect R&D) and competition policy (e.g. co-operation agreements).

OUTLOOK

In the short-term, the economic recession will have an important negative effect on the demand for sporting goods, and consequently consumption of sporting goods will be stagnating.

On the other hand, development of demand is likely to benefit from technical developments and fashion trends. In the longer term however, the combination of these factors together with the economic recovery will result in an increasing demand for sporting goods.

The fierce competition from foreign suppliers makes that production and exports will not increase significantly. Moreover, manufacturers are opting more and more for outward processing, what might lead to a contraction of production in some Member States.

Generally, the successful firms will be those focusing on R&D, market monitoring and on pursuing a niche strategy. Furthermore, brand images will play an ever more important role.

Written by: Netherlands Economic Institute

Overview
NACE 50

The gross output of the construction industry accounts for 10-12% of gross domestic product; value added is about half that. Construction also represents about 60 percent of gross fixed capital formation. The sector is a major employer, with around 9 million employed in contractors, and directly generates employment for 3 to 4 million in construction products. This is around 10% of civilian employment. It probably generates as much again in indirect employment.
Construction is mainly a local activity, with a few large firms, and little export activity. EC firms, however, are successful in world markets. Intra-EC cross-border activity is increasing on large projects, and there is extensive migrant labour.
Future markets are highly uncertain, because they depend on economic growth rates and the level of public expenditure. EC infrastructure needs are expected to boost demand. Privatisation is generally reducing the share of public sector financing, which is approximately half of total demand.
Technology and the use of materials is changing rapidly - research and development, training and quality management are key factors in the future development of the sector.

INDUSTRY PROFILE

Description of the sector

At the simplest level the construction sector has two main constituents: the constructors of works, and the suppliers and manufacturers of construction materials. These groups are not distinct, particularly because of the increasing role of specialist contractors who may both manufacture and install sub-assemblies (such as structural steelworks, curtain walling, air conditioning).

Additionally, although they are treated separately in this book (see chapter 24), architects are important players in the construction sector and, even though their economic significance is quite poor in the light of consolidated GNP, European architects as a whole have a powerful impact on the evolution of the building industry.

The classification of construction activities differs between countries. Most construction activity falls under NACE 500, but some activities by construction firms, such as construction of metallic structures (bridges, towers, industrial buildings), off-shore structures, construction of process industry and energy installations (e.g. steelworks, petrochemical plants, power stations, hydroelectric plants, pipelines) may be classified as metal products or non-electrical machinery. Suppliers and manufacturers of construction materials are mainly classified under NACE 24 (non-metallic minerals) NACE 31 (metal products), NACE 462 (semi-finished wood products) and NACE 47 (pulp, paper, printing and publishing).

Construction is traditionally divided by statistics and regulations into building (NACE 501) and civil engineering (travaux publics) (NACE 502). Some countries further subdivide building into structural works and finishing works. These distinctions are not clear-cut, however, and do not necessarily correspond to distinct types of firms. The main categories of construction firms include the following:

- general contractors (building and civil engineering);
- general building contractors;
- civil engineering (travaux publics) contractors;
- engineering construction contractors (e.g. process plant construction);
- specialist housebuilders;
- craftsmen, artisan firms and very small construction firms;
- specialist trade contractors frequently operating as subcontractors to general contractors.

Many large contractors are active in several or all of these activities and may have separate subsidiaries for each market segment. Specialist contractors have become increasingly important in the last couple of decades. These include, for example, electrical contractors, piling, tunnelling, flat roofing, heating and ventilating, drainage, and operators of specialist machinery.

The design and project management professionals (architects, engineers, surveyors) are an essential part of the construction sector, contributing 6-10% of construction output value. They are classified under 'professional services' (mainly NACE 837).

The construction sector is very fragmented. There are a number of factors that cause this, resulting from the diversity of technology, customers and market sectors.

Distinct technologies

Modern buildings and other constructed facilities make use of a multitude of specialised technologies which provide individual elements of these facilities. Many of these specialised technologies require the coordinated work of a long series of firms to transform basic raw materials into the elements of buildings and other constructed facilities. The need to repair, maintain and alter the existing built environment means that the industry needs to retain a competence in most of the technologies that were ever used in construction. Consequently, the construction industry's technologies range from traditional, labour intensive, site-based crafts to sophisticated industrialised technologies in, for example, the control systems in intelligent buildings.

Many construction firms specialise in one technology or in a small group of related technologies. Because the industry relies on one-off designs, each project brings many specialised firms together to form a unique project team. Therefore, in addition to individual specialised technologies, the industry uses general contractors, with or without independent design consultants to create an overall design and management framework for individual projects.

There are strong technology trends that are changing the character of construction. Computer-aided design (CAD) systems are gradually integrating traditionally fragmented processes. Prefabrication is moving work away from construction sites into factories. At present this is mainly 'light prefabrication' of sub-components such as building frame members and modules like toilet pods, but discredited large scale building systems may again become viable using CAD and flexible manufacturing technology. Electronic control and communication systems are providing a basis for intelligent buildings and infrastructures that are linking the industry's products with its processes in ways that were previously impossible. Environmental demands are calling into question many of the industry's established methods of manufacturing and constructing its products. For example, there are increasing demands that materials and components should be capable of being recycled.

Types of consumers

The sector is also fragmented because of the particular requirements of different types of customers.

- Most customers are small firms or individuals who have a problem that can be solved by simple construction work, e.g. repairs, maintenance or alterations. This creates an industry with many small firms serving local markets.
- A second category of customer (firms or public bodies) needs more substantial construction work but is not an expert in construction matters. They need professional advice that they can trust and they want to be involved in determining the design, the price and the schedule. They tend to use medium or large construction firms working with independent architects or consulting engineers.
- A third category of customer needs construction work and is experienced in employing an appropriate mix of consultants and contractors to provide what they want. They tend to determine contract conditions to suit their own ways of working and to buy specific services to suit the needs of individual projects. Included in this category are many clients in the public sector and utilities who are required by the Public Procurement Directives to organise competition among suppliers.

End-product sectors

Demand is differentiated also on the basis of the function of the end-product. Thus housing, general building, repairs and maintenance, civil engineering and heavy engineering all provide separate markets served, to some extent, by distinct sets of firms.

Recent trends

Construction activity in the EC countries fell an estimated 3.4% between 1992 and 1993 (Table 1), compared to a decrease of 1.3% between 1991 and 1992. Activity grew in Germany (0.5%) and Portugal (1.5%). The FIEC forecast for 1994 is -2.2% for EC countries. The decline in EFTA countries was even greater. The steepest decline in activity for the 1992-1993 period was observed in Finland (-18.5%) and Sweden (-12.0%).

Table 2 illustrates the growth in the various branches of the construction industry for EC countries. For the period 1991-1992, building output fell an estimated 3.4%, largely influenced by the collapse of non-residential private sector construction, which fell by 7.3% compared to 1992. This performance has cast a cloud over the hoped for revival in housebuilding and underlines the fragility of business and consumer confidence.

Civil engineering output grew rapidly from 1988 to 1991, but began falling in 1992 as budgetary pressures have forced cutbacks in public sector projects in most EC countries. Increased investment in infrastructure is now a priority for the EC.

International comparison

Table 3 compares the EC market with USA and Japan. These are presently the largest construction markets in the world, although construction growth may be more rapid in the future in China and later on in the former Soviet Union and central Europe. Construction output in Japan is of about the same value as the EC, but prices are generally believed to be higher than in the EC, suggesting lower physical volume of output. Deliberate government policy has pushed Japanese gross output steadily since 1985 from 15% to 19% of GDP and construction output per head of population, at around 4 500 ECU, is 2 times as high as the EC average.

There are more than ten Japanese construction companies with a substantial presence in Europe. Six key groups are present in the EC: Kajima, Obayashi, Shimizu, Taisai, Takenaka and Kumagai-Gumi. Japanese construction companies also compete with EC firms in areas including Africa, the Middle East and South East Asia where they have a strong presence. In Japan, they operate through a pyramid of subcontractors, specialists, suppliers and designers, in an industry which is dependent on an interlocking system of patronage and non-contractual relationships. Specialised construction contractors, which have to a great extent pioneered industrial manufacturing of products for construction, compete with these general construction companies, but the construction industry is characterised by complex inter-relationships between these actors.

The US market is also of similar size to that of the EC, but it has recently been overtaken in size by Japan. The US market has the benefit of a common language, currency, economic policy, culture and education system. It also benefits from significant economies of scale in the manufacture of materials and components, and common standards, although it is also true that regulations and market conditions differ in the 50 states, creating distinct local construction industries. US firms are particularly renowned for their construction management expertise. For the EC, the main competition comes from large specialist heavy engineering contractors, which are present in the EC as well as the Middle East, and in South East Asia.

Employment

Table 4 shows the total number of persons employed in construction, amounting to a little under 9 million in the EC, only slightly less than in 1983. Employment has naturally followed construction activity levels, which have been cyclical: it is too early to determine whether the decline in employment in 1992 and 1993 is the commencement of a downward trend in employment, but most countries in the EC and EFTA will register a fall in employment for the 1992-1993 period.

According to FIEC statistics on employment, which may not be very accurate, there are approximately 2.2 million self employed workers in construction in the EC (Table 6). It appears that the number of self employed persons, as a proportion of total employment is greater in 1993 (24%) than it was in 1983 (21%). The country with the largest number of self employed persons registered in the statistics is UK, with just under 600 000, (40% of total employment).

MARKET FORCES

Long term trends

Construction is a highly cyclical market. It suffers from the normal 4 to 5 year business cycle, but its own demand variability is greater than most sectors because private sector demand is dependent on investment by other sectors and it is highly sensitive to interest rates. In practice, prices are affected more than volume, because the construction permit system

acts as a rationing mechanism, and the long gestation time of most projects means that queuing and delays have the effect of smoothing output variation.

In addition to the short business cycle, there are long period fluctuations in demand which do have an obvious effect on output levels: these fluctuations are usually caused by wars and major political changes. In Europe's recent past there is a fairly clear long-cycle pattern. A peak of activity was reached in 1974, after which the oil crisis caused a slump in European construction (and a corresponding boom in OPEC countries) for a period of 10 years until about 1985. The recovery really began in 1987, coinciding with the period from the signing of the Single European Act and the accession of Spain and Portugal, and construction generally boomed until 1990/1. The downturn in 1991 is partly a cyclical reaction to the inflationary pressures of the boom, and to the stock of new empty properties. It also coincides with major structural change in world trade, caused by the end of the cold war, the break-up of CMEA (Comecon) and the collapse of the centrally planned economies. The downturn coincides with a general recession in EC economies.

The long term future is, as always in construction, uncertain. Within the EC, future growth will depend, amongst other things, on the success of EC policies to increase growth, employment and competitivity, on the speed of convergence towards monetary integration and the constraints that convergence imposes on public spending, and on the success of national governments in managing the economies in this period of transition. The greatest uncertainties arise from the influence of external factors on the EC economies. These could include, amongst other things, the economic and security situation in the former Soviet Union, consequent immigration from the east, the speed of recovery in central and eastern Europe, the success of GATT, and the effect on world trade of economic development in Japan (which is faltering) and South China (which is booming).

INDUSTRY STRUCTURE

Companies

The structure of the contractors' sector is similar in certain aspects in most countries. As a general rule, markets are strictly national, regional or local, with no truly European or multinational firms, although some of the major firms are now developing activities in several EC countries, and many have significant export activity. There is a small number (usually 5 to 10) of large firms in each country, a relatively less significant band of medium-sized firms, and then the mass of small firms which are either specialists or work in extremely local (travel-to-work) markets. Although each country has a number of well-known names, there are no dominant firms - the very largest have less than 5% of their home markets.

Some of the large firms are expanding by acquisition of medium-sized specialists or by taking interests in firms in other EC countries. Some medium- sized firms disappear either as a result of acquisition by larger firms (although the large firms are often a constellation of medium-sized firms which usually act independently) or by bankruptcy or break-up, in which case they may spawn a larger number of small specialist firms set up by individuals. The number of small firms and self-employed increased in the late 1980s, but fluctuates with the cycles, and has a high turn-over of entrants and wind-ups.

Small firms

In all countries of the EC the construction activities are dominated by a large number of SMEs, with a very long tail of very small businesses. The number of firms of contractors and employees in construction is shown in Table 6. The data also include some self-employed persons, but not all, depending upon whether these are considered to be one-person enterprises or casual employment. The table shows that 97% of enterprise units have less than 20 employees, and 93% less than 10.

These data do not present a full picture of the employment patterns, because it is difficult to record the true number of self-employed persons. Many workers in employment at any one time may in fact be temporarily employed for a short period or for the duration of a project, and then move on or become self-employed for a time, so that their employment pattern has the characteristics of self-employment. Conversely many people registered as self-employed may have long term employment relationships with a firm, but are registered as self-employed to take advantage of more favourable tax and social security terms. It is probable also that the number of self-employed varies with the business cycle. Workers made redundant in the recession phase may change to self-employment or set up a small firm to carry out repair and maintenance or short term contract work, and such enterprises may be wound up when employment conditions are better.

