Tourism represents a complex economic and social phenomenon which affects millions of citizens in Europe as well as all over the world. The impact of tourism on these citizens is felt both as beneficiaries of tourism products and services and as providers of a variety of services which seek to meet the various needs of tourists. The pervasive power of tourism throughout the world on local communities is matched by very few other industries. It entails a complex network of businesses engaged in the provision of accommodation, restauration, travel facilities and services and entertainment for the tourist.

According to the World Tourism Organisation (WTO) definition adopted by the United Nations Statistical Commission in March 1993, a tourist is defined as a visitor staying at least one night and for no more than one consecutive year in a place other than that corresponding to his usual environment. However, when considering the nature of travellers engaged in the various forms of tourism, the term "visitor" represents the basic concept of tourism statistics: there are visitors making pleasure trips for purely tourist purposes or in order to visit friends and relatives as well; and then there are those who make business trips. Another important and growing segment of the market is that of the excursionist or same-day visitor who does not stay overnight away from his usual environment.

The tourism industry is thus, better viewed as a market rather than as a sector given the wide range of related industries

Source: WTO

and services involved right across the economy, the most important of which being the lodging subsector, catering, sports and entertainment, travel services and the transport and crafts industries.

The aim of this chapter is to focus on the following sub-sectors:

- Hotels (NACE 665);
- Other accommodation (NACE 667);
- Travel services (NACE 771);
- Restaurants (NACE 661);
- Recreation parks;

The diversity and fragmented nature of the tourism industry is a disadvantage when collecting and aggregating statistics particularly when making comparisons at the international level. The current work developed by the European Commission in co-operation with EC and EFTA Member States and international organisations such as OECD and WTO aims to harmonise methods and definitions used on tourism statistics in order to gather reliable and coherent figures at the international level.

Recent trends

According to WTO estimates for 1992, over 188 millions of international tourist arrivals were estimated in 1992 in all EC Member States, representing 40% of the world market share.

For the same year international tourism receipts, excluding transport expenditure, represented 84 billion ECU which constitute 39% of the world market share. In order of importance the principal international tourist destinations in the Community, are France, Spain and Italy which together receive 66% of all international arrivals and 58% of receipts.

These figures exclude domestic tourism as well as same-day visitors. The volume of domestic tourism - overnight stays in the country of residence - exceeds outbound tourism considerably. It is estimated that about 2/3 of all holidays generated by the EC population can be classified as "domestic"; 22% is related to international tourism between the EC member States and 13% of all holidays are spent at destinations outside the Community. Domestic tourism is even more important in the Mediterranean countries (84-87%) and in Portugal where the rate (90%) is the highest of the Community.

Same-day visits are confirming their growing importance as part of tourism in many industrialised countries. At the international level, day trips to neighbouring countries, constituted in Europe one out of every two trips in 1992. It is a segment of the market which has doubled between 1980 and 1992.

The fact that tourism constitutes an important source of revenue for EC Member States is confirmed by Eurostat's estimate that tourism contributed 5.5% of the Community's GNP in 1992. In Spain and France the relative importance of tourism activities in their economy. is approximately double that of the Community average, Greece, Portugal and Ireland are also above average.

International comparison

According to WTO estimates for 1992 and 1993, the world travel and tourism industry has maintained its rate of growth, despite a general economic recession. In 1993, international tourist arrivals increased by 3.8% in respect of the previous year, reaching 500 million worldwide. Even if the rate of growth of arrivals was lower than in 92 (4.5%) the increase in receipts has been important, reaching 9%.

In 1993 Europe registered 300 millions internationals arrivals (4.3% more than in 1992). Europe, with a world market share

of 60% of all international arrivals, still represents the principal force of impulsion of international tourism. Between 1970 and 1992, Europe has lost 10% of its world market share to new destinations located in third countries particularly in South East Asia and the Pacific area. Even though in 1992 and in 1993 Europe enjoyed an annual increase of over 10 million tourists, thus reversing the negative trend experienced in 1991 as a result of the Gulf Crisis, the rate of growth is the lowest recorded among all the regions of the world.

At world level in 1993, East Asia and the Pacific area have experienced the most significant progress, with an increase of 12% in terms of arrivals and 15% in terms of receipts.

The United States continued to lead the world in terms of tourism expenditure (37.7 billions ECU) and tourism receipts (41.5 billions ECU) in 1992. WTO's preliminary estimates indicate for 1993 an increase of the receipts of 15%, the greatest recorded for a single country in one year.

With regard to long-haul travel, the United States also represents the principal tourist destination for Japanese visitors - 20% of all Japanese travelling abroad visit the United States - as well as for European tourists outside of Europe: the USA received 3.4 million European arrivals in 1992.

According to the Travel Industry Association, travel and tourism is the America's largest export and America's second largest employer. Employment has grown twice as fast as total US employment.

In 1992, Japan received 2.3 million international tourists, 24% of whom came from Europe. With 18 million Japanese travelling abroad, 53% of whom visited East Asian and Pacific countries. over the last decade, Japan has become the third most important spender in the world on travel abroad. It has been estimated that Japanese tourists spend on average four times more than the European tourists and twice as much as American tourists travelling abroad.

France continues to maintain its position as the world's leading tourist destination, receiving 59.6 million international tourists in 1993. After the United States, France maintains also second place as a top earner of international tourist receipts, followed by Spain and Italy.

Foreign trade

According to WTO, international tourism receipts represent 1.72 of the total GNP of the European Union in 1991. The contribution of tourism receipts to GNP is substantially higher in Portugal, Greece, Ireland and Spain . More than 50% of tourism receipts finance the trade deficit of France, and more than 4O% in Italy and Spain. In Austria , the fifth top earner country in the world in terms of tourism receipts, tourism finances the 2/3 of the trade deficit.

As a positive contribution to the balance of payments, tourism represents 1/4 of the services exported by the Community to third countries.

France, Italy and Spain collect 58% of international receipts in the Community. For the EFTA Countries, Austria alone collect over 50 % of the receipts and Switzerland 28%.

Even though European long-haul travel almost doubled between 1980 and 1992, Intra-Community flows still dominate the market. The most important markets for tourism into the EC are the EFTA countries, United States and Japan.

Europe is also important as a source market for most regions: to South Asia: 39% of international arrivals are originated from Europe, to the Middle East, the proportion was 32% and to Africa, 25%, mainly to Tunisia and Morocco.

With 28.6 billion ECU, Germany is the main European spender, at world level it is second only to the United States. Other main European spenders, between the top eight at world level, include United Kingdom, Italy, France and Netherlands. These five countries represent 36% of the world tourism expenditure abroad.

MARKET FORCES

Demand

The demand for holidays is influenced by a variety of factors which affect the decision whether to take a holiday, what type or length of holiday and where to take it. The most important of these factors include: income, available free time, age and family circumstances, comparative price level , environmental conditions.

One of the indicators used for describing the demand patterns is the level of "trip taking". It is measured by the proportion of the adult population taking a trip of at least one night out of their place of residence. According to estimates by the European Travel Intelligence Centre, the ratio is comprised of between 55% and 87% with reference to the EU and EFTA countries. The latter, and in particular the Nordic countries (Iceland, Finland, Norway and Sweden) show the highest propensity in Europe to travel. The largest proportion of trips abroad made by Europeans are to neighbouring countries, as confirmed by the high share of foreign trips made by Belgian, Luxembourg's and German residents.

Income, linked with education and social status, in particular affect the level of trips-taking. Those with high disposable income tend to travel more frequently. In addition, business travel, which is becoming increasingly important, is usually much more frequent than leisure travel.

According to a recent study carried out by the French Tourism Directorate, France occupies second place, after the United States, in international business tourism market. It has been estimated that in 1991, foreign business tourism, represented for France 20% of total nights spent and 40% of the receipts in foreign currency generating a turnover of 1/5 of total tourist activities. Despite a slowing down due to the overall economic situation, business tourism market is forecasted by the majority of professionals to become a major tourism product which is expected to further grow.

Focusing on holidays (four and more overnight stays) the proportion of the EU population that takes at least one on a yearly basis is estimated at about 55 to 60% of the adult population. The total number of holidays yearly undertaken by EU residents is estimated between 250-300 million in 1991 and 1992. Remarkable differences still occur between Member States: in France and the northern EU countries more than six out of ten people take a holiday, the level is significantly lower in Mediterranean countries. As far as cross-national flows among EU countries are concerned, north-south flows have dominated since the start of mass tourism in Europe. About 70% of tourism where the origin and destination are the EU can be classified as following the direction north-south.

Over 71% of nights spent by international tourists in hotel and similar establishments of the EU are concentrated in four countries, with Spain taking the lead, followed in the order by the United Kingdom, Italy and France. Recovery in the North American and Japanese markets in 1992 has given rise to a slight up ward movement in tourist nights for Europe after two year of negative trends.

In terms of nights spent by international tourist, Austria, which is in second place in the whole of Europe, receives 64% of the total for EFTA countries.

There are a number of new trends which are characterising tourism demand in Europe: the expansion of the short-breaks market and second holidays as well as growth in outbound travel from the southern European markets.

Changes in population age structure also strongly influence the nature, incidence and timing of holidays during the last decade of the century. An emerging fast growing segment market is the "senior travel market" which constitutes the 20% of the trips taken by the Europeans. The European Travel Commission estimates 200 million trips were made in 1991 by the Europeans over 55 years old, 80% of which were made in the country of residence. Between 1988 and 1991, the senior market share has already grown 10% and considerable prospects for future development.

More mobility holiday-makers in terms of changing destinations, seasonality and more active behaviour is increasing. Even though traditional tourist products associated with sun, sea and beach resorts still dominate the market, the interest for cultural activities, in a broad sense, when taking holidays, is growing and may contribute to the staggering of holidays.

Another important factor which may strongly influences tourist flows is the emphasis placed on the value-for-money. As tourists continue to become more sophisticated they demonstrate willingness to receive higher standards of quality and services without being ready to accept a significant increase of the expenses.

Supply and competition

The tourism industry comprises booth a wide range of economic activities and a supply of products which come from a whole range of different types of enterprise. Their common characteristic is the variety of the existing enterprise structures as well as of the huge number of services made available. For this reason in this domain there co-exists various forms of ownership from small sole proprietor to multinational cor-

Source: WTO

porations. Supply reflects demand, both in terms of structure, and in terms of trends. According to this hypothesis, concentration of the industry within a country will only occur in a sustainable manner, if the aspects of demand encourage and justify it economically in the long-term. The basic factors of demand are very asymmetric across the European market, as they vary significantly from country to country. Government regulation together with the number and size of enterprises determines the degree of competition which in the main tourist activities seems to be relatively high.

Production process

According to Eurostat of over 1.2 million enterprises involved in hotel and restaurant activities in the Community, 95% are made up of micro-enterprises (less than 9 employees). Europe confirm its leadership at world level in terms of accommodation capacity. For Hotel and similar establishments, the trend in the Community is towards a reduction in the number of enterprises and a gradual increase in the accommodation capacity in absolute terms as well as on average per establishment. Even though the average size in the Community went up from 43 to 45 beds, the rate is still lower in relation to areas outside the Community. Nevertheless, in this case also, the situation varies from one individual Member State to another:

- lower than EC average in United Kingdom (25 beds per establishment), Germany (34) and Luxembourg (38);
- higher in Denmark (170 beds), Portugal (106), Spain (101) where the boom in package tourism has led to investment in large hotels.

In spite of the difficulty of evaluating the impact of tourism on employment, it is certain that all sectors of the tourism industry are labour intensive. Jobs in tourism activities in the Community number some 9 million. Tourism represents about 6% of total jobs in the Community, taking into account only jobs directly linked with tourism products and services. Besides these direct jobs, it is also necessary to consider the indirect or spin-off jobs created in sectors outside tourism in the strict sense. The structural flexibility and, in some cases, the weakness of this segment of the market may explain the degree of attraction which the sector has for women and young people, often constituting their first employment. Moreover in the services sector, which employs six people out of ten in the Community, tourism also has a high proportion of female employment which varies from 45 to 65% from one Member State to another. The seasonality of employment, another particular feature of tourism, is moreover very variable in different branches: low in cafes and restaurants and in travel agencies, medium in hotels and high in holiday camps and open air facilities.

Considerable new technologies have been introduced into all segments of the tourism industry in recent years. However, the general impact has been on improved quality of service rather than on labour content reduction.

INDUSTRY STRUCTURE

Companies and strategies

Estimates by the World Travel and Tourism Council indicate that investments in these domains in the Member States reached 196 billion USD in 1991, equivalent to 15.3% of total investments and 31% of world investment in transport and tourism industries. By 1994 despite the growth of new capital investments forecasted on a world basis of about 10%, the European Union is expected to register a certain stagnation.

In 1994, in terms of capital investment envisaged for all the industries, the largest investors in travel and Tourism are expected to be Ireland (37%), Spain (24%), Belgium (21%) and Portugal (20%)

The structure of the tourism industry is moving towards rationalisation:

- gradual withdrawal from the market of tiny marginal establishments;
- reinforcement of partnerships in various forms (integrated chains, franchising etc.).

In Europe also, as was the case in the United States, the main trends of the market strategies are:

- concentration on niche markets on a world-wide scale;
- differentiation and segmentation.

In the hotel industry, this approach is being applied: on the one hand, the major European groups through mergers and acquisitions are trying to compete with US groups which are the leaders in the market worldwide; on the other hand, the early 1990s saw the emergence of associations of small hotel groups and consortia whose aim is to improve market awareness.

The performance of the tourism industry can be better achieved through:

- wider integration between the tourism sector and the other economic activities, especially through planned regional development;
- improved balance between price and quality of services provided;
- rapid response to changing tourist behaviour;
- the further application of new technologies in marketing and managing businesses;
- the improvement of the so called "internal marketing".

Human resources are a key factor to success in the process of change being experienced in the sector. The cross frontier mobility of manpower is higher than in other sectors; The full implementation of the internal market encourages mobility and offers reinforced guarantees for employees and their families. The mutual recognition of diplomas also contributes also to this mobility. Conscious of the importance of vocational training, the European Union will continue to support this field in order to improve the quality and performance of labour in the sector and stimulate exchange of experiences at international level between the major actors involved.

REGIONAL DISTRIBUTION

The tourism industry continues to be concentrated in certain regions, generally in seaside and mountain locations. 44% of overnight stays in Greece are concentrated in the Southern Aegean Islands and Crete. In Spain, the Balearic and Canaries Islands with Andalucia accommodate 50% of overnight stays. In Germany, 30% of overnight stays in the country are spent in Bavarian region and in Italy, the Northeast regions take 30% of all overnight stays. Urban tourism, which comprises tourism in the cities of art, is another relevant segment of the tourism market that still continuing to expand. Among the European capital cities, London, Paris and Rome are the principal destinations.

ENVIRONMENT

The success of tourism relies to a great extent on the quality of the environment where it takes place. While tourism activity is influenced by the environment, the environment is greatly influenced by tourism. Without proper planning and management the industry may damage the resources it depends on for its success. Over the last 20 years the European tourism industry has been characterised by sustained growth which has led to development pressures, both in established tourism resorts and previously unexploited areas, particularly coastlines. This has led to resource management problems, both in terms of physical tourism development and management of facilities and visitors.

The growth in general consumer awareness of environmental problems has led to actions by both the public and private tourism sectors to combat the problems which can be caused by tourism. Development related issues can cause substantial impacts on physical and built environments; and tourism in general may cause air, noise and water pollution; congestion; erosion; and various social impacts. The importance of particular locations and seasonal factors may also aggravate these problems while historically the diversity of tourism has made it a difficult industry to plan and regulate. The industry has responded to the call for better environmental practice in a number of ways. These include:

- the development of sustainable tourism strategies in the public sector and the setting up of environmental associations in the private sector;
- the development of various codes of conduct and self-regulation measures by the private sector;
- a range of joint partnerships at European, national and local level related to research on sustainable tourism and pilot projects which test its applicability;
- the development of new holiday products for certain environmentally conscious market segments.

Alongside these activities broader environment policy at European and national level continues to influence the development of tourism. The increasing (on occasions mandatory) use of Environmental Impact Assessment in tourism may signal a first step towards greater legislative intervention in the industry, particularly in the form of taxation related to energy use and anti-pollution laws. Tighter planning regimes at a regional level are already in evidence in many parts of the EU. Often environment focused activity enables parts of the industry to come together to tackle a common and fundamental interest. It is likely that the improved protection of the environment will remain one of the main challenges facing the industry during the next decade.

REGULATIONS

Given the horizontal nature of the tourism industry, a wide range of local, national and EC regulations impact on the tourism industry, although few are prepared with the specific intention of regulating the sector.

Within the framework of the European Union, many measures have had either a direct or indirect impact on the tourism industry because of the sheer number of activities that it comprises. A preliminary assessment of these measures has been made by the Commission in its two communications of May 1992 (SEC (92) 701,702); a wider report on all community actions affecting tourism will be presented by 1994.

The legislation relevant to tourism can be considered in four main groups:

- measures associated with the completion and functioning of the Internal Market associated with the removal of physical, technical and financial barriers;
- measures aimed at protecting the environment;
- measures intending to bring about social and economic cohesion among all the Member States;
- measures included in the Community Action Plan to Assist Tourism.

Of most interest to tourism firms within the Union, are those Community measures affecting the removal of technical and

legal barriers, employment, the promotion of fair competition, the development of a business environment which in particular is more conducive to encouraging small and medium sized enterprises (SMEs) to succeed by promoting transnational co-operation and the use of new technologies and the development of a comprehensive, environmentally sensitive European transport network linking even the peripheral regions.

Enterprise policy within the European Union has been established on two main themes: improvement of the environment in which they operate and support for the development of practical tools to assist them, such as information services and services which facilitate transnational co-operation in the main. The Decision of 18 June 1989 (89/490/EEC) to establish a Community policy to assist enterprises, the Council Recommendation of 28.05.90 on the simplification of administrative procedures and the subsequent report to the Council (SEC (92) 1867, of 27.10.92) which recommended even greater transparency, have been prepared with a view to creating an environment in which SMEs in particular can compete effectively and efficiently. The multi-annual action programme adopted by the Council in 1993, serves to reinforce the main lines of action of Community enterprise policy.

The abolition of tax frontiers and the introduction of minimum rates for VAT and excise duties across the Member States from January 1993 are expected to let market forces pull VAT rates closer together. In the interest of consumers and enterprises much effort (particularly on the part of industry lobbyists) continues to be put in to achieving a greater level of harmonisation.

The Directive 92/77/EEC on the approximation of VAT rates, modifying the 6th VAT Directive (77/388/EEC) set the minimum standard rate of VAT at not less than 15%. However, on products or services of a social or cultural nature - a list of items which includes passenger transport, tourist accommodation provided by hotels and similar establishments, sports and entertainment - the Member States can introduce one or two rates of at least 5%.

Another aspect of the VAT which is under consideration is a simplification of the system with a view to reducing the administrative burden placed on enterprises. With regard to passenger transport, with the removal of border controls which were formally used as a means of levying VAT, proposed legislation is being considered to levy VAT on passenger transport by road or inland waterway in the country of departure of a journey rather than according to all the countries passed through during a journey.

The White Paper on Employment in Europe is a major initiative to tackle the long term underlying presence of unemployment in the Community and stimulate new job creation, growth and employment intensity. The nature of tourism as an employment sector lends itself well to the issues addressed in this initiative and the potential of tourism in this context has

been recognised within the framework of the social dimension. Proposed legislation concerning the regulation of working time and young workers which still under consideration has implications for the Tourism industry.

Supporting tourism development represents an important way of promoting in collaboration with the Member States. With the implementation of the new structural funds for 1994-1999 and the new cohesion fund 1993-99, tourism continues to be an important tool for regional development and the reduction of social and economic disparities between the regions. Within the previous Community Structural Frameworks (1989-93), measures concerning tourism were focused on improving the supply and geographic spread of tourism, reducing the seasonality of the industry, full exploitation of the cultural and environmental heritage, developing rural tourism and developing tourism training for employees. The reforms of the objective areas 1-5, taking place with the implementation of the new structural funds are likely to continue to favour tourism development.

With the creation of the Cohesion fund, an extra 15 billion ECU has been made available to assist Ireland, Spain, Portugal and Greece and those regions which are largely rural or suffering industrial decline and thus lagging far behind the richer regions of the Union. This assistance and investment is intended to enable them to achieve a comparable level of development in terms of communications networks while at the same time ensuring the protection of the environment: both items clearly benefit the tourism industry.

Following the adoption of the Treaty on European Union, consumer policy has been given clear recognition of its role in establishing the internal market. The removal of barriers to freedom of movement offers fantastic opportunities for the development and exploitation of Tourism in Europe. Tourism by its very nature, enables tourists to move outside of their usual environment both in order to purchase and take their holiday. This phenomenon can also make tourism consumers very vulnerable and in special need of information and also legal and economic protection. While the provision of information about products and services, and the provision of assurances of quality and/or of compensation, in the event of a faulty product or service, may seem burdensome for the entrepreneur, in the long term, these measures are necessary for the full functioning of the internal market. Fully informed consumers, safe in the knowledge that wherever they make purchases in the Union they will have access to justice are more likely to take advantage of the opportunities afforded by the internal market, which should in turn lead to increased enterprise activity and competition. In the third Consumer Policy Programme adopted by the Commission in 1993, there is a fair amount of proposed legislation that will safeguard the interests of the tourist but also help to establish a level playing field on which firms can compete fairly with each other.

In the field of Central Reservation Systems, the Council adopted a regulation (3089/93/EEC) on 29 October 1993, modifying the original of 24.07.89 (2299/89) on the imple-

mentation and operation of a code of conduct for air transporters and air passengers using central reservation systems. The scope of the regulation has been extended to non-scheduled services and bundled products. Also the ranking criteria for the display of information on air transport services have been strengthened and clarified. The aims of the code are to ensure the non-discriminatory and transparent use of such systems and improved competition between air transporters coupled with improved information for air passengers.

The proposed consumer measures being considered by the institutions of the Union in January 1994, covers the sale of Timesharing properties, distance selling, abusive clauses in advertising and access to justice for consumers. The Package Travel Directive entered into force 1.1.93 when it was expected that the members of the European Union would have transposed the directive into national legislation. However, to date only the UK, France, Netherlands and Portugal have notified the European Commission of having implemented legislation. The legislation covers various aspects : it seeks to ensure that the consumer is provided with full and accurate information, that the tour operator is able to compensate the consumer and if necessary able to guarantee the safety and security of the tourist. Non-implementation of the directive has at present led to a certain degree of unfair competition since operators in some countries are obliged to satisfy stringent and costly regulations while others do not.

While protection of the tourist as consumer is an essential consideration a balance has to be struck whereby the industry can still function without being overburdened by excessive regulation. This is a key element in the current development of the timeshare and distance selling legislation.

Since January 1993, the first Community Action Plan to assist tourism has been in operation. The three year action programme, with a budget of 18 million ECU aims to ensure the coherency of the Tourism Plan with actions being implemented under other Community measures and policies. This will be achieved by focusing on three main lines of action:

- ensuring that tourism is taken more into account in Community and Member States' policies;
- co-operation between representatives of the sector and its various professional associations;
- support and development of specific actions.

The first objective seeks to achieve greater coherency in the initiatives taken within the Commission, with other bodies implementing policies or taking measures that might have an influence on tourism; with Member States, to complement their actions in certain fields of tourism, develop actions allowing the broadest possible rapprochement of their policies, or provide them with the overall information necessary about the activity, in order to direct their actions better, and encourage all forms of international exchanges on tourism.

The second objective will be implemented basically by means of consultation and co-ordination activities with tourism professionals in order to convey the importance of this business

in economic and social terms, ensure better representation of its interests, and develop information within the industry itself about the policies and measures by the Community with direct repercussions on its business.

The third objective is mainly concerned with actions to guide future policy: to provide better information regarding tourists and those working within the industry; for supporting projects which could serve as examples, and which could be transposed to various regions of the Community; for a general improvement in the quality of tourism services.

Promotion is the subject of various pilot projects, which will enable distant markets to be explored and tested, and the numbers of tourists from those markets to be increased, on the basis of an overall image of European Tourism.

The scope of specific measures will be rather broad, in a very varied number of fields (cultural, rural or social tourism, environmental tourism; vocational training). These actions are directly aimed at the public authorities, industry decision-makers and tourists themselves.

OUTLOOK

The World Tourism Organisation forecasts a growth of 50% in international tourist arrivals by the year 2000. An annual growth rate of 3.5%. is envisaged for the first decade of the XXIst century: by the year 2010 there will be an estimated 937 million arrivals. The generating regions, expected to show the fastest rate of growth include Central and South America, Asia and Africa. Those host tourist regions, which may experience above average growth include the Caribbean, East and South Asia as well as the Pacific area. Even if Europe will still be the main tourist destination, it will continue to lose market shares, mainly to East Asia and the Pacific area.

Written by: European Commission - DG XXIII - Tourism Unit

Restaurants
NACE 661

The restaurant sector includes a diverse range of establishments from fast food take-away to haute cuisine. Throughout the 1980s, changing tastes, rising levels of disposable incomes, greater female labour force participation and increases in tourism expenditures contributed to a steady increase in restaurant revenues. The industry is very susceptible to economic conditions and growth slowed significantly during between 1991 and 1993. Entry and exit barriers are very low. As a result the industry is predominantly populated by small independent establishments, although rapid growth of fast-food chains, particularly franchise outlets, has provided a high degree of uniformity in that sub-sector. While the use of new technology, mainly in food preparation, has been increasing attraction and retention of workers is a growing problem in many Member States. Despite the recent slowdown, the outlook for the industry is relatively buoyant and the factors which drove growth during the 1980s should continue to operate over the remainder of the 1990s.

INDUSTRY PROFILE

Description of the sector

Among the most vibrant and visible commercial sectors of the EC, restaurants are present in virtually every local community. As a sector, restaurants are important to the European economy and to the economies of Member States and regions, but they play their most significant role in their contribution to the local economy of almost every village, town and city in the EC.

There is substantial variation within the restaurant sector, from fast food outlets to high class restaurants, providing very different markets with a variation of the same service, the provision of ready to eat food. Most restaurants are stand alone operations, although some are an integral part of the services provided within other sectors, principally hotels but also including recreation parks, public houses, railways, ferries and night-clubs. There are also other service branches specialising in the provision of food including contract caterers, work canteens and messes and convalescent homes. However, while the type of operations are diverse, the sector is dominated by family restaurants.

There is a fine distinction at the margin between sub-segments of the restaurant industry. Unlike hotels, most grading of restaurants is unofficial, often relatively subjective and generally only applies to the top end of the market.

Recent trends

Eurostat statistics on restaurant turnover varies in content and timeliness across Member States. It is particularly dated in the cases of Greece and Denmark.

Available data indicates that the number of restaurants and cafe-restaurants increased in all EC Member States over the 1986-90 period. A decline in the number of establishments in 1991 in Denmark and in Luxembourg points towards the impact of the slowdown in economic activity which was beginning to emerge at that time.

Restaurant turnover has grown along a well established upward trend over the last decade although there are variations across different Member States and growth has slowed over the last two years reflecting both the onset of economic recession in Member States and the slower growth in tourism expenditures. Within the overall trend increase, turnover in the fast food and take-away sector has been growing most rapidly, although again there are substantial variations across countries with meals in bars and public houses showing the fastest growth in both the United Kingdom and Ireland.

Official employment in the restaurant industry is also available for only a limited number of EC Member States. The evidence indicates that the trend in employment is upward but increasing much less rapidly than turnover. While no official data is available it is likely that employment grew little, if at all over the 1991 to 1992 period.

Restaurant services are not internationally traded although an important market for their services are foreign visitors on holidays or business trips. Estimates for expenditure by tourists on food vary from 20% to 25% of their total expenditure.

MARKET FORCES

Demand

The demand for restaurant services is influenced by a variety of factors including disposable incomes, demographic factors, changing consumer tastes and the level of tourist activity. Restaurants also compete with other leisure activities including cinema, theatre, home video and sports for the discretionary spending of the consumer. The propensity to eat outside the home is most strongly, and positively, linked to increases in disposable income. As a result the general trend in demand for restaurant services has been upwards. Private expenditure on eating out is, however, seen as a luxury in most Member States and is vulnerable to dips in disposable income. Similarly, corporate entertainment, an important factor at the upper end of the restaurant market, is also closely linked to the level of economic activity. Thus, the restaurant sector has shown little growth over the 1991-93 period.

Overall, however, and reflecting this linkage the proportion of total consumer spending on eating out has risen over the second half of the 1980s and it is estimated that the EC average is around 5%. The estimate hides substantial variations among Member States. In some cases these differences reflect the importance of the tourism sector, the proportion is above average in Spain and Portugal, while in others it reflects traditional attitudes to eating out.

If the EC catering industry is to follow the USA, where it is often cheaper to dine in a fast food or family restaurant than to buy equivalent ingredients and cook at home, then the tendency for locals to choose to eat out on the basis of

cost and convenience will become more established. Already in the EC eating out has become both more commonplace and relatively less expensive.

The growth of tourism is clearly a major source of business for the consumer catering industry in the EC. Even when staying in self-catering accommodation the tourist tends to eat out rather than cook for himself; when staying in hotels and similar establishments there may be little choice but to frequent restaurants and cafes. In common with many other companies who deal in the totems of popular culture, the large fast food firms view the relatively young and increasingly affluent populations of southern European Member States as providing the best prospects for continued growth in Europe in the 1990s. The ageing of the EC population will, however, dampen the growth of fast food outlets in the medium term. In addition the "saturation point" for fast food restaurants is approaching in a number of northern Member States and is thought to have already been reached in the United Kingdom. Relatively rapid growth in demand for ethnic restaurants, particularly those with cuisine's which are not well represented at present, is also expected across the EC.

The increasingly rapid spread of communications media, through satellite Television for example, aided by the growth of international tourism flows have accelerated the trend towards greater internationalisation of the restaurant market and aided the growth of US-type food outlets serving hamburgers and pizza. There are significant trends also towards, e.g. health foods, pasta and the replacement of red meat and red wine by their white counterparts and by fish. In addition the number of ethnic restaurants in many European cities is growing reflecting internationalisation trends and the increased confidence and sense of experimentation among consumers. Conventional food service styles, products and concepts are being rendered obsolete by 1990s lifestyles. An exception to these trends is the resurgence of regional cuisine, especially in France, Spain and Germany.

Family restaurants relying usually on local business may also benefit from the growth in tourism. When a slump occurs in international tourism, smaller restaurants in remote places can gain as EC nationals spend their holidays exploring their own countryside. Transport restaurants are also susceptible to fluctuations in tourism.

Supply and competition

The key competitive factors in the restaurant industry are food quality, price and decor. Entry and exits barriers in the restaurant sector are negligible at most levels of the industry and small, often family-run, firms predominated. As a result, and because of the localised nature of competition, there is little danger of monopolistic practices emerging and strong competition is evident both within and across segments of the industry.

Take-away and fast food have been the main growth areas in the European restaurant sector in recent years. US firms are providing the driving force behind this growth. Having expanded initially in the United Kingdom, they are now spread-

ing throughout mainland Europe where they are facing increasing competition from indigenous companies. Theme restaurants are also spreading very rapidly. This spread is not simply driven by "ethnic" entrepreneurs but also by the larger restaurant chains who are increasingly using sophisticated market research techniques to examine concepts, test pilot operations and are utilising Epos (Electronic point of sales) information and geo-demographic databases to determine suitable locations. Like fast food outlets before them a new set of US-based theme restaurants are now well established in the UK - Tex-Mex, Cajun, and 1950s nostalgia themes - and expanding elsewhere in north Europe.

One of the critical issues facing the restaurant sector within the EC over the coming decade will be the availability of labour and the ability of the sector to compete with other industries in offering a worthwhile career to staff. Because it is dominated by family owned enterprises the concept of "employment" in much of the European restaurant sector is blurred. Very frequently husband and wife will work together in a restaurant and they may be helped by grandparents, children and other family members whose remuneration may be "in kind" rather than through cash payment. Throughout the Community, however, owners of family restaurants are discovering that their sons and daughters are being attracted into other areas of employment.

Where employment is regulated, pay and conditions in EC restaurants tends to be towards the minimum for each Member State. There are of course exceptions, but generally employment conditions in restaurants involve long and unsociable hours, relatively low levels of basic pay and a reliance by employees on gratuities and service charges. Pay and conditions tend to be the best where agreements have been reached between employers and trade unions but these agreements also tend to be confined to the larger and more structured employers. Staff turnover in restaurants is high and there is a lack of structured training in several countries.

As demographic patterns develop and family sizes decrease particularly in the north Member States and turnover continues to grow, the restaurant sector will experience staff and skill shortages. This is already evident in the United Kingdom, Germany, Benelux, France and Denmark where restaurant chains are seeking to recruit part time workers, students and senior citizens as well as immigrants from outside of the EC. The problem is not as serious in south Member States. However, tourist authorities in these Member States have expressed concern that there will be migration of restaurant (and other hotel) workers from Greece, Spain, Portugal and south Italy to fill vacancies in north Europe. Such migration is likely to add to pressures to improve wage and other working conditions in the less developed Member States.

Competition in the restaurant sector is similar to that in other services which are dominated by small individually-owned enterprises. The cost of entry to the business is relatively low and this encourages entrepreneurs to enter a local market, particularly when restaurant business is seen to be growing. The establishment of restaurants is however governed by regulations in all Member States. These include the granting of planning permission, the certification of the premises by the local health authority and in some Member States the granting of a license to sell alcohol. Generally different regulations governing restaurants are not a barrier to competition. Future mergers to create national or supranational chains are also unlikely to distort competition in the sector.

Competition within the sector is complex and differs across market segments and locations. Price elasticity tends to be lower at the top end of the market where competition is based on reputation, image and a perceived high quality of food and service. These competitive criteria also exist in the broad segment of family restaurants in which marketing and advertising is rarely undertaken. Location is a key factor but ambience, quality of food and personality of the proprietor are also important. Price assumes greater importance when the reputation of the restaurant is largely confined to the local community. Price as a key factor is also particularly evident in "in store" cafeterias and restaurants, in coffee shops and in the fast food sector. Overall the trend has been for prices to move in line with inflation but strong local competition has kept price increases below inflation in larger cities throughout the EC.

The relatively minor position of corporations and chains in the European restaurant sector and the American base of some major players make it difficult to comment on profitability. Statements from Hotrec, the EC hotel and restaurant lobby organisation, and from national associations of restaurant owners indicate a relatively high level of business failures among EC restaurants over the past decade and that the lack of expansion by the vast majority of restaurants reflects lack of profitability. For nine out of ten European restaurant owners the business is a "way of life" which is sufficient to provide a modest standard of living for a family. In the case of some of the major players such as the retail stores, restaurants provide a service that attracts customers and make a contribution to the overall profitability of the enterprise.

Contract catering

In addition to public catering, the contract catering sector is a fast growing segment in the restoration business (15% a year, according to FERCO). The number of meals served by the EC contract catering industry grew from 1.1 billion in 1980 to 2.1 billion in 1990, it is forecasted that 3.3 billion meals will be served by the year 2000.

The market segmentation in the contract catering business sees the predominance of business, industry and State institutions which account together for 66% of the market. The remaining third is shared by healthcare (14%) and Education (19%).

Contract catering, provides quality food at an economic price. In 1990, sales reached 1 982 million ECU in France, 1884 million ECU in the United Kingdom and 1708 million ECU in Italy. By contrast, sales in the German market did not exceed 445 million ECU.

The future of the contract catering industry looks optimistic: as it expands from offices and factories into schools, clinics and military establishments, the growth projection continues on its steep curve.

Production process

The preparation and service of food has traditionally been a labour intensive exercise and this is still largely true. In most restaurants the raw materials tend to be supplied in a fresh state, prepared by hand, cooked by traditional methods and served to diners at their tables. Fast-food outlets differ from this categorisation in that the raw materials are often semi-prepared and take-away business is of considerable importance. It should be noted that some restaurants have reacted to the recession by moving into the "home deliveries" market.

Some machinery may be used in the chopping and mixing of raw materials and some foods may be stored under frozen or chilled conditions, but these are often the limits of technology in a European family restaurant.

Pressures on the availability of skilled staff as well as high labour costs are however forcing the industry to look towards technology to help reduce unit costs. Automation and technology are playing an increasingly significant role in the preparation of restaurant meals.

While progress in introducing new technologies is relatively slow in the small independent restaurants, use of new technologies are very evident among restaurant chains and larger enterprises. Fast food restaurants and contract caterers have

practised bulk preparation of food and its storage under frozen or chilled conditions for many years. Such methods are also used in hospital catering and in the provision of meals in industry and institutions. Frozen product, including meat, fish, potatoes and vegetables is used extensively in the fast food and "quick service" sectors and there has been widespread development of freezers and regeneration cookers. The refrigeration industry has however been subject to criticism because of its use of CFC gasses in refrigeration units and a new generation of "environmentally friendly" refrigerators and freezers which are "CFC free" is now appearing on the market.

Worries about meal "quality" is a key consideration limiting the spread of bulk preparation methods throughout the restaurant industry. New technologies used in "cook chill" and "sous vide" systems have helped reduce the importance of this barrier. The principal advantage of the "cook chill" system is that food can be prepared in batches to tight specifications and these "batches" can be used to compile meal menus. The ability to cook food in bulk and to "hold" it for several days has enabled restaurants using this system to reduce their staff requirement particularly at night or over week-ends. "Sous vide" originated in France and is growing in popularity at all levels of the market. Under this system dishes, delicate sauces are cooked and preserved in a plastic pouch which is chilled, for regeneration prior to serving. The system has enabled caterers to expand their menu by having additional dishes under storage.

Electronic technology has offered greater control over traditional cooking media such as ovens and gas or electric ranges. The "combination oven" which can cook foods in several ways, is a product of this technology and enables designers to add "cooking cycle programmes" and electronic probes that measure temperature and moisture content of the food during the cooking cycle. Microwave ovens which are now widely used at all levels of the market are also enhanced by electronic controls. Energy costs in restaurants are relatively high and this has led to greater emphasis on energy efficient cooking with the advent of halogen elements in electric ranges and induction cookers providing the most promising developments.

The principal "stock in trade" of restaurants is food in a raw or semi prepared state. At all levels of the industry there is increasing demand for conformity to specification and continuity of supply. The "Quality" system has been employed informally by the vast majority of restaurateurs over the centuries and still works effectively today.

Among corporate-owned restaurants, however, quality is achieved through more formal structures. Detailed specifications are drawn for each food item and there is a greater emphasis on partially processed or prepared foods which are frequently supplied in a frozen state. A growing number of corporately-owned restaurants now operate just in time systems similar to those operated by manufacturing industry.

INDUSTRY STRUCTURE

Companies

While becoming increasingly dominated by big chains, as the growth in the fast food and take-away sector outpaces average growth, all EC countries continue to offer an enormous range of family run restaurants and cafes that are central to the appeal and character of the industry. The increase in market share of the chains has, however, been at the expense of the traditional independently-run operations in addition to capturing overall market growth. A recent Economist Intelligence Report, "Eating Out in the United Kingdom" estimated that the restaurant market was becoming increasingly concentrated.

The sector includes chains of restaurants, often owned and operated by conglomerates, and also embraces the fast food subsector which is largely controlled by American companies operating in Europe through local franchises. The largest ca-

tering group in the EC, McDonalds, fits this profile perfectly. Fast food restaurant chains are both multiple retailers and a production enterprise. In both the facets of their activities they have similarities with multinational multiple retailers and with multinational manufacturing enterprises. Like the retailers, expansion across national borders has occurred first and most substantially in the wealthiest EC Member States.

The most significant group of restaurants, which represent more than 90% of the sector across the EC, are family-owned and employ less than ten people, some of whom may be casual or part time employees. Family-owned restaurants span the full spectrum of dining out in Europe from simple take-away "fish and chips" shops in the United Kingdom to the award-winning restaurants of the famous French chef-patrons. The local family restaurant often offers dishes based on local or regional cuisine. More and more this cuisine is offered outside its country or region of origin. It is no longer unusual to find, for instance, restaurants serving Italian cuisine in France, Greek restaurants in the United Kingdom or French restaurants in Germany. A trend throughout Europe has also been the success of restaurants offering regional cuisine outside of their own regions, for instance Tuscany dishes in Veneto or the cuisine of Andalucia in Catalonia. Similar, many upmarket French and Italian restaurants are adopting more adventurous menus featuring regional dishes and their influence is filtering down to more mainstream European restaurants.

The gourmet segment of the market is dominated by family-owned restaurants and in most Member States it is the personality, reputation and skill of the patron who may be the chef or the maitre d' hotel on which the success of the enterprise is based. Many such family-owned restaurants at the top end of the market are relatively large concerns employing up to 100 people and some, like the Roux Brothers in the United Kingdom and Paul Bocuse in France, have developed ancillary enterprises. More typical even at this level, however, is the restaurant serving 50 dinners each evening, owned and operated by a single proprietor and employing a staff of around 20.

Corporations and chains are rare in gourmet dining, except in the context of hotels. Many four and five star hotels of Europe offer at least one restaurant serving gourmet food. The scale and variety of the food offer in hotels is also expanding. More hotels are now operating ethnic restaurants in addition to the cuisine of their region, an international menu and informal dining in brasserie and coffee shop styles.

Strategies

Investment by corporations has been most obvious towards the lower end of the market, particularly in the areas of popular catering, transport catering and fast food. Groups like Forte's Little Chef (United Kingdom), GIB (DK), Quick (F), GfnBAB (D) and Autogrill (I) have developed successful chains of restaurants close to motorways and associated restaurants can also be found in towns and cities. These chains tend to be national rather than transnational and a dominant EC-wide restaurant chain has yet to emerge.

A transnational restaurant chain may emerge through activities in other sectors such as retailing or hotels. Forte's "Little Chef" is expanding alongside the hotel group's hotel joint ventures in Spain and Ireland. Supermarkets and department stores already operate large chains of cafeteria style restaurants in France, Germany, Benelux, United Kingdom and Italy. The expansion of these stores within the Community would lead to the expansion of their restaurants also. Karstadt, Hertie and Kaufhof operate large restaurant chains in Germany and the Casino supermarket chain operates the largest group of restaurants in France with 238 outlets. Other large scale retailers involved in restaurants include GB Inno-BM of Belgium. In addition individual restaurateurs have opened restaurants offering their own national or regional cuisine in

Source: HOTREC, 1993

larger cities of Member States. The EC capitals for instance are the location for restaurants in the style of virtually all Member States.

Investment by corporations from outside of the EC has been an increasingly important phenomenon since the early 1980s. This has been confined almost entirely to the fast food sector and has been spearheaded by the American chain McDonalds which had around 1,360 outlets in the Community at the end of 1992, growth of over 30% since 1990. Other chains which originated in the US like Burger King (376 outlets), Kentucky Fried Chicken (351 outlets) and Pizza Hut (over 300 outlets) have also been making an impact on this segment of the market - Burger King and Pizza Hut are now owned by United Kingdom companies, Grand Metropolitan and Whitbread respectively.

Popularity of fast food and fast service can be attributed to the European acceptance of American dining culture particularly among young people, to the expertise of the American chains in the areas of product development, location of outlets, staff training, consistency in quality, and to changing living patterns in Europe. The principal food products served in this sector include hamburgers, chicken, pizza, pastry, fish and potatoes. Entrepreneurs in each Member State have established national and regional fast food chains which compete with the US-originating franchised outlets. In this area France, for example, has achieved considerable success with groups like Quick, La Brioche dorée, La Croissanterie and Pomme de Pain.

Investment in the EC restaurant sector has also come from entrepreneurs from outside of the EC opening "ethnic" restaurants. Thousands of restaurants owned by immigrants and offering Chinese, Indian, Thai, Vietnamese, Argentinean, Indonesian and other cuisine's scattered throughout the Community, are seeing their market share increase.

REGIONAL DISTRIBUTION

Restaurants are ubiquitous in Europe. Many restaurants at the upper end of the market are often found in relatively remote rural areas, an aspect which may serve to improve their "charm". In many cases location is a key factor, both in terms of the ambience it may lend to the overall "dining" experience, as in high quality restaurants or in terms of the throughput it helps generate.

In general, concentration and level of competition is related to population densities. Cities and larger towns have more restaurants per head of population than do villages and rural areas. An exception lies in areas of tourism interest that tend to have a large number of restaurants competing for tourism business, although some may operate on a seasonal basis.

ENVIRONMENT

The challenge of increasing interest in health foods is already been met by many caterers, with greater emphasis on appropriate ingredients appearing in an increasing number of middle- and upper-range restaurants. Similarly, choices catering for vegetarians are increasingly common in non-vegetarian restaurants. On the other hand there is less evidence that the demographic shift to an older population which, to-date, has not been a target of the large catering chains, is being addressed.

Restaurants tend to be kind to the environment, and are becoming even more so. Waste is largely biodegradable and recyclable. It is also easily sorted for recycling or other methods of disposal, although the extent to which this occurs varies across Member State. Cooking systems are also generally environmentally friendly. Some concern has been expressed regarding CFC gasses used in refrigeration but this issue is being addressed by refrigeration manufacturers. On the other hand, packaging from the fast food sector is perceived to be a major contributor to litter problems in many Member States. Some chains have taken steps to ameliorate litter problems - McDonalds, for example, now use biodegradable packaging rather than expanded polystyrene.

Some restaurant clientele have also expressed concern about production methods used in the food raw material but this has not as adversely affected the sector to any great extent. Nevertheless, some restaurants are winning popularity by guaranteeing customers that all dishes are prepared from organically-grown produce and that poultry and fish are not the product of intensive growing systems. Consumers are also showing preference for foods that are perceived to promote health and this demand has led to the creation of new style cuisine based on a healthy diet. Eurotoque, the EC association of chefs, has been active in promoting a positive approach by restaurant owners to the environment.

REGULATIONS

There are a wide variety of national and EC regulations impacting on the restaurant trade. The most important include compliance with hygiene regulations and certification by local health authorities, regulations relating to working conditions, and in some cases the granting of a licence to sell alcohol. Hygiene regulations across the EC are in the process of being harmonised, EC labour legislation is constantly impacting on conditions of work, particularly in the less developed states and on-going proposals for a directive on packaging will also affect the industry. Harmonisation of VAT rates (and excise duties on alcohol) will also have differential impacts on restaurants across the Community over the next five years.

The Directive on the hygiene of foodstuffs (93/43/EEC) was adopted in June 1993. Standards of hygiene are set out in the annex to the Directive and a number of ways in which Member States can assist firms in achieving these standards is suggested. Firstly, it is recommended that ISO 9000 quality standards be promoted within the EC. Secondly, it is recommended that codes of practice for food hygiene be drawn up for particular sectors, in order to assist firms and individuals in fulfilling their legal obligations, as set out in the annex. It is envisaged that these codes of practice may eventually be harmonised at an EC level. Thirdly, the use of the HACCP (Hazard Analysis and Critical Control Points) system is to be encouraged among those who have legal obligations in relation to food hygiene.

Restaurants services are not included in the list of goods and services to which Member States may apply a reduced rate of VAT. However, the Member States that were applying a reduced rate to restaurant services at 1 January 1991 are allowed to continue to do so at least until the end of 1996.

OUTLOOK

The restaurant sector in the EC has been growing throughout the 1980s and despite a slowdown in recent years this overall growth is likely to continue during the 1990s.

Growth in intra-EC travel and in the number of visitors from outside the Community will increase demand for restaurant facilities. Having seen their share of tourism growth falter in recent years, Mediterranean Member States should experience more rapid growth over in the medium term, both in volume and value terms. Poor quality was a major contributor to loss of market share in south Europe. Reflecting an increase emphasis on quality and higher value-added tourism, restaurant expenditure per tourist should increase. More short-breaks and second holidays should contribute to increase trips and restaurant expenditure among domestic tourists in north Member States.

Table 8: Restaurants, snack bars, cafes and other eating places
Expected average annual growth rates

(%)	1993-94	1994-97
Turnover	2.0	3.0
Employment	1.0	2.0

Source: Fitzpatrick Associates, Economic Consultants

An important consideration in estimating when growth in restaurant turnover will accelerate depends on when Member State economies emerge from recession. While a growing share of household expenditure was devoted to eating out during the 1980s, this trend may have run its course in some of the more developed Member States. Disparities in Grosso domestic Product (GDP) and private consumption expenditure growth rates will create higher levels of demand for restaurant services in those Member States whose economies grow fastest. With the outlook to the mid 1990s for a recovery in GDP growth across most EC Member States, the Economist Intelligence Unit forecast average GDP growth across the EC at around 1.5% per annum over 1993 to 1997, from zero growth in 1993 and accelerating throughout the period. Increased spending on eating out somewhat above this level is expected.

Employment growth is expected to be below that of turnover. The level of automation will increase, motivated by cost-cutting, service improvement and problems with attracting staff. Restaurateurs are also likely to seek other service innovations reducing labour usage.

National growth rates will also be affected by the prevailing tradition of dining in restaurants, which varies widely across EC Member States. Social attitudes towards eating out are changing and as the EC becomes more integrated, the dining tradition is likely to spread throughout the Community. Although the degree which entrenched national characteristics will be affected over the next three years. Different segments will also grow to varying extents across Member States. For example, in relation to the size and wealth of Germany, France and Spain and the present under-representation of international chains there are good opportunities for expansion by these companies, while continued economic austerity will constrain growth of eating out in Greece. Gira-Sic, quoted in the French trade magazine Néo Restauration, estimate growth of 147% in the number of enterprises belonging to chains in Germany during the 1990s. The corresponding estimates for France and the United Kingdom were 80% and 55%.

Countries with an emerging youth population will also see more rapid growth in fast service and fast food restaurants and those with an ageing population will see more growth in health food and leisure style restaurants. Changing demographics, social patterns and tastes will also offer opportunities for restaurants to increase sales for home deliveries, although this may have some impact on traditional sales. As more people move into urban areas there will be fewer family meals, greater consumption of snacks and small meals and more dining in restaurants as a leisure activity.

Hotels
NACE 665

The hotel sector comprises a disparate variety of establishments in terms of size and range of services provided. Demand for hotel services is predominantly from tourists, with business travellers accounting for a substantial proportion. Fragmentation of demand in recent years has resulted in growth of both affiliated hotels providing a uniform product at different price/quality levels, and of hotels striving to differentiate their product. Concentration in the industry is growing as large hotel chains increase market share, although this increase should not be a source of concern to Competition Authorities. In response smaller hotels are increasingly joining voluntary associations. The industry has experienced a slowdown during 1991 and 1992. This reflects ongoing economic difficulties in major EC and to a lesser extent extra-EC, economies and is expected to be temporary. The outlook is for modest growth during the mid-1990s.

INDUSTRY PROFILE

Description of the sector

The hotel sector comprises establishments which vary widely both in terms of size and services provided. At one end of the scale there are small, single location, family run enterprises providing accommodation services and at the other are large hotels, frequently part of a chain, operated in a highly professional manner and providing a wide range of services. Such services might include restaurant and banqueting, public bar services, health and leisure facilities, bureau de change, shopping facilities, business secretarial services and conference facilities. The number of hotels supplying accommodation only is now relatively small, with a discernible trend towards larger establishments providing a broader range of services. As a result the extent to which the business of hotels impinges on other service sectors is increasing.

Official statistics on hotel turnover and value-added in different EC countries do not exist. Nor are there consistent definitions of hotels and similar establishments across countries, making aggregations and inter-country comparisons difficult.

Eurostat data indicates that the hotel industry is most important in Italy and the United Kingdom. These two countries have considerably more hotels than the other Member States, although the United Kingdom estimate includes inns and guest houses. Definition differences are reflected when beds are used as an indicator of capacity. Italy had an estimated 1.7 million beds in 1991 compared to 1.1 million in France, 0.9 million in Western Germany and 0.8 million in Spain.

Recent trends

Despite definition differences, a trend increase in the volume of turnover in the accommodation services of hotels is evident from guest flows, with an increase in guest nights each year from 1985 to 1992, with the exception of 1991. In value terms, however, turnover is unlikely to have risen since 1990 as many hotels have been forced to reduce tariffs to maintain occupancy levels.

Over the period 1986 to 1991 guest flows through hotels and similar establishments also rose in most Member States. The only exception was the United Kingdom where a sharp decline in bed nights from domestic residents was recorded. Increases of 20-27% were recorded in most northern European Member States.

Analysis of available bed nights indicates an increase in the supply capacity of the industry. The number of bed places increased in most Member States over the 1986 to 1991 period, this shows a continuation of the trend in the first half of the decade. The increase in available capacity was least evident in Italy where growth over the five years to 1991 was only 6%. Denmark, West Germany, Greece, Spain and Portugal all experienced increases in the number of bed places in excess of 20%.

While the number of foreign guest nights fell in some countries, most notably some southern Member States, this was more than compensated for by rises in domestic guest nights. A decline in both business and tourist demand led to some contraction in 1991, with a return to modest growth in 1992.

The increase in the number of beds and bedrooms was against a background of a slight decline in the number of hotels and similar establishments. This reflects the industry trend towards larger units. Occupancy rates in the hotel industry fell sharply in 1991. They were above 60% in 1990 in each of the eleven EC Member States surveyed by Pannell Kerr Foster (PKF), ranging from 62% in Spain to 75% in Denmark. However, in 1991 they fell in all Member States. Low occupancy rates are particularly evident in Southern Member States and in 1991 were 53% in Spain, 57% in Greece and 60% in Portugal.

Data collected by PKF on average room rates across different European countries places France's hotels as the most expensive, closely followed by Spain. Prices in EFTA countries tended in general to be higher than in the EC with particularly high average rates in Austria, Norway and Switzerland. On average, room rates were lowest in the Netherlands and Greece.

Price levels and changes in the EC's capital cities, however, reflect local supply and demand imbalances and local property prices. Analysis by the Economist Intelligence Unit (EIU) indicates that the prices of hotels, fell in response to lower demand between 1990 and 1992. Reflecting lower prices and falling occupancy rates profit levels also declined in 1991 and 1992.

Official employment in the hotel industry is only available for the accommodation sector as a whole and then only for seven of the twelve Member States. The trend in overall employment is upward reflecting industry growth and the limited possibilities for capital substitution. The overall growth in total employment masks a decline in the number of self-employed persons, again reflecting growth rates of larger chain operations at the expense of smaller traditional hotels. However, the high level of employment in the United Kingdom relative to its low number of bed places highlights the problems of comparability using official data. These data problems are currently being addressed by Eurostat.

International comparison

Horwath International's analysis of the overall performance of hotels by global region indicates that income per available room before fixed costs and revenue per room were relatively high in Europe in 1991. However, Horwath data is most pertinent to chains.

Foreign trade

Available data on hotel nights does not facilitate a breakdown into intra-EC and extra-EC "exports" and "imports" of hotel bed nights. Most Member States distinguish between resident and non-resident guest nights. Over the second half of the 1980s the strongest growth, in most Member States, was non-resident guest nights. A slowdown in international tourism growth in 1991, however, has contributed to a decrease in non-resident guest nights in a number of Member States.

MARKET FORCES

Demand

The most important consumers of hotel services are tourists, although their importance varies across Member States. Horwath International's hotel sample survey indicates, that business travellers are of much greater importance in Germany and the United Kingdom.

The period from the commencement of the Gulf War in mid-1990 to the end of 1992 has been one of the most difficult periods in the recent history of the European hotel industry. In addition to the war and its impact on international travel, recession in Europe and the United States have all combined to depress the tourist and business accommodation markets.

The distinction between tourist and business market demand is important as they are affected by different factors. While both are affected by the general level of economic activity, business travellers, and in particular the conference market, are more sensitive to economic downturns than tourists are. International and domestic business demand is higher in northern European Member States reflecting higher GNP levels.

Recent analysis by stockbrokers, Kleinwort Benson Securities in the EIU's Travel and Tourism Analyst suggests the importance of service industry and the level of concentration are important components of the demand for domestic business travel. Large service firms tend to have a greater number of branches than their manufacturing counterparts and thus, generate substantial travel.

Closer integration of the EC Internal Market, and subsequent cross-border expansions will continue to increase the importance of inter-EC business travel. Traditionally, business travellers have been less price sensitive than tourists and while this is still true, the ongoing economic slowdown has made firms more conscious of their travel budgets and costs.

Income levels are an important determinant of overall tourism demand. In more prosperous northern Member States second annual holidays are now commonplace, while in the southern Member States international tourism has recently grown, reflecting rising incomes and increased leisure time arising from shorter working hours. Increased frequency of holiday-taking spreads seasonal tourist flows and favours hotels relative to the other popular forms of accommodation. In addition, with increasing female participation in the workforce and a tendency towards smaller families a growing proportion of European households have two incomes and higher levels of disposable income.

The relative importance of international versus domestic demand varies widely across Member States. The tourist attractions of France, Greece, Italy, Portugal, Spain and to a lesser extent the United Kingdom and Ireland attract substantial numbers of foreign hotel guests. Traditional factors, such as climate and income levels affect the habits of domestic holiday-makers across Member States with relatively greater usage of hotel accommodation in northern Europe. A slight reversal of the traditional north to south tourism flows has been evident in recent years reflecting increased international holiday-taking by southern Europeans and the declining relative importance of sun and beach holidays. Both trends should boost hotel demand somewhat at the expense of other types of accommodation.

Trends towards cheaper and independently organised holidays will adversely affect hotels at the upper end of the market although lower grade hotels will also face competition from non-hotel accommodation. On the other hand, the ageing of the European population and continued growth in the importance of long distance and business travel augur well for hotels at the upper end of the price-quality range. Not all independent tourists seek budget accommodation and many hotels at the upper end of the market are cooperating with other suppliers and adapting their product to attract the more lucrative segments of this market. Thus, many hotels have increased average occupancy rates through the promotion of off-season short breaks, particularly at weekends.

International tourism is highly vulnerable to economic conditions. The number of US visitors to Europe fell substantially in 1991 with little sign of recovery in 1992. The fall was initiated by the Gulf War but the extension of the downturn into 1992 also reflects the downturn in the United States economy and the weakness of the dollar. However, the North American market began recovery in 1993. Visitor numbers from Japan, after doubling in the preceding five years, fell reflecting nervousness about political developments and the wealth effect of stock market falls on potential travellers. Long distance travellers are also much more likely to use hotel accommodation and in particular hotels at the upper end of the market. Long distance origin markets are particularly important to higher end hotels. Tourists from EFTA countries are more likely to use budget or non-hotel accommodation than their long distance counterparts, while initial flows from Eastern Europe may also favour non-hotel accommodation.

Supply and competition

Economic power is important in negotiations between the industry and upstream suppliers, such as major tour operators, but the need to maintain goodwill and quality standards generally tempers excessive exercising of power. Similarly, the emergence of anti-competitive practices through increasing vertical integration are less likely because of the volatility of the tourism demand, the "contestable" nature of the industry and the high degree of inter-dependence between its various segments.

The nature of the hotel industry is such that imbalances between supply and demand are generally localised in either time or space and invariably lead to variations in prices and in profit levels. Surpluses and shortages in "time" are most common. Thus, the downturn in tourism demand over the last two years resulted in good deals for consumers but substantial losses for many hotels. This was particularly evident in the United Kingdom, during 1991 hotel re-possessions reached a record high during 1991 and in 1993 two high profile quoted companies, Queens Moat Houses (UK) and Resort Hotels (UK), both had their share quotations suspended.

Characteristics of the hotel industry affecting competition include: ease of entry and exit, the often localised nature of competition and competition between segments within the industry and non-hotel establishments supplying similar services. These factors ensure that, in general, monopolistic positions are rarely attained; exceptional hotels at specific locations, such as The Gleneagles in Scotland, can maintain excess margins. In addition, in 1992 only 14% of hotel rooms in the EC were publicly traded companies, indicating concentration remains low despite the recent growth of chains. Thus, increasing competition through mergers of large chains in the European market is not a cause for significant concern for Competition Authorities.

Seasonal variations in demand for hotel rooms typically result in generally lower prices (or additional value-added in terms of special incentives) in many rural and resort hotels in the off-season. Many urban hotels are also capitalising on the growing short break market to boost overall occupancy in hotels which are filled during the week by business travellers. Capacity imbalances in some locations may also result in

Table 5: Hotels Employment

Source: Eurostat, Tourism 1991

profit variations around normal margins. In other cases, for example major sporting fixtures such as the Olympic Games, both time and location supply constraints put a strong upward pressure on prices.

Reflecting weak demand, hotel prices, particularly in the moderate/comfortable category, fell during 1991 and 1992. The increases in price vary widely across cities reflecting different supply and demand conditions. Data collected by the Economist Intelligence Unit indicates that the price of a single room in the moderate/comfortable category in Madrid rose nearly fourfold between 1985 and 1992 while the average tariff for a room in a similar hotel in Greece actually fell (in current ECU). In absolute terms, London hotels were the most expensive in 1992 in the "luxury" category, while Madrid was most expensive in the moderate/comparable category. Price levels and price changes in cities reflect local supply and demand imbalances. Local property prices, have the greatest affect on hotel prices.

In recent years, operating profits have generally been higher in chains, i.e. affiliated hotels, than in their independent counterparts. This gap is expected to widen. Analysis by Kleinwort Benson in the United Kingdom indicates very substantial differences in trading margins and profits per room between affiliated and unaffiliated hotels. The importance of scale, particularly in marketing-based economies, is recognised by many small hotels and increasing numbers are becoming affiliated to voluntary associations or franchising. Profit levels expanded alongside demand in European hotels during the second half of the 1980s. However, over the last three years difficult economic circumstances has led to falling profits and trading difficulties for many hotels.

EC hotels cannot compete with most extra-EC counterparts on price alone. The labour intensive nature of the industry ensures that hotels in developing countries have a strong competitive advantage. EC hotels are often reliant on the tourism strengths of their location and other quality factors. For example, the cheaper prices of East European countries are generally counter-balanced by lesser quality, not only in hotels but also in other local facilities and in the absence of flanking attractions. Improvements stemming from ongoing investments by the major chains will remedy some of the hotel specific deficiencies.

The cost of travel to many non-EC destinations is also a prohibitive factor, as demonstrated by the increasing popularity of Asian locations. Reductions in the cost of long distance travel can be expected to divert more tourists from competing EC resorts in the medium term.

Production process

The services provided by hotels vary widely across the industry. At one extreme hotels may simply provide accommodation, although this is relatively rare. More common place is a mixture of accommodation, restaurant food and retailing of alcoholic beverages. However, the variety of services being provided is wide and includes banqueting, health and leisure facilities, a variety of business services, shopping, bureau de change, conference facilities, laundry facilities and touring services.

The hotel industry is a service industry where most of the service offered is based on labour intensive methods. In particular it involves substantial use of part-time and female workers. This labour intensity is creating problems on two fronts. Firstly, labour is a major and increasingly expensive cost item, and secondly, attraction plus retention of labour is a problem. As a result, increased automation is apparent, mostly in northern Member States where problems with labour retention and the attraction of new workers are sharpest. The introduction of the 5 day or 40 hour week, night shift compensation, with weekends and holidays to enjoy, lure people away from labour intensive jobs with unsociable hours. Many hotels and chains have introduced innovative programmes to tackle recruitment and retention problems. Their intent is to enable personnel to move within the industry with clear career paths. They also entail improved cooperation with schools in terms of curricula and their selection of candidates. While the Single Market process will increase the reservoir of labour available to the hotel industry, greater mobility and higher expectations may accentuate staff retention problems.

Increased use of technology, yield management and CRS, front office systems, in-house entertainment, and improved kitchen equipment is contributing to greater skill requirements for hotel staff rather than displacing labour. Among the most important of these is yield management, which applies basic economic principles to pricing and controlling room inventory to maximise revenues. What makes contemporary yield management different from traditional pricing practices is the frequency and scope of the decision making process. These techniques make it possible to update prices for early and late arrival dates, and to match the market's demands each day to more profitable prices. Leisure traffic is normally price sensitive and books early, while business travellers are less price (but more quality) sensitive and tend to book late. Yield management enables the anticipation of late demand and the offer of an appropriate number of rooms at the higher rates these guests are willing to pay. These systems are also useful for market information, identifying clients, and deducing crucial factors affecting decisions.

Driven by economic developments, the spread of large chains, the growing complexity of the industry's market and the availability of sophisticated management information systems, is a growing trend towards more professional management in the industry. This is reflected in strategies for labour saving, such as the increasing number of hotels offering buffet breakfasts.

INDUSTRY STRUCTURE

Companies

Overall the hotel industry is fragmented but the importance of large hotel chains has increased considerably over the last decade. While these chains have brought a degree of homogeneity to the industry in many European countries, the structure and importance of the industry differs across Member States.

In terms of bed places offered, there is considerable concentration among the chains. The top ten chains operating in Europe provide as much capacity as the next forty chains combined. It should be noted however, that while the incidence of branded chain hotels is increasing, in some cases these are run by independent hoteliers on a franchise basis. Pressure for increased size comes from economies of scale in marketing, greater ability to meet the trend toward market segmentation with a complete range of differentiated services and advantages in covering a range of major destinations in any specific area. The strength of the chain to invest in CRS is another factor which will shape the industry in the coming decade, although advances in technology will increasingly enable smaller hotels to avail of CRS.

In identifying the world's top hotels the magazine "Hotels" distinguishes between three different types of hotel companies: corporate chains, with a strong brand identification, professional hotel management companies (HMCs), and voluntary chains and associations. There is overlap between these categories. For example, Best Western, a voluntary group is included among the corporate chains because of strong brand image while many of the larger corporate chains have their own HMCs which may run the hotels of other groups in certain locations. For example, Queens Moat Houses also run Holiday Inns, while the five top HMCs in the world have Hilton (USA), Sheraton (USA), Days Inn (USA), Radisson (USA), Marriott (USA) and Days Inn (USA) among their portfolios.

Other forms of affiliation such as leasing and joint ventures are currently being explored as a means of expansion by several chains, including Accor (F) and Forte (UK). Forte, for example, currently have joint ventures in Ireland (with Aer Lingus), in Italy (with Agip) and in Spain (with Repsol).

By global standards the top EC hotel companies are not as large as North American-based chains, but are larger than their Asian counterparts. The 1993 listing of the world's top corporate chains in 1992 by the magazine "Hotels" included eight North American-based chains in the top ten, although the second largest corporate chain, Holiday Inns, is owned by a United Kingdom brewing conglomerate, Bass Plc. Similarly, the top ten second tier management companies listed by "Hotels" included only one EC company, the troubled Queens Moat Houses Plc. However, reflecting the continued importance of small hotels in Europe the "Hotels" listing of voluntary chains and associations had seven EC-based companies, among the top ten in the world.

Strategies

The most important developments in the hotel industry in recent years have been the expansion of the chains/voluntary associations and segmentation of hotel properties into branded products each aimed at specific clientele. While different levels of service and quality across hotels has always been a feature of the industry, segmentation within the major hotel chains has resulted in increasingly distinctive products. It is also argued that too many brands within some chains may lead to customer confusion. Segmentation in Europe is not as ad-

vanced as in the United States but has increased substantially, to the extent that nearly all major hotel chains now have a range of differently specified products. For example, the French-based Accor, Europe's largest chain with a presence in nine Member States, has a highly-developed set of branded products, ranging from the four-star Sofitel (F) to the one-star Formule 1 (F) and budget chain Primo 99 (F).

The fastest growing segment of the market is the budget and "no-frills" establishments. All of Accor's expansion in 1992 took place within the budget brands sector. Similarly, Forte's joint ventures have all been aimed at expansion in budget brands. Greater economic cohesion within the EC, and demand from Eastern Europe, are expected to contribute to increased demand for low-cost no-frills establishments. Along with as Formule 1, other budget and no-frills chains include the French sister companies Campanile and Premiere Classe, Forte's Travelodges and Holiday Inn's Garden Court. Segmentation is not solely based on simple price/quality features, resort hotels and hotels specialising in the growing conference market are also considerations.

Consistent delivery of good service, particularly for business travellers, is the key element to maintaining loyalty as repeat business is the most cost-effective way of generating profits. Marketing, sometimes in partnership with other hotels or upstream services is a key strategy element in generating new business, but as articulated by Thomas W Storey, Executive vice-president of Radisson Hotels International "We've calculated it costs 15 USD to get a new trial guest and 2.50 USD to get a repeat guest".

Due to different travelling objectives, business travellers and long distance travellers are distinct from the leisure traveller. The discussion on demand trends in the industry suggest that there is need for a wide range of products to keep pace with the increasingly diverse forms of demand. The more a hotel can differentiate itself from its neighbour, for example by reflecting the special character of its surroundings, the more it is likely to appeal to the discerning guest. Similarly, with the growing importance of short break holidays many hotels are becoming the central element in a package of accommodation and leisure activities designed to attract short-break guests, particularly in the off-season. Many resort and medium sized hotels are also adding attractions such as fitness centres and other forms of all-weather entertainment.

Catering for new and complementary forms of tourism, such as activity holidays, also requires many hotels to re-think their strategy vis-à-vis non-hotel accommodation. Evolving packages to attract these new tourism market segments may involve coordination with other tourism and leisure facilities in the locality and other forms of accommodation. Cooperation between hotel groups is also a feature. For example, in order to improve its marketing in Europe Radisson has co-operated with SAS (S) hotels, Mövenpick Hotels (D) and Concorde Hotels (F). Similarly, cooperation between smaller hotels has resulted in segmentation, generally with a stronger leisure dimension, through the formation, or expansion of existing, voluntary chains.

While the top hotel groups in the EC are predominantly EC owned, in general, large hotel chains are international in character and two of the top chains, Hilton and Holiday Inns, originated in the US having recently been purchased by United Kingdom companies. The political and economic changes related to 1992 and German re-unification should have a positive "ripple" effect on hotel investment although the ongoing recession has dampened investment at the present time. A less buoyant demand outlook than during the late 1980s and the effects of the recent downturn in demand, suggest many investments will be in existing premises. In addition there is probably already a sufficient number of hotels in most major EC locations to cater for increases in demand, supporting the argument that most investment will be in the form of conversions and extensions of existing properties. While the flow of tourists to less well-recognised "tourist areas", particularly rural areas is expected to grow, much of the increased capacity required will be met by non-hotel accommodation.

Discernible trends indicate take-overs are the preferred expansion mode, as current players seek further economies of scale and/or expansion into new markets. There have been a number of high profile mergers over the last year such as Accor and Wagon-Lits (B), although the economic downturn has resulted in a slowdown in these activities. Extra-EC hotel chains particularly from the US and Japan, are seeking to expand in Europe. These chains include the US-based Marriott Corporation, ITT Sheraton, Hilton Hotels Corporation and Radisson and Far Eastern chains such as Nikko (JPN), Seibu Saison (JPN) and Aoki (JPN). Encouraged by saturation in their domestic market, US chains are also likely to increase investment in the EC to improve their share in a market which does not include them in the leadership. The nature of the European hotel market and its "modus operandi" is a major constraining factor for US chains, and to date they have been most successful in gateway cities through which most international travellers pass than in locations which attract mainly domestic business. In general and with a view to the longer term, Japanese investment has tended to aim for vertical expansion - hotels, restaurants, leisure facilities etc. - rather than a significant market share in a particular subsector, although the slump in stock market prices in Japan has slowed the flow of investment to Europe.

EC-based chains rapidly expanded across national borders during the second half of the 1980s in anticipation of increasing integration of the EC. For example, the United Kingdom hotel and hotel management company Queens Moat Houses expanded from its domestic base to the extent that almost half its business is now in continental Europe. More recently, economic slowdown is postponing investment decisions although this is likely to be a temporary lull. Increasing investment from large chains is unlikely to threaten the competitive position of the many small, independent hotels and restaurants that create the uniqueness of the European tourism product.

Such fears may be misplaced and smaller independent and efficiently run hotels should be able to establish themselves in their own profitable niche. Retaining traditional ambience and intimacy with their clientele are important marketing characteristics, but small hotels should pay adequate regard to modern marketing, technological and management practices. These practices may include investment to upgrade quality, and cooperation with other tourism enterprises and other hotels in promotion, reservations systems and information systems.

Airport locations provide prime locations for both expansion and the development of new hotels, although increasing emphasis on high-speed rail links should draw both business and leisure travel from the airlines, suggesting that railhead locations will also see new investment. Continued growth in business and leisure travel will also stimulate new investment in hotels at large business parks and in resort areas. Even Spanish resorts which have suffered from stagnant demand during the second half of the 1980s may see further investment as new demand from Eastern Europe materialises - Iberotel (E), for example are concentrating on development in the Mediterranean rather than the Caribbean and the Far East. Increased investment in budget hotels may also see traditional European heavy construction giving way to prefabricated units.

Investment funds are being funnelled to Eastern Europe where there is a substantial supply deficiency, particularly of three star hotels. Some investment may be diverted from EC countries although it is expected that the bulk of the diversion will be from developing countries with the exception of Asia. Another concern is that although freer mobility of capital may encourage the large-scale investors, small operators may well continue to be hampered by the reluctance of banks and other financiers. This will add to the concentration of the industry and the weakening of the independents.

REGIONAL DISTRIBUTION

Venue availability has traditionally been considered the most important element governing the supply of hotel services. In general, hotel location follows demand rather than stimulating it, although there are exceptions. Thus, hotels are predominantly located in cities, specialising in business travellers, and in resort areas, specialising in tourist traffic. These factors, particularly the latter have led to significant variations in the distribution of hotels across Member States and within Member States. For example, the largest hotel in the EC is located in the Canary Islands.

ENVIRONMENT

To date, regulatory pressure on the hotel industry in relation to environmental issues has not been extensive. There are three major pieces of environmental legislation which are, or will when they are adopted, affect the hotel industry: the requirement for an environmental impact assessment which is required for large projects, liability for damage caused by waste and the obligation to clean up contaminated land. The latter two are not yet in effect and in general their impact will not be excessive. However, there is an expectation that regulatory pressure may increase with requirements for improved waste management and more consideration to how well hotel structures blend in with their surroundings.

The IHA has identified the environment as a key tourism asset and warn of stringent regulations if hoteliers did not work to improve their environmental records. They also point out that hotels may save on costs and gain in consumer goodwill by improving their environmental awareness. An annual "environmental award" is presented each year in association with

American Express, while twelve environmental resolutions were drawn up in 1992. These resolutions cover the spectrum of environmental issues affecting hotels including care in planning and designing new projects, energy conservation, waste management, emission of pollutants and sensitivity towards ecological habitats, local populations and culture/heritage issues.

Environmental policies can be improved, in particular, the construction of new hotels in terms of energy conserving design, materials chosen, location and blending with surroundings. With hotels already designed there is also considerable scope for improved waste management both through recycling and energy conservation. Computer-based management systems are contributing to better control of costs including those with environmental implications. Demand size management (DSM), for example, is increasingly being used to control expenditure on energy costs and to extract more out of existing facilities. Attention to such details has been motivated by escalating power plant construction costs, excessive lead time to build new plants as well as the public's increasing environmental concerns. With regard to such aspects the IHA is working on an environment code for existing hotels and for new construction. Hotels groups are also cooperating to promote good environmental practice. Hilton (USA), Inter-Continental Hotels, Marriott (USA), Meridien (USA), Ramada (USA) and Sheraton (USA) are among a number of groups

which recently signed an environmental charter for the industry covering areas such as waste management, product purchasing, air quality, energy conservation and noise pollution.

REGULATIONS

Hotels are affected by a wide variety of regulations (local, national and EC) relating to health and safety, hygiene, sale of alcohol, planning permission and consumer protection. At an EC level a range of regulations affect the hotel industry indirectly. These include the Directive on Package Travel, Package Holidays and Package Tours (90/314/EEC), a body of measures covering the protection of workers, workers' residences permits, environmental regulations and data protection legislation. The industry is more directly affected by the 1986 Council Recommendations on fire safety in hotels (86/666/EEC). The Package Holiday Directive stipulates in article 5 that the package tours organiser is liable to the consumer for the proper performance of the contract, in all aspects including hotel safety (without prejudice to the right of the organiser to pursue other supplies of services). The result is that those in the industry responsible for organising tours are applying pressure and calling for more binding regulations on hotel safety.

Regulations on competition policy, particularly on abuse of a dominant position and state aids also potentially affect the hotel industry. However, the hotel sector is generally regarded as relatively competitive and has not been the subject of attention from competition authorities. With regard to state aids, the hotel industry in quite a number of Member States, most notably southern Member States, received state aid for infrastructural investment. This has not been contested by other sectors or hotel interests in other Member States who are often partly funded by the EC 's European Regional Development Fund. This financial support is generally regarded as regional aid and as such allowable under existing regulations.

Initially, proposed changes on VAT harmonisation would have increased hotel prices and reduced competitiveness relative to extra-EC destinations. This was a particularly worrying prospect for Mediterranean Member States whose hotel prices were also under pressure from prospective EC legislation on other areas, particularly in relation to working conditions. Furthermore, these Member States faced direct competition from non-EC Mediterranean destinations such as Cyprus, Turkey, Malta and north African countries. Swayed, by these and other factors, hotel services are now included among a list of goods and services to which the Member States can apply a reduced rate of VAT.

OUTLOOK

The hotel industry has experienced relatively steady growth over the last decade, slowing sharply in 1991 and 1992. This slowdown is likely to be temporary and reflects the underlying volatility of their demand base. Over the next decade global demand for both tourist and business accommodation will continue to grow at a relatively rapid pace. The factors contributing to growth over the next three years are: a recovery in most EC economies from 1994, increased trip frequency and improved seasonal spread, pushing up room-occupancy, capacity utilisation and profits; more active retired people with high levels of disposable income increase demand for hotel accommodation; increased business travel as a result of both closer European integration and more service-oriented industries in mainland Europe.

However, the EC's share of global tourism revenue is likely to decline slightly, although growing tourism expenditure by southern and eastern Europeans and arrivals from the emerging tourism markets of Southeast Asia will help counterbalance the drift to extra-EC destinations. The EC hotel industry will

Table 14: Hotels

Turnover	3.0	3.0
Employment	1.0	2.0

Source : Fitzpatrick Associates

also face stiff competition from alternative forms of accommodation and from more adventurous and more demanding tourists. The industry has the capacity and the flexibility to tailor its products to suit changing demand, as evidenced by the substantial changes which have occurred over the last decade. Value for money is another emerging criteria among EC tourists but adoption of new technology should enable hotels to provide better service and more targeted marketing while keeping costs from rising, although there will be pressure on labour costs from both a regulatory end and from dwindling supply. Growth in guest nights in 1993 should pick up on 1992 and remain steady, at 3% per annum over the following three years.

Other accommodation
NACE 667

The other accommodation sector is made up of numerous types and sizes of establishments, dominated by the smaller operator. The demand for this type of accommodation is predominantly from tourists and is dependent on tourists' tendencies towards seasonality, domestic travel and less travel during times of recession. Growth slowed in 1992 and 1993, reflecting these trends. Concentration within the industry is very low and the range of products in terms of cost and quality is diverse. There is little regulatory pressure and many smaller establishments are unrecorded and operate without constraints. Overall relatively slow growth is expected during the 1990s, although two significant changes, a shift away from traditional package holidays towards more independent holidays, and the increasing demand for short break holidays, will benefit some subsectors. Areas where new products have been developed will fare better than more traditional establishments.

INDUSTRY PROFILE

Description of the sector

The non-hotel accommodation sector encompasses a wide variety of establishments in terms of type, size and services provided. This sector includes camping-sites, caravan parks, hostels, guest houses, bed & breakfast, social tourism establishments, rural tourism establishments, apartments, second homes, time-shares and integrated resort developments. Services offered by this sector range from simple accommodation with basic amenities at the lower end, to integrated resorts with restaurants, bars, shopping malls and health and leisure facilities at the higher end. The former overlaps with the hotel sector at the lower end of the market while the latter competes with high and mid-range hotels. The services and facilities provided within the sector of the non-hotel sector vary widely. Thus, for example, camp-sites may provide restaurants, bars, swimming pools and other leisure amenities or just the basic facilities.

Recent trends

Due to the diversity and size of the sector official statistics on the turnover and value-added in different EC countries do not exist. The use of different definitions of other accommodation throughout the EC make it difficult to make comparisons and obtain main indicators for this sector. Eurostat data on other accommodation provides detailed information on camping and tourist village accommodation establishments. However, data on other categories such as holiday dwellings and social tourism establishments are far from complete. Much of the data on camping and tourist villages is based on classified camp-sites and, therefore, underestimates the number of establishments and bed places. Furthermore, available data mainly relating to the supply of establishments provides very little official statistics on realised demand.

Data that are available show that the different Member States reflect varying tendencies of non-hotel accommodation availability and preferences. France, followed by the United Kingdom and Italy, have the largest number of camping and tourist village establishments (see Table 1). However, the figure for Germany is based on tourist villages. Research by GFK Marktforschung Gmbh "Camping and caravanning 1989" indicates that Germany is also a main market and has an additional 2 000 camp-sites. Spain has the largest number of holiday dwellings, but this figure must be treated with caution as it includes a large number of small establishments.

While the paucity of the data hinders cross sector comparisons, Eurostat data indicates that most of the bed places provided by the non-hotel accommodation sector are located in camp-sites and tourist villages. France provides the largest number of bed places followed by the United Kingdom and Italy. While Spain has a very large number of holiday dwelling establishments it provides only slightly more bed places than the United Kingdom (see Table 2).

Incomplete and slightly dated data on overnight stays in camp-sites coming from a GFK report on camping and caravanning, indicates that this sub-category of the other accommodation industry is most important for France, followed by Italy and Germany. Comparable information for the United Kingdom and the Netherlands is not available and the data for Portugal, Greece and Ireland are seriously under-recorded.

Self-catering accommodation, which includes rented flats, villas, chalets, cottages and single rooms completely furnished, is reported to represent the largest subsector of non-hotel accommodation. Since a large proportion, perhaps 50%, of self- catering accommodation is let unofficially. The data that does exist suggests that France, Spain, Italy, Greece and Portugal lead in the provision of such accommodation.

Approximately 460 000 European families, constituting 1.5 million holidaymakers, own their own time-shares in over 700 holiday resorts. The greatest number of time-shares are situated in Spain followed by France, Portugal and the United Kingdom/Ireland (see Table 4). This category also includes gîtes which are generally rural properties let as holiday homes. France has the greatest number of gîtes followed by Germany and Italy (see Table 5). While Spain has a relatively small number of gîtes it has over 90 000 officially classified furnished flats. In the United Kingdom, Ireland and Germany bed and breakfast accommodation is very popular. Often their existence is unrecorded.

Integrated resort developments are common in a number of EC Member States, but the most popular formats differ significantly. In Spain and Portugal, most integrated resorts are aimed at the upper end of the market. They have a high quality finish and have associated activities such as golf courses or tennis courts. In some cases accommodation in these resorts is hotel based, although apartments are more common. In the United Kingdom, "holiday camps" such as those run by Butlins (UK) and Pontins (UK) are popular among families and provide a wide range of appropriate activities and leisure pursuits. Similarly, in northern EC countries resort complexes such as those run by Centre Parcs (NL), Sun Parks (B), Dorent and Gran Dorado are very popular short holiday destinations for families, although they also have a wider appeal, including corporate and incentive travel. Club Med (F) resorts mainly cater to for people in their twenties and thirties, generally without children although this is changing., They look to provide activities for the targeted age group.

Hostel accommodation is popular among youth travellers, particularly students. These travellers can be found all across the EC, especially in northern Member States. The International Youth Hostel Federation (IYHF) estimates there were 7.3 million overnight stays by foreign visitors across its hostels in Germany, the United Kingdom, France, Denmark, the Netherlands and Italy in 1991.

It is difficult to gauge developments on an EC wide scale due to the lack of accurate information. Eurostat figures on the growth in the number of bed places provided by camping and tourist villages indicates that the number in Spain increased by almost 50% between 1985 and 1991 while the number in Greece rose by 22%. Over the same period the number in the Netherlands fell by 68%.

Social tourism accommodation increased between 1985 and 1991. Under social tourism schemes accommodation is made available for people who are unable, generally for financial

reasons e.g. pensioners, large families and the handicapped, to go on holidays. The number of bed places in Germany grew strongly in 1991. In Belgium there has been steady growth, although growth did not occur in 1991, in Italy strong growth in the mid 1980s was followed by a steady decline, however, there was a return to growth in 1991. The limited data for the United Kingdom indicates strong growth.

The time-share sector has also shown strong growth with the number of households owning time-share holidays increasing. For example in Spain, time-share households increased by a factor of four and the number for the Benelux countries increasing by over 50%. Moreover, the United Kingdom, the traditional market for time-share, has continued to show a growth in ownership, increasing by ten percent between 1990 and 1992. Student travellers, invariably users of non-hotel accommodation, has been among the biggest growth areas of recent years and is relatively recession proof. Sales of SATA (Student Air Travel Association) tickets almost doubled between 1988/89 and 1991/92 from 634 000 to 1 243 000 tickets. The number of student travel (ISIC) cards issued has also increased.

International comparison

Usage patterns of non-serviced accommodation in the EFTA countries are comparable to those of the EC states; EFTA countries generally have high standards of accommodation with Scandinavian countries, particularly Sweden, noted for chalet style accommodation located in forest surroundings. Though no EC comparable data are available for the US, the US touring market is very large. Americans have pioneered the recreational vehicle market and standards and levels of provision for mobile tourists in the US are very high.

One in five time-share properties in the world are located in Europe, although only 14% of time-share owners are European. This form of holiday accommodation is most popular in North

America and Australia and almost non-existent in the less developed areas of the world.

Foreign trade

There is insufficient data to ascertain a breakdown of non-hotel bed nights in terms of "imports" and "exports". Even if this data were available the large number of establishments that are unrecorded would undermine its accuracy. The proportion of "camping tourists" from outside each Member State is typically in the range 30% to 40%. The ratio in Greece and Luxembourg is believed to be considerably higher.

Excluding youth travellers and those visiting friends and relatives (VFR), long distance tourists to Europe are infrequent users of non-hotel accommodation. The same applies to European tourists travelling to far away destinations. Non-hotel accommodation is popular with East European tourists visiting EC Member States, although it is not as common as might be expected given their income restraints. Over half of visitors to Austria, from Poland, Hungary and Czechoslovakia used hotel accommodation, albeit mainly 2-star hotels according to a recent report on outbound east European travel in the Economist Intelligence Unit's "Travel and Tourism Analyst".

MARKET FORCES

Demand

The demand for non-hotel accommodation is strongly linked to tourism demand. Most of the non-hotel accommodation users are leisure travellers, with business travellers using this type of accommodation only when hotel accommodation is unavailable. The low level of business demand results from the nature of the accommodation which is generally booked well in advance, by the week rather than the day, and is the lower end of the accommodation market.

Increasing incomes and increasing discretionary leisure time are predominant factors in determining the amount and type of travel and use of other accommodation. Both disposable income and available leisure time increased in the EC Member States during the 1980s stimulating the demand for other accommodation. Available leisure time has been expanding over the last two decades as improvements in working conditions have led to longer holidays and shorter working weeks, although this trend has decreased in recent years. Much of the demand for other accommodation, particularly camp-sites and rented accommodation, comes from family groups and tends to be linked to domestic tourism. In other cases, family based demand may relate to budgetary constraints which preclude the use of hotels.

There is a large domestic component in the demand for other accommodation. For a variety of reasons including income levels, the weather and the attractiveness of their own country as a tourist destination, the nationals of southern Member States of Greece, Portugal, Spain, Italy, and France are more likely to holiday in their own country. In the higher income northern European countries, particularly Germany, the United Kingdom and the Benelux countries there is higher demand for foreign holidays as travellers seek better climates and cheaper holidays.

The demand for other accommodation tends to be highly seasonal in nature. It is essentially limited to the warmer months, although winter sports generate demand for self-catering accommodation, particularly in the French Alps. Increased awareness in leisure, health and fitness of Europeans has encouraged growth in activity and sporting holidays. Approximately 10% of all holidays taken in Europe are built around a specific activity or sport. This seasonality results partly from the nature of the product, thus camping and caravanning holidays are more suited to the summer months. Institutional factors such as school holidays are also responsible for seasonality. Holiday parks of the style developed by Sun Parks and Centre Parcs have proved to be highly successful formula by providing facilities such as subtropical swimming pools, saunas and high standards of catering able to generate high occupancy levels throughout the year. Such parks are also tailored to the growing popularity of short break holidays.

The independent traveller and the trend away from package holidays towards the "go as you please" holidays bodes well for many subsectors for the other accommodation sector. While this sector faltered slightly in 1992 and 1993, it is expected to be a temporary slowdown as a result of economic recession. A significant component of this sector highlighting the importance of the independent traveller is the youth hostel market. There were over 8 570 151 overnight stays in European International Youth Federation hostels in 1991, with Germany, the United Kingdom, Austria and France collectively accounting for over one third of these stays. A useful indicator of the major origin markets for youth travel is the sales of ISIC student cards. Demand for these cards is consistently greatest from Germany, the United Kingdom, Spain and Ireland.

The demand for camp-site accommodation is strongly correlated with the use of cars as the transport mode. A survey by the European Travel Monitor considering the mode of transport used for international trips. This indicated that international tourism from Luxembourg, the Netherlands, Germany and Belgium tends to be car based and, therefore, more likely to use other accommodation. Very few international tourists from Ireland, Greece and the United Kingdom use car for even part of their travel, which indicates a lower demand for other accommodation. The opening of the channel tunnel is likely to stimulate international car travel between the United Kingdom and mainland Europe, which should in turn increase demand for the non-hotel accommodation industry.

Use of other accommodation often depends on traveller's national tendencies. At present, British tourists typically do not use non-hotel accommodation when travelling abroad. Holiday villas and apartments are the exception. An article in the Economist Intelligence Unit's "Travel and Tourism Analyst" indicated only 3% of UK holidaymakers travelling abroad used caravan or camping-sites in 1992, while 48% seek hotel and 24% seek villas/apartments accommodations and a further 18% visit homes of relatives. In contrast, only a third of West German holidaymakers in 1991/92 used hotels, while nearly 10% used camping or caravan sites. Similarly, the rapid growth in the share of continental European tourists in Ireland has resulted in very substantial growth in demand for non-hotel accommodation; total visitors to non-hotel accommodation by overseas tourists increased by 50% between 1987 and 1992. Similarly, citizens of Denmark, The Netherlands, France, Belgium and Luxembourg tend to have higher caravan ownership and would therefore tend to have a greater demand for campsite and caravan park accommodation.

The demand for social tourism accommodation is most prevalent in France and Belgium. This subsidised travel works by either providing holiday vouchers or aid for constructing tourist facilities. In France vouchers are distributed by the Agence Nationale pour les Chèques-Vacances (ANCV). These vouchers are accepted by 30 000 establishments and more than 2.5 million French people benefited from the programme. In 1990, 190 million French francs or two fifths of the expenditure was spent on other accommodation with the majority spent at social tourism establishments and rural gîtes. There is still potential for growth in social tourism since there is latent demand for this type of holiday and the associated accommodation. Unlike demand for other non-hotel accommodation, social tourism holidays demand is less dependent on the factors determining growth and trends in tourism expenditures and more dependent on institutional factors.

The rapid growth in short break and weekend holidays may be positive for some subsectors while the same growth may have negative repercussions for the other subsectors of the

other accommodation industry. Generally this sector will not benefit to the same extent as the hotel sector since many of the establishments are not suited for short breaks, and would not attract the higher income groups that can afford second holidays. In addition, growth in short breaks is generally in the off-peak, unsuitable for many "weather dependent" forms of non-hotel accommodation. If anything, growth in short breaks has contributed to a shortening of the duration of main summer holidays. Thus, the demand for caravan parks, camp-sites, chalets and holiday apartments is likely to fall as a result of the trend towards more frequent holiday breaks. Integrated resorts and bed and breakfast style accommodation are more suited for short breaks and demand for this type of accommodation has increased as a result of the growth in the short break market.