The statistics on the number of SMEs among contractors disguises the fact that there is a number of distinct types of small firms:

- small general contractors, in either building or civil engineering, working in a local market or a specific market sector. These are really medium-sized firms in the context of construction. They may have several or many contracts, and use a network of subcontractors and self-employed craftsmen. Such firms have a certain stability, but may be family firms which have a life limited by the active life of their managers;
- specialist trade contractors, mainly in the finishing trades but also in specialist structural work, such as roofers, piling contractors, glazing firms, painting contractors, who may operate over a wide geographical market. These if successful will grow and may become quite large, or be taken over by larger groups (and may or may not then continue to trade as independent companies);

Table 3: Construction
Construction markets in the EC, USA and Japan - 1992

- self-employed craftsmen who may be properly registered as small firms, and may work with family members or casual help;
- opportunistic start-ups by individuals, or partnerships, who are made redundant or seek more independence than working for a larger firm, or by craftsmen expanding their range of activities. In some countries these firms are strongly favoured by advantageous social security and other wage related costs for independent workers. Some of these may only last a short period, because they are unsuccessful, or because the owners voluntarily cease trading to go back into employment;
- one-off companies set up for tax or liability reasons by larger firms to develop a single project. There may be a very large number of these in existence which cease to have any life after the end of a project. These are not in any real sense SMEs yet may appear in statistics on the number of firms.

The fragmented nature of the industry is somewhat reduced by long-term networks of firms, or quasi-firms. This is a well developed feature in Japan, and quite significant in USA and EC. Many firms work with regular subcontractors. Some small firms collaborate to share common administration and sales services.

It is also increasingly common for major customers to develop groups of consultants, contractors and subcontractors that undertake all their work. The important point about these networks is that they provide a practical solution to the problems of small firms. The bigger central, paternal firm (either customer or contractor) ensures that the small firms with whom they work are reliable, efficient, up-to-date and innovative. Their reputations depend on this being so. Franchising is also relevant in this context, especially in repairs and maintenance. The parent franchising firm ensures the competence of the small firms who buy into the franchise.

Large contractors

The EC has some very successful big contractors. Table 8 shows Europe's top 20 in 1992. These are mainly based in the larger EC countries, France (8), the UK (6), and Germany (4). Other lists of top contractors in other publications show some differences. Nevertheless, despite contractors appearing in different positions in the various lists and some big contractors not appearing at all in some lists, the general picture is consistent. The EC has about 45 big contractors; that is firms with an annual turnover in excess of 1000 million ECU at 1992 prices. None of the big EC contractors has a turnover (which includes their payment to subcontractors - often 80 percent of their turnover) which reach 5% of their national market.

Many of the EC's biggest contractors are part of groups of companies that work in several industries of which construction is just one. In many cases these groups engage in work in several construction subsectors, e.g. manufacturing materials and components, providing various services (such as transport, water, waste treatment) and owning property-related businesses. This can make it difficult to determine the size of their construction business. This tends not to be the case in the USA and Japan, where contractors generally concentrate on direct construction work.

The EC does not have any contractors as big as the largest US and Japanese contractors, for example, Fluor Daniel (turnover 17 380 million ECU), Bechtel (14 900 million ECU) and Shimizu (25 535 million ECU). It is perhaps significant that all of the very big US contractors are super-specialists in engineering and infrastructure work and operate as turnkey contractors providing mainly the design, procurement, finance and project management services in-house (but with large number of contract staff not permanent employees). They subcontract nearly all site and manufacturing work. The EC general contractors, that is contractors engaged in both building and civil engineering site work, are bigger than their US equivalents. However, the biggest contractors of all are the Japanese, who also undertake a wide range of building and engineering work.

The EC needs some big contractors which are able to compete with the world's giants. It is expected that such firms will

play a leading role in shaping the industry and its public image, and in taking a lead in R&D. This will not however change the overall structure of the sector. It is necessary to keep an industry structure with a large number of small firms, because the supply offered by the construction industry must reflect the demand of the clients. Big contractors will never contribute more than a small share of total construction output, employment and value added (9% of employment for firms over 500 employees in 1988, see Table 7).

Within the EC it is increasingly common for several contractors to joint-venture in bids for major construction projects. For example, the construction and financing of the Channel Tunnel involves international cooperation between some 10 contractors and over 200 banks and other financial institutions. Many contractors believe that new opportunities are to be found through joint-ventures, strategic alliances, mergers, acquisitions and cooperation generally. There are several kinds of advantage from cooperating. It spreads risks, provides access to a range of technical knowledge and experience not possessed by any one contractor, may well provide access to a wide range of sources of finance, and increases the pool of labour that can be called upon.

Some contractors, in EC countries such as Germany, Spain and France, have formal links with industrial banks. This can provide important advantages in access to finance and allow contractors to take a long-term view in developing their business. (Conversely, the very large number of small and micro-firms, with very poor access to finance, hence relying largely on expensive trade credit, leads to instability and higher costs for very small firms.)

To some extent there appears to be a direct relationship between the size of the biggest contractors and the size of their home market. The Netherlands provides one exception within the EC. It has several big contractors. This may be a result of the industrial policy for construction pursued by the Dutch government. Generally, big contractors come from big countries and this suggests that as the single EC construction market becomes a reality, some of the big EC contractors will become bigger. Indeed this has already happened to a large extent, in anticipation of the completion of the single European Market. In the main, this growth in size has been achieved by international mergers and acquisitions. It is reported that there were 198 new intra-European mergers and acquisitions amongst contractors in 1991; the number fell to 86 in 1992. These are mainly acquisitions of shareholdings in other firms. There have been few outright takeovers or mergers. The countries most active in 1992 were France (17 acquisitions of foreign contractors), Germany (14) and the UK (9) (source: European International Contractors: "Mergers and Acquisitions in the European Community" September 1992).

REGIONAL PATTERNS OF DEVELOPMENT

The EC Structural Funds will be the main determinant of future regional patterns of growth and construction demand. Without such regional policy, however, it is likely that disparities would increase. As long as the Structural Funds increase, there should be rapid construction growth in the Objective 1 regions - but problems of absorption in Greece and the government deficit problem in Spain may restrict the growth in those countries for the next few years.

The total volume of financing from EC funds is very significant. For the 1994-1999 period 141 billion ECU are allocated to the Structural Funds, of which 96 billion ECU will go to Objective 1 less advantaged regions, mainly for infrastructure projects. The Edinburgh growth initiative provides a further 8 billion ECU. The Cohesion Fund agreed by Member States as part of the Maastricht Treaty has added a further facility. EIB loans within the EC, which are largely related to infrastructure, run at about 12 billion ECU/year. It can be assumed that around 100 billion ECU of EC funds will be available for infrastructure, or 20 billion ECU/year. If it is assumed that the average EC component more than 50% of total project funding, the EC funds will in effect influence about 40 billion ECU per year, or about 30% of the 125 billion ECU/year of civil engineering expenditure.

The European Commission's White Paper on Competitiveness, Employment and Growth emphasised the importance of infrastructure, and reaffirms Community priorities for trans-European networks and support for infrastructure investment. The allocation of funds to the Growth Initiative may be increased.

The changing pattern of regional growth is illustrated in Figure 1, based on analyses done by DATAR, the French regional development research agency. The main growth will be in

the Objective 1 regions; nevertheless, the absolute size of markets in Portugal, Greece, Ireland is tiny, and Spain is also relatively small. The main construction markets will continue to be in the backbone of Europe (the banana-shaped region from SE England, through western and southern Germany, to northern Italy) and the growing sunbelt region from the northern Adriatic along the Mediterranean France and Catalonia. There is some evidence of convergence of per capita incomes in the EC regions, but recent evidence shows that overall disparities have not changed much.

The current economic reform in Eastern Europe, accompanied by developments towards stable democracy, with increasing levels of aid to that region and the prospect that the Czech and Slovak republics, Hungary and Poland will join the EC in future, are raising the needs for infrastructure in those countries and transport links to them. This is pulling the focus of development towards them. In the short term the collapse of markets in the emerging democracies of east and central Europe has led to a collapse in construction. In the medium to long term, their reform programmes, and the prospect of their accession to the EC, will increasingly divert investment in industry and infrastructure away from the developing regions of the EC12. Their eventual accession would also divert Structural Funds to them. These countries have a large capacity for construction, with ample experience in managing large projects, but their technology is often outdated and the work practices of their labour force are unproductive. In the short to medium term, therefore, their integration into the western economy would tend to depress western European construction markets and increase competitive pressures in the construction sector; in the longer term they will be a large market for the better western firms who can compete on quality or technology, but also powerful new competitors in low-cost building and basic infrastructure.

The possibility of accession of Austria, Sweden, Norway and Finland to the EC, which is possible in 1995, would bring in countries which under existing rules would make a net contribution to EC funds and hence help increase regional development. These countries, however, have construction markets which have been in decline for several years, and they have powerful contractors who are strong competitors for the existing EC industry.

The regional development and cohesion effects of the Maastricht process have a strong positive impact on construction needs, but monetary integration if followed according to the Maastricht programme is likely to constrain the level of construction demand. The convergence process, by which Member States must achieve budgetary deficits, debt and inflation levels within strict limits, will restrict the ability of states to increase public spending. These restrictions are most likely to affect public building and infrastructure programmes. It may also restrict the freedom of governments to carry out an economic recovery policy, since social security payments are higher in the recession and this tends to squeeze infrastructure spending. The White Paper on "Growth, Competitiveness, Employment" sets out policies to try to remove these constraints, including principally the introduction of private capital in public-private partnerships.

ENVIRONMENT

Construction is the industry of the built environment. Environment is one of the handful of major global issues for the next few decades. The construction sector has enormous challenges and market opportunities, as well as new constraints and costs. The industry is developing new services and products to take advantage of the opportunities, and promote its image for positive contributions to the environment. The built environment is to a large extent synonymous with our cultural heritage. It is difficult to exaggerate the importance of this heritage, and conservation is a major task for the construction industry. It is also worth emphasising the importance of local building practice in creating the diversity which is such an attractive feature of Europe's towns and villages. Small firms of designers and craftsmen continue to have a valuable role in maintaining this cultural dimension.

About half of Europe's energy consumption is related to buildings. Energy conservation remains a priority issue. The designers and contractors will respond to the need for more energy efficient buildings, including the use of passive thermal principles. The existing stock of buildings has potential for refurbishment to conserve energy. There is also likely to be increased use of less energy-intensive materials. These changes will be accelerated if energy prices rise through a carbon tax or other macro-economic energy conservation measures.

In some parts of the EC there is growing concern over the availability of natural resources for construction, and the consequences of meeting future demand. This focuses attention on effective use of materials, and recycling. Waste management and the recycling of construction materials need more research and development. There will need to be changes in site practice, and in design principles in order to minimise the use of materials which are damaging or are not recyclable, and to design for ultimate demolition.

The internal environment of buildings is an emerging area of concern, which requires more research and the development of standards related to air quality, microbiology of buildings, allergenic and toxic effects of materials, and emissions from land and buildings.

Energy- and eco-labelling of buildings and products is beginning to be promoted and will create a market mechanism favouring these changes. The analysis of the environmental impact of specific projects is also increasing through development of techniques and enforcement of impact assessment requirements.

REGULATIONS

The special characteristics of the construction industry have frequently been quoted by the industry itself. They mean that in many respects the construction sector is subject to different policy and legislative treatment from other sectors of the economy. In particular, market forces do not always operate in the public interest, there are many "external" effects, and long term benefits can be pre-empted by short-term decision making. All countries therefore regulate construction and government intervenes directly in a variety of ways. These include land use plans and planning controls (which affect land prices), building regulations and standards, planning permits, building inspection, registration of contractors and professions, regulated fee rates, and so on. Governments also directly control a large share of construction work, and provide research, training and information services.

Construction takes place on temporary work sites, out of doors, subject to bad weather, and can be hazardous. Labour is very mobile, and there is a high proportion of self-employment and casual work. Labour and employment legislation and regulation is therefore very important to the industry. Health and safety legislation is also very important.

Some of the major changes in EC legislation and regulations affecting the industry are:

- Public procurement directives. The Works Directive set out procedures for procurement of construction works for projects over ECU 5 million, requiring advertising of calls for tender, use of specified selection procedures, and the use of European Technical Standards. This has some effect on increasing international bidding for large contracts, particularly for very large public works projects. It also increases competition generally even in local markets, and is having an impact on many of the restrictive practices formerly used by some sectors. The Utilities Directive has brought international competition to procurement in many sectors which were previously excluded from public-purchasing rules and which tended to be reserved for national or local contractors: including water, electricity and gas, railways, airports and airlines, telecommunications.
- Construction products directive. Interpretive documents enabling the Construction Products Directive to be implemented were adopted at the end of 1993, and CEN and CENELEC (the European Standards bodies) are drawing up, under Commission mandate, new harmonised European Standards for construction products, and new procedures for technical approval of innovative products.
- Liability and guarantees. There have been changes in the legislation on liability and insurance requirements in some countries over the past decade. In the last two years committees representing various segments of the construction sector have been discussing proposals for possible harmonisation of liability law and arrangements for guarantees and insurance.
- Health and safety. A variety of health and safety measures affect the construction sector. The Temporary and Mobile Construction Sites Directive, which is being implemented, defines new responsibilities for the lead designer and the lead contractor and require a safety plan to be produced for each construction site.
- Posted workers. A proposed directive will require all workers to be employed under the labour legislation and collective agreement terms of the host country. This will have an important impact on the construction sector, which, in some EC countries, uses a lot of immigrant labour.
- Qualification. Proposals are being studied for classification of construction firms, specifically to serve as a prequalification procedure for public procurement, but it would also if adopted have an important impact on quality assurance systems and marketing by contractors, and on selection procedures by private sector clients.

OUTLOOK

Because construction is closely linked to investment, the future demand depends critically upon the success of the European Union in stimulating economic growth. European integration and socio-economic changes are generating increasing needs, but demand is constrained by public expenditure constraints and the financial capacity of the private sector and households.

There has been a fear in some countries that there might be a long-term, or a once-and-for-all drop in construction demand

as population stabilises or declines, and as major infrastructure and housing needs are satisfied. The EC's construction sector strategy study argues against that view. Social and economic changes will generate increasing construction needs and the problem will be to satisfy these needs. The share of GDP for construction needs to increase, but this will be difficult to achieve, because it implies increasing macro-economic savings rates, at the same time as public expenditure is constrained by tax and public deficit restrictions and more expenditure is needed to meet the needs of an ageing population and long-term structural unemployment.

Overall, there are enormous needs for infrastructure investment in Europe, and in most areas there is a problem of housing quality or housing stock. These must be growth areas. Commercial property needs are weaker. The needs of these sectors are dealt with in the chapters on Building and Civil Engineering.

Demand scenarios

The strategic study of the construction sector carried out for the European Commission in 1992/93 suggested three future scenarios:

- An attainable, but optimistic, high growth scenario, with successful improvements in construction performance, shows construction output doubling by the year 2005, and employment rising rapidly at first and then more steadily, to create 5 million new jobs in construction and 15 million throughout the economies of the EC by the year 2000. This scenario promises continual improvements in housing and cities, and the infrastructure to enable Europe's industry to restructure and become increasingly competitive.
- A more conservative scenario, with GDP growth and construction's share of GDP returning to historic levels of the 1980s, shows a return after about 4 years' growth to the output levels attained in the boom of 1990/1, and then steady growth in construction output, averaging 3% per year. This creates 2 million jobs in construction by 2000 and 6 million in total throughout the EC, reversing the decline in employment which took place over the 1980s.
- In a pessimistic scenario, with low growth and a low share of construction, and also low innovation and low productivity growth, the construction output continues to fall for several years, and then grows slowly, but never returning to the levels of 1992, let alone the boom levels of 1990/1. A further 2 million construction workers and 6 million total workers become unemployed, despite continuing labour intensive technology. In this scenario, the living and working environment will deteriorate, and European industry will become increasingly uncompetitive, and the standards of construction are likely to decline.

One of the sector's greatest concerns is the volatility of construction demand. This is of particular concern at present when most countries are in recession after a very rapid construction boom. The volatility is most apparent in prices, since output is smoothed by the effect of lengthening and shortening planning and construction periods. Profitability is therefore very volatile and this severely inhibits long term planning and investment in training, research and capital equipment.

Changes in industrial structures over recent decades, particularly the decline of steel, shipbuilding and coal mining, have led to new construction demand as a result of migration to new growth areas and rise in service industries, and at the same time a severe need (unsatisfied) for urban regeneration in the declining regions. Such changes will continue to occur.

Table 8: Construction

Possible future declining industries could include automotive and European currency dealing. In future, however, the more sophisticated regional policies of the EC (and free market industrial policies) now in place will permit more rapid and efficient responses to such changes than occurred over the past few decades, and will convert construction needs into construction demand more efficiently.

There is continuous rationalisation of industries leading to plant closures, re-investment and relocation, which will be accelerated by EC integration. The EC is also becoming a more attractive target for inward investment by global, particularly Japanese, firms. These changes in the economic structure and consequent migration stimulate new construction needs. The growth of new industries will generate these needs - IT industries and leisure and tourism have been major sources in the recent past. There will be other growth industries in future, not all of which can be predicted now.

Building
NACE 501

The building sector is particularly influenced by the overall economic situation, by both current trends in economic activity and expectations of future trends. Government policies, directly in terms of economic policy, credit and fiscal policies, and indirectly in terms of regulations, play an important role. Competition has increased markedly in both housing and non-residential building; a fall in prices and the level of demand has been followed in some countries by a reduction in capacity. This chapter focuses on the building sector; factors affecting building are discussed in more detail in the previous chapter entitled construction.

INDUSTRY PROFILE

Description of the sector

There are two key sectors in building: housebuilding (residential) and general building (non-residential).

Housebuilding is a critical sector, with increased political recognition, as there are large housing shortages in some EC countries. These relate especially to social housing and affordable housing in urban areas. Immigration is also likely to be a source of increased demand for housing. Generally housing is expected to be a growth market in most regions of Europe.

Statistics show a small excess of dwellings over households in almost all countries, but there are large numbers of households with poor housing conditions and there is a continuing concern in most countries about a housing problem. Because people's housing expectations rise in line with their ability to pay, it is to be expected that there will always be a proportion whose needs are not met. Because of population movements (inner city to commuter belt in richer areas; deindustrialising north to high-tech south in UK and France) the housing stock is not in the right place. The number of households is increasing as household size gets smaller. Large numbers of rural and inner city dwellings in the less advantaged regions are substandard. Many older houses everywhere need modernising and improvement in energy efficiency. There is a particular need perceived in most countries for affordable housing of an adequate modern standard.

The housebuilding industry is well able to respond to effective demand but it is particularly affected by variable and unpredictable demand. In the owner-occupier market, the main problem facing contractors is that potential buyers often find that because of government economic policy, the cost or availability of finance is variable.

There are significant differences in the proportion of owner-occupiers in different countries within the EC. For example, in the UK over 60% of the population have become owner-occupiers, while the proportion in Germany is much lower at about 40%. Some commentators believe that differences in the standards and cost of the houses in the two countries, low in the UK and high in Germany, account for the differences in home ownership. It is likely that relatively high inflation in UK house prices, the availability of 100% mortgages, and relatively low costs of buying and selling houses (typical costs in the UK are 4.5% of the selling price, while in Germany they are around 12%) are at least equally important factors. German costs are not the highest in the EC; in France, Italy and Belgium, estate agents, lawyers and government between them take 16-22% of a house's value when it changes hands. This is a severe handicap for the house building industry.

General building (non residential) involves a variety of commercial, industrial and social building, including very large developments. Falling commercial and industrial property prices characterise trends in this sector. In some sub-sectors of building, such as schools and hospitals as well as social housing, the influence of public expenditure constraints is significant. In most cities, there is now a surplus of office

and commercial space, but still a large need for upgrading offices to suit modern IT-based work practices, and improving shopping areas. Many industrial and commercial buildings are energy-inefficient and need upgrading. Additional needs for new commercial building stock will be mainly in the developing regions, but there will always be new needs to meet changing business requirements and locations of economic activity.

OUTLOOK

The population of the EC has been growing slowly in the past and is projected to increase by 2% per year to 2000 and then begin to decline. The future level of migration, however, is an unknown: it is expected that there will be increasing pressure for immigration from both the third world (ex-colonies and north Africa) and from the CIS and eastern Europe. Immigration policy may well be conditioned by the ability of the housing and social infrastructure to absorb immigrants, and conversely the level of immigration will influence the pattern of demand for housing and infrastructure.

Average household size is likely to continue to fall, perhaps from the present average of 2.7 to the more typical 2.6 of rich countries, thus increasing demand for dwellings, particularly in multi-dwelling buildings and complexes for singles and childless households. More significant, however, is the changing age structure. The number of older people will increase rapidly after 2000, creating increasing demand for sheltered accommodation, and for communities which are designed around an urban structure with minimal transport needs and small local nuclei of social infrastructure (shops, medical, recreation), in amenable locations, possibly far from the main urban and industrial centres.

Civil engineering
NACE 502

Civil engineering principally involves public infrastructure in sectors including transport, communications, energy and the environment. The level of activity depends primarily on demand from government bodies, so the sector is highly dependent on the budgetary policies of governments and public institutions. Pressures on public financing have resulted in lower investment and demand for civil engineering services. In some projects, particularly roads, communications and energy, private sector finance has provided an alternative to government financing, or an additional source of investment. This chapter focuses on the civil engineering sector; factors affecting civil engineering are discussed in more detail in the previous chapter entitled "Construction".

INDUSTRY PROFILE

Description of the sector

Civil engineering provides the basic infrastructure for transport systems and the utilities. Its traditional market has, in the past, been mainly public sector but this is changing because of the privatisation policies being pursued throughout the EC. Privatisation means that contractors will increasingly face a new style of demand. Rather than the public sector requirements for public accountability and administrative convenience, civil engineering will be faced with demands for speed and economy. This will face civil engineering contractors with new and very different management tasks from those which they are used to undertaking.

The EC's needs for infrastructure will create increasing demands for major tunnelling and bridge building. Both of these activities are very competitive on a global scale. Careful programming of these very large projects, so that demand fits the available capacity, could help EC contractors to build up distinctive strengths. On the other hand if the EC does not work closely with the big EC contractors, much of the work could well go to foreign contractors.

Although some contractors, especially in Germany, Netherlands and Denmark see environmental concerns as a major opportunity, some civil engineering contractors see environmental issues as a threat to their work e.g. the anti-roads lobby in the UK has succeeded in delaying some major road building projects. Civil engineering is faced by particularly insistent demands that account should be taken of the possibilities of recycling. Some progress has been made already, especially in road building.

Many of the factors that are shaping civil engineering, also influence heavy engineering. This particularly applies to the growth in attempts to introduce private sector funding into infrastructure projects. Generally, the financing of infrastructure projects is more complex than in earlier times and contractors are increasingly expected to help find the finance for new construction. This increases the range of the risks faced by contractors but can also provide significant additional demand for construction.

These developments have been taken further by some big contractors and represent a major change in their approach. They are taking the initiative in setting up new construction projects. Various combinations of owning, leasing from government, designing, constructing, operating, and transferring back to governments are being planned and put into practice throughout the EC. Proposals are being worked on by contractors for a great variety of schemes and types of construction. A common feature is the central importance of finance. Big contractors today need a sophisticated understanding of finance or at least joint-venture partners with this expertise.

OUTLOOK

- Transport infrastructure: There are increasing needs for investment in transport infrastructure, to cope with increasing trade and movement of people in the single market, to reduce the cost of transport to European markets from the peripheral regions, to promote development and cohesion in the less developed regions, and to reduce the increasing problems of congestion and air pollution in cities.

All modes of transport have urgent needs. The emphasis in the near future will be on completion of European rail networks, and the development of a high speed railway network. Nevertheless the largest volume of expenditure will be on upgrading and maintaining the road systems, and there are still major motorway programmes to be completed. There are important missing road links, particularly across the Pyrenees, Alps, and links to Portugal, Ireland and Greece. Major new road corridors are also needed to link up to Central and Eastern European centres, and the whole of Central and Eastern Europe has huge road building needs. There will also be increased air traffic, needing development of the single European system of air traffic control, and many new airport developments. Further investment in ports and inland waterways is being planned.

The European Commission is taking an active role in the strategic planning of major EC transport infrastructure, and also in planning the links with eastern Europe. There will be EC financing from the Structural Funds, the EIB and for eastern Europe from the aid funds such as PHARE and TACIS.

Car ownership continues to grow rapidly even in the richer EC states (except Denmark). The poorer states will continue to catch up in car ownership. Transport infrastructure and the superstructure of towns will have to be improved for several decades to cope with the motorcar, but for the longer term there will have to be massive investment in improved public transport and people movers. This may be supported by increasing taxation on fuel and cars and increased application of road user charging which will help finance infrastructure and public transport systems.

- Telecommunications: It is expected that there will be a rapid increase in telecommunications investment in the next two decades, both to bring the peripheral regions up to the level of the centre, and to cope with the demand for new value-added services, mobile communications and ever increasing electronic data interchange. Most of the direct investment is in equipment, but it will generate construction work in towers, cable networks, and in upgrading of buildings.
- Energy: The emphasis of energy-related investment for the next two decades will be on energy conservation, and reduction of pollution from existing energy sources. There has been a long period of little investment in new power stations in Europe: investment is likely to continue on a low but probably increasing level, particularly for replacement of older stations by cleaner energy efficient stations (including gas fired stations). The main energy investment will be in extending the networks of gas pipelines and power transmission networks and their interconnection.

A major source of new construction industry demand will come from the rebuilding or decommissioning of nuclear power stations. In western Europe many nuclear stations are now reaching the end of their useful life and will need replacement in the next decade. More importantly there is an urgent threat to public safety caused by the nuclear stations in the newly emerging democracies of eastern and central Europe. To solve this will require a major focus of western aid resources. In many respects the technology for dismantling and disposing of the materials from these stations does not exist. In addition, the size of the civil engineering problem for nuclear waste recycling and radioactive waste repositories, likely to involve deep underground construction, is enormous.

In the longer term new alternative energy sources will become important. Wind, wave, tidal and solar power have not often been viable up to now because they have very high capital costs - largely construction - but low or zero fuel and manpower costs; and because R&D which would bring down costs has not been funded on as large a scale as, for example, nuclear power.

- Water: Total water use is likely to grow, but more slowly than in the past as irrigation and industrial uses are conserved: nevertheless average household consumption varies enormously between regions and is likely to continue to increase as living and housing standards rise. Recent problems of drought and flood, and past lack of investment in several member states, will lead to increasing investment in water collection, transport and storage. Enforcement of EC water quality directives will require increasing construction for water treatment. The environment legislation and municipal waste water directives will require continuing increases in waste and effluent treatment for at least the next 20 years.
- Other environmental needs: waste disposal and contaminated land are further important sources of future construction work.