The demand from East European countries for other accommodation is low, but increasing. Tourism flows from these countries are likely to increase rapidly as their economies improve. The low income levels in these countries will lead to a higher proportion of holiday makers using budget accommodation such as camp-sites. In addition, the demand for time-share accommodation by East European countries is expected to increase as exchange organisations enable the purchase to be made in the native currencies.

The majority of EC holidaymakers travel to the seaside but these holidays are weather dependent and often seasonal. While many traditional resorts have tried to extend the season by improving their all-weather facilities, it is the hotels who have been the main beneficiaries. Nearly a quarter of all Europeans spend their holiday in the countryside. These holidays tend to be less weather dependent. Rural tourism has shown stronger growth than sun and beach tourism. In France where rural tourism has been promoted by the government, 80% of visitors are travelling independently, 20% are foreigners, and 30% are on short breaks.

The demand for non-hotel accommodation among long distance travellers is generally very low. Therefore, the industry has not suffered as much as the hotel industry from the decline in US visitors associated with the Gulf War and the recession. The growth in long distance tourism originating in the Member States is unlikely to have much impact on the non-hotel accommodation sector since many of these tourists would not use this type of accommodation.

Supply and competition

The supply of other accommodation varies dramatically within segments of the industry. Integrated resorts and time-share developments tend to be capital intensive with organised management structures. Similarly apartments and villa based establishments tend to be capital intensive and many of them are marketed through travel agents and as part of package holidays. At the lower end of the scale camp-sites and caravan parks tend to be less capital intensive while temporary accommodation in bed and breakfast establishment may be provided by altering the use of existing buildings rather than constructing new ones. Barriers to entry in the integrated resort and time-share markets exist in terms of the high set up costs and the long lead time associated with purposely built resorts. At the lower end of the market, especially camp-sites and caravan parks, the set up costs are much lower.

The supply of other accommodation tends to be seasonal in nature and a number of caravan sites and non-hotel accommodation establishments operate at full capacity in the summer while providing limited or no accommodation in the winter. This results in over capacity for much of the year and shortages at peak times. In contrast integrated resorts, theme parks and some time-share accommodation are provided all year round

and significant price differentials are used in order to spread the demand.

The supply of social tourism accommodation is dependent upon state funding and many of these establishments are in need of modernisation and upgrading. To the extent this segment competes with the commercial accommodation sector it may be seen as unfair subsidised competition. However, the degree of competitive overlap is marginal as this type of accommodation is aimed at a particular market segment and is designed to stimulate latent demand rather than divert existing holidaymakers.

A number of non-hotel establishments provide similar services to hotels and compete with hotels at the lower end of the market. Thus tourists might be faced with the choice of a hotel or self-catering apartments. Competition within the bed and breakfast market has lead to improved quality and more direct competition with hotels.

Tourists in the non-hotel accommodation sector are clearly becoming more demanding and expect higher standards of comfort and facilities e.g. sanitation, catering and sports facilities. In France, for example, around a fifth of camping-sites have a swimming pool and/or at least one tennis court. The trend is therefore to improve the quality of the facilities and services supplied by the industry. However there is still considerable divergence both within and between Member States.

Competition within the non-hotel accommodation varies between Member States. In some Member States the market tends to be mainly domestic and the consumers choose between different regions, while southern Member States tend to attract a higher proportion of foreign visitors. It is estimated that nearly 70% of camp-site users in Greece are from abroad. There is, therefore, an element of intra-sector competition, particularly between other accommodation situated in coastal areas where the foreign tourists are sun seekers and less concerned by the cultural and heritage aspects of their holiday. There is also direct competition between hotels and apartments in the package holiday market to Mediterranean resort destinations.

The opening of borders with East Europe has increased the competition for non-EC accommodation. This new market appears to be diverting visitor flows away from EC Member States. ETIC data indicates that nearly 7 million international trips were made to East European countries in 1990. A recent report for the Commission of the European Communities by IPK Munchen found that eastern European countries such as Hungary, Poland, Romania, Czechoslovakia, and Bulgaria generate a healthy balance of payments surplus on their tourism accounts.

Production process

The services provided by non-hotel accommodation vary widely across the industry. At one extreme, camp-sites and caravan parks may provide a pitch or area of land as well as basic amenities, while integrated resorts often have restaurants, bars, shops and health and leisure facilities. The variety of facilities and services being provided means that the production process differs significantly throughout the industry.

Camp-sites and caravan parks tend to be the most land intensive. Generally the industry is not as labour intensive as the hotel industry, since there are fewer services, often coming with an element of self-catering. Many of the workers tend to be part-time, for example at camp-sites and ski resorts, and in the smaller establishments, such as bed and breakfasts, family and female labour is used. The integrated resorts tend to be more labour intensive and the skills are similar to those in the hotel industry.

The majority of the establishments are not technology intensive. Some sectors such as integrated resorts and theme parks which provide other accommodation use computer reservation systems (CRS), as do the apartments and villas which are marketed as part of a package holiday. Many small operators rely on local advertising or links through tourist agencies. Smaller pensions and bed and breakfasts rely upon guide books and literature, rather than depending on travel agents.

INDUSTRY STRUCTURE

Companies

The ownership pattern of camp-site and caravan park ownership varies within the EC. In France, municipal authorities have traditionally been a major force in the ownership of camping-sites but more recently the private sector has increased its presence and in 1991 owned 54% of sites and 60% of pitches. Privately owned sites are overwhelmingly in the hands of small businessmen typically running just one facility, although some of these may operate a number of facilities within a region. The industry is fragmented and dominated by a large number of small enterprises. There are a number of larger players who run organised camp-sites where the camping equipment is provided on site. For example, Haven Spain and France holidays, a subsidiary of the Rank Organisation which also owns the Butlins holiday resorts, offers 37 parks in Spain and France varying in size from under 250 to over 500 pitches. Similarly Keycamp holidays offers 75 camp-sites throughout Europe including mobile homes.

The integrated resort sector of the non-hotel accommodation industry has developed over the last 10 to 15 years. This

represents a much more concentrated sector. The leading developers of health and leisure centres have been Dorent in Germany, Gran Dorado, Sun Parks and Centre Parcs in France and Benelux and Pontins and Butlins in the United Kingdom. The concept is highly developed in the Netherlands where the market is dominated by Centre Parcs. In 1990 there were over 400 000 villa rentals and nearly 2.1 million visitors in the Benelux properties. Demand is also expected to grow; Sun Parks, for example, is seeking funds to double the number of their parks from four to eight.

Club Med is an upmarket tourism product designed for those who enjoy activity holidays. It is based on a system of holiday villages and Club Med currently has around 105 holiday villages with a capacity of close to 68 000 beds in 34 countries around the world. Europe accounts for 55 villages and 39 000 beds.

The new Euro Disney resort in France is the largest theme park in Europe and offers non-hotel accommodation including 14 rustic lodge sites with over 1 000 rooms and 400 wooden cabins. France has a further 35 recreational parks and 30 aqua parks. Most European theme parks are geared to the day trip market and generally don't include accommodation. The arrival of Euro Disney has focusing the attention of some theme parks on the short break market as a supplement to their traditional day trip customers. For example, Efteling, the largest theme park in the Netherlands, has plans to add on self-catering accommodation.

Social tourism initiatives tend to be concentrated in Belgium and France. The VVF (Villages Vacances Familles) in France provide subsidised accommodation and has a capacity of 186 villages with a total of 67 000 beds and an annual turnover of 190 million FF. VVF was largely instrumental in setting up Euro-villages, which now has members in France, Belgium, Germany, Switzerland, Italy, Spain and Portugal.

Strategies

The general strategy within the other accommodation industry has been to improve the quality of the accommodation and facilities. Camp-sites now offer swimming pools, sporting facilities and even cinemas and discos.

The concept in the more sophisticated integrated resorts has been to transfer the ambience and environment of tropical resorts to northern European locations. These resorts also tend to be of a higher quality than the traditional resorts with swimming pools, tennis courts, restaurants and comfortable accommodation. These resorts also tend to be more activity based with numerous sporting and leisure facilities, and most importantly of all a guaranteed environment all year round. The primary target group is families with small children.

The success of the time-share establishments is largely due to their ability to offer exchange location. This initiative means that the owner does not have to return to the same resort every year. They are able to exchange their accommodation for another resort by using the services of the exchange companies. Thus, the owner of a time-share in Tenerife may choose a holiday in France.

REGIONAL DISTRIBUTION

Location of other accommodation establishments has followed demand rather than leading it. Unlike hotels, other accommodation tends not to be concentrated in major cities but is located away from these centres. This reflects the close ties with tourism traffic and in some cases the industry's dependence on climatic factors. The distribution of other accommodation establishments varies from country to country and depends upon the nature of demand and the type of establishment. Camping and caravan sites, and to a lesser extent second homes and time-share accommodation are generally located in coastal areas.

Non-hotel accommodation not located near the coast is generally in rural, rather than urban, areas. These include caravan and camp-sites as well as farmhouse accommodation. Integrated resorts in northern Europe are not as dependent on natural features for their location since they are activity based and are generally self contained. An exception is Centre Parcs which tends to be located in rural and forest areas. Northern European integrated resorts do, however, take account of local population structures in planning their locations. In southern Europe, integrated resorts tend to be mainly situated in coastal areas.

ENVIRONMENT

In general the non-hotel accommodation sector has developed without major damage to the environment. Many of the subsectors such as rural tourism, camping and caravanning depend upon their location and environment as a major selling point, although litter problems associated with camping and caravan sites are a continual source of concern. As most forms of non-hotel accommodation, gîtes, farmhouses, camp-sites and small hostels, although land intrusive, tend to be less intrusive on the landscape than hotels. Environmental considerations favour development of non-hotel accommodation.

Since many other accommodation users are independent travellers there tends to be a high proportion of car usage associated with this type of accommodation. A green paper from the EC indicates that the use of car as opposed to rail or bus increases congestion, produces more pollution and is a less efficient use of energy. At 25% occupancy levels railway use less than half as much energy per passenger kilometre as small engine cars. There may be scope to develop alternative modes of transport or to spread the peak season so that some of the negative environmental impacts associated with the car are reduced.

Under new EC legislation an environmental impact assessment is required for large infrastructure projects. Since many of the non-hotel accommodation establishments are either small in nature or not capital intensive this is unlikely to have an impact on these areas of the industry. There may be a need to increase environmental awareness in the development of integrated resorts and time-share resorts. These resorts benefit from a clean environment and it is in the interest of the developers to ensure that any new developments blend in with their surroundings. The construction of new establishments might be controlled in terms of density, materials chosen, location and more sensitivity to the regions heritage and natural/historic environment.

One area where the non-hotel sector has had a detrimental impact on the environment is the overcrowded holiday resorts where a large number of apartment blocks have been crammed into coastal locations. These types of resorts are often linked to package tours, examples can be found on the Costa del Sol in Spain, in the Algarve in Portugal as well as on a number of Greek Islands.

REGULATIONS

Other accommodation establishments are governed by national regulations covering sanitary services, fire services and safety, food hygiene, and where appropriate licensing regulations related to the sale of alcoholic beverages. As well as these national regulations there may be a number of local regulations with which the establishments must comply. Examples of these include government planning and development acts, and local by-laws on access roads, and sewage disposal. Caravan parks and camp-sites are affected by a number of regulations both locally and nationally. These regulations vary across Member States but tend to cover many of the parks' facilities like: maximum number of pitches, minimum size of the site, adequate drainage of the site, access to and within the site, car parking provision associated with the site and toilet and water facilities. In Spain the camping regulations are under the authority of the autonomous region, in Italy there are some common requirements nation-wide as well as regional legislation on the camp-sites within each region.

Regulations generally limit the proportion of fixed facilities that may be allocated to holiday parks, 15-20% is a typical ratio. It is attractive to the operator to develop fixed facilities, since they bring higher rent and profits. There are a large number of parks which cater to fixed facilities market, like caravan and mobile home owners who usually pay an annual rent for the site. These parks are not operated in the same way as touring or tourist parks since they are not open to tourists, they are, however, subject to similar regulations.

Some of the larger accommodation providers within the other accommodation industry are affected indirectly by EC regulations. The recent EC Package Holiday Directive will affect suppliers of apartments, villas, chalets or other accommodation as part of inclusive tour packages. The package holiday Directive makes tour operators liable if customers are not satisfied with their accommodation or if facilities are not a true reflection of those advertised. The threat of liability faced by tour operators will lead to the imposition of stricter safety criteria on providers of activity holidays and a consequent increase in the prices of these types of holidays.

OUTLOOK

It is difficult to provide an outlook for the non-hotel industry as a whole. While the demand for other accommodation in some Member States has experienced relatively steady growth over the last decade, such as France, Spain, Greece and Italy and others, while in markets like Germany and the Netherlands growth has been more static.

There is also variation within different sectors, for example, lower growth and, in some cases a decline, in the traditional holiday resorts of Spain and Portugal, against the strong growth in integrated resorts in northern Europe. While the development of time-share accommodation slowed towards the end of the 1980s the number of owners is forecast to grow from approximately half a million in the early 1990s to around 1.5 million by the year 2000.

Consumer legislation on the access to computer reservation systems (CRS) will involve the tightening of advertising standards and may affect the way in which package holidays incorporating other accommodation products are sold. One of the fundamental problems is that national legislation cannot cover sales practices in another jurisdiction. The time-share industry has been awaiting the instigation of an EC council directive on the sale of time-share accommodation for a number of years. The single most important aspect of this directive is the "cooling-off period" which is the time that the purchaser has to withdraw from their agreement. In the United Kingdom, as a result of an Office of Fair Trading (OFT) investigation, this period is fourteen days if the contract is concluded in the United Kingdom. Recommendations before the EC Council of Ministers are for periods of up to twenty-eight days which, if implemented, this would have a considerably adverse impact on the time-share industry.

Generally the non-hotel accommodation is regulated in terms of the amount it may charge for the facilities it provides. The scale of charges for different types and sizes of accommodation are normally regulated at a national level. Regulations on the harmonisation of VAT, may increase the price of non-hotel accommodation and reduce competitiveness relative to extra-EC destinations in the medium term. In the short term this is not a major issue because like the hotel sector the rate of VAT applied over the transitional period can be at a reduced rate fixed by national authorities. Although the non-hotel accommodation sector is not particularly labour intensive, the seasonal nature of this sector suggests that EC employment legislation introducing greater protection for temporary, or seasonal, workers will push up costs.

Over the next decade global demand for tourist accommodation will continue to grow at a relatively rapid pace. Increased leisure time and disposable income coupled with more diverse products will lead to an overall increase in demand. How all non-hotel subsectors will fare is less easy to predict. Growth in short breaks will adversely affect accommodation primarily designed for good weather conditions (camping, caravanning,

chalets etc.) but, will boost integrated resort developments. Growing demand from East Europe will favour less costly forms of accommodation, trends towards rural and mountain tourism will make a positive impact, and student travel will continue to grow. The general movement away from traditional resort holidays may adversely affect some subsectors of the industry but generally increased growth will result from the shift towards more independent holidays and the demand for more adventurous holidays.

The shift towards new, higher quality and year round products is likely to continue. The use of CRS and the development of activity and theme holidays around non-hotel accommodation packages will attract new clientele and ensure that value for money is maintained without a loss in quality. Growth in guest nights in 1992 and 1993 will be constrained by adverse economic conditions, but should pick up in the medium term.

This industry is represented on the EC level by: Confederation of National Hotel and Restaurant Associations in the EC (HOTREC). Address: 111 Blvd. Anspach, Boite 4, B-1000 Brussels; tel: (32 2) 513 6323; fax: (32 2) 502 4173.

Recreation parks

The recreation parks sector covers a wide range of tourist and leisure attractions. Overlap between subsectors is increasing and many amusement parks are increasing their share of nature and culture based attractions, joining education and entertainment as an important feature of the recreation parks sector. This monograph mainly applies to amusement parks. Based on comparisons with North America, the European market for amusement parks has not yet reached maturity and there is considerable growth potential. The arrival of Euro Disney in 1992 has tapped a high proportion of any latent demand which existed in northern Europe. The strongest prospects for growth are now in southern Member States where large amusement parks remain relatively scarce. Ownership of large parks is consolidating as a number some major firms expand through acquisition, although private single parks owners will remain important in most Member States. Large parks may harm the environment in a variety of ways, from noise pollution and scenic intrusion to attracting a high volume of motorised transport.

INDUSTRY PROFILE

Description of the sector

The recreation parks sector is fast moving and highly varied, it includes a wide variety of establishments in terms of size, style and services offered. It is difficult to define exactly what constitutes a recreation park, taken literally, municipal parks and nature reserves would be included within the definition. Even excluding these, the sector still includes a wide range of different types of operations. These operations vary from theme parks, other amusement parks and water parks, through holiday camps, to zoological gardens and safari parks. An important element of the recreation parks sector are non-permanent or travelling "enterprises" which often offer many of the same attractions as those available at permanent sites. In general, these are not discussed in this chapter, while holiday camps, such as those operated by Pontins in the United Kingdom, and indoor resorts, like Center Parcs, are regarded as more appropriately discussed under NACE 667, "other accommodation".

This variety in scale and orientation among individual operations reflects the constant evolution which takes place within the industry due to changing technology and consumer tastes. A number of key characteristics can be identified which distinguish recreation parks from other facilities. A recreation park constitutes a visitor destination in its own right. It offers a range of attractions to the visitor, often but not always for a single standard admission fee. Many parks close in off-peak periods, although this is becoming less the norm than has historically been the case. Most zoos, on the other hand, are open all year round.

The level of overlap with other tourism sectors depends on the size of the operation. Non-admission revenue sources such as restaurants and retail outlets are estimated to account for approximately 45% of the total revenue of large theme parks and amusement parks. Only a few larger parks operate hotels or other forms of accommodation (caravan parks, self-catering, etc.). At the other end of the market, smaller parks do not provide accommodation and generate a smaller proportion of revenue from non-admission sources. Nevertheless, receipts from restaurants and retailing, particularly of park related merchandise, are still important to the smaller parks. Considerable overlap is evident, however, in the case of Euro Disney. Euro Disney is now the largest restaurant owner in France, with sales of over 30 million meals a year and if developed as planned the site will have a third as many hotel rooms as area surrounding Paris.

The geographic distribution of the industry is influenced by park size, with large parks generally located at a relatively small distance from major urban concentrations. While recreation parks are to be found in all EC Member States, the largest parks are situated in France, Germany, Belgium, the Netherlands and the United Kingdom. Smaller parks often provide an important part of the flanking attractions which are increasingly required in traditional resorts, particularly seaside destinations.

It is difficult to obtain reliable data on the recreation parks sector and, as yet, no official statistics exist, even though recreation parks generate very substantial levels of turnover and employment. The information that does exist is patchy, and is unlikely to cover more than a particular segment of the recreation parks sector.

In 1991, approximately 300 zoos and aquaria were members of regional and/or national zoo associations in Europe (including non-EC states and some former Soviet Union states)

and zoo attendance was estimated at 125 million, approximately one fifth of total global attendance. Of the EC Member States, zoo attendance is much more popular in Germany than in the other eleven countries.

The International Association of Amusement Parks and Attractions (IAAPA) estimated that there were 63 major theme parks, with annual attendance of over 0.5 million, in operation throughout Europe in 1990, attracting around 60 million paying customers. No data exists regarding smaller theme, amusement or other recreation parks, but the European Federation of Leisure Parks (Europarks) estimates that inclusion of smaller parks would roughly double the annual attendance figure to about 120 million. Employment is estimated to be between 30 000 and 50 000. These estimates pre-date the opening of Euro Disney which is likely to have added a further 10% to these figures. Including Euro Disney and the smaller parks, total revenue is likely to have been nearly ECU 1.5 billion in 1992.

Recent trends

The popularity of zoos and safari parks among day trippers has fallen considerably in most EC countries over the past decade. Some are experiencing financial difficulties and closed down (particularly in the UK and to a lesser extent in Germany) or diversified. In the United Kingdom, for example, Windsor Safari Park (UK) is being rescued from receivership by Legoland (DK) and London Zoo's financial difficulties are well documented, while Chessington World of Adventure (UK) and Flamingoland (UK) have both developed from zoo-based attractions into theme parks.

In general the number of major amusement parks in the EC has increased over the last five years. In particular, American style theme parks enjoyed a boom period in the EC during the latter half of the 1980's. Large scale amusement parks have existed in Europe for many years. Tivoli Gardens (DK) in Copenhagen, for instance, was opened in 1843 and remains one of Europe's largest recreation parks. The opening of Disneyland in California in 1955, however, marked a fresh departure in the kind of product on offer. Since that time, theme parks have spread rapidly throughout the developed world. In Europe, a number of new developments have come on stream in the late 1980's, particularly in France, the most prominent of which is Euro Disney (USA), whose advent has had a considerable impact on the size and structure of the sector.

Surveys by the Economist Intelligence Unit (EIU) indicate that attendance and employment at major parks rose significantly between 1985 and 1992 coupled with the increase in the number of parks, it is evident that there has been sharp growth. The arrival of Euro Disney was expected to substantially boost overall attendance at recreation parks within the EC during the first half of the 1990s. Although, this expectation has been dampened by the economic slowdown in EC Member State economies. The IAAPA estimated that growth in attendance in Europe in both 1990 and 1991 was 2.0%, and while zero growth was estimated for 1992, this latter figure excludes attendance at Euro Disney. Analysis of attendance data of a range of major parks indicates a rather mixed performance during 1992 and is generally supportive of the IAAPA estimate.

International comparison

The standard reference point for international comparisons of recreational parks and, especially theme parks, is the North American market, which is the largest in the world. There was a major boom in theme park attendance in the United States during the 1970's, with the market stabilising in the following decade. During this latter period a number of major operating companies moved out of the market, with control of major theme parks passing to a smaller number of large companies. As a result of this stabilisation, fewer new large-scale investments were undertaken in what is essentially a mature market. Rather, new initiatives have tended to either concentrate on smaller parks serving niche markets, such as waterparks, or on extensions or variations to existing products.

Theme parks are a very important element of the US domestic and international tourism product. Analysis of the US market by Travel and Tourism Research Association (TTRA) estimates well over half of the US population visits theme parks between March and September with an average frequency of visit of 1.9 times a year. Among holiday makers, the existence of a theme park was important or very important in destination choice. The corresponding proportions in Europe are likely to be much lower as is expenditure per capita in the amusement parks. Growth in attendance in the US has remained relatively strong in the 1990s despite economic slowdown and was estimated by the IAAPA to be 3.9% in 1991 and 3.3% in 1992.

Revenue per park is much higher in the US, reflecting their greater importance as a short break, or longer, holiday destination. In addition, according to the IAAPA Business Managers Survey, admission revenues accounted for close to half of all revenues, excluding accommodation, in major European

amusement parks in 1991, compared to just 30% in the United States. This difference does not necessarily reflect higher admission charges in Europe, because while full admission prices are higher than in they are in the US, there is much stronger price differentiation in off-peak periods. Rather, it indicates lower expenditure on ancillary products. This feature of European theme parks, combined with the deflationary impact of economic slowdown on expenditures is a major reason why Euro Disney is not reaching its revenue targets, despite visitor numbers being up on expectations.

The Japanese experience closely reflects that of Europe, with large growth occurring in the 1980's. Disney, for example, opened a park in Tokyo in 1983, and a number of major theme parks were opened in the late 1980's. As in Europe, some of these parks have had financial difficulties. Nevertheless, the Japanese and other Pacific Rim markets are not yet regarded as having matured. Reflecting this, growth in attendance remained very strong in the early 1990s; IAAPA estimates a 9.4% growth in 1991, followed by a more modest, but still strong, 4.0% in 1992. Continued strong growth is expected in the Pacific Rim countries over the remainder of the 1990's.

Foreign trade

Recreation parks are primarily a tourist product, where domestic tourists are more important than their international counterparts. The international attraction potential of recreation parks differs significantly. A number of such parks, Euro Disney being the most obvious example, are international attractions which generate substantial cross-border tourism in their own right. Other major recreation parks could be classified as flagship attractions meaning that they form an integral part of a group of tourism products which attract tourists to a particular country or area. In many cases these recreation parks also attract international excursionists, particularly in northern Europe. Consumers are increasingly willing to make cross-border trips to attend recreation parks, a trend enhanced by the abolition of border controls in 1993. Smaller types of recreation parks are more common as flanking attractions become more important at traditional seaside resorts frequented by international tourists.

US theme parks are important in attracting European tourists. In particular, utilising the major flagship attraction of Disneyworld (USA), Florida has developed a critical mass of theme park and other attractions to draw visitors. Many holiday packages to Florida include a week at a beach resort and a week in Orlando where many of Florida's main attractions are centred. Disneyworld estimates that United Kingdom visitors to Disneyworld out numbered those from the state of Florida in 1991. Anheuser-Busch (USA) also plans to expand their reach into Europe with sales missions to Germany and the United Kingdom during 1993. Similarly, anchored by two major theme parks, San Antonio in Texas is making strong inroads into European markets and these were a central feature of the major Texas promotion in Frankfurt in early 1993.

The majority of park owners in the European recreation parks industry operate a single park. There has been some change in investment activity recently; a small number of firms beginning to open parks, usually theme parks or amusement parks, in other European countries. Reflecting the popularity of US-style theme parks, the largest inward investment to the EC of recent years has been Walt Disney's Euro Disney theme park outside of Paris.

MARKET FORCES

Demand

Consumer demand for recreation parks is volatile. Major factors contributing to this volatility are changing consumer tastes, the weather and economic conditions. Consumer tastes in particular have changed substantially since the beginning of the 1980s. Although demand has stabilised, and in some cases has grown, zoos have lost considerable market share in recent decades. Similarly, attendance at safari parks has plunged since the 1970s when they were very popular. Pleasant weather is generally good news for recreation parks as most of their attractions are outdoors, even though good weather also increases the pulling power of beaches, scenic areas, public monuments and other less expensive leisure pursuits. Poor economic conditions adversely affect all leisure expenditure, and within overall leisure expenditure the larger and more highly priced amusement parks are hit hard, competing with much cheaper, and often free competitors such as beaches and scenery. In addition, ancillary expenditures within the "pay-one-price" parks fall during recessions.

Traditionally amusement parks are either a day trip attraction or part of an overall package of attractions for visitors at resort destinations, particular seaside resorts. However, over the last twenty years demand has broadened considerably and in the US a high number of theme parks have become short break destinations. This phenomena is in its infancy in Europe with Euro Disney being the primary example, although companies such as, Center Parks (NL), Dorent (D), Sun Parks (B), and Gran Dorado (NL) were attracting overnight visitors long before the arrival of Euro Disney. Whether these facilities can be classified as recreation parks is not clear. Similarly holiday camps such as Butlins and Pontins in the United Kingdom have traditionally relied heavily on overnight visitors.

There are several factors influencing demand in the day trip market segment such as: the distance which the customer has to travel, the availability of other destinations such as seaside resorts and national monuments, consumer preferences, chil-

dren's desire to visit a park, climate and cost. The distance factor is of particular importance. The catchment area of a park is usually considered to lie within a 150-200 kilometres (or maximum 2 hours travel) radius of the park itself. Major theme park developments in recent years have tended to be located at non-resort destinations, where the key ingredient in location choice has been the catchment population within a certain radius. The rule of thumb suggested by the English tourist board for a park hoping to attract around 1 million visitors annually is "two hours drive of 12 million residents or one hour drive of a major holiday destination and also two hours of 5-6 million residents". The private car is by far the most significant mode of transport in this sector and the abolition of border controls in 1993 has increased the willingness of consumers to take day trips outside their own Member State.

The central element of any amusement park is the number, quality and variety of attractions, e.g. shows and rides, which it offers, these attractions are generally united by a common theme or set of themes. Variety is important as clients vary from young children to adolescents through to senior citizens, and there must be a sufficient range to hold the attention of each category throughout the day. The proportion of children to adults varies widely across different parks. The average stay at a European park tends to be around 6 hours although this figure also varies widely. In the case of Euro Disney the aim is to provide sufficient attractions to entertain for more than a day and hence attract short break and repeat visitors.

Statistical analysis of the demand for amusement and theme parks by Luiz Moutinho in "Tourism Management" found that the most important factors for choosing an amusement park were, the existence of desirable, fun-rides, little waiting time, the weather, followed closely by overall prices, proximity and family atmosphere. Ancillary factors contributing to visitor satisfaction are becoming increasingly important as tourists become more sophisticated and more demanding in relation to quality. These include, landscaping of sites, absence of litter and cleanliness of toilets and other facilities, maintenance of gardens and green areas, simplicity and clarity of information provision, attitudes and friendliness of staff and ample provision of rest and picnic areas. With the advent of Euro Disney, whose international operations are renowned for due attention to quality factors, there will be increasing pressure on major European parks to do likewise.

As demographics change and more of the European population is older, the emphasis is shifting away from white-knuckle (meaning frightening) rides towards more family oriented entertainment. A leading analyst of the recreation parks sector, Chris Gratton of Tilburg University in the Netherlands, argues that the future of theme parks will depend on increasing the "skill level" of attractions. He postulates that theme parks can be seen as a form of "unskilled consumption", which have the potential for a rapidly expanding market when first introduced, but that maintaining increases in attendance is more difficult over time. Constantly updating rides and attractions with more recent and more thrilling replacements is one, increasingly costly, method of freshening the appeal of theme parks. Another, following Grattan's logic, is to increase skill levels by introducing greater customer participation, for example through educational themes. This is already evident in the increasing emphasis on education and in the choice of themes. In the US there is a move away from white-knuckle rides towards experiences such as simulated earthquakes and tidal waves, which while equally scary may also have an educational element. The educational value is more evident, however, in the increase in the number of shows, and even rides, involving audience, or selected audience member participation. Customer participation and education are two major themes where zoos have been focusing upon in recent years. Hence they have become important centres for environmental education, which helps distinguishing them from other recreation or theme parks.

European amusement parks experience sharp seasonal variations in demand, although they are still among the most visited of tourist attractions. Euro Disney attracted substantially more visitors than any other attraction in the EC during 1992. Similarly, in the United Kingdom Alton Towers (UK) and Blackpool Pleasure Beach (UK) were among the most visited attractions. Given the perceived importance of weather, a string of poor summers could financially cripple a park heavily dependent on outdoor rides, emphasising the need for incorporating weather-independent facilities in future resort plans. Thus, while most amusement parks still feature a high proportion of outdoor attractions, many recent investments in northern Europe have involved covered all-weather attractions. Euro Disney, incorporates a substantial covered element to sustain year round opening. While the requirement for theme and amusement parks to remain open all-year-round is theoretically prudent, in practice it adds considerably to capital costs and many theme park proposals have remained on the drawing board as a result.

A 1990 report in the EIU's "Travel and Tourism Analyst" suggested that the pricing policy of large amusement parks goes through various stages of development. Initially entrance prices are set low to entice first-time visitors and to allow the new concept of large pay-one-price amusement parks to establish themselves. Admission prices are progressively increased as demand increases, and as parks approach their planned market share and as capacity constraints become more evident. This logic is reflected in the argument that other European theme parks would benefit from the arrival of Euro Disney in that it would allow them to charge higher admission prices not only because Euro Disney's admission price is very high relative to most parks. but also because it would speed the education process of consumers regarding the attractiveness of recreation parks. Whether this works in practice remains to be seen.

Supply and competition

The number of recreation parks in Europe expanded over the last decade. Expansion has not been uniform and amusement parks have enjoyed far greater growth than attractions such as zoos, aquaria and safari parks. Indeed, there have been a small number of closures in the latter subsectors, although their prospects have improved with better marketing and by improving the infrastructure, such as restaurants, shops, and in particular the presentation of animals. A number of new amusement parks have opened in recent years, especially in France, with most incorporating specific themes. The advent of Euro Disney is expected to raise the profile of amusement parks and to encourage better product quality, particularly in presentation. In the light of these expectations, several parks are switching investment strategies towards enhancing quality and presentation during the early 1990's. This is particularly the case in the United Kingdom, Germany, Denmark and the Benelux countries, where reflecting an already high concentration of parks there is little room for greenfield investment.

Greenfield investment in amusement parks is a relatively high risk activity. The capital costs of investment are high and demand is uncertain and difficult to predict. Factors which contribute to this demand uncertainty include: the specialised nature of the amusement park business, the wide range of lower priced competitor leisure attractions, seasonality and weather sensitivity of demand along with the varied range, and age profile, of consumers to whom it must appeal. A more recent addition to the associated risks is environmental pressures which increase difficulties and delays, in obtaining planning permission.

Reflecting these risks there have been a number of high-profile failures in recent years. The financial difficulties of Euro Disney are well publicised. Operating performance in many of the recently opened French Parks has been below expectations and a number have been forced to close down or go into liquidation or change hands. Part of the problem is that the operation of these parks is seasonal with little consideration in their design for all-weather attractions. Weather proofing amusement parks is very costly. Thus, investments both from private sources and from financial institutions have been difficult to attract and may become more difficult for the next few years. In the United Kingdom, for example, major investments planned in the recreation parks sector at Corby and Battersea failed to attract the necessary funds. Mintel in a recent study of United Kingdom theme parks point out that environment-related pressures will also favour the expansion of older and dated parks, rather than building new ones.

The capital costs of building new parks from scratch also make the acquisition and expansion of existing parks more attractive for companies seeking to enter the market or to expand their base of operations. This is already leading to mergers and take-overs with older operators selling out to the new theme park owners. The Belgian group Walibi has expanded considerably in recent years through the acquisition of new parks in France and the Netherlands, while the Tussaud (UK) group has grown substantially in the United Kingdom and Lego recently acquired Windsor Safari Park in the United Kingdom. Overall, there is a trend towards consolidation, although the strength and tight ownership control of many parks suggest that consolidation will not reach the levels currently pertaining in the US.

Production process

Given the diversity of packages offered to the consumer, the production process varies greatly, depending on the type of park involved. As such there are a wide variety of different ride types, varying from kiddie rides through roller coasters to simulators, live entertainment and mini golf. The majority of parks rely on a high rate of return visits, and there is a constant need to update and renew the attractions available. Parks whose main focus is white-knuckle rides and similar attractions, are generally obliged to invest in new equipment on a regular basis, usually every two to three years. Another approach is to bring in attractions from other operators for a limited period. Companies such as Walibi or Bembom Brothers who have parks in a number of European countries are able to move attractions from one park to another, thereby reducing the level of innovation and investment required per park.

Technological progress is likely to effect major changes in the production process in the mid to late 1990's, as virtual-reality based products become more widely distributed. These products are considerably cheaper than conventional rides and, once installed, can be readily changed and developed at an even lower cost to the park. This could conceivably lead to more parks being built at a lower cost, or the addition of high quality excitement to attractions offered by smaller parks who have previously been precluded from doing so by the cost involved.

The recreation park sector is both land and capital intensive. In addition to the land required for the recreation park itself, space is required for parking. Thorpe Park in the United Kingdom, for example has space for 9 000 cars and 250 coaches. Recreation parks are also important employers of both skilled and unskilled workers. Permanent core staff are generally well qualified. They include administrative and marketing staff and skilled workers such as carpenters, painters, electricians, mechanics and specialised designers. In the case of zoos and aquaria the requisite qualifications are even higher. A high proportion of seasonal staff are, however, relatively unskilled. According to a recent report in the German trade magazine, "Amusement Industrie", the ratio of permanent to seasonal staff is around 1:4 to 1:5, a limited 1993 survey conducted for the Economist Intelligence Unit indicates a variation around a similar ratio. IAAPA estimates for all world regions indicates a slightly lower ratio with the average park in its survey employing 265 seasonal staff compared to 84 full-time. Reflecting capital intensity of leisure park operations, the "Amusement Industrie" report suggested that in 1989, the average capital spent per full-time employee worker was around ECU 70 000.

Professionalism and good park management are also very important elements in the overall mix of factors which produce the recreation park service. With increase emphasis on satisfying more demanding and sophisticated customers the need for an appropriately good management response will increase.

INDUSTRY STRUCTURE

Companies

In the European recreation parks sector, unlike the US, comparatively few park owners control more than one park and most companies are family-owned and controlled. This is less true in the United Kingdom where a number of major companies, the Tussaud (Pearson) Group, Granada Group and Ready Mixed Concrete are all involved in the sector. Even the large amusement parks have generally been controlled by family firms. This ownership model appears to be changing. The investments of theme park in France in the late 1980s were primarily financed and driven by conglomerates of large leisure companies. In addition, a number of firms are expanding through the acquisition of existing parks or through building additional ones. Examples include, Walibi, Bembom Brothers, Tivoli and the Tussaud Group. While Tivoli Gardens in Copenhagen differs from most theme parks through the absence of neon and plastic and the emphasis on music and flowers, the company has expanded across Europe using a mixture of more traditional amusement attractions and its original formula. Tivoli is involved in: a Rhine side Park near Düsseldorf, a Hans Christen Andersen fairy tale theme park in Odense Denmark and a project in Japan.

It is still uncertain whether Europe will follow the US where, although there are a large number of smaller parks, the large theme parks are controlled by approximately four large firms, Disney, Anheuser-Busch, KECO, and Six Flags. With the North American market regarded as saturated, three of these US companies are now focusing on Europe. Euro Disney is already in operation with ambitious and well publicised expansion plans. Anheuser-Busch is involved in a joint venture to build a new theme park near Barcelona, while Six Flags is said to be considering a theme park in Marbella in southern Spain.

All-weather leisure facilities developed for tourism purposes such as those in indoor resort concepts such as Dorent in Germany, Gran Dorado, Sun Parks and Center Parc in France and Benelux and the Sandcastle Centre in the United Kingdom have become commonplace in EC during the last 10 to 15 years. The concept has a number of elements in common with recreation parks and the more sophisticated of these indoor resorts transfers the ambience and environment of tropical resorts to northern European locations on a year round basis. With the short break leisure market in Europe growing rapidly, some amusement parks are beginning to focus greater attention on this market segment. In the US, Disney parks are primarily a short breaks destination, with other large theme parks relying on the day trip market. This is a pattern which may develop in Europe with only the largest of existing parks attempting to compete with Euro Disney for short break customers. The Dutch theme park, Efteling, for example, is planning a major expansion which includes provision of accommodation. The French theme park Futuroscope is exploring capitalising on its proximity to Euro Disney to boost its own short break business, while Episodes, a tour operator specialising in short-breaks, offers Parc Asterix (F) and Euro Disney as an integrated holiday break.

The availability of European Regional Development Fund (ERDF) money through the Structural Funds is boosting investments in smaller scale recreation parks in some of the less well-developed areas of the EC. Countries such as Greece, Portugal and Ireland do not have the population density or the required transport infra-structures to justify major theme parks, but have made considerable use of ERDF money to leverage investment for small scale recreation park developments. For example, Celtworld in the seaside resort of Tramore in the south of Ireland is regarded as a flagship attraction but is very small by comparison to the major theme parks discussed in this report.

Strategies

As with the European tourism market in general, the recreation parks industry in post-war Europe has been shaped by advances in communications and changes in consumer tastes. Some of the older recreation park types such as zoos, safari parks and traditional holiday camps have experienced mixed fortunes during the post-war period. These attractions have adapted to changed circumstances and are currently retaining their market share. Many zoos, for example, are currently expanding their marketing activities and enjoying improved visitor numbers as a result. Others have diversified their appeal through the addition of shows and rides, while a number have gone further and re-emerged as fully-fledged amusement parks.

At present most parks are idle throughout the winter, although the increasing popularity of indoor and water-based attractions has widened the possibilities for extending the season. This development is both demand and supply driven. Increased demand for short breaks in the off-season is a recent feature of the tourism sector, coinciding with the aim of park operators to increase levels of utilisation of their investment. In addition to extending the season, some parks have tested the market with Christmas and New Year opening periods. Also, many recreation parks are increasingly turning to the corporate sector to boost demand during off-peak periods.

The advent of Euro Disney and the impact which it is likely to have on raising standards will require investment in software areas such as staff training and presentation formats. Theme parks will need to concentrate on improving the less desirable aspects of their product like: adverse environmental effects, misinformation or confused facts relating to themes and staff attitudes to customers.

REGIONAL DISTRIBUTION

While smaller operations are located throughout the EC the larger parks are located in northern Europe, near the major population centres. Unlike the US, European parks are rarely located in traditional holiday areas, although this is less true of the United Kingdom where traditional resorts such as Blackpool, Margate, Skegness, Southsea and Great Yarmouth have large recreation parks, although major parks such as Alton Towers, Thorpe Park and Chessington World of Adventure are all located in non-resort sites.

Attempts have been made to capitalise on the more suitable climate of southern Europe, with the development of a number of smaller parks, especially water parks, in this area. The use of ERDF money is contributing to such developments. With the exception of Euro Disney, recent and planned major greenfield investments in amusement parks are in southern Member States. Some rural areas are also attracting smaller, often culture-based theme parks often with relatively less stress on rides and relatively more emphasis on shows or activities with audience participation.

ENVIRONMENT

The size of most large theme parks and the volume of car visitors which they attract has negative environmental consequences for the areas in which they locate. With large land areas generally required there is a trade-off between sites which impact on residential areas and those which are located in green belt areas and may have an adverse impact on natural habitats, local woodlands etc. Following EC regulations, such developments require Environmental Impact Assessments, although it is also in the interests of major parks to consider the relationship between their park and the local environment. In a market which is increasingly sensitive to quality and to environmental factors, the advantage of a sympathetic landscape in surrounding areas and on approach roads is important. The parks themselves, and their representative organisation, Europarks, are very aware of the adverse impact which heavy reliance on car based visitors can have on the environment. Thus, Europarks have endeavoured to cooperate with national governments to improve accessibility by public transport to their member parks.

While nature themes are common among theme parks in Europe, in particular those which have evolved from zoos or safari parks, strict ecological or environment themes are not common in major theme parks. This may be an area for future developments. It is already evident in the indoor resort sector, with environmental friendliness and harmony with nature being an important feature of Center Parcs' resorts.

Greater concern for the environmental impact of major theme parks, particularly greenfield operations has pushed outward the time required to move from planning to completion. Extensions of existing theme parks can also be delayed. Indeed, to the extent that some theme parks have evolved through a sequence of smaller planning applications, the environmental problems they present may be sharper in that an increases in the volume of intrusive noise and traffic congestion may impose themselves on residential areas which were unthreatened by the initial development plans.

REGULATIONS

All theme parks are the subject of national legislation in relation to safety and local planning laws. As all major parks are also involved in ancillary activities such as food service they are also subject to relevant legislation in the areas of hygiene, certification by health authorities and in some cases licences to sell alcohol. Employment legislation is also particularly important. Developments at an EC level in a number of these areas and in the areas of environmental policy, consumer protection and competition policy are also relevant. In the area of food hygiene, the EC adopted the Directive on the Hygiene of Foodstuffs (93/43 EEC) in June 1993 and Member States are required to incorporate its provisions by January 1996.

Concerning zoos, there exists a Commission proposal for husbandry standards in zoos (COM (91) 0177 final) laying down minimum standards for the accommodation and care of animals in zoos.

EC regulations in relation to employment are viewed as particularly important. The general thrust of EC-based proposals in this area has been to improve conditions of work for employees and in particular to equalise the entitlements of part-time and temporary workers with those of their full-time counterparts. In a number of northern European Member States' work conditions for recreation park employees are already relatively high and there is little concern about the impact of existing and proposed EC legislation, or the principles of the Social Chapter of the Treaty of Maastricht. This is not the case in all Member States, particularly in southern Europe and also in the United Kingdom.

The Directive on Package Travel, Package Holidays and Package Tours (90/314/EEC) which came into effect in January 1993, but has not yet been implemented by all Member States, is of considerable relevance to those recreation parks which rely on coach tours and other forms of organised travel. This Directive is also significant to Euro Disney and those recreation parks whose expansion plans include addition of accommodation facilities. However, with most recreation parks relying on independently organised day trips the impact of the Package Holiday Directive is not likely to be as far-reaching as it is for hotels, travel agents and tour operators.

The recreation parks sector is relatively concentrated and in a number of Member States is dominated by a few major players, the subsector is unlikely to attract considerable attention from national or European competition authorities on the basis of anti-competitive practices. On the other hand, there is dissatisfaction among a number of recreation park operators regarding the high levels of state aid and preferential treatment received by Euro Disney from the French government to entice the company to locate in the Paris area.

Recreation parks is included in the list of products and services on which Member States can levy a reduced rate of VAT. French and Belgian theme parks also benefit from relatively low rates of VAT, 5.5% and 6% respectively, by comparison with competitors in Germany, the Netherlands and the United Kingdom, all over 15%. Rates in Spain, Portugal, Greece and Italy are also relatively low, but their distance from the high VAT northern European Member States reduce distortionary trade impacts.

Safety regulations are dealt with at state or regional level, although the EC had considered introducing a Directive in this area. Member States such as The Netherlands, France and Belgium generally follow German standards, particularly in the manufacture of machinery, and so reasonably uniform standards already exist in northern Europe. Recreation parks will be affected if the draft Directive on product liability in services, which shifts the burden of proof in "service" liability cases from the consumer to the producer, is adopted. The dispute arises when it will be up to the supplier of services to ensure that reasonable precautions had been taken so as to prevent damage or injury to the consumer or his or her property.

OUTLOOK

Given the diversity of the recreation parks sector its prospects for growth are best analysed in terms of its constituent subsectors. As suggested above, the outlook for zoos and safari parks has improved, at least in the sense that it is no longer declining rapidly and that operators are coming up with fresh ideas to enhance their product and making good use of ancillary attractions and shows to enhance their appeal. In addition the combination of environmental education and recreation has stimulated public interest in zoos.

The amusement park market in Europe is generally regarded as not having yet matured. Visits to amusement parks per capita in the US are estimated to be over twice that of Europe. Some of the optimism regarding growth is based on the belief that Euro Disney will benefit other recreation parks by highlighting the attractiveness of amusement parks. This view is particularly prevalent among recreation park operators located a comfortable distance from Euro Disney. Attendance data during 1992, when allowance is made for poor economic conditions, supports the argument that the arrival of Euro Disney has not had an adverse impact on other amusement parks. While weak economic conditions and relatively poor summer weather adversely affected demand in 1993, 1994 should see a return to strong growth in attendance, with even more rapid expansion in the medium term.