Industrial plant construction

Like other sectors, European industrial plant construction has not emerged unscathed from the world-wide recession. In 1992 this sector, with a world market share of 51%, appears to have received new orders to the value of about ECU 56 billion. Its high proportion of exports makes it extremely sensitive to all forms of protectionist tendencies. A positive outcome of the GATT talks is therefore essential for this technically forward-looking branch of industry with its 250 000 employees, bearing in mind also the stimuli which it imparts to its supplying industries. In view of the already extremely keen international competition, the hope in this sector is that there will not be any further worsening of the political background. Basically, its assessment of the medium-term outlook is fairly optimistic.

INDUSTRY PROFILE

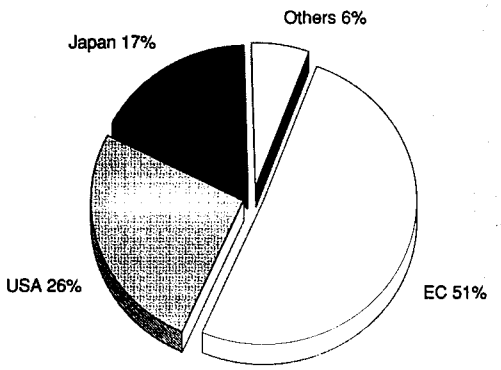
Description of the sector

The construction of industrial plant has two outstanding features: its wide production span and its international structure. Depending on the formulation of the plant contract, its range covers the supplying of a combination of often functionally independent constructional elements such as machinery, equipment, electrical drive units, control systems, connecting elements (steel framework, pipelines, electrical connecting lines) and also building and civil engineering work relating to the plant.

These components together, on the basis of technical production or operating processes, ensure the extraction and preparation of raw materials, the further processing of partially fabricated materials, the making of end-products, the production and transmission of goods and the generation and conversion of industrial energy. The provision of industrial plant is based on comprehensive knowledge of production and operating processes, planning and design, manufacture, procurement and supplying of equipment, assembly and commissioning and also project management. In addition there are important services such as financial engineering and training of the customer's operating personnel.

Important types of plant are thus, for instance, power stations, equipment for the chemical industry, electrical engineering, foundry and rolling mill plant, devices for protecting the environment and plant for the construction and building materials industry. A clear indication of the international nature of this branch of industry is the fact that the European plant construction sector exports its products to nearly 100 countries. Although this sector plays an important role as a measure of the degree of technical development attained by a country, it does not lend itself to uniform statistical recording. The European industrial nations operating in this field all define plant construction in different ways, a particularly difficult problem being where to draw the line between it and mechanical engineering. The same applies to competitors in Japan and the United States. However, regular exchange of experience within the framework of the European Plantmakers Committee (Europlant) does provide an overview of the world-wide trend of business.

Figure 1: Industrial plant construction
The world market for plant-makers



Source: Europlant

Recent trends

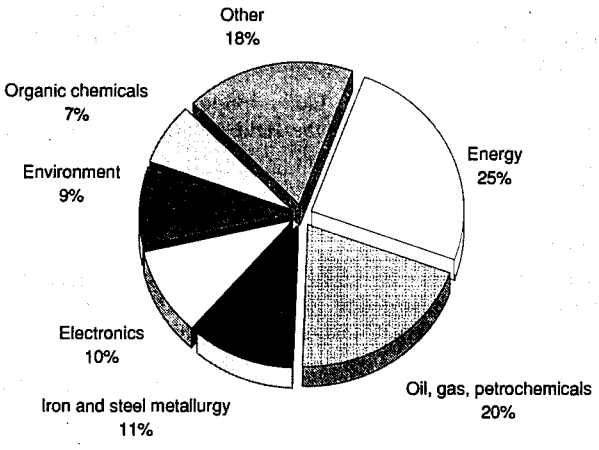
At the beginning of the 1980s plant construction companies were still benefiting from an investment boom chiefly stemming from the surplus oil revenues of a few developing countries. The subsequent collapse to an all-time low was followed by a generally very steady rise of about 10% per year in the volume of orders. The European plant construction industry survived the severe recession in the capital goods industry in 1991 and 1992 relatively unscathed. Experience has shown, however, that the repercussions of recessive trends in the customer industries affect industrial plant construction with a certain time-lag, so that the slumps currently occurring in other branches of industry might still in some cases be just about to affect plant construction.

International comparison

According to various rough estimates, the annual amount of major industrial engineering projects put out to tender is probably between ECU 100 and 125 billion.

Owing to the shortage of statistics, the distribution of world market shares in industrial plant construction is chiefly based

Figure 2: Industrial plant construction
Breakdown of contracts by industrial sector



Source: Europlant

on estimates. The reliable data available for mechanical engineering, however, can to some extent provide a reference point. On the other hand, an industrial nation will be more capable of winning a world market position in general mechanical engineering than in plant construction. That is why the number of potential suppliers of industrial plant to be reckoned with worldwide is confined mainly to three groups: tenderers from the European Community, the United States and Japan. While newly industrialised countries such as South Korea, India and Mexico are already appearing as serious competitors in individual cases, they do not as yet have a wide and continuing range of products to offer. European plant construction would appear to have just over half the world market. The United States, because of its huge domestic market, has over a quarter. Japan's share is 17%.

MARKET FORCES

Demand

Perception of the sectoral breakdown of orders is distorted because the various European suppliers concentrate on different fields of operation. As a generalisation it can, however, be said that the largest proportion of orders - 25% - is accounted for by power stations and 20% by plant in the oil, gas and petrochemicals sectors. On the other hand, the shares in the categories of steel mill construction, protection of the environment and electrical engineering equipment was considerably smaller.

Exports account for 45% of the volume of orders, and a quarter of the latter come from within the European Community. The leading importers during the past decade have been the United States, the People's Republic of China, the former Soviet Union, Iran and India.

From the technical angle, there is less demand than formerly for new industrial complexes on a turnkey basis. Instead, customers are displaying greater interest in modernisation and rationalisation measures, with more importance attached to energy saving and protection of the environment.

Supply and competition

World competition is characterised by a merciless price war. This is forcing suppliers in the European Community with a high domestic cost level, in particular, to seek to obtain the supplies they need from trading partners situated in less expensive places. While this trend has remained confined to hardware in recent years, European plant constructors have recently begun, under the pressure of costs, to offer engineering services also from countries where costs are lower. This has led to the loss of a considerable number of jobs in the European Community. In addition to the price war, a point worthy of mention is the increasingly observable failure to fulfil conditions. The hunger for orders on the part of many competitors has made them willing to make irresponsible promises with regard to guarantee periods, performance undertakings, penalties or the provision of additional items or services.

Finally, another important factor influencing competition in the sector can be found in the field of financial conditions.

INDUSTRY STRUCTURE

Companies

During the last twenty years the great demands made in industrial plant construction have led to an appreciable thinning-out of suppliers. Constant participation in protracted and expensive tendering procedures is nowadays possible only for major companies, which endeavour to cut costs and reduce risks by strategic alliances and international co-operation arrangements. This can adversely affect mobility and creativity, which tend to be the characteristics of small and medium-sized firms. On the other hand, European industrial plant construction still has the advantage of a high technical standard which, if maintained, will enable this industry to continue to play a leading role internationally.

ENVIRONMENT

Considerations of environmental protection are playing an increasingly important role in the engineering business, although, unfortunately, many customers have still not realised that the necessary investment in the plant under this heading is liable to increase the price considerably. Customers are not automatically willing to pay this higher price, because they feel that additional expenditure on environment-friendly plant does not contribute to productivity.

Another important problem is the difference in standards of environmental protection in the countries of the European Community, which has a distorting effect on costs. Suppliers in countries with a propensity (albeit concealed) to environmental dumping are gaining unjustified competitive advantages in this field.

REGULATIONS

Whereas, owing to national assertions of competence and selfish attitudes, there is no hope of seeing, in the foreseeable future, any genuine harmonisation of the different systems of export financing and export credit insurance, which is a matter of paramount importance for competition, the Commission is working on a Council Directive on the sending of personnel to other countries for the performance of services. If these plans materialise, they will push up costs substantially.

OUTLOOK

The course of the European plant construction industry's business in 1993-1994 will depend on how investors in the major branches of industry cope with the recession. The tendencies now prevailing in Europe's chemical, steel and automobile industries give few grounds for optimism. This situation will force European competitors to resort to the international markets, where, as in the past, they will encounter competition from Japan and the United States. The hopes of market opportunities in Eastern Europe following the collapse of the former political systems have not been fulfilled. There is undoubtedly a huge pent-up demand here, but one which, as far as can be seen, cannot be financed without great joint efforts. In the Far East many hopes are pinned on the People's Republic of China, which, after the political opening-up, offers chances especially to major plant construction companies which are prepared to commit themselves in the form of co-operation and joint ventures.

Despite the present state of the world economy, the European plant construction industry is not without optimism for the medium and long term. It will continue in the future to be one of the forward-looking branches of industry in the European Community.

Overview
NACE 61-65, 67

The EC distribution sector is undergoing considerable restructuring. Changes include concentration, reduction in the number of traditional wholesalers, transformations in the retail sector and a tendency towards diversification and internationalisation. Moreover, the future of the distributive trade sector will be influenced by the completion of the internal market and the opening-up of Eastern Europe.
The sector represents about 14% of output and employment in the European Community. These figures have remained relatively constant over the last ten years, showing that the distribution sector has grown in line with economy.

INDUSTRY PROFILE

Description of the sector

The industry is divided into two subsectors: wholesale distribution and retail trade.

Wholesale distribution (NACE 61) is defined as "units exclusively or primarily engaged in the resale of goods in their own name to retailers or other wholesalers, to manufacturers and others for further processing, to professional users, including craftsmen, or to other major users".

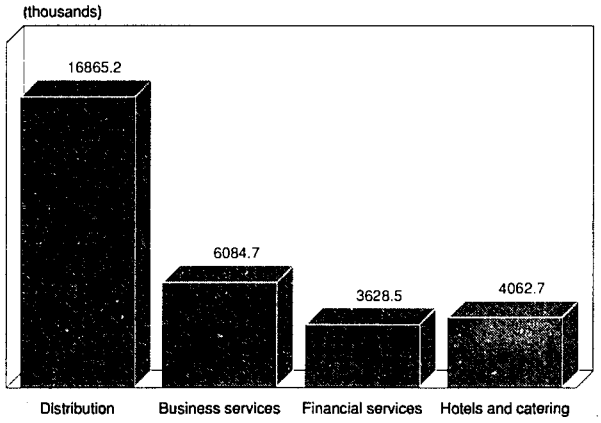
Retail distribution (NACE 64 and 65) is defined as the distribution to final consumers of:

- food, drink and tobacco;
- dispensing chemicals;
- medical goods, cosmetics and cleaning materials;
- clothing;
- footwear and leather goods;
- furnishing fabrics and other household textiles;
- household equipment, fittings, appliances, hardware and ironmongery;
- motor vehicles and cycles;
- motor fuels and lubricating oils;
- books, newspapers, stationery and office supplies;
- photographic, optical, jewellery and other retail distribution.

These definitions describe the function and product areas characterising wholesalers and retailers. They do not cover the fact that many organisations perform both functions, or that the ownership of wholesalers and/or retailers may reside in operators from another subsector of the supply chain (such as manufacturers), or that manufacturers in some areas carry out their own wholesaling and retailing and are not thus covered by the statistics for the latter sector.

A further important point is that the definition of wholesalers ignores the increasingly wider role that many operators within the sector are playing. For example, the change in manufacturing to tightly-managed production techniques (such as Just-In-Time) means that the whole distribution chain is becoming more sophisticated, and that wholesalers are also taking on functions such as packaging, quality control and administration. None of these is included in the NACE definition, but they nevertheless affect the contribution to the economy of the sector as well as the profile of the wholesaler.

Figure 1: Distribution
Employment compared to selected sectors, 1991 (1)



(1) Excluding Italia
Source: Eurostat (Labour Force Survey)

INDUSTRY STRUCTURE

There is great change occurring within and between the subsectors of the distribution industry. This change can be summarised as:

- concentration, expressed in terms of a reduced number of larger operators, and closer vertical links between manufacturers, wholesalers and retailers;
- a general reduction in the number of traditional wholesalers, bearing in mind the fact that the concept of wholesaling seems to have different meanings within different Member States;
- a series of transformations in the retail sector, with significant differences between Member States. Overall a slower increase than before in hypermarkets, a rise in franchising and a proliferation of forms of distance selling are prominent features;
- a tendency towards diversification of activities into other service areas and some specific moves towards internationalisation.

The concentration phenomenon is more evident in northern Member States, with not only a rationalisation in the direct retail sector, but also the emergence of purchasing groups and voluntary chains to benefit from economies of scale.

Wholesaling is often thought of as an activity of the past, in that the traditional operator now often finds himself squeezed out either through a manufacturer's wish to control distribution himself or through the large retailer's practice of upstream extension.

However, some forms of wholesaling are on the increase, such as wholesaler-owned voluntary chains and specialist operators who focus on specific end-users (such as schools and hospitals). "Traditional" wholesaling does survive in raw materials and bulk products because of the logistics involved.