The overlap between zoos, aquaria, safari parks and theme parks is likely to increase. While the trend in recent years has been for such recreation parks to expand or re-orient their operations into theme parks, over the medium term changes are likely to occur in the other direction. Nature themes in attractions will increase alongside the emphasis on education and customer participation and will be apparent through growth in "shows" featuring animals and more children zoos and botanical gardens. However, EAZA and its members do not support this trend as they require high husbandry standards for zoological collections. A report on theme parks in the 21st Century in "Parkworld" magazine suggests that as competition for theme parks visitors will come from zoos, aquaria and museums, parks will adopt these types of attraction as an integral part of their product. Thus, exhibits of art, live craft demonstrations, dance theatres and other cultural-based attractions will also become more common. These changes in emphasis will help attract a greater proportion of older visitors, an important consideration in the EC where family sizes have contracted and the population structure is ageing.

Extending opening hours and incorporating more evening and night time attractions is also likely to become more common as parks tailor their product to suit demographic trends. Increased awareness of environmental considerations and attitudes of staff towards customers are also likely to occur, reflecting changes in the demand base. However, while theme parks will increasingly educate as well as entertain, the latter will remain the primary function.

How technological changes will impact on the future of theme parks is more difficult to envisage. There is little doubt that technology currently exists to provide experiences which assault nearly all human senses in a variety of different ways. How technology will manifest itself in terms of attractions is less unclear, but the potential for revamping the appeal of theme parks through improved attractions will continue to expand. Increased attractiveness is also likely to reinforce the trend growth in demand in the amusement parks market. In addition some new technologies may contribute to equally thrilling but cheaper attractions, such as those based on virtual

Table 5: Recreation parks
Admission charges at amusement parks by world regions, 1990

(ECU) General admission charge	Adult	Child
Europe (1)	9.50	7.48
United States	7.07	5.59
Canada	7.92	5.24
Pacific Rim	5.79	3.20
All regions	7.34	5.56

Source: IAAPA Business Managers Survey

reality. Some of the existing appeal of the larger theme parks is based on the high capital cost of the most thrilling rides and there is a danger that falling prices for major attractions as a result of technological advances may reduce this competitive advantage.

Integration of theme parks into wider retail developments has been mooted for a number of years and the associated costs have precluded such a development to date. Nevertheless, the popularity of US-style shopping malls has increased considerably within the EC, with retail outlets supplemented by the catering facilities, cinemas, amusement arcades, and various forms of small rides and attractions also growing. Few European malls have theme park scale attractions at present but it may only be a matter of time before comprehensive retail/leisure development comprising a wider range of amusement park attractions are built in Europe.

The cost of admission to parks already varies widely across the EC and also differs within Member States, depending on the overall quality of particular theme parks. Various strategies are likely to be employed over the medium term. While some parks will be encouraged by high admission prices at Euro Disney to move up both the quality and admission price of their product, others will concentrate on increasing revenues through ancillary activities. Still others are likely to maintain or reduce existing prices to provide affordable family entertainment. This will be especially true at resort areas where competition from other lower price attractions is keenest.

Travel services
NACE 771

Like 1991, 1992 was a difficult year for many companies involved in the travel services branch of the travel and tourism industry, mainly as a result of economic downturns in major European markets. There are also signs that 1993 may not be the hoped for turning point. On the positive side, however, there are indications that the public is turning more towards travel services to book travel arrangements. Travellers are becoming more sophisticated in their demands and the inclusive tour package (IT) is losing favour to individually tailored products although value for money remains an important criterion. The future success of individual companies in the sector will depend largely on their ability to meet these changing demands and this, in turn, is likely to be linked to their ability to stay ahead of technological developments in the field and strengthen their presence throughout the EC by acquisitions, mergers and other collaborative ventures.

INDUSTRY PROFILE

Description of the sector

The distinction between the various activities of the travel and tourism industry is often blurred. Operations and activities of the travel services branch are indistinguishable from other related sectors of the industry, e.g. retail travel agencies, tour operators, ground handling services and even car rental. As car rental is covered in another monograph, it is only briefly discussed in this chapter. There is considerable vertical integration in the European travel industry. Hotels, airlines and other transportation companies can and do have their own tour operating subsidiaries, developing either fully inclusive tour packages or partial package arrangements to help fill airline seats or hotel rooms.

Moreover, the majority of travellers whether business or leisure do not use the services of tour operators or travel agents to make their travel arrangements. They either book their transportation direct with airlines and other suppliers, or travel by private car, the dominant mode of transportation in Europe. A significant share of hotel and other accommodation reservations are also made directly by the consumer. In addition, other organisations provide part of the services available from companies in the travel services branch. These include motoring associations, tourist offices and non-profit bodies such as trade unions, clubs, company staff associations and media groups. Some EC countries offer "social tourism" organisations which provide low cost holidays.

The difficulties in evaluating the importance of even the core sector activities are compounded by the fact that relatively few companies release operating figures, let alone consolidated results. The industry can be measured in terms of number of sales passengers/clients or volume of sales. The latter terminology is also confusing, since there is frequently no distinction made between real turnover and sales volume. Passenger figures in relation to travel agency sales cannot be readily equated with the number of holidays sold by travel agents, since the real value of the agent's sale is only the commission. Employment poses further problems, since employment in the tour operating and ground handling service sectors is highly seasonal and, therefore, fluctuates widely with no common conversion factors for part-time to full-time jobs.

The distinction between business and leisure travellers, has always been difficult to identify and is becoming increasingly muted with the disappearance of border controls. Balance of payments data, are generally used to measure the currency flows generated by travel and tourism, provide an inaccurate measure since data collection methodology and analysis vary widely from country to country. With ongoing liberalisation of exchange controls, it is even less useful.

Profiles of the leading travel and tourism groups in the travel services branch illustrates that the industry is not built on a combination of the three sectors (tour operating, retail travel and ground handling) nor even with an emphasis on one or two of them. In fact, only one of the top ten groups in the industry in the EC is wholly focused on this sector. On a Member State basis the density of travel agencies is highest in Germany and lowest in France.

The only comparable data on the economic contribution of travel and tourism in the different EC Member States, and other European and non-European countries, concerns the travel and tourism industry as a whole. The 1992 WTTC Report "Travel & Tourism in the World Economy" estimated there were 14 million people employed in the travel and tourism industry in the EC in 1990, generating gross output of 590 million ECU of which 290 million ECU was value-added.

Recent trends

According to the European Travel Monitor there were over 200 million outbound trips in 1992, over half of which involved some kind of bookings through the travel trade. About 30% are fully inclusive tour packages (ITs) usually off-the-shelf programmes developed by tour operators and 23% of trips involve either part package arrangements, transportation and/or accommodation booked through a retail travel agent. An additional 12% or so concern arrangements for transportation or accommodation booked directly with suppliers, and the remainder are fully independent trips, which have no prebooked arrangements.

Relative market shares vary widely but, in general the share of fully inclusive package tour arrangements have been declining slowly since the late 1980s and up to very recently, in favour of partly booked trips. This trend appears to have been arrested. The Mediterranean Member States are regaining market share, as are inclusive package tour holidays. This could well be a blip in long-term trends as people return to tried and tested destinations closer to home in times of economic recession, rather than travelling further afield for their holidays.

Airline ticket sales channelled through International Air Transport Association's (IATA) Bank Settlement Plan (BSP) also provide an indication of the use of travel agents. The net sales volume of airline tickets issued by the BSP around the world in 1991 was 50.7 billion USD. In Europe the corresponding value was 25.3 billion USD. Countries in Europe generating the highest sales volume through BSP were the United Kingdom, Germany and France. However, the decision by IATA to broaden the customer base of the BSPs and to encourage participation by other travel industry service suppliers such as railways, shipping lines, car rental companies,

etc. means the figures are not totally reflective of travel agency sales.

Data on turnover in travel agencies and tour operating enterprises is available from the European Community Travel Agency Association (ECTAA) for a limited number of EC states. This indicates that turnover is highest in the United Kingdom, although the relatively low level indicated for West Germany casts some doubt on comparability.

Data on travel agency operations do not always distinguish between wholesaling and retailing activities. In a number of EC countries, there is little difference between a tour operator and a retail agent. Figures released by the ECTAA, indicate that the retail travel agency sector is expanding slowly, although this evidence is not conclusive and may reflect increasing membership of national organisations.

Analysis of travel agency sales of airline tickets indicates significant growth both in the value and the number of locations in the majority of EC Member States. The United Kingdom and Italy are exceptions, in that significant growth in sales was accompanied by a decline in the number of locations in both countries. France and Ireland both recorded falls in sales.

The apparent increase in number of travel agencies in the EC has been accompanied by growth in employment in some Member States, particularly the southern Member States of Spain, Italy and Portugal.

Overall, 1992 was another difficult year for the travel and tourism industry. Most sectors continued to suffer from sluggish demand initiated by the Gulf War. Economic uncertainties coupled with a loss of buying power in many major source markets largely due to currency fluctuations, and asset devaluation are important reasons for the drop in consumer confidence and consequent fall in spending on leisure and business travel. Although international visitor arrivals and receipts for the year exceeded 1990's level, performance varied sharply from one market and one destination to another. There are also signs that 1993 may not be the turning point for which the industry was hoping.

International comparison

Europe attracted 60.5% of worldwide international visitor arrivals in 1992, or 287.5 million, down 3.5% in 1991. International tourist receipts rose by 7.5% over the same period to 147 billion USD, equivalent to 53% of the world total. Despite continued growth in arrivals and revenues, Europe's relative share of world tourism has been declining since the early 1960s. Data from the World Tourism Organisation (WTO) indicates that Western Europe's share had an overall decrease in the latter half of the 1980s. Six EC countries are among the top ten spenders on international travel and tourism with Germany number two in the world after the USA.

Foreign trade

European inbound tour operators, handling incoming business from overseas markets, claimed increases in revenues and client numbers of up to 30% from 1987 to 1990. Although the Gulf War and economic recession in major markets like Japan and the USA resulted in a 1991 decline of inbound visitor arrivals in Europe.

EC countries generated about 70% of the total international trip volume of 224 million from all European countries in 1992. This was up 8% over the previous year. The other West European countries (EFTA) and East Europe accounted for 44 million and 23 million respectively. Foreign travel accounted for an estimated 20% of total trips, although the relative share of foreign trips varied sharply from market to market. In terms of destination share of travel and tourism, EC countries attracted an estimated 60% share of all European trips.

(3) Estimation
Source: ECTAA

Although there has been a decline in Europe's share of world-wide international tourism, the region's importance as a tourist destination for travellers from outside Europe has continued to grow year by year In the majority of cases, global estimates of travel to Europe can only be extrapolated from national visitor arrivals and outbound travel statistics. Most visitors to Europe cover more than one country on their trip and are often counted twice in some Member States. Airline statistics, where available, cover all passengers and not just those resident in the respective source markets.

MARKET FORCES

Demand

The final consumers of the travel services are all those who take holidays or who travel on business (although there can be intermediaries, such as clubs and associations, or corporations). Private sector sources of statistical information do exist, but these data are generally confidential, reserved for paying clients.

Each year, 60% of Europeans take at least one trip away from home. The level of trip-taking varies widely from country to country, ranging from as high as 87% in Iceland to 51% in Portugal, and still lower in the countries of Eastern Europe. The proportion of Europeans who take a leisure or business trip abroad (inter-EC) tends to be considerably lower. The average share of all Europeans who travel abroad is around 26%, although the level of travel abroad is actually higher than domestic travel in some markets, notably Belgium, Luxembourg, the Netherlands and Germany. Domestic travel tends to decline in favour of foreign travel as the market becomes more travel experienced.

The level of trip taking is very much affected by income, age, education and social status. When incomes rise travel is no longer limited to just one trip per year. In addition, business travel is usually much more frequent than leisure travel. In the less mature European markets, the cost of travel is also an important deterrent to foreign holidays, especially for markets located at great distances from the popular holiday destinations, like Greece and Portugal.

Most business travellers use travel services, at least for airline travel, though it is fairly common for corporations to deal directly with hotel chains when they can get a better deal for room accommodation, and with the railways and car rental companies for ground transportation. New technology is opening up the tourism industry, as well as improving communications. This has both negative and positive effects. For the negative, it is easier for people to book their own travel directly with airlines, hotels and other suppliers. For the positive, travel agents are better able to respond to the increasing demand for more tailor-made products. While dedicated software enables access to information on travel and accommodation to the travel section of large corporations, only travel agents and airlines can issue tickets. This has helped maintain the role of travel agents in the face of technological developments. In the medium term there may be pressure for allowing large corporations access to blank tickets. Similar constraints have lessened the impact of information systems such as, the French Minitel on travel agency sales, although Air France flights can be booked direct with ticket purchased at airports.

Use of a travel agent depends heavily on how clients plan to travel, what type of accommodation they will use and whether they speak the language and/or are familiar with the destination country. The majority of domestic holidays bypass the travel services branch completely, with people travelling by car to their destinations and staying with family, friends, or in their own or rented holiday accommodation.

The different factors affecting demand for travel and for travel services are: price and political factors, the most significant, different taxes on travel, notably on air travel and exchange rate fluctuations. Most recently, the impact of economic slowdown has been crucially important in influencing both expenditure and destination choice.

Increased airline liberalisation theoretically allows greater access to markets by a greater number of carriers and should put downward pressure on fares. However, on many routes it is difficult to see fares falling substantially. The increasing liberalisation of air transport in Europe, preceding and up to the early months of 1993, generated increased competition. This was reflected in sharp passenger traffic growth since the mid1980s. The effects of this growth, and the competitive fares which helped drive it, has created a financial strain in some airlines that is felt by severe capacity constraints and delays at airports. However, it must be noted that current indications are that flight delays are reducing.

Health risks and environmental damage are also examples of factors affecting tourism demand. There have been increasing concerns over dirty beaches and polluted bathing waters in

Table 5: Travel services

Source: IATA as quoted in Travel Business Analyst

the Mediterranean and other popular tourist resort areas. Some travellers (particularly in Germany, where environmental sensitivity is high) have shunned tour operators and destinations that have received bad publicity over their environmental record. Heavy investment in water and sanitary services in Mediterranean Member States (coming from the Community's Structural Funds and the Cohesion Fund) should help improve matters. The importance of "quality" factors in general and the environment in particular has increased considerably in recent years.

There has been a wide range of new products and programmes introduced on the market over the last few years in Europe. These have both helped to stimulate travel and tourism to less developed regions and to encourage a better off-season utilisation of facilities. Most of these new products have been targeted at people who already travel at least once a year away from home for holidays or other leisure purposes. Few have addressed the issue of people not travelling at all. The result has been an increase in number of trips per person travelling and notably, an increase in trips abroad. But the share of Europe's population that does not travel has changed very little. It is important to note that a major reason for not travelling is price: the price wars in the UK and now in other parts of the EC clearly address this problem. One of the fastest growing sectors is the short break market or trips of one to three nights. The bulk of short break travel does not use the travel services' branch, but there has been strong growth in the commercial sector. Not just tour operators, but also airlines and hotel groups have launched their own programmes. Rural and urban tourism have also registered above average growth in the last couple of years, both in domestic and international markets. And in general, travellers are becoming more adventurous and activity oriented.

Supply and competition

Supply is in general more than adequate to meet demand. The suppliers of the travel and tourism industry, e.g. airlines, hotels, etc., are cyclical industries and this can have repercussions on the availability of seats and rooms, particularly at peak seasons. Consumers are in a buyer's market and this is reflected in price-setting and margins.

Travel services for corporate travellers on business trips can cover a wide range of products, not just transportation tickets and hotel reservations. Car rental, theatre and restaurant bookings, visas, the provision of travellers' cheques and foreign currency are all part of the package of services offered. There are also increasing expectations for these services, in terms of price advantages and quality, since corporate travellers provide frequent high yield business. Travel and tourism companies also handle demand for travel to conferences, trade exhibitions and fairs, and incentive travel.

Demand for travel services from leisure travellers is met by tour operators and/or retail travel agents. Car rental bookings are either handled by travel agents, or direct by suppliers. The tour operator is effectively a wholesaler combining travel, accommodation and ground handling services in a single package. The increasing independence and sophistication of leisure travellers are reflected in the product range.

The travel and tourism industry is highly price sensitive in most EC states, though this appears to be less true in countries where the industry is more fragmented. The price/quality trade-offs are also not the same for all groups and all nationalities. Pressure on prices comes from the nature of the demand, but also from the nature of the production process. The industry gains pricing advantages from bulk buying. But it has to ensure that once it has factored in its own operational costs staffing, catalogue production, advertising, computer reservation systems, travel agents' commissions the end result is a product which is still competitive with the product the consumer could put together himself.

Foreign competition is not really an issue, although there are an increasing number of examples of tour operators establishing themselves in the traveller's destination country. The Japanese in Europe are one example. Asian airlines have also introduced competitively priced products in European markets to their own destinations, but these are not a major source of competition.

There is an attempt by all operators to keep price increases to a minimum in a highly competitive market. They achieve this through bulk buying of seats and rooms, in some cases owning several stages in the production process, and by switching more capacity to and promoting more heavily lower cost destinations.

Production process

The main capital employed is access to computerised reservation systems (CRS), except in cases where the travel company owns its own aircraft or accommodation. The cost of these can range from a few thousand ECU to tens of millions, depending on the solution adopted. There is constant pressure to upgrade technology. Leading operators aim to provide real time connections with the consumer through travel agents (or their own sales outlets) with instant confirmation of bookings. In addition to the costs of CRS access, hardware costs and expenses for dedicated data lines, travel agencies in some Member States also require substantial finance for government "loading" schemes.

The industry requires no particular technical skills, though quality management is as crucial as in other industries. It is characteristic of the travel agency industry EC-wide that counter staff are generally relatively unskilled and badly paid.

Table 6: Travel services
Number of persons employed, 1989-92

The industry attracts labour because of its glamorous image and the perceived possibility of free or low cost foreign travel. Labour turnover tends to be high as this perception is frequently not realised, or the realisation is not sufficient to compensate for the disadvantages of the job. Major travel agencies train their own staff, but much training is on the job, or through familiarisation trips to destinations or on courses run by tour operators. The tour operator sector and ground handling companies require seasonal workers, generally with human relations and language skills, to work at destinations during the season. No labour cost data are available and value added concepts do not apply.

Product innovation in the business travel sector takes the form of products which, above all, improve comfort, speed of service and of travel, and flexibility at competitive prices. One significant new development in the industry in the last five years has been the merger of networks among business travel agents as an alternative route to international expansion. EC travel agents are prominent members of these. The two largest are Business Travel International (BTI), incorporated in the Netherlands, and Internet. The EC members of BTI at mid 1992 were Holland International (NL) and its Belgium subsidiary Transintra, El Corte/Ingles (E), Hogg Robinson (UK), Havas Tourisme (F), Hapag-Lloyd (D), International Travel Bureau (IRL) and Kuoni Travel (CH). The European members of Internet are ABR, DER and Rominger of Germany and Gastaldi Tours of Italy.

Innovations in the travel agency sector for the leisure traveller are primarily in improved computerisation. For the tour operator, there is constant innovation through the addition of new accommodation, new destinations and new products like short breaks, one-day plane trips, visits to recreation parks, and to sporting and cultural events.

INDUSTRY STRUCTURE

Companies

There are no composite figures on the turnover of the travel services branch, nor on employment or number of companies. It is clear, however, that the sector is growing in the EC. Recession in some of the major origin markets has been offset by new opportunities in former East Germany and southern EC countries, where levels of holiday travel, and outbound travel in particular, are still catching up with patterns in northern Europe. Travel agencies and many tour operators are members of trade associations, but travel agency membership may be by branch or by parent company, so the figures are not homogenous. The EC travel agents association, ECTAA, is formed by national associations. The European Tour Operators Association (ETOA) represents mainly inbound interests, and the International Federation of Tour Operators (IFTO), represents essentially outbound interests.

Major changes among the leading European travel and tourism groups in the last few years suggest that there has been increased concentration in the tour operating and retail agency sectors. The pace of mergers and acquisitions has been rapid in virtually every EC country. This has not necessarily meant increased concentration in individual market segments. Frequently, it is the result of creating an integrated business. On the basis of figures in an Economist Intelligence Unit (EIU) Special Report, The European Tour Operator Industry, the top ten groups, primarily tour operators, accounted for 63% of the estimated 18.65 million ECU turnover of the top 50.

While there are many examples of expansion within the market segment, it often is part of a strategy to create a horizontally or vertically integrated business across a number of European countries. Companies select their core businesses in one of two directions, business or leisure travel, and from four components, tour operating, travel agencies in their origin and/or in their destination markets, airlines and hotels. Additionally an increasing number of strategic alliances which do not show up in the figures on sales. These include an alliance between LTU (D) and Owners Abroad (UK) through a minority shareholding held by Thomas Cook (UK) and the Business Travel International group in which are number of the leading companies are shareholders.

The leading companies generally sell all types of travel and destinations, subject to their chosen specialisation in business or leisure. But there are a number of specialists in the middle reaches of the industry selling solely to specific markets, e.g. third age, young people and student, religious travel, short breaks or cultural travel.

There are also a number of non-profit organisations which are significant players in package travel and as owners of holiday accommodation. The largest of these is Villages Vacances Familles (VVF) in France. Others are the Deutsches Familienwerk in Germany, Loisirs et Vacances in Belgium and IGS in Spain.

A number of the major travel companies are owned or controlled directly or ultimately by public sector enterprises. The largest are DER (owned by the German railways) and CIT

(1) Worldwide sales of all companies in group. The groups' own consolidation practices are used. These in some instances include associates in which the group has a minority stake, but management control. It should be noted that sales figures in the travel and tourism industry are in any event not strictly comparable as accounting" practices vary. Some companies include VAT in their total sales figure;"" some do not. Some travel agencies report the volume of business; others" only include the commission they receive on the sale. A number of travel agency businesses are run largely or partly as franchises and these are accounted for in different ways. Country is in each case country of incorporation of parent company.

in Italy (owned by the Italian Railways). As most European airlines are still state controlled, the public sector ultimately has an interest in leisure tourism through these as well. Air France (F), Iberia (E), Lufthansa (D), Sabena (B), Luxair (L), Olympic (GR) and Alitalia (I) all have significant tour operating interests.

Strategies

Despite the relatively constant pattern of concentration overall, there has been considerable change at the top of the travel industry over the last five years. This has largely been as a result of acquisitions, many of them cross-border. DER is the only company in the top twenty not to have been involved in a major acquisition or merger since the late eighties and this is a question of time as the German railways move to rationalise their travel agency holdings.

Outside of Germany and southern Europe, leading company growth in the domestic markets of the leading companies has been slowing, particularly for tour operators. This has been only partially compensated by an increase in the number of short break holidays. The showdown has been both growth in tourist numbers and in spending. Both business and leisure travellers have become more cost-conscious. Companies have been looking for productivity gains, synergies and for opportunities in the growth markets, particularly Spain. Concentration on the Italian market has largely been from within. Northern European companies have been moving south, but several companies in southern Europe have been expanding so rapidly that they seem likely to number among the leading European companies in the near future. Grupo Viajes Iberia of Spain and Alpitour of Italy are among them. The industry remains dominated by European companies. American Express (USA) is the key exception to the rule.

In the travel service industry there is no consistent division of business activities or strategies for growth. A company by company analysis of the top 20 tour operators in Table 8 will highlight some of the different strategies. Swiss and Danish firms are included because they are major player in EC markets. The only feature these listed companies have in common is the travel agency business. Seventeen of the firms listed have a tour operating business, even though it may not be a core activity. Examples are Hapag-Lloyd and Wagon-Lits Travel (B), although there are some exceptions to this tendency with Ventana (I) and Viajes Ecuador (E).

Thomas Cook's purchase of LTU in 1992 broke the ground for other collaborative efforts such as: a strategic alliance between Thomas Cook and Owners Abroad; the purchase of Pickfords (UK) and Hogg Robinson (UK), both leisure travel agencies, by Airtours (UK); moves by ITS in the early 1990s to expand its travel agency connections. Now all the leading tour operating groups have travel agency tie-ins. An exception is TUI (D) who operates travel agencies only at its major destinations.

A number have in-house hotel and holiday club chains, e.g. TUI, LTU, ITS, SAS (S) Leisure (?) and Nouvelles Frontières (F) while Club Méditerranée (F) is as much hotel company as it is a travel and tourism business. Wagons-Lits and Nordisk (S), on the other hand are owned by hotel chains. Eight own, or have interests in, an airline. This includes the three United Kingdom companies which all have their own carrier. In no cases do the United Kingdom companies own any hotels or have any investment outside their domestic market. The only other company among the leaders not to have major cross-border interests is Selectour.

The largest cross-border travel agency and tour operating investments have been: TUI investment in Arke Reizen of the Netherlands and in Chorus of France which in 1992 teamed up with Sotair (Jet Tours) of France (and therefore with Havas and Air France); NUR-Neckermann in the Netherlands and in Belgium (under its own name and Sunsnacks); ITS parent Kaufhof either by direct investment or through ITS in Holland International of the Netherlands, Travelplan of Spain, Sun International of Belgium (which in turn has investments in the United Kingdom short break market) and in 1992 in Kuoni; LTU, who already owned travel agencies in a number of destination countries, and in 1992 bought most of the Thomas Cook operations worldwide, including Germany's; Kuoni investment in the United Kingdom, France and Austria; and finally, Nouvelles Frontières in most European countries. Few sell worldwide: Wagons-Lits and Club Méditerranée are the obvious exceptions. LTU is moving in that direction.

Investors in this sector of the industry are varied. TUI is controlled by a group of travel agencies (including DER); Wagons-Lits is owned by hotel group Accor (F); Thomson and Havas Tourisme are owned by media-related operations; NUR is owned by retailing chain Karstadt (which has its own travel agency chain in addition). ITS is also owned by a retailer, Kaufhof; Hotelplan is owned by retailer Migros. Retailers find synergies through the travel agency side of the tourism business. Public companies are few. Club Méditerranée is the main exception.

The fact that there are a number of companies operating both as tour operators and retail travel agencies, incoming and outbound, in several EC Member States highlights the fact that regulation is not a barrier to entry on other EC markets. The difficulties of cross-border expansion typically come from cultural barriers of transplanting their products. Significantly travel agencies, who allow the consumer to select their product

of choice, have expanded into other countries much faster than tour operators. Local preferences to be considered are: language , tastes in food, eating hours, accommodation type, transport mix and quality. These are highly variable from country to country.

REGIONAL DISTRIBUTION

Travel agencies are invariably located in urban areas, both small and large but with a higher density in larger cities. On the other hand inbound tour operators are generally only found in major cities, while ground handling operations tend to be located at gateway cities and major tourist resorts.

Many of the medium sized firms only have a regional attachment area. Specialists in some segments, such as coach holidays, can operate profitably from a local base. Products of the industry are available throughout the EC. Although there are areas where the density of travel agencies is lower, this is not a major issue. Many tour operator products are available by mail and bookings can be made direct by phone and through view data systems. This method of distribution is especially popular in France and notably, for last minute sales bargains and is expected to become more widespread as view data ownership expands throughout the EC.

ENVIRONMENT

There is evidence that the final consumer is becoming increasingly sensitive to the impact of travel and tourism on the environment, although this is not yet true in all countries. In Germany and the United Kingdom, where the package travel markets are the most developed, it is now common for large companies to appoint executives responsible for the company's environment policy and for the monitoring of destination hotel's energy conservation and other environmental practices. Hotels which do not comply with basic minimum standards can be struck off a tour operator's hotel listing. In addition the pressure on a number of Mediterranean resorts to improve their ancillary services and infra-structure represented a mixture of direct pressure from stagnating demand and encouragement from tour operators.

Travellers are more and more aware of the impact of tourism on the destinations they visit, but this concern has not yet translated into apparent concern over chosen mode of transportation. Tour operators may also issue clients with guidelines on preserving and protecting the local environment at holiday destinations.

Major tour operators also work behind the scenes, particularly in developing countries, to help local authorities plan sustainable resort development. Thomson has also been heavily involved in encouraging the recycling of some of the Balearic islands' mature resorts. The main specific regulatory pressures inside the EC come from environmental impact assessment or land use requirements for tourism developments. Regulations on night flying also affect the industry.

REGULATIONS

There are major regulatory differences in areas such as consumer protection, conditions of market access, competition policy, availability of state aids, and attitudes to monopolies and mergers. The EC is addressing a number of these issues, through the Directive on Package Travel, Package Holidays and Package Tours (90/314/EEC). This Directive came into force on January 1, 1993. However, it has not yet been implemented by most Member States. It will impact individual EC companies differently, reflecting considerable variation in national laws at present. It is intended as a start towards harmonising the varying national situations, while still leaving discretion to the Member States in the implementation process.

Other potentially important issues are the future of duty-free sales on intra-EC flights and ships, and the imposition of VAT on the industry's products. Implementation of the former has been postponed until July 1999 and it is still not clear what the eventual outcome will be in relation to the indirect taxes, in particular in relation to VAT on intra-EC travel. Airline deregulation/liberalisation has a potential beneficial impact, at least in theory. However, practical problems exist including the issue of capacity constraints at some major airports and the weak financial position of many of Europe's major airlines. An array of other regulations ranging from environmental limits on resort developments to other aspects of transport policy also have implications for the travel trade.

OUTLOOK

The average holidaymaker's yearning for sunshine, and an inexpensive vacation, will ensure that the traditional Mediterranean's favourite resorts continue to top the popularity lists. Yet, the two-week inclusive package holiday (IT) geared to lying on a beach in the sun will not be enough to satisfy the market's increasingly sophisticated demands in the medium term. This has been recognised by most resorts and there is considerable ongoing investment aimed at raising "quality" both through improving ancillary infrastructures and services and through the addition of flanking attractions.

While the slowdown in IT sales halted in 1992 this form of holiday is still expected to stagnate, or decline, for short distance travel. On the other hand, long distance travel could become more and more organised since it is often less expensive to purchase a long distance package than to try to organise such a trip independently. Choice of destination could increasingly be determined not simply by market demand or tour operator programme availability, but by capacity restraints and bottlenecks in destination countries and on airline routes.

Changing demographics will also have an impact on travel demand and growth in organised "activity" holidays is increasingly including "passive" as well as "active" pursuits. But some of the greatest changes in the market are likely to be not so much demographic as psychological in nature. Personal values, such as having fun, relaxation and self-fulfilment, are becoming more important. New products and programmes introduced in response to changing demographics, social patterns and tastes may stimulate travel to less developed regions and encourage better off-season utilisation of facilities. Member States, helped by the European Regional Development Funds (ERDF) and the European Fund Agriculture Orientation

and Guidance (FEOGA), are increasingly developing the tourism potential of non-traditional tourism areas.

Increasing leisure time due to a shorter work week, more part-time employment and more flexible working hours, is likely to stimulate demand for travel and use of the travel services sector. Increased traffic through Europe's regional airports shows that air travel is finally starting to filter down to the masses. There is still an estimated 40% of Europeans who do not travel at all. A significant share of non-travellers probably would like to travel if there were no economic or timetable constraints. A number of new products need to be developed and measures taken, either by local or national governments, to stimulate this sector of the population.

The future success of individual companies in the sector will depend largely on their ability to meet this need for new products, as well as changing demands from increasingly sophisticated European travellers. This, in turn is likely to be linked to their ability to stay ahead of technological developments in the field and strengthen their presence throughout the EC by acquisitions, mergers and other collaborative ventures.

Market demand is becoming more difficult for the travel services sector to meet, and well-informed travellers seeking greater value for money, more variety and greater flexibility expect travel agents to significantly improve on what they can package together themselves. Technological advancements are increasingly enabling consumers to bypass travel agents and book their holidays directly with airlines or large suppliers of tourism services.

The European car rental market remains highly fragmented in terms of the customer base. Opportunities exist for expansion through both increased penetration in established markets and expansion into East Europe. However, in the short-term the focus is likely to be on improving customer service and brand loyalty, particularly with business travellers.

Table 9: Travel services
Expected real annual growth rates

(%)	1993-97
Turnover	4.0
Employment	3.0

Source: Fitzpatrick Associates

Growth in 1993, despite continued recession in many Member States, should be reasonably strong. It was boosted by relatively poor summer weather in northern Europe and recovery in the United Kingdom, one of the most important IT markets. An expected recovery in the international economic environment during 1993 should lead to further growth in tourism expenditure in the medium term. Overall, average annual growth of 4% in turnover is expected over the 1994-97 period. Employment growth will be somewhat lower, because like other tourism sectors travel service workers are relatively badly paid, and new inducements to retain and attract quality staff are required.

Overview
NACE 7

Transport is a crucial sector for the economy, it provides every citizen with mobility. Freight transport has become part of the whole production process from input to delivery to the customer. Increasing European integration will lead to more interaction and thus to more demand for transport services. Common policies for transport will help create and maintain a competitive environment with sustained mobility, but at the same time will encourage an increasing number of merger and alliances as firms strive to maintain their competitive positions. Expansion of various networks is underway as public and private interests make huge investments in transport infrastructure. This will create the conditions and opportunities for integration and growth in the future and the emergence of new services, including value added services based on transport telematics. However, the competition between privately owned mobility and public transport will continue in the short term to favour private owned vehicles and companies.

INDUSTRY PROFILE

Description of the sector

The transport services industry is primarily engaged in the conveyance of goods and passengers either directly or indirectly. Direct involvement relates to the actual conveyance of goods and passengers by various modes of transport. Indirect involvement relates to such services as handling when changing modes, traffic guidance, travel arrangement, freight brokerage, storage, etc.

NACE 7, the transport and communications industry, comprises the following two-digit classes:

- NACE 71: railway transport;
- NACE 72: other land transport, including urban transport, road transport and pipeline transport;
- NACE 73: inland waterway transport;
- NACE 74: sea transport and coastal shipping;
- NACE 75: air transport;
- NACE 76: supporting services to transport, including inland waterway ports, sea ports and airports;
- NACE 77: travel agents, freight brokers, storage and warehousing;
- NACE 79: communications, including postal and telecommunication services.

It should be noted that the categories above, apart from NACE 79, relate to companies which have as their primary activity transport services. Apart from these companies, however, transport also takes place in other economic units (own account transport) which is not captured in value added and employment statistics for NACE 7. When measuring physical transport activity (e.g. in passenger-km or tonne-km), however, transport in these non-NACE 7 units is included. For example, companies active in manufacturing regularly transport on their own account, as they do not want to rely on external transport services. Similarly, in family households, the use of the private car is not in itself an economic activity.

This leads to a situation where economic transport statistics only relate to companies with transport as their primary activity (excluding own account transport), whereas physical transport statistics relate to total transport (including own account transport). Interpretation of statistics can lead to paradoxical results, and this should be kept in mind.

Of the subsector telecommunications and postal services (NACE 79), only postal and express services are covered in this chapter, telecommunications being covered in another chapter.

Recent trends

Total gross value added at market prices generated by the EC transport industry amounted to 196 billion ECU in 1991, which is approximately 4% of EC GDP (communications and own account transport not included). This value is more than two and a quarter times greater than the result for 1980, since, during the 1980s, nominal value added grew by an average 8% per year (Table 1). However, real growth has averaged just under 2% over the last few years. Also, during the late 1980s and early 1990s, transport contribution to GDP has remained stable at 4%, which gives a good picture of the importance of its contribution to the Community's economy.

On a country by country comparison the importance of transport in economic activity varies considerably by Member State (Table 2). In Germany, France, Ireland and Portugal transport's share of GDP is below the EC average, whilst for Belgium, Denmark and Greece the share in national GDP is substantially larger than the EC average.

In terms of direct employment, the transport services sector is an important employer, with almost 7.9 million employees in 1991 (including communication services), which is approximately 4.0% of total EC employment. Since the mid to late 1980s, the trend in employment has tended upward, from a total of 7.4 million to 7.9 million in 1990. However, due to weakening economic conditions in 1991, the trend reversed as employment as whole declined (Table 1).

Inland transport services, the total of rail, road and inland waterways, accounts for over 45% of total employment in transport and communications (Table 4). Sea and air transport take a share of 6.7%. Transport services, thus, are directly responsible for 52% of employment in the sector total. Indirect transport services, the supporting services and other auxiliary services have a share in the sector's total employment of just

Source: Eurostat (National accounts)

under 20%. The remainder is employment in communication services (NACE 79).

The trend in national and urban/suburban passenger transport has favoured the private car, which has become the primary mode of transport. This type of transport is estimated to take a share of about 79% of the total passenger market, leaving the balance to railways and buses and coaches (estimates derived from Table 5). Over the last two decades rail and bus have lost market share to private cars, which is presenting a number of problems for the environment, particularly congestion and atmospheric pollution. Public transport - rail and bus - tends to compete poorly with the mobility advantages of the private car (except in densely populated and congested areas), nonetheless state and local authorities maintain public service obligations as it is in the public interest and also in order to encourage "would be" private drivers to use public transport instead.

For international long distance passenger transport, air transport has become the most important mode for both business travel and tourism, particularly as the time wasted on travel represents a very real opportunity cost to the business traveller and as the demand for leisure has favoured longer distance for the 'long break' and shorter distance for the 'short break', where in the case of the latter time is again a premium. The impact of the growth in passenger air transport demand over the last two decades has caused congestion problems in the airways and at airports, which are currently being addressed Community-wide within the EC. However high speed rail services are becoming very competitive for medium range distances (around 300-500 kilometres).

The bulk of freight transport is road haulage. This mode takes a share of about 70% in total freight transport activity (excluding air transport and maritime shipping). Rail and inland waterway take about the balance, which is about evenly divided (Table 5). Road haulage has benefited significantly from increasing integration within the Community, since as it is highly flexible, it can quickly take advantage of changing and new demand requirements. Furthermore, growth in the transport of bulk goods, the core business of rail and inland shipping, remains low. Rail and inland shipping do have opportunities, however, in unitised cargo (containers).

Another trend is the increasing importance of air freight transport services. Especially in the field of high value goods and perishable goods, air transport has a competitive advantage with its high speed of conveyance. This service is currently being integrated more and more with express service companies.

International comparison

The share of transport and communication in GDP in the EC is slightly lower than that of the USA and Japan, which have a share of about 6% of GDP each, including communications services. In actual value contribution, the EC transport and communications sector is the largest at just ECU 300 billion, although the figures presented in Table 3 are somewhat dated for the USA. The Japanese transport and communications industry, with 175 billion ECU, is relatively small when compared with the USA or the EC. Contrary to the experience of the EC of constant contributory share to GDP from the sector, the trend in the USA and Japan appears to have been declining.

MARKET FORCES

Demand

The demand for transport depends on economic and social development within the Community. Trends of growth in transport demand tends to depend on growth in GDP, albeit disproportionately, hence accelerating GDP growth does have a more than proportionate effect on transport activity and vice versa for decelerating GDP growth rates.

Demand for transport also depends on other factors, which although may impact changes in GDP, have a direct effect on changes in transport activity. These factors include structural change in the manufacturing sector, which has lead to relocation of manufacturing (usually to non-urban areas) and hence to a dispersal of economic activity with a concomitant effect on both good and passenger movements. The trend towards very flexible production methods (JIT) have lead to lower stocks which in turn have required more frequent deliveries and lower volumes. The very rapid growth in the services sector has multiplied the demand for professional mobility over all distances. Increases in real disposable incomes and the continuing lessening of barriers to mobility in the Community have lead to higher rates of demand for personal mobility and leisure.

Demand for transport is usually separated into passenger and freight/cargo/goods movements and although transport activity over the last twenty years has grown by over 50%, the effect on individual modes has not been uniform. Passenger activity has grown by over 3% a year, whereas goods movements has grown by about 2.3%. The changes in share amongst the various modes for passenger activities between 1970 and 1990 has resulted in an increase in private car use, from 76.1% to 79%, an increase in air travel, 2.2% to 5.6%, and declines for rail (10% to 6.6%) and buses and coaches (11.7% to 8.9%).

For freight transport (excluding maritime transport - which accounts for about 30% of goods movements between Member States), the growth in the share of road transport has been phenomenal, from 51% in 1970 to 70% in 1990, taking share from all the other modes where declines have been profound: rail's share declined from 28% to 15%, inland waterway from 14% to 9%, and pipeline from 8 to 5.5%.

The demand for private road transport, both passenger and freight, has been dramatically affected by the demand for increased mobility and flexibility where the door to door concept has acted as competitive edge unmatched over shorter distances by any of the other modes. On longer distances, road transport for freight still allows for door to door delivery without transhipment that is usually required for rail and inland waterway freight.

Increasingly transport is viewed as a part of the production process, where this concept is more usually applied to freight. "Just-In-Time" delivery is such an example of how transport can be part of the production process. Transport and communication plays a crucial role in maximising the benefits of European integration, as they facilitate interaction and trade between Member States.

Supply and competition

The major impacts on aggregate supply are changes in infrastructure, changes in equipment technology and policy measures to encourage one mode over another or with another.

Infrastructure has impacts on all the various modes. For road transport, freight and passenger, quality and availability of roads are crucial, particularly on intercity routes for freight and on inner city and urban congestion for both freight and passengers. For all rail, improvements in the network, including both network additions and the viability of high speed networks are key components. For air transport, congestion at some airports at peak loads is a serious problem, which coupled with an air traffic control system that requires substantial investment to operate efficiently, causes a real problem for the sector to supply services efficiently and cost effectively. For inland waterway, there is a real limit to infrastructure investment, although links to eastern Europe are slated for improvement.

Changes in equipment technology and infrastructures have had the most impact on air, road and rail transport. In air transport, vast strides have been made in supplying efficient air transport at a cost that has in real terms declined on aggregate over the last few years. For road freight, improvements in truck design and efficiency have allowed a real reduction in operating costs and higher volume per load movements. For passengers, the effect has been less noticeable as changes in technology have allowed some efficiency gains, but these latter have been outweighed by larger numbers of single occupancy movements. Investment in higher quality track and rolling stock for rail has allowed efficiency gains and also in some cases induced additional traffic, both passenger and freight - the drawback to freight still remains inflexibility and transhipment at point of loading and unloading.

These issues are covered in greater detail in the relevant following monographs.

Competition between modes has meant that overall road transport, specifically passenger cars and road freight, has gained share at the expense of its competing modes. In particular, cars have taken share from rail for short to medium length journeys and share from urban/suburban public transport for short journeys in and between urban and inner city areas. Road freight has taken share from rail, and to a lesser extent from inland waterway. Air travel for leisure and business has gained share from rail and coach for medium to long distances within the Community. Competition issues within the sectors and between sectors are covered in greater detail in the relevant following monographs.

INDUSTRY STRUCTURE

Profile

The industry structure of the transport services industry can be broadly broken into public and privately owned, where particular sectors tend to be dominated by one or the other. Road freight and private cars (including taxi services) are completely dominated by private ownership, with only isolated case of concentration - typically in a geographical area - and by definition private cars are privately owned. Rail, including urban/suburban services, is dominated by public ownership.

Air transport has been dominated by 'flag carrying' airlines that have tended to be owned by the state, and on balance most of the major airlines in the Community still remain in the hands of the state. However, there are numerous medium to small sized airlines that are privately (this includes quoted companies) owned and within this sub-sector there is a low degree of concentration. Inland waterways are dominated by small privately owned firms, often of one barge or ship. Maritime transport is largely privately owned.

Strategies

The major strategies in the Community are to move more of the publicly owned firms into the private sector and allow increased competition. The degree of these two strategies varies according to sector. In road transport, particularly road freight, the move has been to increase competition between firms in different Member States by gradually allowing cabotage. In air transport, the liberalisation of the market within the Community in 1993 has meant that the flag carriers that still remain state owned will gradually be moved into the private sector and competition will force more alliances and mergers and acquisitions as companies seek to minimise costs and maximise revenues, and expand their access to markets of critical size in order to compete effectively. Although the United Kingdom is leading the field in privatising rail and encouraging competition, in general changes in the structure of the rail industry will take place slowly as rail tends to be viewed as a quasi-public good as the supply of rail services is in the public interest; moreover, the heavy front-end investment that characterises rail and the continued substantial investment required to maintain the investment are considered to be serious drawbacks to privatisation. The impacts of privatisation and increased competition will have the least impact on inland waterway and maritime services, except from competition from other modes, as these are already internally competitive and typically privately owned.

TECHNOLOGICAL PROGRESS

In all subsectors of the transport and communications industry, progress in technology and possible economic and social benefits are substantial. It relates to the following items:

- the development of new information and communications technology ("telematics"), leading to new communication and value added services;
- the application of telematics enables considerable improvements in transport service quality. Key quality items such as vehicle monitoring, goods and parcel tracking, container handling, traffic management, travel information, route guidance, automatic fee collection, fleet management, driver assistance, etc. have improved due to advanced applications of information and communication technology and Electronic Data Interchange (EDI);
- several research programs, such as DRIVE/ATT (Dedicated Road Infrastructure for Vehicle safety in Europe / Advanced Transport Telematics), IRIS (Integrated Safety Information and Navigation System), EURET (Research and Technological Development Programme in the field of Transport) and EATCHIP (European Air Traffic Control Harmonisation and Integration Programme) have been carried out with the purpose of improving traffic safety, the impact on the environment and integrating approaches to increase transport efficiency on an European basis;
- energy efficiency and reduction of exhaust emissions and to a lesser extent other forms of nuisance such as noise.

The potential of the application of these emerging innovative technologies on the creation of value added services and on the stimulation of economic growth is significant.

ENVIRONMENT

Transport is the dominant source for certain types of air pollutants: in particular, transport is estimated to be responsible for about 80% of carbon monoxide emissions in the EC. For nitrogen oxides and hydrocarbons, estimates indicate that transport causes between 50% and 60% of all man-made emissions, and furthermore it produces 40% of all emitted particulates. Another major pollutant is lead, which is discharged by internal combustion engines using leaded gasoline (dominated by cars and light vans).