Geographic variance remains of great importance in the structure of the distribution industry. The structure of retailing continues to evolve, with marked differences between the north and the south of the Community. In the north, concentration

and larger outlets are the new trends. In the south, smaller shops remain very prominent.

An interesting trend is emerging within the retail sector, whereby,

- retail groups are the typical operators in food retailing;
- voluntary chains feature in non-food retailing; and,
- franchises are moving into services (travel, financial services etc.) as well as goods.

Diversification of activities is occurring, whereby producers (typically non-food) set up retail operations, or where retailers offer services such as travel, financial services, restaurants, etc.

Internationalisation tends to occur towards neighbouring Member States at first, because of cultural similarities. Non-food retailers are the operators most prone to internationalise, with great attention having to be paid to national consumer tastes. The Euro-consumer does not yet exist, even if consumption patterns are moving closer together.

REGIONAL DISTRIBUTION

The most obvious influence of geography on the sector is in the different definitions of what a wholesaler is, and in the role of the small retail outlet.

In Germany, for example, wholesaling tends to be thought of as the distribution and procurement activity of manufacturers. In France, the tendency of manufacturers to subcontract sales activities and of retailers to subcontract buying, results in wholesaling being seen as a large growth sector. The Dutch import-export agencies, which are major economic operators, contribute to that country having the feeling that the sector is dynamic, while in the United Kingdom, a more restrictive view is taken, namely that of the old-style "middle man" between manufacturer and retailer, now in decline.

Taking these differences of perception into account, the major feature of geographical variance in wholesaling is that the northern Member States exhibit much more evidence of a blurring of activities between manufacturer, wholesaler and retailer then do those in the south.

For retailing, countries in the two main groups - Mediterranean and Northern Europe - may have similar sales formats, but these may not be at the same stage: concentration in retailing is thus correlated with the level of economic development of the Member State, except for Italy, which retains its high number of small shops. Franchising, cooperation networks in general, discount shops and non-shop retailing are also notable for some geographic variance, explained in the monograph on retail distribution.

ENVIRONMENT

Traditionally, the distributive trades have been seen as pure intermediation functions, only operating in response to supply impulses, and therefore not at all involved in the environmental debate. This view, however, is set to change. Distributors, especially purchasing centres in the retail sector, are increasingly playing a pivotal role in translating trends in consumer preference into final demand and are thus able to boost the sales and the production of so-called "eco-goods".

Moreover, more and more distributors are taking on new functions, including packaging. This activity entails a series of environmental issues which has to be taken into account by the sector.

OUTLOOK

The changes inherent to the sector itself (concentration, increased used of technology, vertical integration and diversification) must be seen together with extraneous developments such as the creation of the Internal Market by 1 January 1993 and the potential opening-up of East European markets.

While the achievement of an integrated EC market will require a European distributive systems (and the Community's actions in the transport, competition, investment, structural funds and enterprise policy areas are helping this to come about), operators in the distributive sector face two conflicting pressures in seeking to meet the challenge. The first is the increased competition from other Member States as the concentration and integration in the sector, encouraged further by cost reductions following the completion of the Internal Market, forces them to broaden their horizons and seek cross-border opportunities. The second feature is the continuing requirement to respect local culture in delivery of services, a feature which reduces the scope for rationalisation and internationalisation.

The key may thus be effective streamlining of operations through technology, enabling the operator to carry out more activities at an overall higher level of sophistication. Electronic

Data interchange (EDI), Electronic Point-of-Sale (EPOS), and Direct Product Profitability (DPP) techniques are used widely as essential tools in upgrading activities.

The problem is, of course, for smaller players, who may find that the required investment in technology is too great for them to support.

The opportunities created for logistics planning and management by the abolition of internal frontiers should contribute to expansion in physical distribution activities. Taken together with the liberalisation in road transport, this area should see major change. This will in turn produce a situation where distribution strategies will influence consumption patterns and where marketing activities typically performed by manufacturers may be taken on by distributors and traders.

Lastly, reduced consumer spending on retail goods will reinforce the battle for market shares and therefore influence the present structure of the industry.

Wholesale distribution
NACE 61

Wholesale trade is a hidden force in the European economic process. It employs more than five million people (4% of the EC working population) and consists of approximately 700 000 businesses. It provides the integration of different added value functions that have to be performed to distribute products from manufacturer to users such as catalogue composition, sourcing, storage, assembly, re packaging, distribution, support and financial services. The position and power of wholesalers in the distribution chain depend on their ability to create unique added value for suppliers or buyers. Based on the distribution dynamics wholesalers have three strategic options: distribution partner for suppliers; sourcing partner for buyers; and integrative wholesaling. The single European market and the opening of the Eastern European market create many opportunities among which are the need for European wide distribution networks, integrated chain management to create total quality for buyers and alternative distribution modes. The European wholesale trade has a strong base to face this challenging future.

INDUSTRY PROFILE

Description of the sector

Wholesaling is a difficult activity to define. Its function has evolved over time and different types of wholesale organisations still coexist in various phases of development stages. There is still, according to the NACE 61 code , a definition of wholesale distribution. This class includes units exclusively or primarily engaged in the resale of goods in their own name to retailers or other wholesalers, to manufacturers and others for further processing, to professional users, including craftsmen, or to other major users. The goods can either be resold in the same condition or after undergoing the kind of processing, treatment, packing or repackaging to which they are usually subjected by the wholesale dealer. Generally speaking, the latter's role involves, on one hand, the storing of goods and, on the other hand, taking title to and/or having the right to dispose of the goods in question. In addition to a breakdown according to range of goods, there are classifications based on other criteria which are also useful for the wholesale trade, e.g.: breakdowns according to economic links and geographical area of activity (import export, transit and domestic trade).

Wholesale trade provides the integration of different added value functions that have to be performed to distribute products from manufacturers to users.

Increasingly, wholesaling is focusing on the flawless execution of integrative management because many of the functions, especially those with capacity-like characteristics, can be contracted out to specialised third parties. The wholesaler will always perform the most critical functions which truly create the added value for the buyers by himself. Transport and distribution, for instance, are outsourced while the composition of the assortment is performed in house. Storage could also be outsourced, but is rarely done. The position and power of wholesalers depend more and more on their ability to create unique added value for suppliers and buyers in the distribution chain.

Throughout the distribution chain the functions necessary for the economic process can either be found within independent wholesale businesses or upstream and downstream in the distribution chain with sales companies of suppliers or purchasing departments of buyers.

The function of the wholesale trade is focused on the transformation of processes surrounding purchasing (creation of large volumes, sourcing, storage, catalogue composition and inbound logistics) into those surrounding sales (market oriented assortments and services, commercial support, distribution, customer service and training). Wholesale trade is, therefore, bridging differences in the distribution chain between place, time period, quantities, capacities and price requirements.

Wholesale trade is a very diverse service industry. It performs its intermediate role throughout the total economic process from raw materials to final end user products. The sector's divisions, therefore, can be very diverse. Orientation by product would produce divisions like raw materials, semi finished goods and non-food and food consumer products. Geographic orientation results in subsectors such as international trading houses, importers, exporters and, for the domestic markets, distributors and cash and carries can be distinguished. A functional orientation will produce sections such as logistics service providers (physical distributors), commercial traders (agents), financial brokers and the full service wholesaler. The sector

can be partitioned by types of ownership like integrated wholesalers (sales companies and purchasing departments/companies) and independent wholesalers.

International comparison

All Member States have their own distribution (infra)structures and trade history. Therefore, we cannot speak of one EC wholesale service industry. The scope of this monograph does not permit an in-depth analysis of the differences, but in the following paragraphs, some characteristics are described.

France

The wholesale trade holds a strong position in the French economy, especially in the international trade business. Concentrations have taken place resulting in the emergence of large, multi dimensional trading houses with specialised divisions. These international trading houses are strong in food and capital goods. In the domestic market, cooperative structures have emerged between regional wholesalers to share resources. Typical for France are also the wholesale centres where a variety of wholesale companies work together and present themselves together to the market. The French wholesale trade is especially strong in non-food consumer goods and industrial supplies. In the French food market, wholesale trade has decreased.

Germany

The wholesale trade position in Germany is comparable to France. A strong concentration has recently taken place and is the reason why the average wholesale company in Germany is larger than in the other EC Member States. The German wholesale trade is especially strong in industrial supplies. In food, its the wholesale trade position has been taken over by the strongly concentrated retail sector. Large parts of the national imports and exports are organised by international trading houses. Often, these trading houses have historical links with the steel industry. The concentration and the links with powerful industries have made of the German wholesale trade a professional service industry with a respected reputation in the labour market; professional in the sense that substantial investments are made in systems and procedures to create new added value services.

United Kingdom

The wholesale trade in the United Kingdom is especially strong in non-food consumer goods. The concentration in the retail business has limited their role in the food market. Contrary to the other Member States, food wholesalers in the United Kingdom started voluntary retail chains to counterbalance the power of the retail giants. In the exports and imports business, independent merchants play an important role as well as the international trading houses. These trading houses are important namely for the imports of machines, means of transport and agricultural products. Exports merchants and trading houses are involved in approximately 40 50%. For imports this is much less (15%).

Italy

Most wholesale companies are of medium to small size: 93% of them employ less than 10 people. Traditional, family-owned companies are still mainly located in the southern regions.

There is a big difference between food and non-food wholesale: the former has been stable during the 1980s due to the rapid concentration of food points of sale and to the stronger concentration of the volume of goods dealt with by large distributors. The latter, on the other hand, has been developing in all the non-food marketable goods, following the trend towards fragmentation and specialisation of non-food retail.

The Netherlands

The Netherlands has a strong wholesale sector just like Germany and France. They are very internationally oriented and offer overseas producers European distribution. They also play an important role for the imports and exports; approximately 60-70% of the imports are organised by the wholesalers as well as 30% of the exports. There are some large international trading houses with strong Asiatic links. Strong wholesale sectors are capital goods and agricultural products.

Belgium

The majority of the Belgian wholesalers are small or medium sized and often family-owned firms with a local area of operation. In international trade, larger cooperative organised wholesalers play an important role.

Denmark

Denmark probably has the highest concentration in wholesale trade. A few large wholesalers and trading houses (for international trade) dominate the primary distribution level. Food and non food consumer goods are their main markets.

Ireland

Ireland has, like the South European countries, a fragmented distribution structure. Therefore, the wholesale trade in Ireland is also an important linking pin. The international trade is dominated by the English trading houses.

Southern Europe

Spain, Portugal and Greece are characterised by a very fragmented distribution structure. Retail and wholesale trade are small scaled and have a traditional orientation. In all sectors, wholesaling plays an important role. Wholesale trade holds an especially strong position in imports of capital goods. In exports, the wholesale trade in these countries maintains a strong position in the textile and agricultural product markets. In Spain, the concentration process has started, initiated by foreign investments.

Eastern Europe

Eastern Europe does not have a specific wholesale culture. Large state owned departments had taken and still do take care of the distribution of goods and materials. The larger European wholesale companies invest in Eastern Europe to build up a wholesale market for foreign products. They possess the international trade and distribution logistics know-how that the state-owned companies lack to a large extent. Wholesalers who open up subsidiaries in Eastern Europe have to face the limitations of poor infrastructures and an almost non-existent communication networks. Eastern Europe is, for many wholesalers and trading houses, a challenging market.

Japan

The distribution of machinery in Japan is influenced by history and social structure. The large trading houses, "sogo shosha", are economically and politically powerful business entities. Their primary role is providing links between various industrial activities and parties, benefiting from their own global information network and their financial ties. Although the Japanese multi level distribution structure is very effective, the EC distribution structure tends to be more cost efficient. In Japan, distribution fulfils a strategic function, perceived as being as important as technology. This makes Japanese producers more powerful (and threatening) in the market.

USA

The distribution structure for machinery in the USA is more or less similar to the EC, although distributors in the USA focus more on satisfying customer needs and service requirements. The market focus makes producers and distributors organise distribution according to the grouping of client's needs. Distribution in the USA is used as a strategic tool to realise corporate objectives.

Supply and competition

Wholesaler functions are performed at different stages in the process from raw materials to end use. This process can be divided among the supply and distribution chain. Raw materials and semifinished products typically apply to the supply chain, while capital goods and consumer goods apply to the distribution chain. In both chains, different requirements exist for logistics, commerce and finance. The customer service requirements in the distribution chain, for instance, differ greatly among the three distribution options.

The structure of the supply and distribution chain is based on the efficiency and effectiveness of distribution rules. The smaller and more numerous the buyers, the more distribution levels are necessary for effective distribution. The price levels depend on the multiplier which is determined by the distribution flows in the total market. These price levels are more or less balanced and justify the lines of supply. Therefore, a wholesaler will not, in the long run, supply large buyers because the margin is too small and suppliers will not distribute to the medium sized buyers because this will ask too much sales effort. The wholesale trade is influential in the distribution chain because it gives direction to the lower levels and distributes directly to end users and industries. By this very fact, the wholesale trade influences direct deliveries from suppliers to end-users.

The European economy is going through a change process that largely can effect the distribution chain and the position of the wholesaler. Many important changes are the integration of the value chain, direct delivery from supplier to retailer and an increase in product range. The integrated value added chain is dismantled so that shifts take place down-stream and up-stream leading to concentration and specialisation of European production units. For example, assembly or customisation of packaging will be outsourced to third parties near the customer base. This creates added value opportunities for wholesalers. More and more, fast moving products are delivered directly from supplier to the retail outlets or the end users. This trend is strongly initiated by the decreased transport lead times and improved information technology. The value of a wholesaler being located close to the market becomes less important. Suppliers are still increasing their product ranges to satisfy the demanding customer. Numerous articles will not be delivered directly because turnover volumes are too little. The logistic role of the wholesaler, therefore, will focus more and more on storage and consolidation.

For many industries, distribution is becoming a key factor for success. Especially in mature businesses where product quality and specifications very quickly become standards. The only discriminating factor will be the variable features of the products (customer service and availability) provided by distributors.

The industry focuses more on core business and searches for specialised partners to take care of distribution and customer services.

New parties enter the market for distribution services such as specialists in warehousing and physical distribution that provide European distribution services to large manufacturers. These logistics service providers do not interfere with the commercial process (like wholesalers do) but often, these suppliers take care of marketing and sales, or plan to do so. These specialists are ready to take over the logistics activities of industry and wholesalers because they have their information systems in place and have locations throughout Europe. They are often part of large transportation companies willing to invest in the creation of these services. Their margins are substantially lower compared to the wholesale trade, but do not include the full range of additional services wholesalers offer.

Source: Gathered by A.T. Kearney from various sources

Although wholesaling is local business, internationalisation and concentration through mergers and acquisition will continue for reasons of economies of scale in sourcing, warehousing and formula exploitation. Large European suppliers ask for distribution partners that can supply European distribution services.

Professionalisation of management techniques, profiling and market approach will continue on all levels such as commercial profiling, formula development, and the use of managerial techniques which are already used in other business sectors (direct product profitability, market segmentation and private labelling).

Suppliers and buyers require improved integration of business processes in order to realise higher levels of customer service at reduced cost. The developments in electronic data interchange (EDI) provide excellent opportunities to link the business processes of the different players in the distribution chain. The use of bar-coding and scanning techniques and on line computer links will, to a large extent, impact cost efficiency, human resource policies and the need for large investments (in the initial phase).

INDUSTRY STRUCTURE

Companies

The wholesale trade employs approximately 5.5 million people, which is 4% of the EC working population. The differences between the Member States are minor. Female employees account for approximately 30% of the EC wholesale trade work force. For the individual Member States, these percentages vary between 23% (Ireland) and 38% (Germany).

The turnover generated by the wholesale trade in the EC is around ECU 1 750 billion. Turnover has grown during the last years in most Member States by 2% to 3% annually. Important growth sectors were capital goods and agricultural products.

Almost 700 000 businesses are involved in wholesaling in the EC. The majority of these businesses are small scale with about 75% employing less than 10 persons. Only 5% of the businesses are responsible for 30% to 40% of the total turnover. Most of these large businesses can be found in the steel and electrical sectors. The wholesale trade in the southern countries, in particular, operate on a very small scale. In Germany and France, one can see a trend towards concentration.

The structure of the wholesale trade is largely due to the rather low entry barriers for new businesses such as minimal legal requirements, no specialist education required and relatively low start up investments. Therefore, many wholesale businesses start every year and many also fail after a while. Research has shown that half of all new wholesale businesses fail within the first five years of their existence.

Strategies

In the distribution chain a power struggle is going on. The four areas where the relative power position of the players in the distribution chain differ are the areas of the large brand suppliers, the large purchasing chains, the wholesalers and where large brand suppliers share margins with large purchasing chains.

The situation in many markets differs largely. In the food market for example, the big brand suppliers and large retail stores struggle for dominance, which has caused a repositioning of wholesale trade. In the electrical materials market, the independent wholesalers are dominant although the brand suppliers become stronger and stronger. Another example is the toy market where chains have taken over the position of the wholesalers. In capital goods it is still the wholesalers/importer (which can also be the sales companies of the manufacturers) that directs the distribution chain.

In this power struggle, wholesale trade has the largest added value for medium and small sized buyers who do not have the facilities and volumes to buy, import and export directly from suppliers.

The strategic options of the wholesale trade depend on the market situation. In a market situation where many buyers exist as well as many suppliers of 'me too' (or non unique) products, the role of the wholesaler is typically the 'independent specialised' one. This market situation requires the typical wholesaler, who has a complete catalogue, to perform the requested logistics services well and have good sourcing channels to more or less cover all its clients' needs.

If, however, the market situation is different in the sense that only a few unique suppliers exist with many small buyers, the wholesaler should be a distribution partner for these suppliers. In this case, the wholesaler is specialising in logistics services such as storage, distribution, information (EDI) and customisation.

In the third case, when there are a few large buyers and many 'me too' suppliers, the opposite happens. The wholesaler is a sourcing partner for the buyers, taking care of the well organised supply, product selection and efficient sourcing.

These three market situations require three different strategies.

Option I: Distribution partner for suppliers

Based on the market situation with many buyers and a few unique suppliers, the wholesalers provide distribution services to the European manufacturers. These services are usually geared towards: making available products as 'wide spread' as possible (European distribution), offering customer services throughout Europe to the buyers, having up to date EDI systems with on line links in the suppliers information system, providing inventory management and providing market information to suppliers. The suppliers often have branded products and take care of marketing themselves. They often need a partner to take care of the logistics operations and distribution, however.

Option II: Sourcing partners for buyers

When many 'me too' suppliers share the market and only a few large buyers dominate the demand, the strategy calls for a sourcing partnership with these buyers. On a tailor made basis, these sourcing partnerships can offer: global sourcing of products, account management, storage facilities and inventory management and integration of supply with the buyers' just in time needs. The wholesaler in this case becomes an integrated part of the (reduced) purchasing department of a selected number of buyers.

Option III: Integrative wholesaling

In the many buyers-many suppliers situation, the wholesaler fulfils the total range of consolidating and integrating functions in the field of commerce, logistics and finance. The critical functions are: the creation of catalogues and their actualisation, effective usage of direct product profitability mechanisms to know the profitability of products and client groups, high quality EDI systems to create quick response services and creative and innovative power to actualise services offered, add new products and services and to professionalise the organisation on a permanent basis. In real life, these three strategic options can be implemented within one wholesale company for its different market segments. The organisation has to fit the implementation of the three different strategies in the organisational principles which means separate management procedures and systems.

REGULATIONS

The EC regulations will also effect, directly or indirectly, wholesale trade in Europe. The sector will be directly influenced by a set of previously adopted measures concerning VAT harmonisation, product liability, the status of trade agents, exclusive agreements, safety, technical standardisation and competition.

Regarding VAT harmonisation, under the terms of the agreement of June 25, 1992 (Directive 92/680/EEC), from January 1, 1993 the Member States must have a standard VAT rate of at least 15% and abolish the higher VAT rates. They will be allowed to maintain the zero rate and the extra low rate (1% and 4%) which were existing on January 1, 1991, but will not be allowed to introduce new reduced rates except for Spain and Luxembourg who will be able to apply new extra low rates. The VAT will be collected in the country of destination. This means that pre-financing is no longer necessary for companies selling products in other Member States. Definite decisions on this part have not yet been made.

The internal market will also entail harmonisation of the rules regarding product liability. The regulation (Directive 85/374/EEC) speaks of a reversal of the burden of proof. The plaintiff will no longer have to prove fault on the part of the defendant. Another change is that not only is the manufacturer considered the producer, but the importer of products from outside the EC is deemed to fulfil the same role. This regulation will lead to increased costs (supplementary insurance premiums, higher claims for damages, increased number of claims) for wholesale companies which import products from non EC countries, wholesale companies that market goods whereby the consumer cannot discover the identity of the producer, wholesale companies selling goods under their own brand name and wholesale companies which change some part of the goods.

Directive 86/653/EEC regulates the position of the independent trade agent. The purpose of this regulation is to stimulate freedom of establishment of agents within the EC. This directive regulates the relationship between the principal (i.e. machinery producer) and agent including their mutual rights and obligations, such as providing each other with appropriate information and compensation and the ending of the agreement.

Contrary to agents and producers, distributors are not very well protected in the EC. Only in Belgium and Finland are distributors actually protected and entitled to legal indemnity. Although a more positive jurisprudence towards legal indemnity for distributors is developing, the distributors are still at a disadvantage as compared to the producers with respect to legal protection.

Exclusive agreements between producer and distributor are not allowed in the EC because protection of territory is prohibited. The EC council directive 83/83/EEC lists some conditions under which an exclusive agreement between supplier and distributor is exempted. There are bilateral agreements between one supplier and one distributor, concerning the resale of goods (not services).

Directive 89/655/EEC requires that all existing, new and second hand work machinery and equipment comply with the minimum on safety and health. The consequences of this directive are a simplified inter-community trade, decreased costs and therefore increased exports. The harmonisation of the safety requirements is visualised through the introduction of the EC label.

In 1992, the European Commission published a Green Paper on reform of the Community's efforts in the field of standardisation. The aim is the creation of uniform standards in sizes and weight, qualifications, safety, hygiene and veterinary requirements and all other technical standards which are specific to certain sectors. This harmonisation will simplify and stimulate international trade. The European Commission has now proposed the creation of a European Standardisation Forum, increased participation of interest groups and advocates greater visibility and implementation of European technical standards.

The European Commission stimulates free competition. Concentration of industries creates economic advantages but should not limit free competition. The EC therefore prohibits mergers leading to possible unfair competitive positions (Directive 89/4064/EEC). Mergers between companies that have to be examined by the Commission have two characteristics. These are: the aggregate worldwide turnover is more than ECU 5 billion and the aggregate community wide turnover of at least two of the companies concerned is more than ECU 250 million.

Besides controlling the wholesale service industry through directives the EC acts as a stimulator of alliances to share know-how and cooperate on technological innovations. The European Interest Grouping is the first EC legal entity that enables European companies to cooperate on a legal and European basis.

In addition, the EC works indirectly as a catalyst for the wholesale service industry through the liberalisation and harmonisation of transportation and financial services, making international trade easier and financially more attractive. Cost advantages because of the liberalisation and harmonisation could be partly counter balanced through increased preliminary controls and certification.

OUTLOOK

The European wholesale trade has a strong base for the future. It performs functions that have to be performed at some stage in the supply and distribution process. In some market sectors, it holds a strong position while in others, its functions have been integrated with suppliers or buyers. For the coming years the European wholesale trade faces some interesting challenges.

The single European market is expected to boost the European economy. Also, manufacturers are concentrating on their core business while leaving the other business processes to specialists with local, technical and logistics knowledge. Both facts are developments that can contribute to a strong future position in the wholesale trade.

The single European market and the opening of the East European market will require European distribution networks. Logistics service companies are building up these networks which include sophisticated communications networks. Wholesalers have to take part in the creation of these European distribution networks through alliances, mergers or acquisitions.

The integration of the levels in the supply and distribution chain means that the borders between companies become fluent. Systems have to be integrated and procedures and commercial policies coordinated in order to improve the total quality for the buyers. Suppliers and buyers will, therefore, reduce the number of business partners they are working with. The intensified relationships will require investments and management time which will force a reduction of business relations.

The dynamics in the supply and distribution chain will force wholesalers to make strategic choices for logistics partners, sourcing partners or integrative wholesaling. The European wholesale trade has challenging opportunities but these require specialisation on a market segment with specific wholesale functions for a selected number of business partners. Focus on the business process of the customer and find ways to add value to this process will be the key factor for success.

Concentration will continue in retailing. Euro-retail chains will emerge that integrate wholesale functions in their own organisation. Alternative distribution forms will arise with the help of the continuing developments in EDI. Direct computer links between buyers and suppliers or public sales information systems will make the representatives of the wholesale companies redundant. The wholesale trade will be forced to innovate its services on a continuous basis focusing on adding value to the business process of its buyers or suppliers.

Retail trade
NACE 64, 65

Retailing is an important and significant force in the European economy. About 3.3 million enterprises in the EC are involved in retail trade, offering a point of sale where manufacturers are able to display their products and where the final customers make a choice. Through this choice, the end user strongly influences the success or failure of numerous marketing strategies and campaigns of manufacturers, retailers and their advertising agencies. Campaigns are focused on creating customer preference. Although the retail trade in Europe strongly reflect national characteristics, a number of common themes can be identified. Core market development has occurred alongside diversification into other retail and service sectors and geographical markets. At the operational level, retailers have increasingly adopted the marketing concept as they seek to increase sales. Consequently, these developments lead to investments in ways to control costs and to manage the operation more efficiently.

INDUSTRY PROFILE

Description of the sector

Retailing is a dynamic and complex sector involving a range of company types of varying scale. Its structure reflects the cultural characteristics of the society it serves, and any sociological, economic and technological developments have an impact on retail trade. Prominent among these factors are population patterns and associated social trends (e.g. ageing, mobility and urban development). This dynamism and the traditional lack of attention paid to the retail sector makes national comparison of statistics relating to the retail trade difficult. Despite the existence of NACE classifications, national statistic offices and major trade associations produce data based on a range of different definition criteria.

Data is commonly collected on the basis of a variety of definition aspects which mix features such as type of business (independent, multiple chain), type of establishment (department store, hypermarket), selling technique (mail order, self-service) and product range (food, clothes).