In 1992 the European Commission published a Green Paper on The Impact of Transport on the Environment - a community strategy for sustainable mobility. This Green Paper was a milestone in attempting to look at the issues of the impact of transport on the environment from a global perspective taking into account the inter-relationship of transport within the Community and economic welfare and the relationship between the various transport modes. Although the Paper focused on atmospheric pollution, it also covered in some depth

Table 5: Transport services
Community goods transport by mode of transport, 1987-1991 (1)

	1987	1990	1991	Change 1990/87 (%)	Change 1991/90 (%)
Road	65.7	68.8	70.2	3.1	1.4
Rail	16.9	15.1	14.9	-1.8	-0.2
Inland waterways	17.3	16.1	14.9	-1.2	-1.2

Source: IRF (World Road Statistics 1987-1991)

the other forms of pollution or nuisance that are often skated over in considerations of transport. In particular, it discussed the impact of noise on the environment, water pollution (inland and maritime) from the effects of transport, soil impacts, vibration, land use and intrusion, congestion and the risks inherent in transporting dangerous goods.

In assessing the impacts of transport on the environment, the Paper concludes that operational pollution is the critical issue for all transport sectors, with the main culprits being the road, sea and air sectors. Land use and intrusion was ranked second in importance (particularly the one caused by the road and rail sectors). Congestion interestingly was ranked third although it contributes to atmospheric pollution and sometimes exceed infrastructure limits. This third place was largely due to congestion tending to be prevalent only in inner-city and densely populated urban areas and in terms of the whole picture had less impact. Bottom of the ranking was the transport of dangerous goods, although politically sensitive, due largely to the small quantities moved within the EC compared to the volumes of other goods.

The Paper also sought to provide possible measures and research programmes for discussion on a common strategy based on a global approach requiring different types of initiatives. The essence of the Paper is to ensure that transport continues to fulfil expectations in terms of its contribution to social welfare, economic cohesion and growth whilst minimising its impact on all aspects of the environment. Within this global approach to strategy were outlines of various approaches that could be made or adopted to achieve these ends.

REGULATIONS

Most of the EC transport market is currently regulated on a national basis and therefore relatively fragmented. In 1985, a ruling of the European Court obliged the Council to work out a common transport policy along the same liberal lines that hold for the rest of the economy under the rules of the EC.

The implementation of the common transport policy involves two elements:

- freedom to provide services and eliminate competition distortions;
- improvement of infrastructure and production means.

The latter element relates to large investments in infrastructure and new innovations in means of transport as the Community contributes to a number of infrastructure-related projects, which are dominated by the high-speed rail network. However, the Community programme has limited funds, and there are a number of projects important to the Community that are not funded by the Community: e.g. the Channel Tunnel, the Trans-European Motorway, the construction of the Rhine-Main-Danube Canal and the Bælt Link in Denmark.

Innovation in transport is dominated by European R&D programmes aimed at traffic safety, reductions in energy consumption and in exhaust emissions and at adding new telematics-based services. Also, the harmonisation of technical standards continues as part of general harmonisation in the Single Market.

In terms of broad policy issues on transport in the Community, the Commission published a White Paper on The Future Development of the Common Transport Policy at the end of 1992 (COM(92)494). This communication from the Commission is a crucial tool in setting out the issues that need to be discussed as it seeks to set out a global approach to transport issues enabling due consideration of all views before the launch of particular initiatives. It recognises the importance of each transport mode in the global picture, and seeks to balance transport policy in terms of its impact on the environment with sustainable mobility for the Community as a whole. The communication enlarges on the major issues of modal disequilibria, capacity constraints, system and network developments, environmental issues, safety, and social issues.

Whilst the desire to create a Common Transport Policy that maximises all requirements is existent, there are a number of regulations and policies that are mode specific and in general these are designed to tie into the master plan. The important regulations by mode are entered into more detail in the following relevant monographs. However some of the more important ones are summarised below. The major changes in regulations have been aimed at stimulating competition by removing artificial and regulatory barriers.

In terms of freedom to provide services and eliminate distortions of competition, the Commission has produced several communications on the establishment of the conditions for cabotage, with the most progress being achieved on intra-EC road transport. Bilateral authorisations for transport between countries were replaced by EC permits at the beginning of 1993 with an elimination of all quotas.

In inland shipping, there is relatively unhindered competition on the Rhine River, but initiatives are being taken to extend this to other waterways. Initiatives have also been taken to allow cabotage: each ship with an EC-flag is allowed to provide services within other Member States. This will increase competition on the European waterways.

The railway directive of June 1991 (91/440) is aimed at giving limited access to the national railway networks, which commenced at the beginning of 1993. The directive was designed to encourage the national railway companies to form international alliances for both passenger and freight services under single management structures, and allow a measure of free access to the entire EC railway system for private companies involved in combined transport. However, in rail transport, cabotage is not practicable as rail companies often transfer transport responsibility to another company at the border due to differences in the technical aspects of the national networks. New infrastructure with harmonised technical standards will enhance the introduction of rail cabotage in the distant future.

As regards the shipping market, in June 1992 the transport ministers decided to deregulate the market in four stages between 1993 and 1999. The first three stages refer to the deregulation of the EC sea freight market. The fourth and last stage concerns the deregulation of the EC market of passenger traffic by sea. There are however some exceptions concerning Greece (temporarily) and strategic goods.

Since 1987, European airlines have been subject to a process of deregulation, which has taken place in three stages. The third stage became operational on the 1st January 1993. Although it is the most far-reaching package so far, the programme did not bring about a totally deregulated EC air transport market in 1993. It still includes some safeguards on issues such as free settlement of fares and also a transition period for the introduction of cabotage. Cabotage will only be introduced in April 1997. In the meantime conditional cabotage is allowed.

In the field of regulation aimed at environmental protection, measures concentrate on emissions of exhaust gases and particulates. The general aim is to reduce the burden for the environment caused by the transport sector. The standards for carbon monoxide (established in 1985) depend on engine size and became effective during the 1988 to 1993 period. One of the consequences of this policy is the use of three-way catalytic converters in gasoline-fuelled automobiles. Also, aeroplane engines will have to conform to Stage III regulations on noise and emissions by early next century.

Policies in passenger transport aim at reducing private car use to the benefit of public transport. This is being done to alleviate congestion problems on the networks in and between major conurbations in the EC. Additionally, it is beneficial to environmental protection initiatives.

OUTLOOK

The prospects for the EC transport industry remain positive. With increasing European integration, transport demand is likely to grow both in terms of the volumes of goods and passengers and in terms of the distances to be covered. This growth will tend to follow the trends in economic growth, however there will potentially be a number of spurs adding to the momentum. Industries externalising their of transport and logistic services in order to minimise costs will act as a fillip to the growth in professional transport services. The opening up of the East European economies will also contribute, although, during the initial period of economic restructuring, only marginal growth in transport demand may occur. Also, transport services suppliers from these countries will be limited in their ability to compete with EC companies.

The growth prospects will differ for the different modes of transport. In the longer term, the investment cycle in rail transport will tend to moderate annual growth rates and freight transport by rail is expected to grow slower than passenger transport. Road passenger transport is likely to exceed average growth rates as private car use and ownership has not yet reached a maximum. Road freight transport will grow much faster due to the liberalised market and new opportunities, although tighter environmental regulations will act as a counter force. Inland waterways transport will maintain its upward trend with small rates of growth. Seaborne trade is expected to grow slowly in the short term, but faster in the medium to long term: recovery in long-term depressed markets such as steel and iron will be very gradual. The outlook for air transport is very positive as advances in managing congestion through improvements in air traffic control and investment in additional airport capacity at the more congested airports takes place. Also the upward trend in real personal disposable incomes will act to buoy the trend.

Large investments in infrastructure that are currently being undertaken to extend the network capacity of the various transport modes, as some existing networks are operating at or above capacity levels, will create new transport possibilities which are necessary for the growing integration of the EC market. This effect can be increased by the deployment of transport telematics tolls and services.

The Common Transport Policy, which aims at liberalising and harmonising the EC transport market, will improve the industry's efficiency. This will enhance competition and improve the quality of service offered under the condition of further economic growth.

Written by: DRI Europe

Railway transport
NACE 71

Railway companies are controlled by single national operators, which precludes competition between individual railway companies and between railway companies and private firms. To increase competition and profitability some countries intend to privatise their railway. In the framework of the Common Transport Policy, the competitiveness of the railway sector should be improved by the possibility of more accurate reflection of the real cost burdens the various modes impose. Also competitiveness will be enhanced by continuing investment in high-speed rail services, and which, ultimately, may result in an integrated European high-speed rail network.

INDUSTRY PROFILE

Description of the sector

This sector includes units that are exclusively or primarily engaged in the transport of passengers and goods by rail. It also includes the equipment and facilities required to provide this transport, including private branch railway lines.

However, it does not include: railway networks solely or primarily serving a single town or city (NACE 721.1); locomotive, carriage and wagon repair workshops (NACE 362.3); local units of railway enterprises which operate regular bus or motor coach services (NACE 721.2); and the operation of sleeping-car and dining-car services (NACE 666).

Recent trends

Rail passenger traffic has remained relatively constant over the last decade, growing at an average of 0.7% since 1980 to reach the 1992 level of 241 billion passenger-kilometres. The recessionary pressure emanating from the weakened EC economy in 1991 ensured that passenger traffic stagnated compared to the previous year, and the results for 1992, although an improvement, are only just over 3% higher than the 1990 level.

For the individual Member States, the strongest growth in 1992 came from Spain (+8.8%) and Italy (+4.2%), whilst passenger traffic in Ireland (-5.0%), Denmark (-2.4%) and the United Kingdom (-1.1%) declined. The remaining Member States all had positive but very marginal growth in the order of 0.1-1%.

Aggregate EC freight traffic has declined over the same period by an annual average of 2.6% per year to the 1992 level of 166 billion tonne-kilometres. The major part of this decline has occurred since 1989, as freight declined by over 3% per year, whereas in the early to mid 1980s rail freight remained almost constant. However, there has been a partial structural shift in cargo carried away from low value added dense products to higher value products, often carried in containers or on road units (combined road/rail traffic). Estimates put the recent growth of this latter type of traffic at around 7.5% per year; with its share in total rail freight transport increased from 7.5% in 1985 to about 13% in 1992.

The only Member States to record strong freight traffic growth in 1992 were Portugal (+6.4%) and Ireland (+5%). Freight traffic declined in seven Member States, the worst being Spain (-10.5%), followed closely by western Germany (-9.9%). Intra-EC rail freight traffic is dominated by four Member States, Belgium, Germany, France and Italy which between them account for over 80% of intra-EC rail freight. The major intra-EC flows are between Italy and France, Belgium and Luxembourg, Belgium and Germany, Germany and France, Germany and the Netherlands and between France and Belgium. These flows account for one-third of total intra-EC rail freight traffic.

The most recent estimate for employment (1991) shows that the number of employees has continued to decline. Current levels are just over 900 000, which is a decline of almost 20% since 1985. However, the rate of decline in unemployment has slowed recently: employment in the late 1980s was declining at rate of 3.2% per year, whereas at the turn of the decade this rate had come down to 2.8%.

International comparison

Table 6 reveals the significant differences between the railways in the EC, Japan and the USA. Although the data for comparison is somewhat dated, it does enable a useful comparison. The US railway is heavily dominated by freight traffic, with only a relative small number of passenger-kilometres, as freight is moved over long distances in a country which is sparsely populated between the major cities or population centres. Japan by contrast is dominated by passenger traffic, due to the heavy population concentrations in many parts of the country and extreme road traffic congestion. Falling between the two is the EC with a fairly even divide between

Table 1: Railway transport

Source: UIC

freight and passenger. However, railway density is very similar between Japan and the EC at around 54 kilometres of line to every 1 000 square kilometres. The USA is less than half of this at 22.

The approximate length of railway line available in the EC (excluding eastern Germany) is 121 000 kilometres, which is substantially more than Japan at 20 000 kilometres and half that of the USA at 243 000 kilometres. Given the different nature of the railways in these three countries, it is difficult to use a labour productivity measure, however, the comparison of number employed per kilometre of track shows that the differences in structure are enormous. The USA employs almost 4 worker per kilometre, Japan almost 10 and the EC 12.5. This confirms the strong correlation between employment and the type of traffic, i.e. the higher the passenger share of total traffic the more staff required.

MARKET FORCES

Demand

Demand for rail services is divided into passenger and freight. Passenger demand is composed by leisure travel and business travel. The substantial portion of business demand is daily commuting between the workplace and home. The demand for commuting places peak load strains on the network services at the start and end of the working day, often placing networks with a substantial logistics load in terms of equipment positioning. Leisure demand does not have the same daily peak impact, but does have seasonal peak impacts, for instance at Easter or Christmas. Within the two passenger demand segments are sub-segments that depend on the distance travelled. Typically, these subdivisions are split into three: intra-urban, inter-urban/city domestic and inter-urban/city international.

Freight demand does not have the same time sensitive profile as passenger, as freight trains can be run to meet demand during non-passenger peak times, which is often at night.

The industry in the EC has undergone a structural change away from the traditional transport-intensive industries such as coal and steel, on which rail was particularly dependant; this has affected the rail freight industry severely. Also, part of the changing structure has meant that technical and organisational developments in other industries (just-in-time stock management and sophisticated distribution networks) has accelerated demand for quick, flexible and predictable deliveries of relatively small quantities of cargoes. These developments have been detrimental to rail transport, because of its perceived relative inflexibility and high transhipment costs. Moreover, lack of integrated, inter-border co-ordination has not helped the demand for international rail transport, although, the advent of the Single Market has eased much of intra-EC border delays.

Supply and competition

Rail competes with all other transport modes, road (car, truck and bus) for both long and short haul freight and passenger journeys, air for some passenger routes and inland waterway for some bulk freight. Increased private car ownership with the concomitant ability of car drivers and passengers being able to travel door to door without changing mode has affected passenger rail traffic negatively. Surveys of travellers have indicated that for business commuting, travelling speed and convenience are rated the most important factors in the mode

choice decision. This priority is much less important for shorter distance (50 to 300 kilometres) leisure travel, where price comes higher up the list. Rail tends to win share in instances where it can compliment other modes by providing almost seamless travel, for instance rail to metro, and where road traffic congestion is bad enough to negate the convenience factor of door to door travel.

In competing with air travel, the development of high-speed rail services has provided an opportunity to divert traffic from air to rail. Air traffic's comparative advantage over rail transport i.e. speed, is under pressure on some routes in the EC as over shorter distances the flight time is only a minor portion of total journey time which is compounded by increasing congestion in airports and air corridors. The train, which is traditionally less expensive than flying, can become particularly attractive for journeys between 300 and 600 kilometres. For example, on the stretch Paris-Lyon, air traffic's share of passenger traffic on that route declined from 30% to 9% after the introduction of the TGV. Moreover, in some EC countries, policy is aimed at positively influencing the demand for rail transport. Current concern with congested roads, airports and airspace, as well as with pollution due to road and air traffic, are underlying this change in policy.

Passenger pricing for rail travel is usually worked on a per-kilometre basis and tends to be uniform in mainland EC, hence the longer the journey, the higher the price. However, prices from BR in the United Kingdom are not uniform, especially for the captive commuter belt surrounding London where prices are much higher than proportionate travel elsewhere in the UK.

For cargo, rail has the distinct advantage in its ability to move large volumes of freight in a single unit between specific points over short, medium and long distances. However, rail's share of freight traffic has declined over the last two decades. In the early 1970s the share of freight moved by rail was around 30%, but by the end of the 1980s it had declined to just over 16%. This loss of share is attributable to the increase in movement of freight by road, as road can move cargo from point to point, whereas rail freight requires modal symbiosis as the many cargoes need to be transported to and from rail freight terminals.

In 1991, the aggregate for labour costs in rail were over 60% of total operating costs and subsidies came to more than 40% of the operating revenue of the EC railways. At the same time, the EC railway companies suffered a joint loss of 7 billion ECU. The dominant contributors to this deficit was the German (west) and Italian railways with a loss of ECU 5.4 billion, or more than three quarters. This is no improvement on 1990, when these two railways combined contributed ECU 4.8 billion to the aggregate loss of ECU 6 billion.

INDUSTRY STRUCTURE

Companies

The top four rail companies in terms of network length are the SNCF in France (33 000 kilometres of track), DB in western Germany (27 000 kilometres), BR in the United Kingdom (17 000) and FS in Italy (16 000). These four combined have 75% of the available track in the EC. At the other end of the scale is CFL in Luxembourg with 275 kilometres and the next smallest is CIE in Ireland with just under 2 000 kilometres.

The national EC railway networks are controlled by single national operators. Rail transport services in the Member States can be characterised, to varying extents, by state regulation, the importance of non-commercial obligations and political objectives. Large subsidies from the state generally cover operating losses and/or investment (see Table 5). The single nature of the rail transport system largely precludes competition between railway companies or free market across national boundaries.

Strategies

The various railway companies in the EC have been collaborating to improve both international passenger and freight services. The strategy for international passenger services has been to provide day-train services under the brand name of 'EuroCity" in order to harmonise the service provided by the participating companies, and night services under the "EuroNight" banner, which are designed to provide uniform services with three categories of comfort. International freight services in containers (refrigerated and non-refrigerated) have come under the auspices of Intercontainer-Interfrigo (ICF), which provides the logistics and networks to move containers throughout Europe. ICF is owned by 27 railway companies in Europe.

In order to increase competition and profitability some Member States - Germany, the Netherlands and the UK - are in varying stages in the process of privatising their railways. In the UK, the law required to privatise British Rail was passed recently by the UK government. The break-up of the rail monopoly is expected to create seven private rail companies by 1995, and about 35 key rail routes will come under tender in 1994. The new rail companies will rent rail infrastructure from Railtrack - a new body that will be formed to operate the infrastructure.

In the Netherlands, the plan is to privatise the Dutch Railways in 2000. The Dutch railways expect passenger traffic to double by the year 2010 and have been investing in equipment and infrastructure improvements to meet the current growth in demand and future requirements.

Apart from efforts from individual Member States, the European Commission is seeking to liberalise the EC railway industry. In June 1991, the EC Transport Ministers opened the door to liberalisation when they agreed upon the Directive aimed at increasing access to the EC railway market.

One of the major pressures on most of the EC rail companies is their historic debt burdens. Huge debts have been incurred as railways have invested in the infrastructure and equipment required to provide the levels of service demanded by both customers and the fulfilment of a public service obligation. High interest rates coupled with steep competition that reduced revenues has compounded the problems. Some of the EC railways have had their debt burdens substantially reduced (BR in the UK) and/or rescheduled. However, the companies and their associations are lobbying for government commitment and assistance to reduce the debt burdens as there is still a long way to go in the EC before many of the rail companies could be considered as 'going concerns'.

ENVIRONMENT

Rail impacts the environment principally through air pollution, noise and land-use. Pollution into the atmosphere is both direct caused by emissions from diesel engines, and indirect from the power stations that generate electricity for trains using electrified track. The impact of noise is particularly acute in urban areas, although track tends to be placed in areas of lowest population density; in addition, track that is forced to go through densely populated areas is often placed in a way that minimises the noise, for instance in cuttings.

Although rail does cause atmospheric pollution, it is the most environmental-friendly form of transport. At full capacity both rail and buses have the lowest consumption of energy per passenger-kilometre than other forms of transport. Intercity and urban trains consume in the region of 0.3 MJ of primary energy per passenger-kilometre at 100% occupancy compared to between 0.6-1.1 MJ for cars. High speed trains consume around 0.7 MJ compared to almost 1.5 MJ for a Boeing 727. Even at low occupancy rates rail consumes less energy per passenger kilometre than most other forms of transport (the exception being bus). The difference for freight is not so marked, as bulk rail freight traffics estimated to consume 0.6 MJ per tonne-kilometre, whereas the equivalent figure for an articulated truck at 100% capacity utilisation is about 0.7 MJ. However, trucks rarely have 100% capacity utilisation as this implies that both the outbound and inbound journeys are full, hence, assuming a capacity utilisation for trucks of around 50-75%, then energy consumption is around 1-1.5 MJ per tonne-kilometre for an articulated vehicle.

Electric traction could also allow different energy sources to be used, for instance gas generation rather than coal, which would further reduce the impact of rail. In practice, however, railways tend to buy their electricity form national grids and hence cannot choose the method of generation.

REGULATIONS

In July 1991, the EC Transport Ministers agreed upon a directive (91/440) aimed at improving the efficiency of the railways and encourage their adaptation to market conditions by widening access and separating infrastructure management from infrastructure usage as much as possible, which became effective in January 1993. The directive allowed certain possibilities of access to the rail network for new categories of railway operators, but free access to the entire EC railway system, however, is limited in general only to private companies involved in combined transport, which accounts for only about 5% total freight transport by rail. Consequently, the accessibility for private newcomers is at present marginal and passenger traffic is totally excluded.

Existing national railways from different countries have been able to link up under the agreement, giving them access to each others' network and to the networks of railways in countries separating them. This applies to both freight and passenger traffic. In addition, national railway monopolies have to account separately for infrastructure and operating cost.

The Commission's White Paper on The Future Development of the Common Transport Policy (COM(92)494), that was adopted by the Council in December 1992, has important implications for the rail industry, as one of its cornerstones is the ability to stimulate modal shifts. Policy instruments that encourage modal shifts tend to favour modes that are viewed as having the most favourable balance between positive economic development and minimal environmental impact. Rail is considered to be the most serious contender for meeting both objectives within a global transport plan. By 1st January 1995 the Commission has to report to the Council on further measures needed to develop railways in the Community.

In late 1989, the Union Internationale de Chemins de fer (UIC) launched the P.A.R.I.S. (Pricing, Accounting and Rolling Stock Interchange Simplification) in order to set about increasing international rail competitiveness and revenues in passenger traffic. Within the recommendations was the possibility to revamp the prevailing price structure. It is deemed as rigid, complex and unable to respond to specific market conditions and it also makes revenue accounting and settlement slow and inefficient. Further rolling stock interchange rules would be simplified and more geared to market conditions. The programme consisted of two stages. The first stage ended in September 1990. Recommendations on pricing, accounting and international route management were submitted and ratified in October 1990. Then the second phase was launched, including the implementation of the recommendations from the first stage and to come to further recommendations.

THE EUROPEAN HIGH-SPEED RAILWAY NETWORK

In 1989, the Community of European Railways (CER), comprising the Railway Authorities of the EC countries and those of Austria and Switzerland, published a blueprint for an integrated continent-wide high-speed network across all European countries to enable rail to compete more effectively against airlines on many major intercity routes. In December 1990, the EC Commission adopted the proposals and the Transport Ministers gave the scheme a favourable welcome. The creation of an optimal Community railway network hinges on new or upgraded infrastructure in 14 key rail corridors, covering a total of 30 000 route-km (30% new 250-350 km/h infrastructure and the rest upgraded tracks for at least 200 km/h). It was thought that the recommended system could be operational by 2010. This seems optimistic considering the time taken to activate and finish current projects. In addition to the infrastructure investments, technical harmonisation is a prerequisite to maximising the potential of the high-speed train in the next century's European passenger market. Standardisation, for example, will be required for:

- the electrification system (currently four different systems are operational in the EC: see Table 7);
- the signalling system (virtually each country has at present its own signalling system);
- rolling stock (very different technical concepts are underlying the rolling stock, momentarily in use in the various EC countries.

There is still a long way to go before a fully integrated European high-speed network will be operational. Nevertheless, the projects currently carried out on a national basis, such as the construction of high-speed lines (e.g. in France, Germany and Spain) and the upgrading of existing lines for higher

speed offer prospects for the realisation of such a network. In 1993, France completed the TGV Nord line of 333 kilometres, and in 1994 the Channel Tunnel will open, linking the United Kingdom with France. Also, in 1994, the French TGV South-East line to Valence (83 kilometres) and North/South-East link (70 kilometres) are expected to be completed. In the period 1994 to 2000, an additional 564 kilometres of new line is expected, with an additional 3 496 added in the first few years of the 21st century.

OUTLOOK

Rail's future share in the (growing) European transport services market will depend on its ability to meet customers requirements concerning speed and flexibility and the effects of the Common Transport Policy.

The prospects for rail passenger traffic are for positive growth of 3% in the short to medium term. Improved railway services and increasing congestion in other modes will help favour rail transport. The high-profile high-speed rail services will continue to contribute to positive customer awareness as well as continuing to compete with air traffic on distances between 300 and 600 kilometres.

In the short and medium term, rail freight will continue to lose market share to road due to its relative inflexibility and as the modal relative cost structure favours road haulage, but in terms of volumes moved, rail will see some marginal growth. In the longer term, the integration of the European railway system and deregulation of the EC railway market will help garner some of the share back onto rail. Also, within the framework of the Common Transport Policy, measures that genuinely reflect the real costs of each mode will act as fillip to rail.

Cost and debt pressures will continue to force rationalisation within the industry, which will have further negative implications for employment. The planned privatisations of the railways in Germany, the Netherlands and the UK will exacerbate the decline. Privatisation of the Bundesbahn is estimated to cause over 30 000 job losses.

The industry is represented at the EC level by: Community of European Railways (CER). Address: Rue des Colonies 2, B-1000 Brussels; tel: (32 2) 525 3050; fax: (32 2) 512 5231.

Public transport
NACE 721

Public transport has become the target solution to alleviating traffic congestion and pollution, especially in urban areas. Substantial investments continue to be made to improve public transport services, both in the provision of new equipment and infrastructure and in modernising and improving existing stock and infrastructure. The tendency to privatise particular segments of public transport will continue, improving competition between operators and modes, but with the possible drawback of a reduction in frequency, geographic coverage and network integration.

INDUSTRY PROFILE

Description of the sector

Public transport (NACE 721) consists of city underground, surface and elevated railways; tramways, regular bus and motor coach services. There are two subgroups; city underground, surface and elevated railways (NACE 721.1) includes units exclusively or primarily engaged in the transport of passengers by electric rail services - mainly underground and overhead - solely or primarily serving a single city or town. Tramway, regular bus and motor coach services (NACE 721.2) includes units exclusively or primarily engaged in the operation of city, suburban and inter-city tramways, bus and motor coach services insofar as they are operated as regular or special services. Regular services provide for the regular transport of passengers on scheduled routes and follow a fixed timetable; they pick up and set down passengers at stops marked on their routes. Special regular services cater for specific categories of persons to the exclusion of other passengers (e.g. workers, school children and air line passengers).

Recent trends

Reliable statistics for the sector are sparse, but an estimate produced by the OECD indicates that on average the importance of whole sector in terms of revenue or numbers employed is between one third and one half of the significance of the freight sector. On average the sector has seen growth of over 50% in the last twenty years, however, the share in total transport has declined. This is particularly true for buses and coaches, which had a share of 10% in 1985 and which had declined to less than 9% by 1990.

Use of urban transport has declined substantially between 1989 and 1991. In 1989 total passenger journeys in major urban areas in the EC exceeded 21 billion, but this had fallen to less than 15 billion in 1991. The impact on vehicle kilometres was similar. Declines were recorded for nearly all the Member States - the only exception being Luxembourg. In size, Germany is the largest country in terms of passenger journeys (4.2 billion in 1991). The next most important countries are France and the United Kingdom with 2.3 billion each followed by Italy (1.9 billion). Also in terms of vehicle kilometres, Germany is the biggest next to the United Kingdom. Both countries account for about 1 billion vehicle kilometres.

National bus and coach services fared better than urban transport, managing a growth between 1989 and 1991 of almost 50 billion passenger kilometres to reach just 350 billion. Amongst the Member States, the results were mixed despite the aggregate growth. Germany, Spain, Italy, the Netherlands, Portugal and the United Kingdom all showed some growth. In Belgium, Denmark and Greece passenger kilometres stagnated, whilst the remaining countries recorded declines. Italy has the most passenger kilometres for national bus and coach services, with 85 billion, followed closely by Germany with 78.5 billion, and some way behind are the United Kingdom, France and Spain with passenger kilometres in the 40 billion range.

Bus services are the most widespread mode in public transport in the EC. Estimates provided in 1993 indicate that in urban and suburban public transport buses account for about 60% of passenger trips, 59% of vehicle fleets and about 90% of all transport systems. Measured in terms of fleet size, route length and number of routes, the larger operating bus systems are to be found in the large European cities like Paris, Athens, Rome, Madrid, and London. Commuter rail or local train services follows far behind with 18% of passenger trips and 28% of vehicle stocks. Underground railway ranks third with 13% of passenger trips and only 8% of total vehicle stock. Light rail is the smallest of the usual modes in the EC, accounting for about 7% of passenger trips. The least significant public transport mode is trolley buses with only a tiny share in total passenger trips.

MARKET FORCES

Demand

As discussed in the monograph on road passenger transport, the demand for extensive private mobility, arising from the desire to travel door to door with maximum flexibility, the absence in some countries of adequate alternative public transport and rising real personal disposable incomes have been the main factors behind the extensive growth in private car ownership and use. This has meant that growth in passenger travel has been largely in private cars at the expense of public transport, both for urban areas and for national bus and coach services. Although this is the observable aggregate trend, the impact has not been uniform. Substantial excise duties on fuel prices have barely influenced car ownership and car use as the user perceives the additional incremental cost as minuscule compared to the improvement in mobile efficiency.

In most EC countries, transport by private cars has been increasing faster than overall mobility, in part fuelled by households owning more than one vehicle. The highest share of private cars in total passenger transport has been reached in the United Kingdom, where it is close to 90%. In the traditionally lower car density countries in the EC, car ownership and use will continue to grow and outpace demand for public transport, as the use of buses and coaches within these countries has increased less than total passenger transport. However, with increasing congestion in major cities as local car densities exceed the limits of the road infrastructure, it is likely that a threshold will be reached where the negative effect of congestion on the efficiency of the private car will outweigh the inconvenience of using public road transport, especially in zones where there are dedicated lanes and zones for bus and coach movements. This is particularly true for users of metro, light rail and urban rail services, which tend to be very cost and time efficient where the total journey only requires the use of one mode. However, often the total journey requires more than one mode in varying combinations for instance bus-metro-bus or car-urban rail-bus, and it is where these combinations remain prevalent that the substantial flexibility of the private car will continue to compete effectively with a non integrated public transport system.

As indicators of demand, Table 3 presents the number of passenger journeys and the population served for the major urban areas. The 107 million people living in the EC's largest cities completed 15 billion journeys in 1991. In providing an estimate for service coverage, Table 3 shows the ratio of passenger kilometres per head of population served in the various EC countries. These ratios should be viewed with some caution as local or national circumstances can influence the indicators substantially, but at the same time provide a useful broad overview of the level of demand. The ratios indicate that broadly the number of passenger kilometres per head of population is fairly even in the EC, the exceptions being Belgium (low) and the Netherlands and Portugal (high).

Table 3 provides similar statistics for the number of passenger kilometres and the population served for national bus and coach services. For these services some 349 billion passenger-kilometres were made in 1991, serving 342 million people. As national bus and coach services by definition tend to involve journeys of longer length than urban transport, the ratios provided are much larger than for urban movements.

Supply and competition

The supply of public transport is usually separated into national bus and coach services and urban rail services. Within national bus and coach services, there are two distinct subsets, inter-city services and urban/suburban services. The equipment for these two is significantly different due to the different operational nature of the services. The long distance services typically use luxury coaches with a high level of interior furnishing and amenities, and tend to stop infrequently on a journey. The urban/suburban services have a lower grade interior and are designed for high volume-short distance passenger use, hence access to the buses is designed to allow large flows on and off. This service is also characterised by frequent stops to load and unload passengers.

Urban rail services are usually separated into metro, light rail and urban/suburban services. These services usually have different equipment that is not compatible. Metro is designed to run underground and also over ground - sometimes on elevated levels - and the length of an individual trainset is determined by the length of the shortest station platform on a route. This is often one of the underground stations as building underground stations has had and continues to have a high cost, hence planner have opted for high frequency services rather than long train sets. Light rail is similar to metro in

that it has shorter trainsets and frequency services than urban/suburban rail services. The latter traditionally have been designed to match inter-city and other rail services, hence the trainsets tend to be longer, there is a greater compatibility of equipment and services tend to have a lower but well-defined frequency.

Entry of new operators into national bus and coach services has historically been regulated, thus reducing competition but usually ensuring a broad geographic coverage. In inter-city/international operations cost barriers to entry are low - typically the purchase of equipment and insurance - but due to the continued existence of regulations the number of new entrants is still limited in most EC countries. The cost barriers to urban/suburban services tend to be higher as typically an entrant would need to provide a network of services and this reduces the possibility for small owner-driver operators. Except in the United Kingdom, there is minimal competition between firms providing similar services due to the low number of competitors for particular routes or geographical areas. The major competition comes from other modes of transport, typically the private car.

Over longer distances, added competition from improvements in domestic rail networks and the introduction (and extension) of high-speed trains in some Member States threatens the inter-city national bus and coach transporters. However, the experience of the TGV in France, where the TGV has operated for over ten years, indicates that high-speed trains do not necessarily stimulate overall demand for public transport services; additionally, high-speed trains have tended to take market share from regional air services rather than from the passenger transport by buses and coaches. Nonetheless, international coach services from the United Kingdom to mainland Europe will come under increasing competitive pressure from rail due to the Channel Tunnel link.

In urban/suburban services the main competitor to buses (apart from the private car) is metro/light urban rail services (and vice versa); however, as mentioned above, there is a degree of complementarity between the services, and supplying services that involve using more than one mode combined with a fare structure that easily allows mode combinations provides significant competition to the private car.

One major hurdle that operators face in providing services, is communicating schedules/timetables and fares to potential and existing users of public transport services. A regular user of the service will know the schedule and route for the usual route used but may be ignorant of other opportunities, and this is particularly acute for the casual user of the service, for whom the need to find the correct route and estimate the potential cost is a substantial barrier to use.

One of the issues in executing public transportation policies is the principle for fare collection. This relates to the extent of cost recovery from fares and to the system of fare levels. In general, fare systems are based on zonal rates.

Certain modern fare collection systems operate by using modern micro-electronics. This requires the sales of so-called smart cards (i.e. cards with magnetic strips or micro-chips on which a number of "units" are stored). Customers consume units while using the network. Such modern systems are already in use in Hong Kong and Singapore and are currently being tested or slated for testing in various EC cities. Berlin is currently running trials, London and Manchester will introduce a limited trials. The advantage of such systems is that the use of electronics enables a good tracking of transport demand, as data on each trip can be stored on computer, and reducing fraud and administrative costs. Such tracking opens possibilities for in-depth analysis of traffic demand to improve the service quality and to identify bottlenecks very quickly. It can also enable proper division of fare revenues in case of multi-operator fare collection (e.g. cards valid for more network systems). Smart cards will only be added gradually as the investment required is substantial.

Large investments continue to be made in public transportation. Estimates indicate that expenditure on new rolling stock and vehicles in Western Europe are in the region of 4 billion ECU per year with replacement rates averaging about 5%, but ranging from 2% in Belgium and the United Kingdom to 8% in the Netherlands.

Total investments in urban rail systems (both underground and light rail) through the 1990s is expected to be around 31 billion ECU. Large programmes exist in France (e.g. extension of the RER network in Paris, new systems in Strasbourg and Rouen), Germany (integrating eastern German networks), United Kingdom (e.g. extension of the Jubilee Line in London

and the Metrolink in Manchester, light rails in Birmingham, Sheffield and Bristol) and Italy (e.g. underground in Naples).

Table 4 presents some indications of supply of public transportation in the EC Member States. For all modes in major urban areas, the number of vehicle-kilometres per capita served indicates a relatively high service provision in countries like Denmark, Ireland and the Netherlands. The figures indicate that populations in major urban areas in these countries have over 40 vehicle-kilometres per person. Relatively low service levels per capita occur in Belgium, Portugal (the lowest), Italy, Spain and France. These figure do to some degree reflect differing population densities and should be viewed cautiously. Similarly for national bus and coach services, the ratios are even more distorted by country size vis-à-vis population, however the figures indicate a high service supply in the Netherlands (dense population, small geographical area) and Luxembourg (very small geographic area), whereas it is very low in Portugal (accurately reflecting the actual level of available vehicle-kilometres).

INDUSTRY STRUCTURE

Usually both rail and bus urban/suburban services are dominated by public services provided by the city or local borough. The rationale behind this ownership concentration is that providing the service is deemed to be in the public interest. This is particularly the case for low volume routes where commercial private sector operations would be expected to reduce service obligations. On some low volume routes operated by private enterprises there is often an element of subsidy provided by local authorities to maintain the route in the public interest.

Intercity national bus and coach services tend to be dominated by one national firm, which is usually state owned, the major exception being the United Kingdom where services are deregulated and there are many private bus companies.

ENVIRONMENT

Strategies of public transport operators are very much dominated by public transport policies of national governments and the European Commission. These strategies are aimed at stimulating the use of public transport and discouraging private transportation (cars). These policies relate are aimed at alleviating road congestion and particularly air pollution. In large urban and inner-city areas, congestion and pollution from motorised transport have become an especially serious problem which could be alleviated by increased use of public transport over private cars. Policies to discourage private transport use include increasing the tax burden on cars and fuel, whose revenues could be used for subsidising public transportation operations and investments, providing park-and-ride schemes, charging increased premiums for parking in inner-city areas and allowing only residential parking in suburban areas.

Although a comparison on a vehicle to vehicle basis between buses and private cars shows that a bus produces more NOx, HC, CO2, SO2 and particulates (but less CO) than the average petrol-engined car, in terms of emissions and energy consumption per passenger and per passenger kilometre the bus is considered the most environmentally friendly transport mode. On average for both urban and non-urban utilisation, the bus requires 15 passengers to one passenger in a car to equate NOx emission, 2 passengers to equate HC emission and 4 passengers to equate CO2 emission. This simple arithmetic, which is based on the data provided in the European Commission's Green Paper on Transport and the Environment, ignores the added benefit that a passenger in a bus may mean one less car on the road. Suburban electrical rail services are estimated to consume less primary energy per passenger-kilometre, at any occupancy over 25%, than private cars but marginally more than a bus. In emissions of CO2, bus and coaches are estimated to contribute only 1.6% of the total in the Community and rail (all passenger services) 2.8%, compared to 55.4 % for private cars. Additionally, as buses generally contribute to less traffic congestion, journeys are more efficient and consume less fuel with a concomitant effect on reducing emissions. The Green Paper also indicates that at a minimum occupancy of 25%, bus and rail services are very similar in primary energy consumption per passenger kilometre and substantially less than cars (diesel or petrol) and aeroplanes. Clearly the benefits increase as the occupancy rate increases.

In its Green Paper on the Urban Environment the European Commission has suggested the following actions:

- consider in detail the potentials for using economic instruments in private car transport such as road pricing and pay-tolls for the right to enter city centres.

REGULATIONS

The White Paper produced by the Commission at the end of 1992 on The Future Development of the Common Transport Policy (COM 92/494) has started the ball rolling in terms of a global approach to viewing all modes of transport simultaneously and hence providing a frame work for policy that integrates all modes. The White Paper is one of the most important documents from the Commission on transport issues and the discussions and negotiations that it has started will have far reaching impact on all modes of transport in the Community. One result the White Paper is likely provide in

the long run is to substantially encourage public road transport, however, the approach will be cautious so as to minimise the effects of sudden changes in policy and hence mobility.

Competition between operators in public transportation is rare. This is particularly the case for urban/suburban rail systems and most urban/suburban bus services. This is due to the regulatory environment in which they operate. The regulatory environment varies from one Member State to another. In the next paragraphs the main features in the various countries are summarised.

Belgium

The responsibility for public transportation by bus is with the three regional governments of Flanders, Brussels and Wallonia. The national bus company and the urban public transport companies are reorganised into quasi-commercial regional companies owned by the regional government. Five local subsidiaries are created, which operate under "contrats de gestion" for four to six years providing monopoly power within the area. The regional public transport company decides on fare levels and the allocation of subsidies to operating companies. It also co-ordinates various activities such as ordering vehicles, a common statute for personnel, common services between operating companies, etc. Operating companies determine timetables and can decide on subcontracting operations externally.

Denmark

Danish county councils (except Aarhus and Fyn where the local authority is responsible) have created regional transport companies for the management of all regular public transport within the area. In general, these companies organise, plan and market the services offered. Operations are generally licensed out to (mostly private) companies. Revenues go to the regional transport company; deficits are financed by the county council.

In the Capital Region (Copenhagen and surroundings) the situation is different. A new law came into force on January 1st, 1990 engaging the Capital Region Public Transport Company in general transport planning, network preservation and integration of fare structures with those of the railways. Currently it is licensing out bus services in long term contracts by way of competitive tender procedures. By April 1st, 1994, 45% of all bus services should be licensed out in this way.

Other local rail services are operated under agreements with local governments. Agreements related to service levels to be provided and fares and subsidies to finance the services. A particular example is the metro service in Copenhagen.

Germany

Local and regional authorities in Germany control and co-ordinate public transportation solely by determining routes and fare systems and deciding on the licensing of services to private companies. In practice companies active in this field cooperate extensively with each other. Licenses can apply to all modes of transport, but the period of validity can vary. Subcontracting to other operators is allowed. In principle, fares must be set at a cost covering level. Where this is not possible, subsidisation will be defined by the authorities. The State Government investigates the possibilities for deregulation.

Competition between bus and railway has always been strictly avoided. The Deutsche Bundesbahn itself operates various rural bus services through its subsidiary Geschäftsbereich Bahnbus (GBB; split in 25 regional companies) as a replacement for former rail services.

In former East Germany, the old situation was a very heavy involvement of public authorities in public transport operations. The situation is currently changing towards the present system in the western part of Germany.

France

In the Ile de France area (Paris and surroundings) the Syndicat des Transport Parisiens governs the main operators (RATP and SNCF) plus another 80 small operators belonging to professional associations. The STP defines policies, route coverage and revenue structure (fares versus subsidisation). Existing services cannot be moved from one operator to another. For new services, an operator can be chosen. Operators are allowed to subcontract service operations to others.

In the rest of France, the "départements" are responsible for regional bus transport. Usually bus services are provided under monopoly franchise contracts guided by administrative coordination of these services. In urban areas the "autorité organisatrice" controls local transport. This body determines itself service structures and fare levels and grants single area monopoly contracts for a limited time period. Three major groupings (Transexel, Transcet and CGFTE) control most of the operators in the market.

Greece

Prefectures govern Greek regional and local bus transportation. They grant public transport licences to co-operative associations in the regions. A co-operative consists of individual bus owners providing buses and drivers, and revenue collection staff for fare collection. In Athens, three government owned bus companies run the public transportation services within the city under the control of the separate public body OAS. Thessaloniki and Rhodes have systems slightly different from the prevailing system in the country. In Thessaloniki, a private operator has a license for 21 years duration to operate services; in Rhodes city a municipal operator runs the services in the city proper under the guidance of the prefecture.

Spain

Spanish authorities, usually the municipal council, grant concessions of between 8 and at maximum 20 years for the operation of a network of scheduled local bus services. The authorities determine the route structure and fare levels. Special regular services are allowed on condition that they do not compete with scheduled services.

Urban transport is provided by 185 companies, of which 28 are municipally owned and three are labour co-operatives. Private companies also operate in 129 of the 134 small sized towns (less than 100 000 inhabitants). In four of the five large cities (population above 0.5 million) the municipalities take charge of public transport themselves.

In inter-urban bus services, regional authorities grant concession rights to private operators. In case the service crosses the regional boundary, the concession is granted by the national government. Concession conditions are generally the same as those for urban transport.

Passenger services by rail are mainly provided by the state railways RENFE. In some regions, however, the regional government owns the network. Sometimes services are provided by way of a concession to a private operator using this network. Metro services (Barcelona, Madrid and Valencia) are provided by either state owned or municipality-owned organisations.

Ireland

Irish public transport is operated by the state-owned holding company CIE. This company owns three subsidiaries: Dublin Buses for bus services in the Dublin city region, Provincial Buses (Bus Eireann) for inter-urban and rural services and local services in the two major towns outside Dublin, and the Railways for all rail services including the rapid transit line in Dublin. The government is currently considering to introduce competition in the provision of transport services. A new authority is likely to be created for putting out to tender particular services and issuing licenses.

Italy

Public transport in Italy is governed by a concession system. In general, concessions are granted for long periods under monopoly conditions. In larger cities, the concession usually goes to the (generally municipally owned) local public transport company. Regional authorities provide long term franchises for longer-distance services and services in rural areas. In some cases, national authorities issue concessions for inter-regional and other long-distance services. These concessions can be granted to any operator, either private or publicly owned. The body issuing the concession usually determines services, timetables and fares.

Luxembourg

In Luxembourg four networks exist in public transportation. These are:

- Luxembourg City Buses (AVL) for local and out of town services in the city of Luxembourg under the control of the city government;
- RGTR: a number of private operators providing bus services under the control of the Ministry of Transport;
- bus networks in the cantons of Esch-sur-Alzette under the control of a syndicate of cantonal authorities;
- CFL: the railway company provides not only rail services but also bus services on formerly existing railroad links and on routes determined by the Ministry of Transport.

The core body is the Ministry of Transport. It determines fares, timetables and services, co-ordinates the provision of services throughout the country and it grants 10-year concessions to operators with automatic renewal.

Portugal

Most public transport in Portugal is provided by public sector companies. Some local and regional bus services are in private hands under a concession agreement granted by the national or local government. In 1990, a law was passed to deregulate public transportation.

In Lisbon, Oporto and Coimbra, services are provided by companies owned by the municipality. For Lisbon and Oporto commissions have been established to control the implementation of a public transport plan. This plan should regulate the public transport system in the area.

In the rest of the country, the government strives for complete deregulation by imposing only qualitative restrictions in licenses for operators. Control over maximum fares is retained. Local authorities are authorised to supplement the network with subsidised services.

Netherlands

Dutch public transport is a fully monopolised system via a licensing procedure under the Passenger Transport Act. In urban transportation municipalities grant licenses to either the local public transport company (nine largest cities) or the regional public transport company (45 cities). Licensing in inter-urban and regional transport is governed by the Ministry of Transport. Licenses are granted to 16 regional bus companies, which are all 80% subsidiaries of the state-owned holding company "Aandelenbezit Streekvervoer" since 1982.

Since 1988, private operators have the possibility to compete with the regional transport operators. Measures are taken to privatise bus companies. As a result, these companies engage in coach services and road passenger services. The Ministry of Transport continues its policy to stimulate public transportation, but more and more requires efficient cost-based operations and limitations to subsidies.