The NACE 1970 classification of 'Retail Distribution' encompasses classes 64/65 and is essentially based on the product groups sold, namely: food, drink and tobacco (641/642); dispensing chemists (643); medical goods, cosmetics and cleansing materials (644); clothing (645); footwear and leather (646); furnishing fabrics and other household textiles (647); households equipment, fittings and appliances, hardware and ironmongery (648/649); motor vehicles and cycles (651); motor fuels and lubricating oils (652); books, newspapers, stationery and office supplies (653); and other "non-food products" (654/655, 656).

Under the new scheme of NACE Rev 1, "Retail Trade, except for motor vehicles and motorcycles; repair of personal and household goods" is found in Division 52 of Group G and is due to come into operation in 1993/1994. This classification has moved the motor trade to a new category, defined more detailed products groups, and incorporated second-hand good retailing and repair businesses into the retail trade category. The NACE Rev 1 involves the retail sale of: non-specialised stores (521); food, beverages and tobacco in specialised stores (522); pharmaceutical and medical goods, cosmetic and toilet articles (523); new goods in specialised stores (524); second-hand goods in stores (525); non-store sales (526);and repair of personal and household goods (527).

Retailing is the final link in the distribution channel between the customer and the product manufacturer for the majority of consumer goods. In its simplest form, retailing is the activity which makes goods and services available for purchase and consumption by consumers. The role of retailers in the distribution channel varies with such factors as the characteristics of the products and service concerned and the type and nature of business relationships with others involved in the channel. Traditionally, retailing does not in itself create goods and services, and, consequently, the activities performed by retailers reflect this role. Increasingly, retail activity now adds value to products and services and enhances them in the eyes of consumers. More and more food retail chains offer all types of products under their own private labels, thus offering

articles of high (A-brand) quality with lower prices than the A-brands of manufacturers. They can also try to create a brand out of their outlets. In Western European countries, we see more upstream integration meaning that an increasing amount of fast moving products are delivered directly from suppliers to the retail outlets or the end users. This trend is strongly initiated by the decreased transport lead-times and improved information technology.

Recent trends

Notwithstanding the problems of comparative data in this sector, the retail trades are a significant contributor to the European economy. Best estimates from Eurostat suggest that retail sales in the twelve Member States amount to around 1 335 billion ECU. This turnover is generated by almost 3.3 million businesses and over 13 million persons employed.

Although more and more manufacturers offer 'Eurobrands', products that are available in all European countries under the same label, and retail chains are increasingly undertaking cross-border activities, it is naive to view the retail trades as a single homogeneous international entity. The saying 'retail is local business' is still correct, not only because of its geographically determined cultural differences, but also because of its organisation and selling techniques. The following types of businesses in the retail trade are distinguished: independent retailers with one outlet, retail chains, multiple chains, franchisees and consumer cooperatives.

The independent retailer with one outlet may chose where to buy, but often is associated in a purchasing association for reasons of economies of scale. The owner typically is directly involved with the day to day management of the operation and hardly has any opportunity of managing several outlets.

A multiple chain tries to get control over a broad assortment of consumer products through exploiting several chains with different formulas for different assortments, ranging from products for end users to offering products and services to professional and/or corporate users.

Franchisees are dependent retailers, committed to the franchiser who offers them a complete programme, including the shop formula, the assortment, marketing programs and sales actions. The franchisee can be characterised as a dependent independent entrepreneur.

Consumer cooperatives are organisations owned by consumers operating under specific national legislation defining a cooperative. This ownership pattern provides cooperatives with a distinct, highly democratic, administrative, structure. The fortunes of consumer cooperatives within the EC have fluctuated. Major difficulties have occurred in France and Germany, while these organisations remain significant forces in Denmark and Italy.

A second, yet distinct, dimension of retailing is the selling technique employed. This dimension has several aspects, the importance of which again varies from country to country and with retail product sector. Aspects of selling techniques include: nature of sales point, sales method, scale of outlet, product range and location.

Nature of sales point

The majority of retail sales occur via fixed retail outlets or stores. However, for certain product groups and in certain markets, itinerant outlets and non-store retailing should not be discounted. Non-store retailing involves mail order, door-to-door selling, vending machines and home selling and is more important for non-food lines.

Sales method

In fixed retail outlets, traditional counter service has been replaced in many cases by self-service sales techniques. This has implications for store layouts, staffing and customer service.

Scale of outlet

For fixed retail outlets, statistical distinctions are often made on the basis of size, particularly in the food trades. In spite of a broad international consensus that supermarkets are self-

service stores with a sales area in excess of 400 m^2, conflicting definitions arise for larger units. For example, while the French define hypermarkets as stores of over 2 500 m^2 with a high proportion of floor space devoted to non-food, German definitions distinguish between self-service warehouses in excess of 5 000 m^2 and consumer markets of 1 500 m^2 and above, while the British superstore definition of over 25 00 ft^2 (2 323 m^2) does not take into account any expected proportion of non-food floor space.

Product range

Distinctions are also drawn between specialists (retailing a single product group), niche players (retailing very narrow product lines) and mixed retailers (retailing a number of product groups, often referred to as 'scrambled merchandising').

Location

Distinctions in location may involve both the physical location such as in-town, edge-of-town or out-of-town sites, and also location features such as controlled environments like shopping centres, for example.

Organisational form and selling technique are two separate features of retailing which are often confused in statistical series. Independents and retail chains may both operate self-service and counter service stores of different sizes in different locations.

International comparison

Within all markets of the EC, regional differences in consumer tastes, particularly for food products, necessitate some product range adaptation by retailers. Also, there are differences in access to certain types of retail facilities between rural and urban areas throughout the Community. The scope of this monograph does not permit an in-depth analysis of the differences, but some characteristics are described in the following paragraphs.

France

France was one of the first countries in Europe to introduce large scale distribution. Despite the expansion of modern large scale store formats (hypermarkets and large area specialists), French consumers remain attached to the traditional neighbourhood stores and street markets. However, the proportion of small businesses is increasing, particularly in food retailing. Hypermarkets and large supermarkets that are mainly food retailers also sell significant quantities of non-food products. To face competition from large scale retailing, small businesses have organised themselves into franchise chains or buying groups. Meanwhile, major retail groups have launched operations in foreign markets to widen their base for further growth.

Germany

Germany has shifted to the centre of attention since its recent unification. The fall of the Iron Curtain has given it the opportunity to act as a 'trade bridge' between Eastern and Western Europe. The entry of the Eastern Länder into the commercial scene was marked by a considerable increase in demand for customer goods. West German distributors, especially large groups, are encouraged to adapt their strategies to the needs of the new regions and their consumers and, thus, benefit from this expansion. They have set up many new outlets, particularly hypermarkets, DIY chains and department stores. In Western Germany, increased purchasing power has made consumers more quality-oriented but also more price-conscious; it is important to note, however, that purchasing power in Germany is set to decrease as a consequence of the economic recession and increasing tax burden. As in France and the United Kingdom, the German distribution sector has sought to diversify and globalise its operations in recent years. There is a growing concentration in the food sector and in other areas (e.g. mail-order houses, DIY chains and department stores). In certain sectors, these developments will lead to a clear reduction in the number of businesses and local units, although total sales area and productivity will increase.

United Kingdom

During the 1980s, British retailing was regarded as one of the most efficient in Europe with major retail groups experiencing a rapid growth in sales and high net margins. Leading British retail companies performed strongly due to favourable economic circumstances and farsighted management. Economies of scale and scope were achieved as market concentration rose and multiple chains grew to dominate most product sectors. One important feature of British retailing reflecting many of the trends and structural changes within the industry during the 1980s is the growth and changing nature of 'own' brands. The immediate issues facing British retailing in the short term arise from the current recession and corresponding stagnation and fall in retail sales.

Netherlands

The Netherlands belong to those countries where cooperation between retailers is well developed. About one quarter of all Dutch retail businesses (excluding motor trades) joined some form of affiliation, mostly buyer's cooperatives, franchising and voluntary chains with wholesalers. Other links include voluntary cooperation between manufacturers and retailers and horizontal sales organisations among retailers. Small and medium sized retail firms continue to be an important feature of Dutch retailing. Frequently, they are turning to cooperation to confront competition from multiples. Within 10 years, affiliated small and medium sized retailers increased their market share from 29% to 40%. This is quite a unique development in Northern Europe where integrated groups have been gaining importance over the past few years.

Belgium

The distribution system in Belgium is midway between the highly concentrated system in Germany or the United Kingdom and the fragmented system in the Mediterranean countries. Today, independent retailing retains a dominant position with approximately 78% of retail sales. On average, Belgian retailing is rather concentrated; about 20% of the companies contribute almost 80 % of total retail turnover. Most hypermarkets are controlled by highly diversified enterprises with several branches. The international dimension is an important characteristic of Belgian retail trade. It is evidenced by presence of foreign retailers on the national market, growing investments of Belgian enterprises in foreign countries, purchasing policies based on international sources and transborder trade.

Luxembourg

As in other Member States of the European Community, small firms are finding it increasingly difficult to cope with the growing competition of hypermarkets and large scale non-food specialists. The number of firms involved in grocery has steadily decreased. The outlet density in the larger municipalities is above the European average.

Denmark

The 1980s saw a continuous fall in the number of enterprises. Small food shops suffered most because of strong competition from large supermarkets and discount chains. Concentration in Danish retailing is still quite low. The food sector is the most concentrated and has the highest share of local outlets. Competition in the high growth discount sector is expected to intensify and bring about changes in Danish retailing behaviour.

Italy

The retail structure and commercial methods have changed radically over the past ten years. The 1980s were marked by an increase in the number of self-service outlets, especially in food retailing (opening of large stores and shopping centres and expansion of cooperative links) and an increase in the number of small independent shops and franchise outlets in non-food retailing. Transformation of the Italian distribution system was often hindered by administrative entry barriers. Opening large supermarkets and hypermarkets is still difficult. The current concentration trend, especially in food retailing, will improve service standards for modern forms of retailing, but it will also reduce average outlet density with possible supply problems for remote areas.

Ireland

Similar to the situation in other EC countries, the principal Irish retail groups mainly operate in grocery retailing but are increasingly diversifying into other sectors. The largest Irish retail group has an interest in the hardware business, while another large retail group owns a number of clothing outlets in addition to its supermarket chains.

Spain

One of the most relevant issues of Spain's modernisation process is the struggle between traditional and modern traders in the domestic market. This dichotomy between traditional and modern outlets has subsisted over the past two decades and still explains the behaviour and performance of the sector. Intense competition for market shares between large groups operating modern formats has introduced a new phenomenon in Spanish retailing.

Portugal

Over the past few years the retail landscape in Portugal has been profoundly modified in both the food and the non-food sector. The appearance of large food stores and the introduction of specialised foreign chain stores (very often under franchising arrangements) have helped to diversify supplies and have brought about a modernisation process.

Greece

The performance of Greek distribution has fluctuated over the past years. Most recently, the political upheavals in former Yugoslavia have started preventing a free flow of goods by road and rail from the rest of Europe. The retail sector is already feeling the impact.

Supply and competition

The demand and supply issues in retailing may be addressed by making reference to trends in retail sales volume and the operational strategies of retailers. At the operational level the emphasis has been placed on both enhancing sales and controlling costs. Both of these have been aided by the application of technology and the development of management skills in the retail sector.

Customer demand for the services provided by retailers is shown in part by changes in retail sales volume. Indexed sales figures for the 1989-1992 period reveal national differences in growth in total retail sales volume. Such figures alone, however, disguise fluctuations from year to year and between retail product groups. Annual changes in retail sales volume of two or three percentage points are not uncommon as retail sales are very vulnerable to changes in consumer confidence. Britain is a case in point where strong credit-driven growth in the mid 1980s disappeared at the turn of the decade. Similarly, differential demand is observed between retail product groups. Food, as the largest retail sector, tends to mirror the overall changes in retail sales volume and is less prone to dramatic swings in sales volume. Other non food sectors such as clothing and household goods are more prone to fluctuations in volume since, as non essentials, they are more dependent upon customer confidence, and disposable income. Purchases of these products can be postponed or eliminated more readily than those of food products. During times of recession, however, pricing strategies for food retailers also become increasingly important and discount enterprises become more favourable to the customer from every profile type.

The adoption of the marketing concept has been fundamental to the drive to enhance sales. The retailer is the closest of all the institutions in the distribution channel to the consumer and is increasingly using the knowledge derived from this position to develop activities more suited to consumer needs. Companies in the sector have recognised that consumers' perceptions of organisations and store formats are central to the retailing business and have responded accordingly. In general terms, one observes a trend from a mass or generalist retail offer to a specialist retail offer. For example, in mail order retailing this is reflected in the trend towards "specialogues" at the expense of general mail order catalogues. The aim is simply to apply basic marketing principles of segmenting the market, identifying target customers, their motives and values and providing a retail offer to meet these needs.

This does not mean that the mass or generalist retail offer is totally inappropriate. For some consumer groups and purchasing decisions, and in certain environments, this type of offer meets consumer needs. The growth and spread of the large scale food store (whether hypermarket or superstore) shown in Table 4 is testament to this. In the large store sector, which is commonly associated with mass retailing, specialisation is taking place. Large store specialists are developing in most retail product line areas (furniture, DIY, garden centres, clothing, shoes, records and toys), and many department store companies are adjusting their product ranges, effectively becoming large textile specialists.