United Kingdom

British public bus transport on long distances has been privatised to a great extent. The then National Bus Company and Scottish Bus Group were split into 71 separate companies in order to get smaller more flexible entities offering long distance coach services. These companies should be able to compete with each other by way of pricing and service provision. While this has led to improvements in efficiency and quality, it has also resulted in a reduction in service frequency.

In local areas, services are also run on a commercial basis in which the operator determines fares, routes and timetables. In addition there exist subsidised services on certain routes. For London however, subsidisation prevails as London Regional Transport (LRT) compensates losses incurred by the bus and underground companies. Some services are provided by other bus operators under concession agreements with LRT.

Train services are generally provided by British Rail under a legal monopoly. In some local areas, however, a local network is operated by separate institutions.

OUTLOOK

Traffic congestion and environmental problems have initiated a new attention for public transportation. Especially in urban and suburban areas, public transportation has become an important issue and this importance will increase. There is also a tendency to privatise public transportation activities to some extent. In this respect, private capital could become important next to publicly available capital.

Large investments will be needed in constructing new and modernising old infrastructure, similarly fleets, modern fare collection systems and service quality.

Investment in railways, light rail and tramway systems has the added spur as these are perceived to minimise damage to the environment. However, continuing research and development in buses is increasingly aimed at minimising gaseous pollutants and will benefit this mode. In addition, combination modal facilities, such as park-and-ride, will continue to gather pace, and passenger information facilities will continue to improve.

As the tendency towards privatising public transport systems gather pace in some areas, the burden on authorities will be reduced as the private companies seek to provide more cost-based pricing and efficiency improvements in order to be profitable. This may however, have a negative impact on service frequency and services to low populated areas. A two-pronged policy approach to encourage people to use public transport rather than cars by providing low fares and improving the quality and quantity of the service, and at the same time increasing the costs of private car transport, will act in favour of public transport.

Further integration of public urban transport systems with other modes of transport will continue as witnessed over the last few years with improvements in connections with the railways network and local railway networks with important airports.

Written by: DRI Europe

The industry is represented at the EC level by: International Union of Public Transport (UITP). Address: Avenue de l'Uruguay 19, B-1050 Brussels; tel: (32 2) 673 6100; fax: (32 2) 660 1072.

Road passenger transport
NACE 722

The road passenger transport sector is primarily composed of regular bus services, charter coach services and taxi services. The private car remains the most important competitor for this mode for short and long distances, followed by all public transport for taxis, and rail and air for medium to long distances for coaches. Enterprises in the coach sector are continuing to invest in upgrading equipment in order to attract new business and maintain existing business.

INDUSTRY PROFILE

Description of the sector

The road passenger transport sector includes companies exclusively or primarily engaged in the operation of taxi-cabs, chauffeur-driven hire cars, occasional motor coach services, horse drawn cabs, etc. The sector does not include regular bus and shuttle services (NACE 721.2) and self-drive car hire (NACE 844). The major part of the sector consists of taxi and mini-cab firms and coach services for tourism.

Recent trends

Reliable statistics for the sector are scarce, but recent trends in the sector have remained broadly flat over the last few years. The only Member States to have seen reasonable growth rates since 1988 have been Portugal and Italy, and Table 1 shows how important the sector is to Italy compared to the other Member States. Italy has had the largest number of passengers-km over the last seven years. The importance of bus transport (including regular services) in Italy is also reflected in the high number of enterprises which are involved in road passenger transport. However, the Italian enterprises are relatively small when comparing the average number employed per enterprise. During the 1980s the development of all bus/coach transport differed significantly from country to country: the transport mode has lost importance in the United Kingdom, whilst, in other Member States small growth rates have been achieved.

The stagnation of growth in the use of this transport mode is reflected in the weak growth of the overall stock of buses and coaches.

International comparison

According to last year's estimates, the USA and Japan development's of the stock of buses and coaches - with annual growth rates of 1.4% and 1% respectively - also reflects a limited growth of this transport mode. In the USA, among other factors, the intense price competition among American airlines has caused people to favour air transport instead of coach services, and in Japan high-speed inter-city rail services provide a competitive edge over coach services.

MARKET FORCES

Demand

The demand for extensive private mobility, arising from the desire to travel door to door with maximum flexibility, the absence in some countries of adequate alternative public transport and rising real personal disposable incomes have been the main factors behind the extensive growth in private car ownership and use. This has meant that growth in passenger road use has been largely in private cars. Substantial excise duties on fuel prices have barely influenced car ownership and car use as the user perceives the additional incremental cost as minuscule compared to the improvement in mobile efficiency.

In most EC countries, transport by private cars has been increasing faster than overall mobility, in part fuelled by households owning more than one vehicle. The highest share of private cars in total passenger transport has been reached in the United Kingdom. In the traditionally lower car density countries in southern EC, Greece, Portugal and Spain, car ownership and use will continue to grow and outpace demand for public transport. In particular, the use of taxi services within these countries has increased, but possibly less than total passenger transport. A continuation of this trend is expected for the near future within these countries. However, with increasing congestion in major cities as local car densities exceed the limits of the road infrastructure and the availability of parking, it is likely that a threshold will be reached where the negative effect of congestion on the efficiency of the private car will outweigh the cost of using taxi services, especially

in zones where there are dedicated lanes, primarily for bus and coach movements but also used by taxis.

A significant proportion of the sector is coach services for tourism. Tourist coach services in combination with accommodation arrangements (inclusive tours) is popular among lower and medium income households and among senior citizens. Operators, however, are trying to attract other market segments by offering high quality services on long-haul routes. This aspect of public road transport is important for the tourist industry as it provides a convenient and predictable leisure schedule that is extremely cost efficient.

Supply and competition

The supply of road passenger transport is usually separated into coach services and taxi services. The equipment for these two is significantly different due to the different operational nature of the services. The long distance services typically use luxury coaches with a high level of interior furnishing and amenities, and tend to stop infrequently on a journey. The taxi sector is characterised by semi-luxury vehicles, often the lower luxury segment of the major car manufacturers, usually with diesel engines as these are very efficient and long lasting for the extreme number of average kilometres driven.

The cost of entry of new operators into coach services has historically been low - typically the purchase of equipment and insurance - but due to regulation overhang, the number of new entrants is still limited in some EC countries. The lowest cost barriers to entry is in taxi services, however, this is still regulated to some degree in most Member States. The regulations usually only govern the type of service and fares offered, while the number of licences is limited in many cities. For coach services competition between firms is muted as they provide similar services and also due to the low number of competitors for particular holiday schedules. The major competition comes from other modes of transport, typically the private car, rail and air. Competition amongst taxi services tends to be is acute, usually not based on price but more on location and fleet availability.

Over longer distances added competition from improvements in domestic rail networks and the introduction (and extension) of high-speed trains in some Member States threatens the road transporters. However, the experience of the TGV in France over the last ten years indicates that high-speed trains slightly stimulate overall demand for transport services and have tended to take market share from regional air services rather than from the passenger transport by buses and coaches. In urban/suburban taxi services the main competitor (apart form the private car) is availability of metro/light urban rail services; however, given the vast investment required to develop or expand these services, the degree of competition already existing will not change much in the near future.

Taxi services provide an excellent point to point service, with in-built efficiency as the taxi driver tends to know the layout of the area of operation hence usually taking most efficient route, avoiding congestion where possible, and saving time and fuel by not having to locate parking. One fillip for taxi services has been the increasingly tough stance Member States are taking on drink-driving. In the United Kingdom, which has one of the better records for improvements to reduce drink-driving via publicity awareness campaigns and a stronger police presence, a proliferation of mini-cab firms, typically servicing a local area, has occurred.

In terms of passenger safety, buses and coaches have significantly less passengers and drivers killed or seriously injured (KSI) per passenger-kilometre compared to cars. On average, it works out at about 1 to 18. Nonetheless there are still demands to improve safety for coaches, including such measures as compulsory wearing of seat-belts and in some Member States improvements in the road worthiness of the vehicles.

INDUSTRY STRUCTURE

The public road passenger transport sector varies considerably from one Member State to the other. In general the sector is fragmented with a large number of operators with fleets of varying size and although some very large operators exist, the majority of the enterprises are small-sized. Hence the sector is generally considered unconcentrated. In the coach sub-sector, the variance between Member States is significant, with

some Member States having a dominant carrier, whilst in the others the reverse is true. In taxi services the picture is different, as typically there are large numbers of small taxi firms serving local markets: many are owner-operators or have small fleets of around 5 to 10 vehicles. In the major cities, there is a tendency for large taxi firms; however, this does not preclude small operators as fares tend to be regulated. Medium and large sized operators tend to work more in the international market, in contrast with smaller companies which operate in national and regional markets.

Amongst the larger operators in the EC markets are National Express in the United Kingdom, De Jong Intratours and Beuk in the Netherlands, Iberbus in Spain, GTI in France and Deutsche Touring (subsidiary of the German railways) in Germany. Most of these firms also offer regular services. Also, for international European coach operations some 40 operators of international regular services are members of Eurolines. This consortium allows co-operation and efficiency in arranging and pooling service schedules as well as sharing the costs of marketing. Another such organisation is Europabus, which operates in Germany.

The greater part of the investments made by enterprises is for replacement of depreciated vehicles. Particularly in the longer distance market, the intensifying competition and customer expectations on quality standards forces enterprises to operate with high-quality buses and coaches with a broad variety of modern features (e.g. air conditioning, air pressure suspension systems, video facilities, catering etc.).

ENVIRONMENT

Although a comparison on a vehicle to vehicle basis between coaches and private cars shows that a bus produces more NOx, HC, CO2, SO2 and particulates (but less CO) than the average petrol-engined car, in terms of emissions and energy consumption per passenger and per passenger kilometre the bus is considered the most environmentally friendly transport mode. On average for both urban and non-urban utilisation, the bus requires 15 passengers to one passenger in a car to equate NOx emission, 2 passengers to equate HC emission and 4 passengers to equate CO2 emission. In emissions of CO2, buses and coaches are estimated to contribute only 1.6% of the total in the Community, compared to 55.4% for private cars. Additionally, taxis contribute to less traffic pollution, as cars are generally recent models which incorporate the latest technologies, and because journeys are more efficient and consume less fuel with a concomitant effect on reducing emissions. The Green Paper also indicates that at a minimum occupancy of 25%, bus and rail services are very similar in primary energy consumption per passenger kilometre and substantially less than cars (diesel or petrol) and aeroplanes. Clearly the benefits increase as the occupancy rate increases. A taxi carrying passengers, by default, always has an occupancy of two or more and with less time spent finding adequate parking will contribute to lower aggregate emissions.

REGULATIONS

The EC legislation has established three types of international coach services: occasional, shuttle and regular services. Occasional and shuttle services are basically tourist services. International regular services are subject to similar rules for national services (timetables, set routes and prices).

There is also a category known as special regular services, which mainly consists of the carriage of employees to their place of work and carriage of school children.

As far as national coach transport is concerned, the categories of service vary from country to country and within certain States there is no category of shuttle services.

The EC Council of Transport Ministers has adopted in 1992 the regulation on the freedom to provide intra-EC services for road transport by coach and bus. Under this regulation, an authorisation is no longer required for most occasional services and for shuttle services if accommodation is included (inclusive tours). For regular services and shuttle services without accommodation, however, authorisation is still required.

A proposal for a regulation on the conditions under which non-resident carriers may operate national road passenger transport within a Member State, has recently been adopted. The new freedom allows operators to provide certain non-regular services under the same conditions as resident carriers as from January 1, 1993 and all such services as from January 1, 1996.

The degree of regulation of coach services varies greatly between Member States. Certain Member States, such as the United Kingdom, have a very liberal system, where basically only qualitative controls govern the operation of a service (Transport Act). The Netherlands also have a relatively free system (Passenger Transport Law) for coach operations. Regular bus services (public transport) is strictly regulated. On the other hand, in Spain the 1987 LOTT legislation prescribes very detailed provisions governing all road passenger transport.

Furthermore, a Directive has come into force on 1 January 1990, strengthening the existing provisions for becoming a passenger transport operator. In particular, it specifies precise minimum financial requirements to ensure the viability of existing and potential operators and it makes the passing of a written examination compulsory for new entrants.

The White Paper produced by the Commission at the end of 1992 on The Future Development of the Common Transport Policy (COM 92/494) has started the ball rolling in terms of a global approach to viewing all modes of transport simultaneously and hence providing a frame work for policy that integrates all modes. One result the White Paper may provide in the long run is to favour public road transport; however, the approach will be cautious so as to minimise the effects of sudden changes in policy and hence mobility.

OUTLOOK

The growth rate of passenger road transport, however, will be lower than overall mobility growth, as private car use is yet to reach its maximum. Policy instruments from national governments, local authorities and potentially the European Commission to discourage private car traffic in order to reduce road congestion and air pollution by cars, are not likely to have significant consequences for the ownership and use of private cars in the short term. This is especially the case, as mentioned earlier, for habitual car owners and users who have a substantial tolerance for mechanisms involving increase taxes and fuel excise. However, Member States that increase pressure on drink-drivers are likely to see additional demand for taxi services. The opening up of Eastern Europe has and will further expand tourist destinations for coaches. Investments in high-speed trains is not expected to threaten the road passenger transport in the short term, however, improvements in ordinary rail services will have some negative impact coach services.

Road freight transport
NACE 723

Road freight is the dominant sector in the movement of cargoes within the Community, taking a share of 70% of all modes, and is a major contributor to economic growth. The single market will help improve capacity utilisation of the European road goods transport industry and drive further growth of intra-EC traffic. Community policy aims at eliminating physical barriers and harmonising taxes within the EC. In close connection with the EC policy on infrastructure and pollution the European Commission will give special attention to the less developed areas in the EC. The Commission's White Paper on The Future Development of the Common Transport Policy is ensuring that road freight is considered in detail in discussions of a global policy, and it is a major step forward in looking at the future of road freight within this global framework. The opening up of Eastern and Central Europe will tend to favour both passenger and freight traffic by road, and its impact on the EC road transport sector is expected to be substantial already in the short-term.

INDUSTRY PROFILE

Description of the sector

The goods transport sector includes units exclusively or primarily engaged in the transportation of goods - regular or otherwise - by trucks and vans or similar vehicles e.g. trailers, semi-trailers, road tankers, removal vans, articulated vehicles and truck-trailer combinations.

The market for merchandise road transport is organised by a national regulatory framework and Community measures.

Recent trends

Estimates for total road freight indicate that it increased by 7% in 1991, to around 800 billion tonne-kilometres. This particularly strong growth was due to the inclusion of ex-DDR data in German traffic, and represents a reversal in the slower 4% trend observed in 1990. In terms of volumes, 1991 domestic road freight continued the downward trend observed in 1989 and 1990, falling some 2%. However, international traffic bounced back from the major decline of 1989 and the stagnation in 1990 to record growth of close to 10%.

In 1992, for which preliminary estimates exist for the individual Member States, freight traffic growth was rather limited. The star performers were Ireland (+7.8%) and the Netherlands (+5.2%), followed by Portugal and Greece with around 5%. The balance of the Member States saw growth in 1-4% band with the exception of Belgium and Luxembourg, both flat, and the United Kingdom, which had a decline of 3%.

In 1990, the Netherlands and Belgium were the dominant countries for international road freight, with 40% of international freight between them. Germany and France also have large shares of international road freight, 19% and 15% respectively. On most recent estimates, these shares of international freight appear to be stable. In domestic road freight, Germany is by far the largest with 2.7 billion tonnes, followed by the United Kingdom with 1.5 billion tonnes and France with 1.4 billion tonnes. With the exception of the Benelux, all the EC countries have comparable market shares for international and domestic road freight operations, averaging just over 1% for intentional volumes moved.

Total road traffic between the Netherlands and Germany is very intense at 7.9 billion tonnes/km from the Netherlands to Germany and 7.4 billion tonnes/km in the opposite direction. The same intense road traffic can be observed between Belgium and France, as well as between Germany and northern Italy.

Transport growth has been exceptional in Spain and Portugal. In 1989 total international road traffic increased by 9%, whilst transport to the Iberian peninsula grew by more than 20%.

The EC total fleet of 15.6 million vehicles is smaller than that of the USA and Japan, respectively 43.6 and 22.2 million vehicles.

MARKET FORCES

Demand

Road freight generally offers an efficient and facile method of transporting and distributing goods to wholesalers, retailers and consumers. The level of economic activity is a major component in the demand for road freight, and there is a strong correlation between growth in economic development and growth in the demand for road freight, both internationally and domestically. As well as being dependant on the level of activity, the road freight industry plays a crucial role in assisting economic development. Road goods transport is usually divided into two segments, short-haul and long-haul. Although there is no precise haul length to divide these two, short-haul is predominately intra-urban and long-haul is inter-urban/city including international.

The recent advent of the Single Market should act favourably for the road goods transport industry through the reduction of trade barriers. This reduction will allow more intra-EC trade for a given amount of EC output, as international freight movement is an intensive user of road freight. The increase in competitiveness between EC countries and industries will lead to a degree of industry and sectoral rationalisation around larger producing units. These will tend to be further from both consumers and suppliers, hence increasing transport demand - similarly for retail distribution networks. Historically, low-value goods have faced cost obstacles to long distance transportation. However, fewer trade barriers will reduce costs, hence promoting the movement of lower value commodities over long distances which may also translate into heavier unit loads. Also, the Single Market improves competition in the EC road goods transport industry and encourages it to innovate and upgrade its services in order to meet develop-

ments in demand, by shifting from general goods transport to a wide range of specialised and sophisticated transport services. Hauliers will be engaged more in distribution than just in physical transport. Increased competition and the pressure to innovate will entail a process of concentration and co-operation. On the other hand an increase in the demand for specific services offers prospects for specialisation.

The major extra-EC market to use the road goods transport service from the EC is Eastern and Central Europe. However, eastern European countries have been unable to cope with the resulting substantial increase in road traffic. Estimates put the average additional time required to travel a specific distance in Eastern and Central Europe compared to the equivalent A road in western Europe at 20%. Road maintenance, upgrading and the construction of new motorways will be required to ease congestion and to ensure rapid flows of goods and passengers. Implementation of these measures require both considerable investment and time. The TEM (Trans-European Motorway), prepared and carried out under supervision of UNO, has the objective of ensuring the construction of an integrated Pan European road system. However, the TEM-project is not expected to be realised before the turn of the century.

The use of information and communication technologies, e.g. Electronic Data Interchange, Tracking and Tracing systems, will act as a fillip for market growth, as the services offered by the players in the road goods transport market can provide better quality (e.g. Just In Time, reliability, flexibility and probability of damage) and/or cover a far wider range of destinations thanks to efficiency improvements.

Supply and competition

Road goods transport is able to supply a flexible range of services that moves a wide range of products over a very broad geographic area. One of the cornerstones of road goods transport's competitive position vis-à-vis rail and inland waterways is this geographic flexibility. For short haul movement of goods, road goods transport has a distinct advantage. It is typically on long haul point to point bulk services, where rail can collect from point of initial loading and delivers to point of final discharge, that rail offers its most competitive threat to road goods transport.

In the road goods transport industry, a distinction can be drawn between 'Own-account', which is a company transporting its own products in its own fleet, and 'hire and reward', where a company transports good on behalf of a third party. It is possible for an own-account operator to make up load by selling part of its space on a hire and reward basis. In the last few years there has been a marginal but noticeable trend for companies that used to use own-account transport to downsize their fleets and move to using third party transportation. The decision to do so rests on the relative efficiencies between owning and maintaining a fleet with the relevant labour force and just paying on a per load or load contract basis.

Increasing trends towards specialised cargoes have required investment in specialised vehicles, such as trucks/trailers capable of carrying hazardous chemicals or gas. However, specialisation often means that the return journey is empty.

The enforcement of regulations on working hours have still to be improved in the Community. This, coupled with variations on hours kept at loading and discharge areas can severely affect the logistics and scheduling of road freight movement. Additionally, permissible weights for particular truck and trailer types, which vary from country to country in Europe, have an indirect impact on cross-border movements, although there is now conformity in the Community.

On the supply side the trend in the 1980s has been one of steady growth, accelerating in the last few years. Liberalisation and harmonisation will affect the supply side in several ways. Firstly, as discussed above, trade between Member States and thus intra-EC road traffic will continue to increase. Secondly, as cabotage is liberalised, competition between hauliers from different EC countries will intensify, pushing freight rates downwards, which in turn will benefit the industry as more cargo will be diverted to road.

Comparison of market shares confirms the strong competitive position which the Netherlands hold in intra-EC road freight, in relative as well as in absolute terms. Belgium also is well placed on the intra-EC market. The intra-EC market shares of Germany and France are also high, but compared to their national traffic their contribution to intra-EC traffic is of minor importance. Spain is the only other country where intra-EC traffic is significant to the sector.

Production process

The production process is relatively straightforward. Cargo is collected en masse at point of origin, or it is consolidated by a transport firm. The consolidation may involve collecting small parcels of freight from many different locations using smaller vehicles before transhipment for the major stage of the journey. Delivery of a large single cargo is to point of

destination, where it may be used in its entirety or broken down into smaller parcels for onward delivery. A consolidated cargo is delivered to a point where it can be distributed or it is distributed on by the vehicle used for the major journey leg.

The average carrying capacity of semi-trailers (based on Germany, France and Belgium) has increased from 22.7 to 23.7 tonnes between 1986 and 1989, whereas the average carrying capacity of lorries and trailers has remained unchanged at 1.8 and 7.0 tonnes respectively. These low figures are of course due to the large number of smaller vehicles. Based on seven countries of the EC, approximately 7% of trucks have a carrying capacity of 7.0 tonnes or more and these larger trucks account for 45% of the aggregate carrying capacity. However, the EC average of tonne-km per vehicle in 1989 was 51 200. Greece, France (due to the large number of vans) and Ireland and Portugal tend to have lower than average utilisation-rates. Denmark, Spain, and Italy are operating close to the average, whilst the other EC countries operate above average. Germany, Belgium and the Netherlands have all utilisation rates of approximately 100 000 tonne-km per vehicle.

INDUSTRY STRUCTURE

Companies

The market is fragmented into many small transport companies. However, in some EC countries, the number of road transport firms is gradually declining, indicating a tendency towards some co-operation between companies or concentration in the sector. However, the barriers to entry in road freight are minimal due to low initial capital requirement and also minimal product differentiation, hence, substantial concentration is very unlikely. The only area for potential concentration of monopoly is in the very specialised sectors, such as hazardous cargoes, which require a more substantial investment in equipment and particularly in expertise in order to comply with regulations.

Member States differ considerably in the number of hauliers, the evolution of this number, and the distinction made between own account transport and transport for hire and reward. However, broadly, there is a degree of inter-relation between country size and number of companies. The main exception are Spain and Italy, which have an unusually high number of enterprises. Traditionally, Member States have had different market access rules for long distance and short distance goods transport respectively, however, as harmonisation progresses this will be less apparent.

Strategies

Investment in expanding road infrastructure has not matched the development in the road freight industry. The growth in the number of trucks and vans coupled with increases in the dimensions and weights of trucks and containers have exceeded the capabilities of some road networks. This in turn is causing serious problems for road maintenance, congestion, and technical and operational logistics. The lack of sufficient investments in road infrastructures becomes a serious threat to the goods transport sector. Governments are essentially monopoly suppliers of roads, and this is reflected in their investment decisions. Competition from rail may increase due to additional investment in railway transport, particularly investment in high-speed trains as well as in the improvement of the overall quality of railroad transport. The major investment of the Channel tunnel and the link between Sweden and Denmark will lead to changes in transport flows and logistic locations. Since, token first ground was broken in September 1993 on one of the largest European transport infrastructure engineering projects this decade - the link between Sweden and Denmark. The Øresund Link crosses some 16 kilometres of open sea, and is slated to be 11 km on a high span bridge and the balance in tunnel. The final decisions on the exact nature of the infrastructure has not yet been finalised, as it is waiting on final contractor bids. The investment is slated to exceed ECU 4.5 billion and will be largely privately financed through a public share holding in the Holding company. The Link is expected to open in 2000 and is expected to draw some 6.2 million passengers per year.

ENVIRONMENT

Road goods transport is coming under substantial pressure from concerns over the environment. Road traffic is responsible for a large contribution to air pollution. Among the major air pollutants are: Sulphur dioxide (SO_2), Nitrogen oxides (NO_x), Carbon monoxide (CO), Particulates (Aerosols), Lead (Pb) and Carbon dioxide (CO_2). Both gasoline-driven and diesel vehicles emit carbon monoxide, hydrocarbons, nitrogen oxides and carbon dioxide, though diesel vehicles emit CO and NO_x at lower rates. Furthermore, gasoline vehicles emit lead, and diesel vehicles emit SO_2 and particulates.

Whilst most emissions are produced by private cars, the emission of particulates originate mainly from diesel engines - important for freight traffic. New EC standards for heavy vehicle emissions, Euro I and Euro II, will reduce emissions by these vehicles by 55-65%, except for CO_2. In the short term, there is no expected major technological revolution in engine design that will substantially reduce emissions. Hence,

Source: Eurostat (Carriage of goods 1990)

a major option is to ensure that the effect on the environment is costed correctly. The Commission is reviewing options on how to cost this effect, for instance through a combined tax on energy and carbon. This could be used to stabilise the emissions of the greenhouse gas CO_2 over the coming decade, with emissions in 2000 remaining at the level recorded in 1990. Such a tax could increase operators costs on fuel by between 6% and 10%. However, the external costs of road freight are yet to be quantified objectively, as the many studies undertaken have produced a wide discrepancies in results, and hence there appears to be no straightforward method of costing the externalities.

REGULATIONS

The issue of authorisations, the fixing of tariffs and driving times, the imposing of technical standards and taxes on motor vehicles, are actions that can affect the supply side of the market, for instance, the number of vehicles on the road. From January 1st 1993 onwards, all bilateral authorisations, transit and Community quotas have been replaced by Community authorisations, but these will not be subject to quantitative restrictions. From then on permission to enter the market will depend on qualitative criteria. On January 1, 1990, the old tariff system for international journeys within the EC was replaced with free price fixing.

By improved co-ordination, the EC is trying to improve the observance of social measures, i.e. to extend its span of control, to prevent drivers from neglecting the measure dating from November 1985 which regulates their hours of driving.

Other EC measures that may affect the road transport of goods are associated with the EC policy concerning environment and infrastructure. Other measures are especially aimed at improving the infrastructures of the economically less developed areas.

Another important aspect of goods transport is cabotage, which was not permitted in road goods transport by any host state in Europe until recently. EC ministers have approved plans for motorway tolls on trucks, in the form of windscreen vignettes, to proceed. This is seen as a method of harmonising road transport operating costs and will be introduced in Germany, Denmark and the Benelux States from 1 January 1995. Additionally, gradual road transport cabotage liberalisation has been approved, with measures starting on 1 January 1994. This will take the form of a substantial increase in the number of cabotage licenses issued in the Community and by 1998 will allow complete cabotage freedom. There still remains some opposition to the general introduction of cabotage, partly related to the differences in taxes and tolls.

The Communication from the Commission in the form of a white paper entitled The Future Development of the Common Transport Policy (COM(92)494), of December 1992 seeks to set out a global approach to transport issues enabling due consideration of all views before the launch of particular initiatives. It recognises the importance of road transport in the global picture, and seeks to balance transport policy in terms of its impact on the environment with sustainable mobility for the Community as a whole. The communication enlarges on the major issues of modal disequilibria, capacity constraints, system and network developments, environmental issues, safety, and social issues.

OUTLOOK

The liberalisation and harmonisation of the EC transport market, the resumption of positive economic growth and the continuing move towards fast and flexible transport will affect both the volume of total transport and modal choice. Environmental regulation, Eastern and Central Europe, investments in road transport and other modes of transport and information and communication technology are other important aspects.

For road transport operators, the European integration may produce some general advantages such as an increased transport volume, more third-country transport, less empty return loads, simplified foreign settlement, and co-operation with foreign transport operators. Intra-EC traffic will grow significantly faster than national traffic, as the effects of the Single Market act as boost to the sector. Meagre investment

in infrastructure will, in some cases, act as brake on the efficient expansion of road goods transport. However, investment in infrastructure in some areas of congestion will do little to relieve the problem.

The use of new information and communication technologies will act as fillip for the transport companies as developments in this field have undergone rapid improvements in recent years.

Inland waterways transport
NACE 73

About 40% of all goods moved between EC Member States is transported by inland waterway. Following the crisis of the early 1980s, demand picked up momentum during the latter part of the decade. However, overcapacity has hampered the development of an equilibrium between demand and supply in the sector. Scrapping and modernisation policies at the Community level have made some progress in improving the situation, which, if extended in 1994, will further these gains. Together with increasing demand (especially in the transport of hazardous goods and unitised cargoes) the prospects for inland shipping are moderately positive.

INDUSTRY PROFILE

Description of the sector

NACE 73 includes units exclusively or primarily engaged in the transportation of passengers and goods on rivers, canals, lakes, lagoons and within river ports. Tugs and push boats operating on inland waterways also belong to this NACE group.

The largest portion of inland waterway transport consists of companies operating ships of various sizes to convey goods throughout Europe on the available inland waterway network. As passenger transportation is limited to a few ferry boats across rivers and boats for river cruises, this part of the sector is very small and beyond the scope of this monograph. Most inland shipping operates with unscheduled services for operations using fixed schedules are very rare.

Inland waterways goods transport is usually divided into liquid or dry cargo on the North/South route or Rhine, with an additional separation of free/market/bourse or not.

Next to companies operating ships as their primary activity (professional transport), there are companies active in manufacturing that operate ships on their own account (own account transport).

Recent trends

In terms of tonnage transported in 1990, the country with the largest volume is the Netherlands with over 2.5 million tonnes. Germany ranks second with a total tonnage of 216 million. Belgium follows in third place with 96 million tonnes and France is in fourth position with 64 million tonnes. In the other countries of the EC, inland shipping is a marginal activity. In the United Kingdom and Italy, only domestic shipping takes place; in Greece, Portugal, Spain and Denmark, inland shipping is virtually non-existent.

When measuring transport activity of inland shipping in terms of tonne-kilometres, the ranking changes. Germany takes first position followed by the Netherlands. France ranks third and Belgium fourth. Although, the Netherlands has a greater length of navigable waterways in use than Germany, these comprise mostly of canals, whereas Germany has substantial lengths of arterial navigable rivers in use (3 000 kilometres). Also, the majority of inland shipping activity is accounted for by goods transported on the Rhine River (622 navigable kilometres in Germany). Nearly 300 million tonnes are transported annually on this main artery of inland transportation for the European continent. Hence, the combination of the traffic density on the Rhine and Germany's greater stretches of arterial waterways provide the higher tonne-kilometre result for Germany. The river is the most important connection between the large ports in the Le Havre-Hamburg range (e.g. Rotterdam and Antwerp) and the European hinterland. Dutch and German inland shipping operators benefit from this advantageous situation.

National differences occur when looking at the distribution of goods traffic. In some countries, domestic transport is important, particularly for France, where half of inland shipping is domestic. In the Netherlands, exports dominate inland waterway transport with 41% of inland shipping, whereas only 19% is imports. In Germany, the situation is reversed, with 43% of inland shipping due to imports and only 24% is exports. In Belgium, imports are close to half of its total inland shipping (measured in tonnes) and exports account for 29%.

Total tonnage in transit on inland waterways in the EC amounted to some 62.5 million tonnes in 1990. The Netherlands with over 32 million tonnes is the most important transit country, followed by Germany with another 15.8 million tonnes. In Luxembourg, transit traffic is the most important traffic category: in terms of tonnage 80% is in transit (8.7 million tonnes); in terms of tonne-kilometres it amounts to 97%.

Source: Eurostat (Transport Annual Statistics 1970-1990)

Inland shipping specialises in the transport of large quantities of bulk products, such as sand, ores, coal, chemicals, and oil. These are clearly divided into dry and liquid bulks. The larger volumes of goods transported are petroleum products (16%), iron ore, iron and steel waste, etc. (13%) and the largest group, crude and manufactured minerals, (33%). In practically all countries, crude and manufactured minerals are the most important cargoes. In 1990 just over 26% of total German inland shipping was crude and manufactured minerals (61 million tonnes), in France 54% (35 million), in the Netherlands 35% (99 million), in Belgium 25% (25 million), in Luxembourg 17% (1.8 million) and in Italy 19% (140 thousand).

Most of inland waterways transport throughout Europe takes place within the EC. Transport to and from non-EC countries mainly relates to transport links with Switzerland (Rhine) and the East European countries along the Danube and the Elbe rivers.

The average annual growth of total tonnage transported throughout the EC during the period 1987 and 1990 was just under 2% per annum. This has meant a partial recovery from the very depressed situation that existed at the beginning of the 1980s. Annual rates, however, fluctuate considerably. In 1987, a drop in tonnage transported of about 0.8% occurred, whereas in 1988 growth recovered and soared to 6%; this was then followed a slight decline in 1989, which was marginally compensated by some positive growth in 1990. Growth rates by Member State also provide an inconsistent picture, with Germany averaging growth of 4% between 1987 and 1990, the Netherlands 5.4%, Belgium 6%, whilst the United Kingdom and Italy recorded average negative growth, -1.3% and -34.7% respectively. However, the base volumes for these countries are very small, hence the impact on the EC aggregate is minuscule.

Comparing the tonne-kilometres results for the Member States with major inland waterway cargo traffic, the average annual growth rates for Belgium, Germany, France and the Netherlands have remained relatively stable at around 2.5%, with Germany having the greatest growth at 3% and France the lowest at 1.8%. The total tonne kilometres for these four countries was 88 billion in 1990.

MARKET FORCES

Demand

Over the years, demand growth in inland shipping had been fairly limited. In other types of transportation, growth rates of demand have been much higher. The major factor underlying this disparity in demand for inland waterway compared to other modes is that demand has been dominated by types of cargoes such as traditional bulk products used as inputs for traditional industries (e.g. refineries, steel industries, chemical plants), where growth rates of industrial activity have been either moderate or in decline.

Source: Eurostat (Carriage of goods 1990: Inland waterways)

The cost structures of these industries have supported the requirement for inexpensive transportation for bulk goods, where the transportation costs can sometimes exceed the raw material costs. Speed has not been an important factor, but continuity has been crucial as interruptions of cargo flows would distort the production process in the plants.

There has been a structural tendency to reduce the volumes of goods to be transported. This has been done by transferring the initial processing of raw materials to the origin. As a result, total tonnage of raw materials has declined and the tonnage of processed materials increased. However, this increase of semi-processed and processed cargo has not fully compensated for the decrease in raw materials.

Another problem on the demand side is that there is a tendency for monopsony power: demand is with a limited number of large industries, which are able to exchange information on the inland shipping market. In the Netherlands, for example, the transport of sand and gravel has been controlled by a cartel of sand and gravel traders and producers. Furthermore, some industries have arranged long-term transport contracts with shipping companies at guaranteed prices. In addition, some industries have their own vessels (own account shipping). They only need to employ additional (independent) vessels to meet peaks in their transport demand.

In the last five to ten years, unit cargoes like containers and roll-on roll-off (e.g. equipment for agriculture, cars and trucks) have become increasingly important for inland shipping. These form the less time-sensitive portion of unit and ro-ro cargoes, and shippers have gained from the relative reduction in costs that, although movement of these cargoes by inland waterway is slower than other major modes, is time reliable. Also unit cargoes can be easily handled in multi-modal (combined) transport concepts: a combination of rail, road and inland waterway transport. Such packaging of non-bulk goods is likely to continue and allow inland shipping to diversify away from traditional bulk tonnage.

Another tendency is that inland shipping has become important for the transportation of dangerous cargoes, such as highly poisonous or explosive chemical products. These substances require a high level of safety and safety standards from the transportation service providers.

Supply and competition

Inland shipping is capable of meeting the industry's requirements for bulk transportation which is cheap, energy-efficient, safe and reliable. The application of information and communication technology allows modern transportation that is cost efficient and compliments concepts such as just-in-time delivery and door-to-door transport. A key advantage offered by inland waterways in comparison to other modes of transport is the relatively low burden for the environment since both the energy use per tonne is very low and there are no severe bottlenecks in the network.

The EC inland waterway fleet in 1990 had a carrying capacity of 12.2 million tonnes. The Dutch fleet accounted for 49% of the total capacity, while the German fleet held second po-

Total transport	48.7	33.8	17.8

(1) Based on tonnes and dispatch figures.
Source: Eurostat (Carriage of goods 1990)

sition with 25%. The key fleets all declined in 1990 in both vessels numbers and carrying capacity, with the exception of the Dutch fleet which although declined in numbers increased it carrying capacity. Overall, the EC fleet carrying capacity fell in 1990 compared to 1989 and partial observations for 1991 and 1992 indicate the fleet is continuing to decline, but at a much reduced rate.

The fleet is characterised by the existence of a large number of private owners mostly operating only one vessel with the owner's family living on board. In general these vessels are old and relatively small in size and not in line with the latest technological standards. These ships are not demolished as the owners operate at or below economic cost prices, accepting very little or even negative returns. Large shipping companies exploiting fleets of 20 to 100 vessels mainly operate on the Rhine and its branches. Their fleets are generally large modern units capable of high productivity and short turnaround times.

The existence of small family-owned vessels which have not yet been scrapped and the introduction of modern large sized vessels has caused a structural imbalance between supply and demand. Overcapacity, therefore, has become a structural phenomenon in inland shipping. During the 1980s overcapacity was estimated at some 20% of the EC fleet.

Overcapacity has been blamed for its negative impact on the evolution of prices on the free market. Price regulating and cargo sharing systems were introduced, basically to guarantee ship owners a minimum income. This social policy exacerbated the problem of excess capacity.

Minimum price tariffs currently operate under official systems in some Member States. Germany's plan to liberalise the German market on 1 January 1994 has been met with fierce action from German operators, who blockaded the Rhine and ports in protest in September 1993. This followed a similar protest by Dutch operators when the Dutch government set about liberalising the Tour-de-Role tariff and freight sharing system.

REGULATIONS

To remedy overcapacity problems, Council Regulation (EEC) No. 1101/89 of 27 April 1989 was introduced to remove the structural imbalance between demand and supply in the inland waterways market. This established principles for an EC-wide capacity-regulation policy which also applies to Switzerland. It created two set of measures:

- the granting of premiums to reduce the capacity of the active inland waterways fleet; and
- curbs on investment in extra vessels in the course of the co-ordinated scrapping scheme.

The main elements of the EC scrapping scheme for inland waterways are:

- It applies to Member States that have inland waterways linked to other Member States and whose tonnage of inland fleet exceeds 100 000 tonnes. Vessels from other Member States that operate on the shared network have to adhere to one of the scrapping schemes.
- The total active fleet registered and operating in the Member States is subject to the scrapping scheme. There are a limited number of detailed exceptions.
- The initial target was to reduce 10% of the dry cargo fleet and 15% of the tanker fleet in 1990.
- New tonnage was only allowed on one of two conditions; (a) equivalent old tonnage was scrapped to match the new tonnage; or (b) a premium was required equivalent to the scrapping premium for the type of vessel brought into operation, which was paid into the scrapping fund.
- Vessel owners paid annual contributions to the scrapping fund based on the tonnage and types of their vessels. The fund would be used by governments to provide interest free loans to the inland navigation industry, repayable over a number of years. All states ensured that the loan details would be identical.
- The Swiss authorities introduced simultaneous and parallel measures.

On November 1993 a report from the Commission on the effect of the structural improvement in inland waterway transport as introduced by the Council Regulation was published as COM(93) 553 final - SYN 475. This report notes that scrapping activity in 1990-1992 took 2 000 dry cargo vessels

out of the fleet with a carrying capacity of 1.1 million tonnes, 260 tanker vessels were removed with a carrying capacity of 260 000 tonnes and 30 000 kilowatts of push boat capacity was removed. Total expenditure to achieve this is estimated to be 104 million ECU. In general, the conclusion is that the scrapping scheme has achieved a measure of stability between demand and supply, but needs to be extended beyond the original five year life for another five years.

On the Rhine River, a free market situation prevails. The Act of Mannheim of 1868 guarantees free shipping on the Rhine and its arteries for all ships with flags belonging to countries signatory to the Act (Germany, France, the Netherlands, Switzerland, Belgium, and the United Kingdom). The Commission is in favour of including the Rhine-regime in the EC Transport Policy. However, a complicating issue is that Switzerland is not a Member State.

In view of the aims of the Single Market, initiatives will be expanded to allow cabotage with each ship with an EC flag is allowed to provide services within other Member States. This will increase competition on the European waterways. Also the tour-de-role system is under investigation by the Commission as it reserves and allocates cargo at specific tariffs, which may be construed as anti-competitive.

THE NETWORK

The Rhine, being navigable over a distance of 1 000 km from Basle in Switzerland to the North Sea at Rotterdam is clearly the backbone of the EC waterway system. Other rivers like the Meuse, the Schelde and the Elbe are interconnected with the Rhine by means of canals navigable for vessels of at least 1 350 tonnes, (classified as a Europe, class IV, standard vessel). Furthermore, a coherent network has been created by waterways navigable for units with a loading capacity from 1 350 to 10 000 tonnes (pushed convoys on the Rhine and certain other sections) which covers most of Germany, the Netherlands, Belgium, Luxembourg and the northern and eastern frontier zones of France.

This network will be extended to Eastern Europe in 1990s if the capacity of the Rhine-Main-Danube Canal can support the large size vessels. Since its opening in 1992, this canal has exceeded initial expectations on volumes, and reached 4.2 million tonnes of cargo in its first year of operation. This was achieved despite the blockade of exports to Serbia. Except for this route, a northerly transit to Eastern Europe between the Netherlands and Germany is also possible through the Mittelland canal. It is not yet clear what measures will be taken to improve its capacity.

In the French hinterland, the rivers Seine and Rhône, being navigable for pushed convoys of 5,000 tonnes, play an important role. However, to date, these rivers are only connected with the main European network by narrow canals. Networks in Italy and the United Kingdom basically relate to the Po River in Northern Italy and navigable rivers and canals in the UK (e.g. Thames, Humber, Clyde).

Table 8: Inland waterways transport

Source: UN (Transport Statistics)

Although no major bottlenecks exist, investments in new infrastructure continue to be necessary. Increasing ship size requires enlargement of locks and canals, the deepening of waterways and adaptation of inland water ports. Modern navigation facilities are also needed along the waterways.

OUTLOOK

Demand for inland waterway transport is likely to maintain an upward trend at moderate growth rates. In view of economic integration, transport demand among Member States will increase in terms of both volume and distance to the benefit also of inland waterways. In the field of hazardous goods transport and unitised cargoes, inland waterways are likely to gain.

The developments in Eastern Europe will affect traffic in two ways. Firstly, positive developments will emanate from German unification and the opening up of the Eastern European economies. New market opportunities and intensifying trade will occur, but in the short term these effects will be limited. Secondly, negative developments may occur as fleets from East European countries enter West European markets, especially via the Rhine-Main-Danube canal. This canal is slated for privatisation, and expectations are for 6 million tonnes of traffic per year by the end of 1995. However, ship sizes are small and service standards are not expected to meet Western requirements, although the low-priced Polish operators have almost driven out German competition on the Polish-German trades. In this case the German Transport Ministry has been negotiating with Poland to seek a 50:50 cargo share with minimum freight rates.

Concerning capacity, the EC scrapping system is likely to continue its initial successes. Together with the present trends in demand, equilibrium between demand and supply will closer to realisation. This will allow improved incomes and capacity utilisation.

Shipping
NACE 74

The EC shipping industry is moving into a stage of advanced maturity, where the number of players will be dominated by increasing concentration in the top ranks, supported by a number of smaller niche players in specialised trades. Hence expectations are for the current largest companies to continue to expand by acquisition and alliances, with fewer operators around by the end of the century. In the global liner industry, an EC company has moved into pole position, while the EC liner industry continues to maintain five places in the top twenty ranking.
The gradual recovery of some of the major trading power houses and developments within the EC will contribute to a further improvement of trade with the EC, although the impact on the EC shipping industry is potentially mixed. Developments within the EC concern further deregulation of the EC shipping market and the effects of an EC shipping policy aimed at achieving an efficient and competitive EC shipping industry. European liner companies are increasingly becoming multi-modal operators and expanding European distribution networks via purchase or alliance to meet customer requirements for inter-modal transport and value added services. The tanker and dry bulk fleets are continuing to be dominated by older tonnage and will have to undergo significant renewal in the 1990s if scrapping accelerates. The EC cruise industry is growing and looks to expand significantly over the next few years as real disposable incomes increase.

INDUSTRY PROFILE

Description of the sector

The sector includes units exclusively or primarily engaged in the transportation of passengers and goods in sea-going and coastal vessels. Also classified under this heading are units exclusively or primarily engaged in the operation of sea-going tugs. Deep-sea transport refers to shipping on long sea routes; coastal shipping or short-sea shipping refers to the conveyance of passengers and goods between national or European ports, including those on the Black Sea, the Mediterranean and Moroccan Atlantic.

Within the merchant shipping industry, cargo is usually analysed in sectors, which are dry bulk, tanker (also known as liquid bulk) and liner (typically scheduled services with consolidated cargo from many shippers). These sectors are usually further subdivided: dry into major dry bulks, such as grain, and minor dry bulks, such as bauxite; tanker is usually divided into crude and products (or dirty and clean) and gas carriers; liner into container and non-container (or general cargo). Usually tanker and dry bulk is dominated by tramp (non-scheduled) services. There are also specialised vessels that do not necessarily fit into any of these categories, such as refrigerated ships, forest product carriers, car carriers, steel product carriers and combination carriers. This situation is further complicated by non-standard operations, as for instance it is possible to have a tramp operator moving containers, or a scheduled operator moving bulk coal, and some vessels can be used for conveying more than one commodity type, for instance a gas carrier could be used for 'clean' oil products.

Recent trends

Growth rates derived from Table 2 indicate that, during the period 1986 and 1992, world seaborne trade achieved an average annual growth rate of 4.7% in tonne-miles; however, the growth rate has decelerated over the last three years to average 3.3%. The various sectors of seaborne trade have shown a similar development pattern over 1986 to 1992, although their pace of development varied widely. During this period, most of the sectors averaged rates of around 4% per year; the two exceptions being iron ore (averaging only 2.1%) and crude oil (7.3%). The picture for the sectors' rates of growth for the period 1990-92 is not so rosy, with both iron ore (-2.3%) and oil products (-0.6%) recording declines but, despite a slowdown in its development, crude oil managed to maintain strong growth at 6.3%.

Dry bulk and tanker

The dry bulk and tanker sectors form the largest part of seaborne trade in volume terms. In 1992, liquid bulk's (crude and products) share was 47%; the three main dry bulk commodities (coal, grain and iron ore) accounted for 27.5%. Hence the three major dry bulks and tanker account for almost three quarters of world trade in tonne-miles. In terms of tonnes, SS&Y Research estimates that out of total dry bulk trade, the major three account for about 55%, whilst the remaining 45% is the intermediate and minor bulks (these estimates cannot be related to the tonne-mile figures in Table 2 due to differences in collation methodology). Estimates put about one-third of the world's bulk traffic (in tonnes) as originating

from or arriving in Europe and the overwhelming portion of these flows (90%) is inbound.

The iron ore trade depends predominately either directly or indirectly on the steel industry, and to a lesser extent so does the coal trade. In 1992 world steel production fell to its lowest level since 1986, due to lower production from the EC, Japan, the CIS and Eastern Europe (competition from these latter two is presently weakening). In the Community, crude steel production declined by 3.6% in 1992, to its lowest level for nine years and the latest estimates from DRI's Industry Consulting Group indicates that 1993 is not providing an upturn, due to the continuing weakness in the market exacerbated by competition from Eastern Europe. This had concomitant effects on iron ore shipments. Preliminary estimates for iron ore into the EC indicate that the trade declined by more than 2% in 1992. Exports from the EC's two main external supplier of iron ore by sea, Brazil and Australia, which account for 60%, recorded export declines of 8.5%. Coal has fared substantially better, as domestically produced coal has declined and been substituted by imports. These imports from non-EC countries are estimated to be between 135-140 million tonnes in 1992, compared to 132 million tonnes in 1991.

Grain trades (wheat and coarse grain) rose by about 13% in 1991-92 (grain years are often reported July to June) to reach a seven year peak of just under 200 million tonnes. The primary exporters of grain in 1991-92 were, the US (44%), Canada (14%), the EC (13%), Argentina (7%) and Australia (4%) where the figures in brackets are the approximate world export shares.

Intermediate dry bulks (bauxite, alumina and phosphate rock) have had mixed fortunes over the last few years. Aluminium production in the EC has declined in recent years, with volumes falling by 7% since 1989. There are three major factors causing this decline in production: first, aluminium production has been shifting to lower energy priced producing countries; second, the recent recessionary pressures in the EC; and third, low-priced imports from the CIS and Eastern Europe. This has meant a slowdown in imports of the raw products for aluminium production, but a boost for imports of smelted aluminium and products. Phosphate rock imports into the EC have fallen consistently since 1987. In western Europe, last year's imports were only 50% of the volume achieved in 1985.

Minor bulks, amongst which are steel products, pig iron, ferrous scrap, fertilisers (sulphur and potash), agricultural products (soya, rice and sugar), coke and cement, have witnessed some weakness in trade in 1992. EC imports of steel products rose by close to 15% last year to approximately 12 million tonnes (the bulk of the increase coming from eastern Europe), whilst exports fell some 5% to around 19 million tonnes. This trade has been dominated by various trade disputes, the most important of which is the anti-dumping duties imposed by the US, which threaten some 1 million tonnes of EC exports. The latest data for pig iron indicates that imports into Western Europe fell by almost 40% in 1991, but that ferrous scrap imports increased marginally to 21 million tonnes from just over 20 million tonnes in 1990. The EC trade (dominated by imports) of fertilisers fared badly in 1992, as sulphur imports into the EC declined, and this decline was compounded by a decline in potash imports. Soya trade was buoyant in 1992, increasing from 27.5 million tonnes in 1991 to just over 30 million tonnes in 1992, the major exporter being Brazil (30%), Argentine (21%) and the US (20%). The EC is the major importer of soya, and account for almost 50% of world imports. The global sugar trades have remained almost flat in recent years, with a small decline of around 3% in 1992. Exports of sugar from the EC declined quite dramatically in 1992, by just over half a million tonnes from just under 5 million tonnes in 1991. Western Europe imported 6.7 million tonnes

Source: ISL Bremen

of coke in 1992, with Luxembourg taking the lion's share with 17% (it has no coke ovens). Imports to Europe of petroleum coke declined sharply in 1992 following strong growth in 1991, largely due to declining economic activity, the major EC destination is Italy, which accounts for over 10%.

In the tanker trades, imports of crude oil and products averaged 10.8 million barrels per day in 1992, an increase of 2% on 1991. Of these, OPEC accounted for 55% (6 mb/d). The major crude oil tanker trades were in general positive, with the Near/Middle East supplying 3.3 mb/d, Africa declining slightly to 2.73 mb/d, while "other", excluding intra-EC and the Warsaw Pact, reached 1.95 mb/d. The largest portion of total EC imports of products is intra-EC trade (1.8 mb/d in 1992). However, total products imports recorded a decline in 1992 as EC refinery capacity utilisation continued to be high (a trend caused by the Gulf War) as imported crudes were refined within the Community.

In the gas carrier segment, the major sources of LNG for the EC are Algeria and Libya to the EC. In 1992, Algeria's exports of LNG to the EC are estimated to have been almost 14 million tonnes, the major importers (in quantity) being France, Belgium, Spain and Italy. Libya exported 1.23 million tonnes to its major trading EC LNG trading partner Spain in 1992. The EC is the second largest importer of LPG after Japan, followed closely by South Korea. Extra-EC imports of LPG are estimated to have dropped by some 15% in 1992, reflecting increased intra-EC trade.

Liner trades

The liner trades are dominated by movements of goods in containers. An analysis of the container trades is an excellent indicator for overall liner trades, with the proviso that there is a trend in the industry to move more liner-propensive commodities into container. Hence, although liner trades are already dominated by containers, container penetration is increasing. In 1992, the total volume moved in containers on the major trades was 29.4 million twenty-foot equivalent units (TEUs), and of these trades Europe-Far East accounted for 11.2%, and the transatlantic trade (Europe-US/Canada) accounted for 8.4%.

The growth in demand for liner shipping averaged around 9 percent in 1980 to 1985, slipping slightly to around 6% in 1985 to 1990, and around 4.5% on average in the last three years. In recent years, the major growth has been in the intra-Asian market which now accounts for about 12% of world trade. Deep-sea liner trade into Northern Europe grew by about 4% in 1992, after a minor set-back in 1991, and initial indications for 1993 indicate that growth has stagnated. On outbound trade, growth in 1992 was fairly strong at about 5% and 1993 estimates indicate that this pattern is continuing. The pattern for Southern Europe is somewhat similar, with inbound liner trades falling in 1991, recovering in 1992 but with stronger growth in 1993, and the outbound trades maintaining growth of around 5% in 1992 and 1993.

Cruise shipping

Cruise shipping has grown considerably in the last ten years, predominately fuelled by the demand in the United States. However, cruise shipping in Europe has been expanding too, albeit at a slower pace, with more cruises available to places previously difficult to enter - for instance the territorial water of the Warsaw Pact.

MARKET FORCES

Demand

In general terms, both manufacturers and retailers need a reliable and continuous flow of products at a reasonable price. Regarding major bulk commodities, which are inputs in the oil refineries (crude oil), the iron and steel industry (iron ore, coal and petroleum coke) and electric power plants (steam coal), the customers are largely in control of the flows to secure their regular supplies. They operate on a global scale.

In general and containerised cargo, customers are moving increasingly toward a global strategy, particularly with just-in-time inventory control, and global purchasing options that mean that purchase can be made from suppliers providing the lowest unit cost for similar goods. Additionally, there is increasing pressure from shippers on the shipping companies as these customers require door-to-door delivery at prices usually associated with port-to-port deliveries. Shippers are under significant pressure to reduce costs and improve time-to-market product delivery, hence it is becoming much more important for shipping companies to provide responsive, flexible, cost efficient and dependable services.

Supply and competition

The shipping industry is very fragmented: it ranges from major diversified shipping companies with liner, dry bulk and tanker operations and hundreds of vessels to one-vessel captain-owners. There are large producers who carry their own cargoes, for instance in the banana and car trades, and there are owners specialised in bulk shipping or solely in the rental or leasing of ships.

Short sea trades

The European short-sea trades, including the intra-EC seaborne trade, still have the characteristics of regional markets. Mediterranean trade comprises largely national traffic, which is in

own- national flagged vessels, and international traffic between the Mediterranean and North African countries. Therefore, in these trades there is imperfect competition. By contrast, in and around the North Sea, there is fierce competition between short-sea carriers due to the trade being open to all flags. Germany, the Netherlands and Denmark dominate international short-sea trades.

Short-sea owners dominate specialised trades under European flags, many owners of larger vessels having opted out of the trade under these flags. Specialised trades include chemical vessels, liquid-gas tankers, reefer trade, car carriers, the carriage of heavy lifts, and chartered containers. Markets for liquid-gas and reefer trades are much less volatile than those for tankers and bulk carriers, because owners either charter their vessels to the traders or join freight pools.

Deep sea trades

Regarding general cargo North-South trades with many developing countries (particularly those in Africa and Latin America), conference trade has often been divided in accordance with the 40:40:20 formula of the Unctad Code, whereby the national carriers in the trade between two countries each have a share of 40%, the remaining 20% to be divided among cross traders. The UNCTAD Code applies to conference cargoes only, but some developing countries have striven to bring their whole liner trade within the scope of the Code, which would enable them to regulate the share of non-conference lines, generally referred to as outsiders. As far as the EC is concerned, the shares obtained by EC lines within a conference on basis of the UNCTAD code are redistributed on the terms of the Regulation no 954/79, the 'so-called Brussels package.

Many liner companies, both conference members and outsiders, are operating on the principal East-West routes and although the world's largest container operators are involved in this, trade market shares of more than 10% are rarely achieved. Most of the shares are in the range of 2% to 9%. Furthermore, in the (for the companies) relevant North-South trade, the shares vary from 10% to 20%. Consequently, no single liner company is dominating the trade; the market is very competitive, which is enhanced by the prevailing excess capacity in the liner industry.

To cope with the fierce competition as well as to meet the ever increasing needs of the clients, some carriers are aiming at providing global operations. The creation of the Single EC Market has further encouraged the concept of globalisation as a spur for greater penetration. Globalisation involves "one-stop shopping" (i.e. door-to-door transport) and "no sweat arrangements". One-stop shopping refers to geographical coverage of the transport service; no sweat arrangements refer to the so-called value added services (i.e. integrated transport and ancillary services).

Fleet and capacity developments

A comparison of the development of the various fleets with the development of the relevant commodities shows differences in the fleet development compared to cargo growth. Between 1987 and 1992 the average world development of crude and product dedicated tankers increased by 1.9% in dead-weight (DWT) and 1.5% in numbers of vessels, i.e. slower than the growth of trade (7.4% in tonne-miles). For dry bulk products, particularly over the period 1990 to 1992, the opposite was the case, as the dry bulk and combination carrier fleet average 2.6% in DWT and 1.3% in number of vessels compared to cargo growth of around 1.2% in tonne-miles. The relative increase in the capacity of the dry bulk fleet, together with the decline in cargoes for these vessels due in part to the world-wide decline in the iron and steel industry, has put substantial downward pressure on freight rates in 1992. Indications for 1993 are for a positive improvement in these rates, but they are still below the levels of 1991. The rates in the liner trade have also been under pressure from excess capacity. The rapid increase in container capacity in relation to the development of "other commodities" has enhanced rather than relieved the pressure on the rates. Excess capacity is expected to continue in the liner industry with no let up in container over-capacity. The liner fleet is relatively young and active, so there are no extensive scrapping programmes. Instead, replacement of first and second-generation container vessels will not entail significant withdrawals from the market. Although the older liner vessels are considered too small and inefficient for the main east/west arterial trades, they are useful in feeder trades and in supporting secondary services.

Between the end of 1986 and the end of 1992, the number of vessels over 300 grt in the world's merchant fleet increased by 675 vessels, which is an average annual growth rate of 0.3% . However, the relative growth of its carrying capacity (cwt) and container capacity (TEU) was higher. In particular, the growth of container capacity was quite significant, averaging 6.3% per year. During the past two years, the development of both the world fleet and capacity have accelerated and although their development varied considerably, the container fleet increased fastest.

In mid-1992, the world container fleet stood at 7.3 million TEU, of which 3.6 million was owned by the carriers and 3.4 million by container lessors. The EC portion of the world fleet is approximately 1.8 million TEU. Container production in 1992 reached 1.15 million TEU (910 000 in 1991), of which approximately 85 000 were manufactured in the EC. Companies adopted an expansive approach as they ordered significant numbers of containers in early 1992 in anticipation of accelerating demand for trade in containerised commodities. Much of the addition of capacity came from the leasing in-

dustry, which added about 15% to its capacity, compared to the figure for the industry of 6-7%. The slowdown in container demand towards the end of 1992 forced price reduction in some container types, with dry containers averaging a 7% drop in prices. The average in Europe was a 5% fall for 20 foot containers and almost 11% for 40 foot containers.

The development EC fleet has not kept pace with the world fleet. Unlike the world fleet, the number of vessels in the EC fleet declined over the past five years, although the capacity has increased marginally. The EC registered fleet decreased by almost three hundred vessels between 1989 and 1992. The US and Japan have faced similar declines in their merchant fleet over this period. For example, in the USA, the number of ships declined by almost 8%, while container capacity increased by 5.4%. Contrary to the developments in the EC, the USA and Japan, the "open registry" and "other" (countries) flag categories showed significant growth in both their fleets and their fleet capacity. Part of the explanation for these figures is the move of some EC carriers to flag out their vessels in order to reduce costs.

With the exception of Denmark, France, Luxembourg and the Netherlands the merchant fleet as well as the carrying capacity of all Member States declined over the period 1989 to 1992. The substantial increases in the Danish and Luxembourg fleets are due largely to formation of a second Danish register - the Danish International Register (DIS) - and the introduction of the Luxembourg register that have allowed cost-effective movements from other flags into these registers. In particular, Belgium's fleet declined substantially as most of its private fleet was transferred to Luxembourg. Other countries facing considerable reduction in their fleets were Spain and the United Kingdom. Spain's fleet was reduced by almost a quarter and the United Kingdom's by 21%. Only two countries, Spain and the United Kingdom, had a decline in their container capacity. In the remaining Member States, container capacity increased with the major increases in container capacity occurring in Denmark (52%), the Netherlands (41%) and Germany (18%). However, aggregate container capacity in the EC registered fleet has increased over 1989 to 1992 by nearly 200 thousand TEU.

Greece has the largest share in the EC fleet, 27.5% of the vessels and 49.5% of the DWT, due to the large number of bulkers and tanker owned and operated by Greek concerns. Greece is followed at some distance by Italy with 15.4% of the vessels but only 10.8% of DWT, due to a large number of smaller vessels on the Italian registry. In liner shipping, Germany accounts for the largest share in the EC's container capacity (31%), followed by Denmark (18%) and the Netherlands (14%). The differences in the fleet structure of the Member States are clearly presented in Table 8, since the composition of the fleet varies widely by Member State. The fleets of Belgium and Greece consist for the greater part of tankers and bulk carriers; by contrast in Denmark, Germany, Spain and Ireland, general cargo and container vessels account for more than half of the fleet. For the EC as a whole, general cargo vessels hold the greater share. The same is true for Japan, where general cargo vessels account for more than half of the fleet. In the US, tankers are the main vessel type.

National governments and the European Commission want to maintain an EC fleet not only for strategic and commercial reasons but also because of its contribution to Member States' economics in terms of income, employment and balance of payments. Employment of EC nationals has decreased from about 250 000 crew members in 1980 to about 120 000 in 1992. The decrease has been mainly due to the movement of owners and operators away from EC flags to open registers where there are stringent manning conditions and costs tend to be lower. In 1992, EC nationals made up 84% of the total employed in the EC shipping industry. This share varies considerably by Member State, e.g. it is relatively low in the Netherlands, where it is 61%; for France and Italy these percentages are much higher, at 93 and 96% respectively. In Spain and Portugal, no foreigners are employed at all.

INDUSTRY STRUCTURE

Companies

Tanker and bulk

In the EC, the tanker trades are dominated by time charters of tankers plying specific routes and ships owned and managed by the major oil conglomerates. The bulk trades are formed of three distinct groups, time charters, the single cargo same route and tramp vessels, where the vessel location and voyage depends on cargo availability. The latest and substantive details on the major players in these two sectors were not available at the time of publication of this chapter.

Liner

The liner industry is moving from the product life cycle stage of maturity to advanced maturity, where customer sophistication is the highest, product differentiation is low and concentration substantially increases. Hence, in this final stage of the life cycle, the two types of carrier that will survive tend to be the first tier carriers with established multi-modal presence and the niche operators that trade in speciality trades. Most companies in-between these two extremes are likely either to disappear or merge over the coming decade.

Towards the end of the third quarter of 1993 the aggregate capacity in service of the top 20 container carriers totalled 1.6 million TEU, representing 43.7% of the world's total available slots. The share of the top 20 liner companies has been

increasing steadily: it was 41.9% in 1992, against 32% in 1982.

Traditionally the Asian carriers have dominated the rankings. However, although this situation continued in 1993, an EC line, Maersk Line, has moved into first place. The Asian carriers dominate the top 20 with 10 carriers, of which 5 are in the top 10. These carriers together accounted for 782 000 slots, or very nearly half of the top 20 operating capacity. Sea-Land and APL are representing the US in the top 20 with an aggregated operating capacity of 217 000 TEU or 13.6% of capacity (in 1992 it was 14.4%). Apart from ZIM Israel Navigation, UASC and the Mediterranean Shipping Company, the remaining operators are from the EC. The EC lines occupy five places amongst the top 20 and their aggregate operating capacity was 437 000 TEU or 27% of capacity, which is substantial gain in share from the 1992 result of 23%.

With regard to the individual top 20 carriers, the change in ranking of the leading firms is remarkable; in 1993 Maersk's take-over of EACBen in April 1993 boosted Maersk's capacity by almost 30 000 TEU. Amongst the other EC carriers CGM dropped out of the rankings this year due to the suspension of its Europe/US East, Gulf and West Coast services and selling two 1,060 TEU vessels from its Indian Ocean service, whilst DSR Lines joined at the twentieth place. The other EC operator with a significant increase in operating capacity is P&O Containers, which increased capacity by about 60% to move from fifteenth place to sixth.

Cruise shipping

Cruise shipping is dominated by the US, which accounts for some 85% of the world cruise industry. The US industry has expanded by almost 10% per year for the last few years, with passengers up from 1.43 million in 1980 to 3.86 million in 1991. However, as the industry comes under increasing pressure to advance safety standards, it will see some structural change in the major players. At least half of the fleet is over 20 years old, and the latest regulations from the IMO will accelerate the division between the major groups with modern tonnage and the 'others'. Also, the demand for cruises has undergone a shift away from longer cruises to those of 3 to

5 days, which should act as fillip to the EC cruise industry which has tended to specialise in short-sea cruises. Increasing concentration in the industry will mean a bipolar orientation towards the major players and the much smaller specialist operators.

Strategies

In the last two to three years, there has been a shift in the operations structure of the major liner carriers. Historically, there have been a small number of global carriers, with many companies operating in just one or two of the three major trades and niche operators filling the smaller trades. However, increased globalisation has led to acquisitions and alliances.

The response of the major EC liner carriers to the global and European challenge has been very different. Nedlloyd and P&O have built up large transport networks and restructured them in line with the growing importance of intra-European trade. Container logistics on a world-wide scale and inland activities (storage, distribution and transport) on a European scale are underlying Nedlloyd's policy, which aims at being present throughout the whole transport chain with the view to providing a full logistic package. In 1988, therefore, Nedlloyd Road Cargo, Nedlloyd Air Cargo and Nedlloyd Lines Agencies were established. In addition, acquisitions were obtained in countries like Germany and the United Kingdom. However, due to financial difficulties, Nedlloyd has re-scaled and re-organised some of its inter-modal capabilities and divested some of its non-core business.

P&O has followed a similar multi-modal policy. It has invested in key areas of surface transport industries and follows a strategy of acquisition. Furthermore, it developed P&O European Transport Services (POETS), grouping together European haulage and distribution activities. It has also been investing substantially in Chinese ports. Unlike P&O and Nedlloyd, CMBT, Bolore and Hapag-Lloyd continued to focus on their core transport activity and enhanced operations for their deep-sea service clients. CMBT (largely owned by SafMarine) has taken steps to become a leading door-to-door operator for the European market. Its deep-sea strategy is concentrated on North-South traffic. Hapag-Lloyd concentrates on inter-continental door-to door transport, although they currently provide some distribution in Europe for Far Eastern clients and have continued to sub-contract many inland modal movements for cost-efficiency reasons.

As for non-European carriers, Sea-Land's activities have acquired a truly European dimension, for haulage on European roads, Sea-Land used a joint venture with Frans Maas as part of a policy of forming alliances to enter the EC market. 'K' Line announced an agreement with McGregor Cory in 1992 to combine its deep-sea movements with inland distribution.

The number of conferences, capacity sharing agreements and alliances continues to grow as companies try to come to terms with over-capacity.

ENVIRONMENT

Increasing pressure is being brought to bear on EC (and non-EC) shipping companies in the areas of environment and safety. In its Communication "A Common Policy on Safe Seas", the commission expressed the main points of its future policy in this field, and the Council, in its resolution of 8 June 1993, fully supports the objectives of the Commission and the measures outlined in its action programme. Starting from the observation that although adequate international rules exist to cover many aspects, often ships are not constructed, maintained or operated up to those standards, the action programme from the Commission is based upon a coherent package of measures including:

- measures to establish a convergent implementation of existing international rules in the Community;
- measures to ensure a tighter and more effective control of ships, regardless of their flag, by the State of the port;
- measures to promote coherent and harmonised development of navigational aids and traffic surveillance infrastructure, bringing maritime safety into the electronic age;
- measures to support international organisations enabling them to strengthen their primary role in international standard-setting.

The Council has adopted the Commissions first proposal on mandatory reporting by ships, and is close to adopting proposals on common criteria for ship inspection and certification bodies and for the training of seafarers. Many other proposals will follow regarding port State control, marine equipment, non-convention vessels, fishing vessels, segregated ballast tankers, traffic surveillance and aid, and the establishment of a "Committee on Safe Seas".

Estimates put pollution from maritime transport at 12% of the total pollution entering the sea and the average loss of life at sea is around 1000 per year. The major problem has been and will continue to be one of enforcement.

CFCs continue to be an issue in the refrigerated industry, as production of the more damaging ones is phased out globally and replacements have yet to be fully proved. This is impacting the industry for refrigerated containers and the purpose built refrigerated vessels, as equipment needs to be changed over the next few years to allow for the use of the CFC substitutes.

REGULATIONS

Governments have offered throughout the years incentives to owners to keep their vessels under national flags. Nevertheless, an increasing number of vessels owned by EC nationals have been transferred to open registers. Initially, these registers were used to avoid tax liability but, in the last few years, cost reduction (particularly of manning costs) has been the main motive. The main open registers are those of Liberia, Panama and Cyprus. Some cost-saving measures have been made by governments, such as investment allowances and government-supported research to advance automation and innovation, to help EC owners with high labour costs under national flags.

Some countries have tried to mitigate the owners' plight further by creating offshore registers or similar schemes which may allow wider employment of foreigners at lower wages and of nationals at reduced levels of taxation. Denmark introduced a separate international register for Danish vessels, and Germany authorised a similar scheme in 1989.

These initiatives have now been followed with a proposal from the European Commission to introduce positive measures through EUROS as a Community ship register. EUROS would operate in parallel to the existing national registers (i.e. certain vessels already entered on national registers could as an option of the ship owner also be registered in EUROS), in which case such ship owners may be entitled to financial and fiscal benefits with a view to improving their competitive position.

The decline of tonnage under EC flags due to the relative high cost position vis-à-vis more liberal registers (resulting in a drop in EC employment), external relations to remedy protectionist practices and other distortions underlie the development of an EC shipping policy. A start on such a policy was made in 1986, when the Council adopted four major shipping regulations: 4055/86, 4056/86, 4057/86 and 4058/86. These regulations focus on liberalisation, protectionist and competition practices, which refers both to non-EC countries and EC Member States. The principles underlying these regulations are fair and free competition.

The main purpose of regulation 4056/86/EEC was to lay down rules for the application of the competition rules in international maritime transport and aims to ensure that competition in international maritime transport services from or to one or more Community ports is not unduly distorted through restrictive practices, while avoiding excessive regulation of the market. It applies to international maritime transport services other than tramp vessels. The regulation granting a group exemption to liner conferences vis-à-vis the EC competition rules was aimed at stability, guaranteeing regular and reliable services to transport users.

Regulation 4057/86/EEC is designed to deter unfair pricing practices in maritime transport; caused by unfair pricing (continuous under-pricing) practices of some non-EC countries. These practices are detrimental to the competitiveness of EC

ship owners in international liner shipping. The regulation allows for a redressive duty to be imposed on the foreign ship owners concerned.

Regulation 4058/86/EEC is aimed at safeguarding free access to cargoes in ocean trade. The regulation provides for a procedure to be applied when certain trade practices by a non-EC country threaten to restrict free market access by Member States' shipping companies.

Regulation 4055/86/EEC applies the principle of freedom to provide services to maritime transport both between Member States and between Member States and non-EC countries. This regulation provides for the phasing out or adaptation to Community legislation of agreements between a Member State and a non-EC country containing cargo sharing clauses and of unilateral national restrictions on the carriage of goods wholly, or partly, preserved to the national flag. This practice could seriously affect the trading interests of all countries by substantially increasing transport costs. Adjustment to Community law of agreements concerning trades not governed by the United Nations code of conduct was to be completed by 1 January 1993.

Further mention should be made of the deregulation of the EC shipping market, implying the freedom of cabotage (i.e. the freedom of a shipping company established in one Member State to operate on the domestic market of all the other Member States). In December 1992, the EC Transport Ministers adopted the regulation applying freedom to provide services to maritime transport within Member States. The text provides for a series of derogations for different trades in certain areas of the Community.

The following maritime transport services carried out in the Mediterranean and along the coast of Spain, Portugal and France are temporarily exempted from the implementation of the regulation:

- cruise services, until 1 January 1995;
- the transport of strategic goods (oil, oil products and drinking water), until 1 January 1997;
- services by ships smaller than 650 GT, until 1 January 1998;
- regular passenger and ferry services, until 1999.

Island cabotage in the Mediterranean and cabotage with regard to the Canary, Azores and Madeira archipelagos, Ceuta and Melilla, the French islands along the Atlantic coast and the French overseas departments is also exempted until 1 January 1999. This derogation extends for Greece until 1 January 2004 for regular passenger and ferry services and services provided by vessels less than 650 GT. In those areas outside the geographical scope of the above mentioned derogations, liberalisation was completed as from 1 January 1993.

An issue that has gained significant prominence in the last twelve months has been the application of the EC competition rules to maritime transport. Investigations by the Directorate for Competition (DG IV) have found that some EC lines have been acting uncompetitively, particularly in the North-South trades. The Commission imposed substantial fines on some EC lines offering services between Europe and West and Central Africa under the accusation that they were breaching Articles 85 and 86 of the Treaty of Rome and regulation 4056/86.

Finally, the new EC banana policy which came into effect on 1 July 1993 has imposed a new set of quotas on banana imports into the EC. Bananas are estimated to have about a 40% share of refrigerated trade; hence there are dedicated operators, terminals and distribution services for bananas, and the impact of the tariffs may be significant on EC consumers, as producer and shippers pass on the tariffs to consumers in the form of higher prices. It is too early to assess the impact of the new tariff regime on the banana shippers, except to note that the new regulations, as much as the previously preferred status of some exporters, cause distortions in the market.

OUTLOOK

Global developments will continue to fuel growth in global sea-borne trade. However, although developments within the EC will improve trading conditions, the outlook for the EC shipping industry is mixed. "Europe 1992" and the resulting gradual deregulation of the EC shipping market coupled with improving economic growth in the EC will provide an increase in the Community's share of world trade. The four regulations adopted by the Council of Ministers at the end of 1986 and

recent discussions on the future of the Common Transport Policy, aimed at increasing the competitiveness of the EC shipping industry towards non-EC countries which apply unfair trading practices, may contribute to less protectionism. The aim of the Commission to achieve an efficient and competitive EC shipping industry should also enable EC ship owners to regain a major role in world shipping using ships registered in the EC. The proposed EUROS register should contribute to that end. However, the downside is that the EC shipping companies are facing and will face increasing competition from lower unit cost carriers such as those from the Far East. This may result in a reduction in the EC shipping industry and more global alliances, as the export of cargo is viewed as more important to the growth of the Community on the world stage rather than the growth of the shipping industry per se. Increased competition should reduce the price of traded goods through lower transport costs and hence EC exports and imports will have lower wholesale prices.

A large part of the tanker and bulker fleets will have to be renewed in the 1990s as the existing fleet becomes increasingly aged, which may entail problems in private financing, given the risks and the huge amounts involved. The availability of both finance and reputable ship owners in Europe will help the EC to play a larger role in bulk transport. The vessels involved in merchant shipping will be of proven design, with the exception of double-hulled tankers and hatchless container ships, but there will be a tendency towards larger container vessels.

The development of the world economy and implementation of the measures aimed at increasing the competitiveness of the EC fleet are expected to have the greater impact in the medium-term. Total carrying capacity is expected to increase at a much slower pace than container capacity: container penetration in the liner trades continues to grow and most of the prospective growth is expected in the liner sector.

Employment of EC nationals in the EC shipping industry is expected to continue to decline as shipping companies continue to flag out, although the EUROS register, if and when approved by the Council of Ministers, may contribute to halting or even reversing this trend.

Air transport
NACE 75

Air transport is starting to move out of the doldrums caused by the recent economic weakness of some of the major trading blocs and the Gulf War. Deregulation has spurred competition within existing airlines in the EC and will prompt both an increasing number of privatisations of the traditional EC state carriers and allow airlines to consolidate operations through mergers and alliances. These will act as a spur for the globally oriented airlines to improve their competitive position vis-à-vis the airlines from the other major geographical blocs. Hence, although in the short term the pain of the adjustment process will continue, a leaner, fitter and aggressive industry will emerge. New entrants to the industry will find that the major barrier will be a lack of the availability of capital investment from market sources, which will act as a partial brake to improving competitiveness.

INDUSTRY PROFILE

Description of the sector

The air transport industry comprises enterprises which are exclusively or primarily engaged in the transport of passengers and goods by air on scheduled or chartered services as well as helicopter and air taxi services, local pleasure flight operators, etc. Air transport also includes the town offices of airline companies.

Air traffic (excluding military) is usually divided into commercial and general aviation. Commercial aviation consists of passenger travel, both charter and scheduled, and air freight, which includes air freight on freighter aircraft, combination passenger/freight aircraft and freight in the hold of passenger aircraft, and air courier and mail services. General aviation includes private use of planes and air taxi services.

This monograph will focus on the commercial aviation subsector, with particular emphasis on the major airlines of the EC Member States.

Recent trends

Average growth rates in demand for air transport during the latter period of the last decade were healthy, with an average annual growth rate of 6.85% for passenger-kilometres and 8.4% for tonne-kilometres (freight) for the period 1985 to 1990. During the same period employment grew by some 3.2% per year. This rate of growth was due to the positive economic growth experienced by the countries, both within the EC and externally, that the EC airlines served. However, the industry experienced a severe and unexpected downturn in 1991. This downturn was due to recessionary pressures emanating from the United Kingdom, the USA and Japan, and the weakening of economic growth in other major countries in the EC, in particular Germany and France. In addition, the downturn was exacerbated by the effects of the Gulf War with the result that between 1990 and 1991 passenger-kilometres declined by 4.6%, and tonne-kilometres by 2.7%. The downturn had negative implications for the labour force, which fell by 3.3%. EC air transport staged a recovery in 1992, driven largely by the improving economic environment of the United Kingdom, Japan and the USA. Growth on 1991 was 14.6% for passenger-kilometres and 3.4% for tonne-kilometres. However, comparing the out-turn with 1990, the growth rate for passengers was a healthy 9.4%, whilst freight only managed 0.6%. Despite this improved performance, the financial pressure put on the EC airlines during the downturn, whilst capacity was accelerating, has meant that the aggregate financial results of the airlines have continued to be in large deficit.

Recent indicators for 1993, issued by the Association of European Airlines for year-to-date August 1993, underscore the continuation of the recovery in air transport, with passenger traffic up some 8% on the same period of 1992, and a major improvement in freight, up some 6%. These figure should only be used as broad indicators, as there are definitional differences to those shown in Table 2.

Growth in the EC's regional airlines' traffic has been over 2 time greater than the industry average over the last six years, and indications for 1993 show a growth of 12.3% for the first six months. The regionals fleets have also been under going a change, with more of the larger regional aircraft (40+ seats) being added to fleets, and more 50% of the regional fleet is under six years old giving it one of the younger aggregate fleets.

International comparison

Figure 1 shows the relative sizes of the aggregates of the EC, US and Far East airlines. It includes domestic traffic, and hence the US airlines account for more passenger-kilometres than the EC and the Far East combined, and also more than double the EC.

Looking at the most recent individual results of the carriers for aggregated domestic and international, as in Table 6, there are only two EC airlines in the top ten world airlines, one Far Eastern Carrier, whilst the balance is dominated by 6 US airlines. However, the ranking changes dramatically when only the international portion of the passenger-kilometres is reviewed. In this situation, 4 EC airlines make the top ten, with British Airways in pole position, with only 3 US airlines, but given the average distances for the Far East it is not surprising that 3 Far Eastern airlines have joined the top ten. Table 6 also provides a clear picture of the level of dependence the EC airlines have on international travel demand, as their markets for domestic air travel are much too small to support the airlines. Looking at the international top ten, the proportion of international travel for the top EC airlines is 91.2%, compared to 35% for the US airlines, the corresponding figure for the Far East airlines is similar to the EC at 89.3%.

MARKET FORCES

Demand

At the aggregate level, changes in the demand for air travel are highly dependent on the growth prospects for the world economy. There is a very strong relationship between air transport demand and trade, which in turn is driven by the level of economic activity. However, the major components of air travel (i.e. business, leisure and cargo) respond to different pressures. Air travel for business purposes is primarily driven by activities that require face-to-face contact. Leisure travel is dependant on the levels and growth of real personal disposable income and available leisure time, whilst air freight depends largely on international trade. Hence periods of economic growth or recession can impact air travel significantly:

for instance, in a period of strong economic growth business expands generating more business travel, real incomes increase generating growth in leisure travel and trade improvements generate more air freight. In addition, patterns of leisure travel have changed due to increasing available leisure time and income allowing for a greater proportion of major holidays to involve long distance travel, as well as short breaks that require flights.

Supply and competition

Most of the EC 'flag carriers' provide global services, whilst the small to medium sized EC airlines concentrate on predominately intra-European services (British Midland and Luxair), specific inter-continental services (Virgin Atlantic Airways) or niche point to point routes. However the SMEs do have alliances and equity partnerships that allow them access to much larger and global route structures. Within the EC the scheduled airlines are increasingly competing on a level playing field due to de-regulation. However, as many of these airlines are providing some form or other of global offering to passengers they face severe competition from the major airlines of other geographic regions that are also global in nature. The main competition comes from the US 'megas' and the Far Eastern airlines. In addition, EC schedule services continue to face competition from the EC charter carriers.

However, one longer term direct effect that European de-regulation may have is on the charter industry. Prior to de-regulation the charter industry was able to offer point to point services for leisure travel at a substantially lower unit price and cost than the scheduled carriers. On the price issue, it was the double approval regime that helped the scheduled airlines to maintain potentially artificially high fares, whilst the charter airlines were pricing on cost equated levels. The charters were able to do this as they were in essence wholesaler's offering direct flights, whilst scheduled service were typically retailers, also, charters could match supply to the seasonal peaks and troughs of demand that was typically leisure dominated. Under the new regime, intra-EC scheduled traffic can almost be charged at a price that an airline desires to attract traffic while remaining 'profitable'. This means that some of the intra-EC charter traffic may decline as the scheduled carriers take some of the traditional leisure traffic away from the charterers. The point is somewhat moot as charter services are now allowed to be retailers by appearing on Computer Reservation Systems (CRS) and tickets can be purchased by the public in the same manner as scheduled services.

One could argue that this makes the charter airlines operations into scheduled services, except that charter operators affirm their commitment to remaining the major suppliers of wholesale passenger air services meeting point to point seasonal demand. Presently, the charters do not have the same liability to passengers as a scheduled service. There is, however, pressure within the scheduled industry to force charters to conform to the same liability as scheduled carriers. This in turn will force up the charter carrier costs. The end result is that within the Community there may be a decline in intra-EC charter traffic, but that charter traffic from within the EC to destinations outside the EC, where the current bilateral agreements continue, will strengthen. It is, however, also possible that as charter carriers are forced to compete with the scheduled carriers for intra-EC traffic with a more similar cost base than currently, the charterers will start to use quality as an argument to woo customers. If the charter's traffic in the EC declines, the partial vacuum created by the demand for leisure travel will be filled by increased use of scheduled services by leisure travellers. In which case, the load factors and hence productivity of scheduled services will improve. However, the charter is likely to remain essentially a wholesale supplier matching seasonal patterns. In some cases, one fillip the charter offers passengers is a time saving due to the point to point nature of the operations.

A number of studies undertaken in the late 1980s comparing the efficiencies of the European airlines with those of the USA (and, in some cases, with the Eastern carriers) highlighted some interesting conclusions. Three inter-related factors have stood out as crucial to the relative efficiencies of airlines, namely the operating regulatory environment, the structure

Table 7: Air transport

of airline operations and labour costs. Issues such as fuel costs or scale economies do not appear to highly relevant. Many of the large airlines are active in the spot oil market, and hence fuel costs are more or less an even field. Scale economies tend to bring some benefits but also incur cost penalties: for instance, size confers the ability to benefit from large scale marketing, with particular emphasis on frequent flyer programmes, and allows better co-ordination of schedules and airport capacity utilisation. However, scale economies do not confer some magic status on cost management, as the demise of some of the largest airlines has shown, i.e. Pan Am and TWA.

Some of the Far Eastern carriers fare well in efficiency comparisons as they operate in capacity constrained markets with long stage lengths and a low-cost workforce. In comparisons between the US megas and major European carriers, the US ones appear to fare better on transatlantic traffic, however there is some question as to whether the US airlines are using revenues from the huge domestic market to partially subsidise their transatlantic routes.

The studies also looked at competitive issues for labour, as this is presently the most controllable cost and typically the European airline staff, in particular cabin and cockpit crew, are more highly paid than their US and Eastern counterparts. This higher wage burden on the European airlines is not offset by higher productivity. In fact, the US and Eastern airlines appear to have a higher average degree of productivity than their European counterparts. This is one indication that the European carriers still have a long way to go before they match the productivity levels of their major competitors.

Table 8: Air transport
Employment and fleet of AEA's scheduled carriers by Member State, 1992

	Employees	Fleet	Aircraft on order	Employees/ airplane	Total revenue/ employee (1 000 ECU)

Total	247 449	1 083	256	228	119.9

Source: AEA Statistical Yearbook 1993

In particular, a study undertaken in 1987 found that in the United States productivity improvements increased by 3.0% per annum for US airlines prior to deregulation, compared to 4.5% for non US airlines. Post regulation, the US airlines productivity was improving by 3.3% per annum compared to 2.8% for non-US carriers.

Production process

The production process is intensive in both its use of high technology (CRS, airlines, air traffic control, etc.) and human resources. A passenger purchases a ticket, which is then presented at check-in. The passenger then passes through two set of controls, customs and passport control and baggage and security screening. The passenger then boards the aeroplane through boarding control and is served on board with meals, snacks and drinks at a level of cabin crew to passenger only usually found in restaurants. On landing the passenger again goes through additional screening before leaving the arrivals area. In addition, any baggage not considered as hand-luggage has to follow a similar process. Hence the amount of interaction with staff of the airlines and the airports is extraordinary.

INDUSTRY STRUCTURE

Companies

Scheduled passenger services

In the EC there is typically a three tier structure in scheduled air passenger transport defined by numbers of routes and age of operation. The first tier includes those carriers that have been and still are the so-called "flag carriers", the second tier consists of the carriers that operate reasonably large networks, either within in the EC or internationally or both (for instance British Midland and Virgin Atlantic Airways) and the third tier comprises the regional carriers, i.e. Manx Airlines which operates an number of regional routes in the UK, Ireland, Channel Islands and the continent and the tiny niche point-to-point airlines, i.e. Orient Air, which operates from Waterford, Ireland to Gloucester, England via Dublin. However, in scheduled international and domestic services, the EC air transport industry is dominated by the small number of flag carriers. The ownership structure for the flag carriers in 1992 is presented in Table 11. The dominant four flag carriers share more than 70% of the services operated by the EC flag carriers in terms of passenger-kilometres (including domestic scheduled services) (Table 3).

This would indicate that the scheduled EC carriers are dominated by the 'flag' carriers , however, although the figures indicate that the industry could be considered concentrated, the number of EC airlines actually in operation is substantial. IATA lists 35 airlines operating scheduled passenger services. The European Regional Airlines Association (ERA) lists another 20 regional airlines that are not included in the IATA list. The regional airlines account for 1 in 7 of intra-Community passengers on scheduled services with 32 million passengers per annum. Also, the regionals operate a fleet of over 600 aircraft in the Community. There are also a number of much smaller regional airlines operating that are not members of either organisation. Hence, excluding freight only operators

Table 9: Air transport
Ownership of European Community airlines, 1992

and the non-member airlines there are at least 55 scheduled passenger airlines operating in the Community.

Table 3 shows the ECU revenues of the major carriers that are AEA members for international geographical European operations as a proportion of total international passenger revenues. The average exposure of the European majors to Europe is around 42%, but with wide disparities. There appears to be a weak relationship between European exposure and the carriers financial results. In 1992, KLM and Air France were among the lower carriers with European exposure, yet they both turned in some of the worst net financial results in 1992. However, British Airways, which also has a low European exposure turned in the best results among the Community flag carriers. The relationship appears to be stronger at the negative end of the scale, where the higher the exposure the more effect the general economic malaise in Europe has had. This is particularly true for Luxair, Aer Lingus and the southern Europe carriers.

Charter passenger services

In the EC, some of the schedule carriers operate charter services directly or through subsidiaries as well as there being 35 mode specialised charter operators. The importance of these charter operators is pinpointed by ACE, the European Community's Independent Airline Association, which estimates that 60% of international revenue passenger-kilometres performed in Europe by the combined membership of ACE and AEA are performed by ACE members. Also, its members employ almost 20 000 staff (1992 figure).

Air freight services

Air freight is often referred to as the poor cousin in the air transport industry. This misnomer is due to the lack of accurate and substantive data on the sector, coupled with the market being a mainly sellers market. The scheduled passenger airlines are indeed extremely reliant on the freight forwarders to fill up the cargo holds on scheduled routes.

Often, the amount of cargo space is finalised at the last moment when the final number of passengers on the flight is known, usually an hour or so before departure. There are, however, very good early estimates of available cargo space based either on maximum passenger capacity and/or bookings for the flight. The scheduled freight carrier, whether independent or a subsidiary of a scheduled airline, typically has a scheduled route for cargo on dedicated freighter aircraft.

Amongst the EC carrier members of the AEA, the air freight sector is dominated by two airlines, Air France and Lufthansa, which together account for almost half of the recorded market. British Airways and KLM follow in third and fourth place. Comparing the revenues for scheduled passenger traffic with freight traffic in Tables 3 and 5, freight accounts for just over 14% of revenue.

Strategies

There are three dominant strategies observable in the EC at present, of varying degrees of importance and influence. These are privatisation of national flag carriers, the formation of alliances and, less importantly, the formation of start-ups and expansion of the small regionals.

On balance in the European industry, it will be the process of privatisation, which is encouraged by de-regulation, that will have the largest aggregate impact on the industry. Subsidy availability from governments to the Community flag carriers to cover the substantial operating losses will be severely restricted in the new environment. Airlines will have to operate profitably in order to survive, and this in turn will require a change in the corporate environment. This re-working of the corporate environment is most likely to come about by the benefits brought about by privatisation, which will allow the flag carriers to react more swiftly to changing circumstances and free these airlines to form strategic alliances and mergers. An example of the ability of the first tier carriers to react to changing circumstances is illustrated by some of the carriers reactions to contain costs during the recent downturn. British Airways reacted very rapidly to the downturn by reducing employment levels in 1991 by some 12%, whereas, amongst the larger state owned carriers the reaction was either weaker of contrary to expectations, with Air France reducing employment by 1.2% and Lufthansa increasing employment by 4.2%. It was only in 1992, that these two carriers reacted more strongly with Air France reducing employment by 7.5% and Lufthansa by 2.6%. Both these airlines have announced further and substantial reductions in staffing levels.

Privatisation will have a substantial impact on employment: for instance, in the run-up to privatisation British Airways reduced staffing by one third through a programme of voluntary reduction and early retirement schemes. This amounted to almost 20 000 employees, and if similar ratios are applied to the present expected round of privatisations Air France and Alitalia, staff reductions could reach 20 000 or almost 8% of employment of the AEA members (Table 10).

The most rapid transformation of the industry structure is taking place through alliances, both within the EC and globally. These alliances take a number of forms, from equity investment to code-sharing agreements. Typically equity alliances involve an EC airline purchasing minority stakes in other airlines, for instance, British Airways currently owns 24.6% of USAir, 25% of Qantas, 49% of Deutsche BA, 49.9% of TAT, 40% of the Plimsoll Line, and 31% of Air Russia, as well as absorbing Dan Air in October 1992.