The targeting of consumer groups and the development of specialist retail offers is particularly visible in smaller store formats. A number of consumer values have been identified and specific formats have emerged to serve these needs. A selection of values and corresponding retail formats are discussed further. The limited line discount store meets customer requirements for low prices via stores retailing limited, low priced product ranges that consist of a few lines and are sold in sparsely decorated and staffed outlets. The convenience store provides for customers seeking to conserve time in their shopping habits. These stores carry relatively wide product ranges with limited lines that usually consist of a single major brand per line. Store decor typically stresses efficiency; accessibility is a premium characteristic and is achieved via store location and long opening hours. The specialist store provides for choice through narrow product ranges but with considerable depth of lines and brands. Staff are generally capable of providing expert advice on the products carried as the customer motive for visiting these stores is to make a choice within a predetermined product group. A style shop provides exclusivity or design originality via quality products in stores which carry few lines. Store fittings are of high quality and customer service in its various forms is also high. The branded goods store supplies assurance to consumers who value the reputation of a single brand. These stores only carry the single brand valued by the customer. Service shops provide the customer with a skill or service usually within a short period of time period. Locally specific shops respond to the consumer's wish for impulse or emotionbased purchases following a particular experience. The product range, theme

and location of these stores are closely linked to a particular experience. In all these store formats, the product range, store ambience and customer service levels are specifically tailored to meet the needs of identified consumer values.

Each type of outlet (e.g. department store, hypermarket and large scale specialist) can be compared to a product with a specific life cycle. In countries with a modern retail system (Germany, France, the Netherlands and the United Kingdom), variety stores and conventional self-service outlets (supermarkets and mini-markets) are experiencing a decline in growth. Large scale specialists in the suburbs and discount stores, specialist chains and convenience stores in the inner cities are in their growth stage.

As certain traditional retail formats disappear, they are replaced by others that then start their life cycle. The new formats are usually more modern and better suited to local requirements. The stage reached by a given outlet format is not the same in all countries. The hypermarket format is expanding rapidly in southern Europe (Spain, Italy, Greece and Portugal), but its growth has slowed down in northern Europe because the phenomenon first appeared in the 1960s and as a consequence of restrictive government measures. Southern Europe has not only caught up in terms of modernisation: indeed, the hypermarkets being opened nowadays are of the most up to date technological standards. A great effort is needed to modernise northern European hypermarkets.

Beside marketing as a main factor for increasing sales, retail management focuses on managing cost structures. The largest element is the cost of purchasing the product for resale. For that reason great emphasis is placed upon maximising buying power benefits through scale or efficiency. Scale is related to the volume of products sold within a product range, sales growth via internal development, acquisition or collaboration. The breadth of product ranges and number of brands stocked also influences power as sales volume is concentrated or dispersed over the lines or brands. Finally, efficiencies in decision-making, preliminary through centralisation or the coordination of purchasing, provides for greater buying power. Food retail outlets particularly optimise shelf-space management, which is a determining factor in buying decisions.

Closely associated to the cost of buying, particularly for retailers with a high stock turnover, is management of the delivery and distribution of products to stores and customers. A clear trend in Europe is a move towards the centralisation of physical distribution, where suppliers deliver to a central point for redistribution rather than direct to the store. Often this process may involve the subcontracting of this activity to a specialist third party distribution companies.

A third element of cost structure which has changed significantly over time is employment structures. Retailing is a major employer, particularly of women, and increasingly of part-time employees. Employment ratios however vary from nation to nation as do hourly labour costs. The trend towards part-time employment allows greater control over labour scheduling by matching staff levels with peak trading times, and also aids in the control and management of labour costs.

Supply chain management is increasingly important to improve both marketing and control. Buying terms and conditions are still the subject of debate between suppliers and retailers; however, the nature of these discussions becomes more and more collaborative. Coordination of the supply chain has grown, enhanced by improved information on product movement and the increasing power of retailers who regard the outlets as a brand. The combination of activities, products and services offered by the retailers "add value" to the basic product offering and provide a means of differentiation from competitors. The growth in retailer advertising reflects this trend, as does the development of retailer brand product ranges. Especially in the food sector, the role of the retailer brand has changed. The original market position of these food brands was a low price/lower quality alternative to manufacturer brands; but, as these brands carry the retailer's name and are unique to the store, they have been repositioned, their quality improved and are increasingly associated with new product launches. In some food retail chains, private labels already take 30% of the fast moving product assortment. This forces the supplier to emphasise quality control, product development and a soundly perceived quality/price ratio.

All of these operational issues have been aided by the introduction of technology in retailing and the development of management skills. Initially, technology investment was driven by the desire for better management of assets and the associated productivity improvements. Increasingly, a number of retail businesses are appreciating the potential for information technology to aid marketing and strategic management decisions. The acceptance of universal standards that allow item identification, data transmission and electronic processing have been central to the adoption of technology in retailing. For example, without agreements on bar-code standards, investment in item identification equipment such as scanning could not take place.

Investment in such technologies has provided the information infrastructure upon which application technologies such as electronic funds transfer at the point of sale (EFT-POS) and electronic data interchange (EDI) are based. These application technologies provide the information basis for improved management of the company. Technology alone, however, will

not manage a business. Managers must still make decisions based on the information provided by technology. As the information available to managers has increased and changed in nature, management styles and structures have evolved to maximise the benefits. Although management styles differ, there is some evidence of a trend towards centralised decision making, whether at regional of national level. One could argue that the growth of franchising and the changing membership conditions of buying groups and voluntary chains represents a similar step among independent businesses to create a more uniform image and benefit from economies of scale and replication.

INDUSTRY STRUCTURE

Companies

The largest retail companies in Europe are now of significant size in terms of turnover to be ranked alongside businesses in the production sector of the economy. Given the size of the food sector, the majority of the largest companies are predominantly food retailers, although mail order companies such as Otto Versand (D) and Schickedanz-Quelle are featured in any listing of major companies, along with a few department stores as well. In the Fortune ranking of the world's largest retail based organisations, 20 EC companies rank in the top 50.

Of these major companies, the vast majority have either diversified operations or have made important international contributions to turnover. The exceptions to this observation are the British food retailers. Tesco and Argyll which are essentially domestically based 'core' business operations; however, they cooperate in international retail associations and show a tendency towards internationalisation.

The retail sector is accustomed to rapid change. Companies which were on top in the early 1980s, like department stores, have declined and have been replaced by food retailers. Companies like Carrefour (F), Asko (D), Argyll (UK) and Ahold (NL) have effectively been formed since the 1960s. These companies have grown rapidly through the introduction of new forms of retailing (e.g. the hypermarket and large store discount outlets) and growth through acquisition and collaboration.

Strategies

The power struggle in the supply chain continues. The four areas where the relative power position of the players in the supply chain differ are: large brand suppliers, large purchasing chains, wholesalers and where large brand suppliers share margins with large purchasing chains. As they grow in size, retailers have increasingly developed clear strategies to maintain growth and service within the market place. We distinguish four strategic options: seek product market dominance, diversify beyond the original activities, integrate upstream and diversify geographically

One basic strategy has been to seek product market dominance. Growth is sought within the existing 'core' product market as companies seek to increase their share of sales through new outlet development, or through cooperation with, or acquisition of, others operating in the market. Within every country and retail product market in the EC, examples may be found of companies employing this route to growth. The clear consequence of this strategy is product market concentration with a greater share of sales attributed to single organisations or collaborative groups.

An alternative strategy is to diversify beyond the original activities of the business into related or new product markets. This may involve a redefinition of the existing retail product market as existing ranges are widened to encompass related products or services. Similarly, other segments within a known product market may warrant attention. An established hypermarket operator, for example, may develop smaller formats such as discount or convenience stores. Possibly the most risky option is to diversify into new unrelated retail products or service markets of which the company has no experience or knowledge. Generally the diversifying business will have management expertise in one retail sector which is felt appropriate to the new sector. The consequence of this option is that the organisation develops a portfolio of different retail businesses. For example the seven largest DIY retailers in

Table 7: Retail trade
Largest retail based organisations in the EC by turnover, 1992

Company	Country	Turnover (million ECU)	Change 1991/92 (%)	Sector
Tengelmann	D	21 568	1.2	Food
Rewe-Handelsgruppe	D	18 485	1.6	
Carrefour	F	17 838	24.3	Food
E. Leclerc	F	15 533	20.7	
J. Sainsbury	UK	13 213	20.9	Food

Europe are now subsidiaries of retail organisations with their main activities in other retail product markets.

Upstream integration is another option for the retailer, and may include activities like wholesale functions. This enables the retailer to become a more powerful purchasing partner for the supplier.

A further type of diversification is geographical diversification that involves activities outside the domestic market. Internationalisation in retailing takes a number of forms. At one level, there is technology transfer where a retail format or innovation - such as the limited line discount store, the convenience store or hypermarket - is developed in a number of national markets. This transfer may or may not be directly linked to a single company. In addition, certain retail activities such as purchasing and management systems may involve an international dimension. The formation of international buying groups in the late 1980s reflects this trend. Large retailers generate a significant proportion of sales from overseas activities. The management involvement in international operations will range from a financial stake in existing companies, to franchising and everyday management control.

The changing retail environment further reinforces the importance of management information systems and management skills. While some of these organisations remain private businesses and finance expansion through cash flow and bank loans, an increasing number are turning to the stock market for funds. This is particularly true of British and Dutch companies, and increasingly true of French corporate chains.

ENVIRONMENT

The concern over ecological issues in Europe generally has some impact on the retail sector. First, the growing demand for 'green' or environmentally sound products (such as cosmetics, washing powders and paper products) has been taken into account in product range selection. A potentially greater impact, however, is in the area of packaging and packaging waste. This issue has come to the forefront in Germany with legislation placing the responsibility for the recycling of packaging materials on manufacturers and retailers, and is also on the political agenda in a number of other countries. In Germany, the Netherlands and France, a number of leading retailers have already begun to take an active role in waste disposal. Another trend is the responsibility of material in electric household appliances that might cause environmental pollution when disposed of (e.g. appliances containing chlorofluorocarbons). Legislation is in preparation in Germany to require the producer, wholesaler and retailer to take the material back for remanufacturing.

REGULATIONS

The regulatory framework affecting retailing in the EC largely takes place at the national level. The scope and range of policies specifically directed at the retail sector varies from country to country, and broad legislative activity to regulate industry, in general, affects retailing (e.g. taxation and social protection legislation). Retail-specific legislation has tended to be reactive rather than proactive in most countries, formulated in response to particular problems and political pressures rather than forming part of an overall strategic approach to the retail sector. In general, legislation exists to control unfair competition (whether through monopoly control policies or the regulation of discriminatory and restrictive practices), to monitor establishment of retail business and premises and to protect consumers.

The scope and effect of legislation is varied across the EC. Legislation to control the growth of large stores exists in a number of markets, with the effect of slowing growth (France) or preventing growth (Belgium). Differences in sales tax and excise duties have lead to cross-border shopping in a number of markets, such as on the Danish-German border and the Irish-Northern Ireland border. Competition policy has prevented proposed mergers in the United Kingdom and Germany.

At EC level, various aspects of the single market will influence the retail trade. The mutual recognition of national product safety standards, along with the removal of border controls, will influence the sourcing, transport and movement of product. Fiscal harmonisation (particularly of VAT) will potentially affect the final transfer process to consumers; aspects of the social charter will influence employment structures.

OUTLOOK

Retailing is an important sector of any national economy and will remain so in the foreseeable future. The total retail sales in the EC declined significantly throughout 1992 and continued to fall in the first half of 1993; a recovery, however, is still foreseen.

As retail internationalisation in its various forms increases over the next decade, similarities in the retail formats and management techniques seen in different countries will grow. This will be particularly noticeable in Southern Europe as the retail trade 'learns' from the northern countries.

The ongoing struggle for power between the manufacturers and retail chains will lead to an increase in product quality for the consumer, while a decline in the number of products offered is foreseen. Despite these trends, retailing will however retain distinct national characteristics. In most countries and retail product markets, the dominance of large organisations is growing. Scale will remain a key issue in retailing; contractual chains will provide an important means of achieving some of the scale benefits for independent businesses.

For many of the larger organisations, national market shares in their retail product sectors are approaching limits which may attract the attention of public policy agencies. Continued growth through acquisition in these sectors may also be limited by a dearth of target companies. Attention will be increasingly focused not only on diversification and internationalisation as a strategic route to growth, but also on marketing and management control activities to increase the return from existing operations.

Overview

NACE 665, 667, 771, 661

The tourism industry in Europe is in a constant state of evolution. This is in direct response to the changing demands being placed on suppliers by tourism consumers who are becoming ever more sophisticated in their tourism expectations in terms of quality of service, diversity of tourism products, and improved provision of accommodation, restauration, entertainment and travel services. With more disposable income and leisure time to devote to leisure, traveller are bringing about increases in both the taking short-break and long haul holidays segments of the tourism market.

Thus far, the European tourism industry, in the main, has responded to the current challenges put before it by developing appropriate tourism products to satisfy the new demands. Rapid changes in demands means that analysis of this constantly evolving market continues to be necessary. Tourism is an extremely horizontal industry which comprises a wide variety of services and industries. The performance of the industry to date on the world market and home markets has continued to grow and to improve.

Analysis of market forces, trends and the regulations which impact on the development of tourism in Europe, all indicate a positive outlook for the future development of the industry. However, in order to improve the performance of the European industry, future strategies should incorporate greater diversification of tourist products, bearing in mind the "value-for-money" aspects.