Shared equity stakes could follow the pattern of the abandoned 'Alcazar' alliance between Scandinavian Airlines System (SAS), KLM Royal Dutch Airlines, Swissair and Austrian Airlines. These four medium sized airlines announced plans in April 1993 to set-up a jointly owned company with SAS, KLM and Swissair owning 30% of the equity each and Austrian taking the remaining 10%. The joint venture would have had a single management structure and balance sheet. The new company would have matched the individual European majors in size and passengers, and would not be too far behind the US 'mega-carriers'. Longer term expectations are that the four airlines will now form mergers or allied operations with other EC or non-EC airlines as their individual markets are considered by them to be too small to compete globally. This example provides a clear insight into forming strategic partnerships based on equity investment.

Typical non-equity alliances follow the pattern recently announced between Lufthansa and United Airlines as Lufthansa seeks a strategic link with one of the US mega-carriers. The form of the alliance will include ticket code-sharing, collaboration on frequent flyer programmes and marketing, and some sharing of airport facilities: essentially, it will allow Lufthansa access to the 200 cities served by United. This desire for an alliance with one of the American majors has also materialised into BA's partial equity purchase of USAir, Air France's co-operative agreement with Air Canada (and hence potential links with Continental), KLM's stake in Northwest, Delta and Swissair's cross-equity, and the proposed SAS-KLM-Swissair-Austrian alliance discussed above.

Increasing concentration in the airline industry, particularly through alliances, continues to dominate strategic thinking in Europe, especially following the third package. Many of these alliance involve code-sharing and block-space agreements. Code-sharing provides a seamless flight that may involve two or more airlines (usually two) and potentially a change of aircraft. The advantage of the code-share is that it shows up on CRS as a single flight and hence appears before flight combinations with two or more flight numbers. Blockspacing is where airlines add their code to another carrier's flight and vice versa, where the two carriers have blocked space on the flight of the other carrier.

The liberalisation of the EC skies, discussed below, has allowed the smaller niche regional carriers to expand services where previously route rights and slots were hard to come. In addition the regulations on start-ups should foster additional point to point small airlines, as they take away some of the competitive edge previously held by other airlines through prior legislation. However, there is currently a shortage of investment capital for start-ups and this may seriously threaten expansion in this niche field.

Frequent flyer programme

Frequent Flyer Programmes (FFPs) are used as a competitive tool by airlines to win frequent travellers by providing rewards for flights taken on a particular airline or groups of airlines. These rewards usually take the form of points which count towards free flights, ticket upgrades, leisure travel and holidays, amongst others. Many airlines view FFPs as defensive, in order to maintain competitiveness and existing customer base rather than gain additional custom. The programmes have two advantages for the airlines in that they provide a useful marketing tool for matching customer requirements more exactly and developing new marketing strategies, and since they are usually restricted they enable airlines to balance loads on flights. The major drawback are the costs associated with administering the programmes and providing the rewards. The airlines in the EC have introduced FFPs cautiously and with a tremendous variation in the levels of rewards.

Two major changes have been observed recently, in that more airlines are rewarding the lowest fare leisure traveller compared to the original requirement of business or fully flexible economy tickets. Hence, airlines are keen to fill up the back of the aircraft on a marginal cost basis, and secondly, there appears to early indications of an FFP war, as airlines have been increasing rewards, in some cases doubling them. The Community has being studying the requirement for monitoring FFPs and a report issued by the Commission in early May entitled 'Frequent Flyer Programmes in the Internal Aviation Market' indicates that the code would guarantee that FFPs do not distort competition. The report notes that there are three principal areas where FFPs may contravene competition laws, the most important of which appears to be when an FFP is designed as a target rebate by requiring a member the FFP to attain certain flight-mileages within a specific period. At the end of 1992, the number of members of the major EC airline programmes was around 700 000, which is a tiny number compared to the 80 million participants of the US airline schemes.

ENVIRONMENT

The two most important environmental impacts of the air transport industry are noise and air pollution. Noise is particularly important, estimates included in the Commission's Green Paper on The Impact of Transport on the Environment suggest that the percentage of the population exposed to aircraft noise above 55 db(A) varies from 35% in the Netherlands to 1.7% in Denmark, and above 65 db(A) from 1% in Germany to 0.3% in Denmark. Hence, the location of airports close to residential areas is a key factor in noise pollution. Estimates released by the AEA show that the modern jets generate about the same level of noise as a TGV, but for a comparatively minute distance (some 4 kilometres). However, the discussion about noise continues at full pace, and most services that land or take off at airports near residential areas have strict requirements about night flights and the levels of thrust that can be used. This has a detrimental impact on the airlines costs as it can take much longer for an aircraft to reach optimum cruising altitude and hence the fuel burn and the time taken for a particular stage length is higher.

Estimates for air pollution put carbon dioxide emissions second to road transport but the gap is considerable, with road accounting for almost 80% and air taking almost 11%. Other emissions such as nitrogen oxides are still under investigation, however, some figures from the UK indicate that air emissions of NOx account for only 1%. Further research is being conducted on the measurement of NOx in the troposphere, where it is feared that the effect of the greenhouse gases is greater than at ground level.

An important caveat to understanding the relative pollution of air transport vis-à-vis other modes is that the advances made by modern technology are substantially reducing both air and noise pollution.

REGULATIONS

The Commission of the European Communities has taken a gradual approach to deregulation in order to avoid the pain experienced by the US industry following the deregulation of the US market. In 1978, the US government deregulated

the domestic market by abandoning the geographical limits to route networks, fare regulation and refusing to enforce the hitherto powerful economic regulations. The result of deregulation in this market was a proliferation of new entrant carriers in the early 1980s. The lower unit costs arose from the surplus of experienced labour that had been made redundant by the established airlines. However, a large number of these new entrants were later either taken over by the larger airlines or went bankrupt and ceased operations, as well as some of the very large operators. The effect of this was to concentrate the US domestic and international air travel in a handful of 'mega' carriers with a number of substantially smaller 'niche' carriers. As a result of the deregulation in the US and in some other markets, deregulation is often accused of aiding or at the very least not stopping concentration as there appears to an inherent inability of airlines to adapt to the new regimes by changing cost rigidities, particularly labour rigidities: airlines are hence unable to compete and either go bankrupt or are taken over.

Following the US, European support for liberalisation of air transport policy gathered momentum, with the United Kingdom being one of the leaders. In 1984, the UK signed a new air services agreement with the Netherlands, which was further modified in 1985 and in essence completely freed air services between the two countries. The agreement allowed free entry of new carriers, open route access by designated airlines to any point in either country, no control on capacity and a double disapproval fare regime. This agreement represented the first major break in the usual bilateral traditionally found in Europe. More agreements followed in Europe, some of which were very liberal in that they removed any controls on the points that could be served in each country by the other county's airlines. In theory this offered equal opportunities for either countries' airlines.

Typically, the bilaterals that were negotiated in Europe during the mid 1980s allowed first, third, and fourth freedom rights, but more importantly relaxed the limits on capacity as well as fare regulation and propagated the double disapproval fare regime.

The Commission of the European Communities added weight to the existing agreements in a series of three packages, which enforced new agreements on members that had not negotiated liberal bilaterals, and, more importantly, allowed more extensive fifth freedom rights, as well as paving the way for cabotage later in this decade.

Although the first two packages were quite limited in scope, they nonetheless underscored the Commission's commitment to deregulating the air transport sector within the European Community.

The main achievement of the first two packages was to harmonise national legislation at the then most achievable level for competition as well as providing the foundations for the third package. The process has been quite gradual due to the negotiation required between the individual Member States and the need to keep in line with the progress towards the Single Market. The first and second packages were thus not viewed as deregulation since there remained a number of legislative constraints including continued capacity limitations and some fare regulation.

It is the third package that came into force on 1 January 1993 that really liberalised the air transport market in the European Community and that will influence most of the future organisation of the sector. This package essentially allowed any airline, existing or start-up, to operate anywhere in the Community with whatever capacity and fare level the airline chooses. There exist a small number of exceptions, such as very thin routes which can be protected, but these do not detract from the aggregate effect of liberalising air transport in the European Community. However, in order to obtain an 'air operator's certificate (AOC)' for start-ups, the airline has to provide the relevant authorities with a business plan that includes minimum capital requirements and the ability to operate for a minimum term. The main issue outstanding is one of cabotage, where it is currently restricted to 50% of capacity and is only allowed if the airline starts or finishes the flight in its home country. However, cabotage will be completely unrestricted from April 1997.

So far, the reaction by the airlines to the third package has been relatively cautious. There has been no explosion of fare reductions or added capacity, however alliances, whether equity based or not, are increasing, both amongst the EC airlines and between EC airlines and non-EC airlines. This increasing concentration is based on both the EC airlines' desire to seek positive positioning within the EC and the need to act global. This somewhat mirrors the situation that was observed in the US in the 1980s, but with less equity involved.

Recent agreement has been reached by the EC transport ministers on a code of conduct for computer reservations systems (CRS) which in essence ensure that airlines that own a CRS are prevented from poaching passengers from other airlines that participate in the same system.

OUTLOOK

There is a growing optimism for some of the European airlines since the weakness in the industry appears to have reached the bottom of the trough, and although the short term prospects

for 1993 are weak, a number of European airlines are very well placed for improved performance commencing in 1994. These expectations are based on the improving economic picture for the US, the UK and the gradual recovery of other European countries. Table 17 illustrates the AEA forecast by country, with nearly all countries providing reasonable average growth rates for the period 1993-97.

The deregulation of the skies will force continued consolidation within the industry in order for airlines to remain competitive with both their competitors within the EC and outside the EC. Hence the number of major EC operators is expected to decline in the future, whilst the number of smaller niche point to point airlines will increase.

One blight on future growth of air traffic in the EC is the limitations of Europe's Air Traffic Control (ATC). Eurocontrol, Europe's largest air traffic control grouping, has re-iterated warnings that significant investment is required to harmonise and update Europe's air traffic control in order to avoid the crunch that is looming. At present, 23 countries of the European Civil Aviation Conference have 31 different air traffic control systems. These systems rely on 18 different types of computers and 30 incompatible programming languages. In 1992, almost 13% of delayed short/medium haul flights (delays over 15 minutes) in Europe were due to airport and air traffic control reasons. Although improvements to ATC are being provided, there is still a long way to go in terms of investment capital and time before a harmonised system of ATC will be available that is comparable to the one currently in existence in the United States. One fillip for international airlines, including those of the EC, is the Future Air Navigation System (FANS), which if approved by the 33 members of the UN International Civil Aviation Organisation (ICAO) will move much of the current ground-to-air based navigation and air traffic management to satellite-to-air. Estimates on the savings for airlines reaches as high as ECU 7.8 billion by providing more efficient routing and reducing delays caused by air traffic control.

Postal and express services
NACE 79

In the past decade private operators have been able to capture a substantial portion of the market for (non-reserved) high value added services. They have invested in efficient networks with large capacities to provide predictable, rapid door to door services. These were features required by users in that particular segment of the market, which the traditional postal administrations were traditionally unable to offer. The situation in the EC is changing considerably as postal administrations continue to invest in expanding and enhancing their services to meet market requirements enabling them to compete with private operators without relying on monopoly status. Further policy initiatives put forward by the European Commission will cause further structural changes in the services provided by both postal administrations and private operators.

INDUSTRY PROFILE

Description of the sector

NACE 790 includes all units exclusively or primarily engaged in transmitting sounds, images, documents and packages for the benefit of the general public. Apart from postal and express services, this NACE heading includes telephone, telegraph, telephotography and telex services.

This monograph deals exclusively with postal and express services. In particular it concerns the activities of postal administrations of Member States and private operators. However, postal administrations are also involved in financial services like postal giro offices (NACE 812) and post office savings bank branches (NACE 813.1).

Postal and express services provide the mechanism whereby letters and packages are moved between two distinct groups of users. The service provides transmission for business to business, business to private, private to business and private to private.

The distinction between letter services and parcel services for both postal and express is determined by weight and contents (typically letters carry 'communication'; parcels carry 'goods', although letter services can carry small goods). Pricing of the services is determined by weight, geographic destination (where zonal price differences are typically differentiated into domestic, EC, and substructures for the rest of the world) and required speed of delivery.

Letter services provided by postal administrations can be categorised in three main areas:

- Standard letter services for letters, post-cards, printed papers and small packets with or without priority delivery;
- Subsidiary letter services, which include registered letters, recorded letters, certificate of posting/advice of delivery, special delivery, express, direct bags ("M-bags"), post office boxes and post restante;
- Additional letter services, such as postal electronic mail, "hand delivery", "city mail", periodics (magazines and newspapers) and un-addressed direct mail.

Postal administrations typically provide letter services under a monopoly (reserved services). In general a concession is granted to the postal administrations, in which they have special and exclusive rights for offering these services. The provision of the service is then obligatory. Parcel and express services are offered in a competitive environment (non-reserved services), where postal administrations may dominate in some parcel sub-services (such as private-private), whilst private operators dominate express services and general parcel services. In some non-reserved services, postal administrations are expected to provide a service under universal service obligations, known as obligatory non-reserved services, where usually the obligation allows for packages up to 20 kilograms.

In financial services, postal administrations offer the following:

- postal payments (money orders, postal orders and cheques, "valeurs declarées");
- girobank operations (tele-payment, interior accounts/deposits/pay-out, foreign currency, mortgages and charge/credit cards);
- savings bank operations (home savings and common funds investment);
- other payments (pensions, welfare services, licences, taxation and public payments).

The distinction between postal administration priority services (often called 'express') and private operator express services is that the private operators are providing precise predictability, using time reliable, door to door services and facile track and trace capabilities. Generally, the postal administration priority services are not predictable as there is only an estimated

day of arrival, letter and packages often have to be taken to a post office (and if not, involve an extra fee) and although track and trace exists in most cases, it does not allow for rapid tracking. However, improvements in recent years have meant that the United Kingdom, France and Germany have substantially improved the predictability of their priority services.

Recent trends

The postal services sector is an important sector for the European Community, employing in excess of 1.7 million staff. The sector is critical for most business and private interaction and trade, as it provides an important mechanism for communication, which although it competes with other forms of communication such as telephone, fax, and international travel, remains the major force.

Measured in terms of the number of items handled, the largest postal administration in the EC is France's La Poste. This administration is estimated to have handled more than a quarter of all the EC's items handled in 1991. The German postal administration ranks second and the United Kingdom third. These top three provide more than 55% of item movements amongst the postal administrations.

Over the last few years the number of post offices open to the public and the numbers of employees have remained relatively stable.

Competition from private operators has taken some of the aggregate market share as in the late 80's private express services had strong growth with rates in the range of 30-40% a year. In market size the estimates for the total volume of items in the intra-European express market is around 30 million per year, which is significantly smaller than the comparable total for the postal administrations (including extra-European movements) of over 80 billion.

The private operators have caused a shift in the market for postal services. The national postal administrations, have been faced with increasing competition in the non-reserved services from the private international operators aggressively moving into the market, especially in the field of parcels and priority express services. This has hastened some of the more aggressive postal administrations into improving their own priority and package services.

International comparison

Comparing postal administrations in the EC with those in the USA and Japan reveals that the EC administrations with a total of some ECU 60 billion have the largest turnover. In the USA total turnover amounts to around ECU 30 billion, and in Japan turnover is around ECU 10 billion.

On average each EC citizen received 260 mail pieces in 1990 (243 in 1988). In the USA however, the number of mail pieces received annually by citizens is much higher at 650. This difference is due mainly to a much higher level of direct mailing activity - addressed and non-addressed. In Japan the average amounts to about 160 pieces.

Within the EC there are large differences in the average number of per capita mail items received. In Denmark and the Netherlands this number is the highest with over 400 items per year. On the other hand, in Greece and Portugal the average is below 100 items annually. Figures for Japan reveal that in Tokyo mail received per capita amounts to 388, whereas in some rural prefectures this is less than 60 pieces.

Comparisons of relative efficiency of the postal administrations often use the number of items handled per employee. Recent estimates for the US and Germany indicate that the US Postal Service handles 160 billion pieces for 800 thousand employees, that is 200 thousand pieces per employee, compared to the Deutsche Bundespost, which handles 17 billion pieces for 280 thousand employees, or 60 thousand pieces per employee. These comparisons, although partially useful for broad brush comparisons, are fraught with problems as the number employed by an administration may include workers who are irrelevant to postal services, for instance in the girobank division, and the structure of mail services differs significantly within the Community.

MARKET FORCES

Demand

Customers of postal services are either businesses and organisations or individuals. About 80% of all mail originates from businesses and organisations, of which around 45% is destined for the same business and/or organisational group. About half of the mail from individuals is destined for businesses and organisations. The other half goes to other individuals. For parcel services the distribution is slightly different. Businesses and organisations send about 85% of all parcel items, the bulk of which (70%) is received by individuals. About two thirds of parcels sent by individuals are destined for other individuals.

For postal administrations the market is rather evenly spread over various end users. The more important outlets are the

publishing industry, which sends periodicals to its readers by mail and accounts for about one fifth of the shipments made, and direct marketing/advertising mail; for instance non-addressed mail delivered to household in 1992 by Belgium's La Poste was 51 million items, which is more than 7% of all items. Another important segment is mail ordering.

The largest users of services by private operators (mostly parcels and express shipments) are industry and mail order companies and the services sector. Industry constitutes about a quarter of total shipments, whereas mail ordering takes another 20%.

During the seventies and the eighties, mail order continued to develop as a competitor of store retailing services. This development allowed postal services to benefit from the growth in package movements created by mail order, as they have been able to meet with requirements such as customer communication, catalogue distribution, statement sending and goods distribution. Anecdotal evidence indicates that there has been a tendency, however, for private operators to take more of this market from public administrations by providing better service quality, security and reliability, specifically for the movement of the purchased articles in packages.

Advertising by mail (direct mail) has also become of considerable importance for postal services over the years. An increasing share of marketing and sales budgets is spent on direct mailing activities. But in this market segment also, postal administrations are loosing market share to private operators, particularly in urban areas, where local services are advertised using private delivery of sales and marketing information.

Distribution of publications by mail remains important for postal administrations. They can offer cheap mailing services

at preferential tariffs. However, private operators are competing with this low value mail services, as other requirements can be important (e.g. a guarantee to deliver the next day).

Supply and competition

Timeliness, reliability and service quality have become the major competitive factors that have provided the spur for the expansion of private operators. Postal administrations with their historical monopolies on letter mail services allowed these factors to be neglected in the past. This has allowed private operators to capture a significant part of the market for high value added express services, whereas public administrations with their obligation to provide reserved services have to a large extent been confined to low value added postal services. Private operators account for about 45% of turnover in the market with only some 5% of total shipments.

Large private operators increasingly offer a range of services that exceeds pure postal services. This change on the supply partly reflects changes in production management in the manufacturing industry, with increasing need of just in time deliveries and door to door transport. In addition, an enlarged range of services also results from excess capacity. Having created networks with large (air freight) capacities to enable fast deliveries all over the world, private operators have been affected by over-capacity as growth rates, although strong, have remained lower than original expectations. Hence, companies of 'integrators', started to extend their service package to transportation and distribution services. Some companies have developed into suppliers of complete logistic chains for manufacturing companies which wanted to externalise their transport and distribution activities.

Production process

The production process of postal services can be divided in five stages: collection of mail, sorting for destinations, transportation, final sorting and delivery of mail. Mail delivery is the largest cost item with about 60% of operational costs. Next comes transport and sorting for destination with a combined share of 25%. Mail collection accounts for 10% of total operational costs, whereas the remainder (5%) goes to

final sorting for delivery. However, these figures are aggregate approximations and individually vary widely between different administrations.

A good network is of crucial importance for postal services. The complexity of the interactions between all the different points in a network demands a good logistics chain. For international mail the problem is even more complex, as domestic networks have to be matched. Essentially there are two network systems: the hub-and-spoke system, in which a region is serviced from a central "hub" via "spokes" with local centres; and the spider's web system, in which local centres interact directly with each other.

Productivity is very different between the postal administrations of the EC countries. On average, postal administrations have an estimated turnover per employee of 22 000 ECU. On the other hand, private operators have a turnover per employee that is more than double the postal administrations. These differences arise from the different value added provided and consequently they are highly dependant on the type of services offered. Also, network quality, labour costs and productivity are among the factors that cause wide ranges in tariffs for what, apparently, are the same services. Private operators charges are substantially higher, since customers pay for a higher service quality.

A good indicator for service quality in postal administrations is the percentage of domestic mail delivered the day after collection. In small countries like Denmark, Netherlands and Luxembourg this rate is in excess of 95%. In Germany, a very large country relative to the previous ones, the Bundespost manages 90%, which equals the goal set within the Conference of European Postal and Telecommunication Administrations (CEPT). In Italy, however, a substantial portion of mail is not delivered the day after collection. This comparative poor service quality of the Italian postal authority has allowed private operators to gain a larger market share in Italy, than in most of the other EC countries. These estimates of delivery rates are not strictly comparable, and should only be used for broad comparisons.

INDUSTRY STRUCTURE

Companies

Private operators can be classified into four categories: companies operating globally or intercontinental, pan-European companies that are essentially EC domestic, national operators and local operators. The globals include companies such as the big four 'integrators': DHL, Federal Express, GD Express World-wide (a joint venture between TNT and the postal administrations of France, Germany, the Netherlands, Sweden and Canada) and United Parcel Services (UPS). They offer services which go beyond postal services and integrate various forms of transport and distribution. Examples of the second category are Kühne & Nagel (D), Jet Services (F), TAT Express (F) and Securicor (UK). In the national and local levels a host of small companies offer express services that range from long distance indigenous city to city pairs, to city or conurbation area delivery by specialist motorcycle couriers. There are often links between firms in the various categories, for instance a city motorcycle company may offer an international service through an account agreement with one of the major global operators.

The initial strong growth in the market for express services has attracted companies active in other fields of transportation and forwarding. For example airline companies like KLM, Lufthansa, British Airways and Air France support the services offered to the market by providing inexpensive, but otherwise redundant, cargo space in their aircraft to the freight forwarders and consolidators. Freight forwarders and railroads have started express services. Postal administrations have set up their own international express service (EMS) in order to take advantage of the higher value added market, and in some cases are involved with the private sector, for instance GD Express Worldwide.

Recently, however, the large private operators have been faced with weakening growth and have experienced some setbacks due to the downward pressure on the high value added end of the market caused by recessionary constraints. Rationalisations and closure of some activities has occurred as well as a fall in aggregate employment in the private sector. Federal Express has reduced its presence in the Community, and TNT has sold most of European its network into what is now GD Express Worldwide.

Table 7 profiles the legal status of the postal administrations of the Community in 1991. All administrations are controlled and owned by the various governments. However, more than half have financial autonomy and part of the Netherlands' Post Office is slated for privatisation in 1994.

Strategies

Postal administrations have become increasingly commercial in recent years. This has been due in part to the competition from private operators, but also to a tendency of individual governments in the Community to commercialise (and privatise) some public enterprises. Coupling this with a drive

to reduce budget deficits has in some cases forced postal administrations to operate as a firm in the traditional sense. Examples provided by the United Kingdom and the Netherlands have shown that postal administrations are able to turn postal services into profitable operations, both the Royal Mail and PTT Post realise surpluses on mail services. Similarly, the Japanese Postal Service has been able to generate profits from 1981 onwards by improving services and operations efficiency and expanding business activities without resorting to postal rate increases or substantial government subsidies.

In some countries, the profitability of financial services provided by postal administrations is high, sometimes well above 10% of the turnover in that sector. This enables a partial and sometimes full compensation of losses on postal services, but at the same time begs the question of what is the level of cross-subsidisation in the administrations.

Apart from commercialisation on the demand side, public administrations have also tended to improve efficiencies on the supply side. This has been achieved by investments in automatic sorting of mail in the sorting centres. Also the efficiency of operations in the network has been improved by a more cost-based attitude.

In the private sector market for global parcel and express shipment services, the level of demand has placed a limit on the number of operators. Hence there has been a number of mergers and strategic alliances, which is likely to continue in the short to medium term. These have and will continue to involve integrators, carriers and forwarders, and also postal administrations.

A key example of the changing structure of the industry is TNT Australia, which sold most of its European network to GD Express Worldwide, which in turn is combined with at least five postal administrations in the Netherlands, Germany, France, Sweden and Canada. Hence, although TNT has a global presence, it no longer has a truly global network. In GD Express Worldwide the five key member administrations combine their EMS services with the international express network of old TNT network. This alliance is attractive for postal administrations as they have reduced their exposure to the old bilateral agreements structure.

REGULATIONS

In each country governments have legislation for postal administrations to provide universal postal services. Provision requirements differ from Member State to Member State.

In non-reserved services the market has tended to regulate itself. For reserved services however, a body has been responsible for regulating the monopoly market. Historically the regulator was also the operator, i.e. the postal authority. The recent trend has been for Member States to try to separate the regulatory authority from the operational function by establishing a body under the responsible ministry, however, this ministry is the same one that is responsible for the postal administration.

In an international perspective, postal authorities co-operate in various organisations, such as the Universal Postal Union (UPU) of the United Nations and the Association of European Public Postal Operators (PostEurope). The former is a worldwide organisation providing the basic framework for co-operation and discussion between international postal services. The latter includes not only the EC authorities, but also those from other countries in Europe.

In the continuing formation of the Internal Market, the Commission is developing a common policy for postal services throughout the Community. This requires substantial policy harmonisation in the various Member States. Many issues in this respect are being reviewed, such as the definition of reserved and non-reserved services, principles of cost-oriented tariffs and competition. The Commission presented a Green Paper in June 1992 on the development of the single market for postal services. This was followed in June 1993 with a communication from the Council to the European Parliament on Guidelines for the Development of Community Postal Services (COM(93) 247 final). This latest communication has taken into consideration the large (and generally positive) response generated by the Green Paper, and consequently seeks to provide a detailed approach to action by specifying the measures required. The communication discusses in some detail the following topics: the common definition of the universal service; the maintenance of reserved services; service quality standards; measures that may be required to promote harmonisation in the Community; separating the functions of regulation and operation; and some aspects of extra-EC postal interaction. In order to harmonise and liberalise the EC postal services, a provisional implementation process is proposed, which acknowledges that legislative action will be required at the Community level; but that strongly strives to avoid measures that will lead to a deterioration of the level of service provided in Member States.

The removal of custom barriers within the EC in 1993 has helped level the competitive playing field between postal administrations and private operators for intra-EC services, by significantly reducing the cost of the private operators that

were required for customs clearance. Previously, these costs were minimal for the postal administrations as they were directly borne by the service users. However, the position of the private operators will continue to be affected by the legislation in force and any envisaged legislation changes. For example changes in the definition of non-reserved services could affect the private operators at the core of their activities. A major issue of current concern is the potential changes in remail activities.

REMAIL

A special issue in postal services is the remail service. This is a cross-border mail service offered by private operators. The most common type of remailing is the A-B-C mail: a private operator collects international mail of a large customer in country A, transports it to country B from where it is posted for delivery in third countries C. A second type is A-B-B mail, in which the mail (collected in A) is posted by the private operator in country B for delivery in B. The third type is A-B-A, in which the private operator posts the mail (collected in A) in country B for delivery in country A.

Remail has evolved from operators taking (price/cost) advantage of the weaknesses of the terminal dues system for international mail agreed in the UPU, where some postal administrations are able to charge less for international routed mail than the original pricing available in the originating country. However, the major drawback to remail is the loss of timeliness observed by users of the service and the lack of predictability, but this has been accepted as a necessary evil in order to achieve cost reductions. However, there a few instances where remail can be faster than via a public administration, particularly in the A-B-C case where the international service quality in country A is poor. There exists some a priori observations that although remail is less expensive than using the regular postal administration services, the overall cost efficiency is actually worse using remail due to hidden costs arising from the relative delay in the mail.

OUTLOOK

The outlook for postal services differ according to the type of service offered. For traditional letter services, growth is expected to continue but only at a marginal rate due to competition from advances in modern communication such as facsimile, electronic mail and EDI. In parcels and express services, growth is expected to be substantially higher. The integration of the European market implies increased interaction (in terms of traffic and trade) between the Member States at lower costs. However, this increased interaction will continue to put pressure on postal administrations to provide high quality services. Additionally, the trend in industry towards externalisation of transport and distribution will benefit the integrators.

Another strong growth market will be with direct marketing & sales related mail, possibly reaching the levels currently observable in the US in the long term, and to a lesser extent mail order. This will be a market with strong competition between postal administrations and private operators.

Of crucial importance for the competitive position is the application of modern technologies. Private operators are already at a high level, but some postal administrations seem to be far behind and may need a large investment program reach the same level as the private sector.

Another important issue is the regulatory environment. A community policy for postal services will seek to reduce the present lack of harmonisation in legislation concerning reserved and non-reserved services, to introduce a more cost-oriented tariff system and to apply free market principles where possible.

Sea ports and other sea transport facilities
NACE 763

Supporting services to sea transportation are highly heterogeneous in nature. Services are provided by port authorities and private companies depending on the regulatory environment in the port and the extent of subsidisation in national port policies. Competition among ports is very severe. Investing heavily in modern infrastructure, suprastructure and facilities is an important way of keeping ahead of competing ports. Community initiatives could examine the competitive environment.

INDUSTRY PROFILE

Description of the sector

This group in the NACE classification includes all supporting services to sea transport and coastal shipping. In effect these are sea ports and other sea transport facilities. Examples of service types are tugs at sea, pilotage, lighthouse operations, buoys and other navigation facilities, stowing, stevedoring, loading and discharging of sea-going vessels, and operation and maintenance of sea harbours, piers and docks.

Recent trends

In 1991 the 179 seaports in the EC, reporting data to the MERC World Ports Database, handled total traffic of about 2 162 million tonnes of cargo. The three top individual country volumes were handled in the United Kingdom, with some 428 million tonnes in 39 ports, the Netherlands with 375 million tonnes in 12 ports, and Italy with 327 million tonnes in 23 ports.

Total traffic in the top 12 EC ports growth flattened in 1992 to almost nil after a 2.3% increase in 1991. Within the top 12 EC league, the two largest ports, Rotterdam and Antwerp managed to increase cargo volumes slightly in 1992, but in the case of Antwerp this achievement followed a decline in 1991. On average, the largest French ports witnessed a decline in traffic in 1992, which was exacerbated by industrial problems during the year that caused some traffic to be diverted to the ports of other member states.

Passenger transport

In most ports in the European Community, passenger traffic is negligible or even non-existent. For some ports, however, it is the main activity. The ports on both sides of the Channel depend heavily on ferry traffic between the United Kingdom and France, and to a lesser extent Spain. The opening of the Channel Tunnel by 1994 will be a major competitive threat to the ferry operations on the Channel and as a consequence to the ports along the Channel. There are also important ferry links between mainland United Kingdom and Ireland and Northern Ireland.

A number of ports in the Mediterranean have significant passenger facilities for ferry links. Particularly important examples are in the south of Italy, where ferry connections exist with Greece and the countries in Northern Africa. Also, Greek ports generally have passenger facilities providing for domestic inter-island ferry links in the Aegean Sea. The Thessaloniki Port Authority completed development of new passenger terminal in spring 1993 to cope with the growing international cruise line operations.

Finally, mention should be made of the ports in Northern Germany and Denmark. From these ports, important ferry links exist with Sweden and Norway. Copenhagen is currently building a new passenger terminal due for 1994 enabling the handling of 10 vessels simultaneously. However the proposed bridge between the south of Sweden and just south of Copenhagen across the Öresund will have a major impact on traffic currently on ferries between southern Scandinavia and mainland Europe (potentially similar in effect to the Channel Tunnel).

An important issue in passenger transportation is the existence of duty and tax free sales on ferry boats and in passenger terminals. Originally, the European Commission was keen to abolish these sales on ferry links between Member States. However, after further consultation it was decided that this would harm the passenger transportation sector severely as a substantial share of their revenues are from sales of duty-free goods. Abolition has now been postponed until 1999.

Container transport

Container traffic emerged from the need to unitise general cargo items into manageable units of equivalent size. For this purpose the twenty-foot container was developed which could be easily filled with general cargo for transportation and easily unloaded when reaching its destination. During its development, containers of different size emerged, but the standard unit of measurement has remained the twenty-foot container. Traffic flows are thus expressed in Twenty-foot Equivalent Units (TEUs).

In 1991, total container handling in ports throughout the world amounted to some 90.7 billion TEU (86.1 billion in 1990: +5.3%) and initial estimates for 1992 indicate that there was further growth of over 4%.

The largest container ports are currently Hong Kong and Singapore, handling almost 8 million and 7.6 million TEU respectively in 1992. These ports have become major hubs in the Southeast Asian region for container traffic flows and Hong Kong's growth reached just 30% in 1992, whilst Singapore managed a healthy growth of 19%. The Japanese ports, however, show a poor performance in 1992 for container handling, with declines in Kobe (-1%) and Tokyo (-3%) and a small increase in Yokohama (+5%). In the USA, the ports of New York and Los Angeles recovered from the poor performance of 1991 to record reasonable growth in 1992 of over 12% each, whereas Long Beach, which bucked the trend in 1991, managed an increase of only 3.5%.

In the EC, Rotterdam is the largest container port, as well as being ranked third world-wide. In 1992, following growth in container movement of close to 10%, it regained this place that it lost in 1991 to the Taiwanese port of Kaohsiung. The other major EC container ports all improved their performance on 1991. Felixstowe, the 16th largest world and 4th largest EC port came second in the growth stakes with just under 8% on 1992. The other ports container growth varied from 4% for Antwerp to 3% for Bremen.

Port authorities and container handling companies make heavy investments to create an attractive infrastructure where containers and container ships can be handled as fast and as reliably as possible. Modern container terminals operate with highly automated container location and tracing systems. An example is the Maasvlakte-terminal of ECT in Rotterdam, where modern straddle carriers can trace containers automatically. Large gantry cranes also need to comply with the increasing ship size: the largest ships (of so called 'post panamax size') carry up to 4500 TEUs.

International comparison

In the 1960s and 1970s European ports were among the larger ports in the world, however, in the 1980s ports in South East Asia and Japan emerged as the among the largest in the world's top 12 seaports. Japan's success in the league is spectacular, with half of the top 12, with ports like Kobe, Chiba, Nagoya and Yokohama. The port of Singapore has second position with large volumes of general cargo (mainly in containers) and liquid bulk (mainly oil). There are presently no north American ports among the world top 12.

The EC has three ports in the world's top ranking, which are Rotterdam, Antwerp and Marseilles. In 1992 Rotterdam celebrated its thirtieth year as the world's largest port. Total traffic handled in Rotterdam amounted to 292 million tonnes, which is over 50 million tonnes ahead of second placed Singapore. Traffic (1991 figures) handled through Rotterdam is dominated by liquid bulk (oil, oil products, chemicals, etc.) at 140 million tonnes, and dry bulk comprises 93 million tonnes, mainly consisting of iron ore and coal for the German steel industry. In general cargo, Rotterdam used to be the largest container port in the world, but now lags far behind the two larger container ports Singapore and Hong Kong, to rest in third place.

Antwerp, the second largest European port, moved up to the eighth position in the world's top 12 in 1992, displacing Hong Kong. It has a growing share in container traffic, but is also strong in other types of general cargo handling. Antwerp is an important competitor for Rotterdam. The third largest European port is Marseilles with some 90 million tonnes in 1992. Traffic through this port consists mainly of oil.

In 1992 the top three ports in the USA, according to ISL, are Long Beach, Los Angeles and Corpus Christi. Their current size varies from 66 million metric tonnes for Corpus Christi to 75 million round tonnes for Long Beach handled per year, which puts them into the medium sized bracket in comparison with European and Japanese ports. The most important types of goods handled are liquid bulk, which is essentially oil and oil products, and containers.

MARKET FORCES

Demand

Demand for seaport facilities and services comes primarily from transportation activities. Transport companies are in need of such facilities in order to move cargoes from origin to destination and from one transport mode to another. The demand for these companies (in effect the demand for transport services) comes from shippers wanting their goods to be transported and thus depends largely on the economic activity in the hinterland of the port.

Supply and competition

The variety in the supply of seaport facilities and services is very wide. It concerns not only the handling of cargo from one mode of transport to another, but also storage of goods, distribution facilities, customs clearance, towing and berthing of ships, food and fuel supply services, customs handling, ship-repair and other services.

Over the last ten years, there has been a tendency to broaden the variety of services available within the transportation services - which was traditionally limited to cargo handling and movement. Hence, transport companies have changed into service providers offering a complete logistic chain from door-to-door. In addition, increasing automation and electronic data interchange techniques have made transportation and handling processes substantially more efficient than what was available in the early 1980's. This has enabled transport companies to more closely match customer requirements, for instance, just-in-time delivery systems for industries.

INDUSTRY STRUCTURE

Port traffic

Most of the EC's largest ports can be characterised as importing ports as incoming traffic is much higher than outgoing. There are only few ports where exports exceed imports: Calais, Rouen, Algeciras-la-Linea and Tyne. Similar situations exist in the USA and Japan. In the USA, only Duluth is effectively an export harbour; in Japan, Tokyo can be characterised as such.

The breakdown by type of traffic in Table 4 shows which is the dominant traffic through the EC's ports for the major ports. In each Member State, one or a few ports specialise in liquid bulk traffic. These are essentially the locations for import of oil and oil products. Examples are Le Havre and Marseilles in France, Wilhelmshafen in Germany, Trieste in Italy, Sines in Portugal and Southampton in the United Kingdom. Similarly, specialisation exists for dry bulk traffic. Ports like Bremerhaven and Lubeck in Germany and Limerick in Ireland handle practically only dry bulk goods. Finally some ports can be characterised as general cargo ports, such as Brugge-Zeebrugge, Calais, Dublin, Valencia and Felixstowe.

Strategies

There is substantial competition among ports on the northern seaboard of Europe (the Hamburg to Le Havre range) to attract container traffic and become the one of the major hubs in Western Europe. Expansion by investment in facilities is seen by the ports as a major weapon in maintaining or improving their relative competitive positions. The Port Authority of Rotterdam is particularly ambitious to maintain its pole status with large investment plans. These investments should enable the port to reach 400 million tonnes of traffic handled by 2010. The total investment budget amounts to some 11 billion Dutch guilders, of which 7 billion will come from the central government. In addition, private companies will have to invest another 20 to 25 billion Dutch guilders in superstructures and facilities. The dedicated terminal for Sea-Land operated by ECT - the largest container stevedore - was officially opened in 1993 and is the first stage in increasing the number of containers handled in Rotterdam to 6 million by the year 2010. This Delta 2000-8 plan is a joint initiative of the port authority and ECT, and allows for at least eight new container berths to be constructed over the rest of the decade.

Additional multi-modal access to the port will be crucial in the development of the port of Rotterdam, requiring investment in more infra-structure. Very important for Rotterdam will be the planned construction of the Betuwe-lijn, a freight-only railroad connecting the port with Germany, which is currently under discussion. Another issue is the opening of the Rhine-Main-Danube canal, enabling Rotterdam to extend its hinterland connections to the countries bordering the Danube and

the Black Sea. Furthermore, the transformation of certain parts of the port area into specialised port locations have been rated as a success; in particular the 'Distriparks' distribution centres, with nearly all of the allocated land being taken up.

In Belgium, significant investment in port expansion is planned. In Antwerp, the Left Bank development will cost about 37 billion Belgian francs. Further plans are in progress to construct a second container terminal, which will cost about 13 billion Belgian francs, of which the port authority has allocated 750 million Belgian francs in 1993. This second terminal is expected to manage 600 000 TEU a year following completion due in 1996, which is similar volumes to current facilities. Also, plans to renovate existing docks and locks are under way costing another 13 billion Belgian francs. The Port of Zeebrugge authority is investing in a new container terminal, which will provide three berths. The first of these berths is scheduled for completion by the end of 1993, and the other two by the end of 1994. The amount of the investment is put in excess of 10 billion Belgian francs.

In Germany, two operators of Hamburg, HHLA and Eurokai, have invested in improved infrastructure and equipment to boost capacity. Also, a new container complex is under discussion for the Altenwerder area of the port, which would expand the ports throughput to 4.2 million TEU per year by 2000. This project has, however, come up against resistance from environmental concerns and the current status is unclear. Bremerhaven is building two new container ship berths by extending the existing container terminal. Completion of this expansion will allow Bremerhaven to offer 12 berths for container vessels.

France's second largest port, Le Havre, is currently expanding by extending the dock extension, which is due for completion in 1993. Additional expansion is planned in the next five years.

Europe's larger ports not only have investment plans. Smaller ports also want to improve their position by investing in infrastructure, superstructures and operation facilities. An example is Bordeaux's study entitled Port Avenir 2000. In Spain, the Port Authorities of Barcelona and Valencia have initiated major container terminal developments in view of attracting direct liner calls. Barcelona is on of the larger container ports in the Mediterranean, and is planning to construct a new container terminal with multi-modal links that will expand current capacity from 500 to 700 million TEU per year. In Greece, the port of Piraeus also has ambitious plans: over a five year period the current central harbour facilities will evolve into a pure passenger and cruise terminal, and the cargo handling facilities will continue to be relocated to the 'west-side', where additional investment is in place to expand facilities. The port of Thessaloniki is planning to invest 30 billion Greek Drachmas by 1998 to expand port facilities and land area.

REGIONAL DISTRIBUTION

With Rotterdam, Antwerp, Hamburg and Le Havre, most of the EC's larger ports are to be found in the Le Havre-Hamburg range. These ports are the most important gateways to industrial and consumption areas on the European continent. This hinterland can be reached easily by way of a high standard infrastructure in terms of road, rail and inland waterways. The Rhine River is especially important for the port of Rotterdam. This connection and its good geographical location on the North Sea have combined to help Rotterdam evolve into the world's largest port.

Ports in the United Kingdom and Ireland have their domestic markets as their hinterland, which has typically kept their ports smaller than similar ports on mainland Europe. Good connections exist from UK ports to the major industrial areas. These connections mainly consist of motor ways and railways. Inland waterways have declined significantly over the years, plans abound for the revival of these canals. An important activity of UK ports (especially in Scotland) relates to the offshore activities on the North Sea. A port like Aberdeen, for example, is highly dependant on service provision to oil rigs in the North Sea and on oil handling coming from the North Sea oil wells.

In the Mediterranean, Marseilles and Genoa are important ports, especially for the import of oil and oil products. Their hinterlands can be found in the southern part of France (e.g. Lyon and surroundings) and the North Italian industrial areas (e.g. Milan and surroundings), respectively. Other goods handling activities are very dispersed over the broad variety of small ports along the coasts of the Mediterranean, Adriatic and Aegean Seas.

ENVIRONMENT

Increasingly, port authorities are taking a positively robust stance on environmental issues in their ports. The major issues that cause concern are accidental or illegal discharges of waste, leakage or spillage of fuels, spillage during bunkering, and pollution from in-port hull cleaning and re-coating operations. Port and ship operators will have to comply with environmental legislation that is becoming more stringent each year. Also shippers, in many cases, want their products transported in an environmentally responsible way in order to avoid negative publicity from environmental pollution and accidents that could be associated with these products. In some cases, the shippers require environmentally friendly transport facilities which exceed those obligatory by national legislation. This acts as a spur to port operators to make additional investments in environmentally sound handling facilities.

REGULATIONS

The supply of seaport facilities and services must be distinguished in the provision of infrastructure and superstructural facilities and handling services. Facilities are generally managed by a port authority, whereas handling services are mostly in the hands of private companies. The situation however, differs very much from country to country. Port authorities and companies can be either publicly owned or privately owned (or a combination).

In general, three types can be distinguished concerning the principle of exploiting port facilities:

- fully centralised ports, where exploitation is in the hands of the port authority. This authority is a state body. It does not exclude collaboration with private companies, but decisions on investments are mainly with this body. Examples are most Spanish ports, Italian ports, some ports in France and Denmark.
- decentralised ports, where the port authority is a municipal or collective body. Examples can be found in Belgium, the Netherlands, Germany, the United Kingdom and Portugal.
- fully private ports, where the port authority is a private company. Examples can be found in the United Kingdom, where Associated British Ports is the owner of 21 ports throughout the country, in Germany (e.g. Wilhelmshafen), Greece and Spain.

A very difficult issue is port pricing. Various principles of port pricing are used and depend effectively on the extent of subsidisation defined in national port policies. An extreme principle is that port pricing should be such that all costs of the operations together with depreciation and financing costs of infrastructure and superstructure have to be recovered. The other extreme is that port services are public services to be priced at marginal rates. Cost recovery is then made from subsidisation originating from public budgets.

In practice, port pricing is generally made on the idea that costs from operations and superstructures should be recovered. Investments in infrastructure are generally subsidised by central or local governments. The deviations are however large, which can cause onerous competition among ports. However, the industry would consider that in competitive pricing issues, the question of subsidising infrastructure is not a major threat to competition.

The European Commission is currently developing guidelines for integrating ports into trans-European transportation networks. Further, complementary initiatives on ports could examine the terms of competition among EC ports. In particular they could address the possible distortions from financial support by public authorities and the recovery of infrastructure costs from its users. At present the Commission is considering expanding the transparency of the ports and the operators.

Another issue is cabotage. For the transport sector as a whole, cabotage will become important in the future. New regulations will allow domestic transport by operators from other Member States which may cause shifts in transport flows throughout the EC and, as a consequence, shifts goods handling through EC ports. If this occurs then clearly some ports will benefit whilst others will could be harmed. Some of the smaller ports may lose cargoes to the larger hubs, but at the same time may remain competitive for the smaller niche cargoes, that are either required or manufactured for export in the localised hinterland of these ports.

OUTLOOK

The outlook for cargo handling depends heavily on the prospects for world trade and world shipping. As world shipping is beginning a cyclical upturn, especially in bulk transportation, the future for cargo handling is reasonably bright. In the next two to three years, growth in European ports may reach about 4% on average, and in the longer term annual growth rates will weaken slightly.

The outlook for container handling in ports is more optimistic. It is expected that liner cargo growth will be about 5-6% for imports and 2-3% for exports over the next four years. Also, the penetration of containerisation for general cargo will continue to increase, hence, container handling growth rates are thus expected to somewhat higher. Some ports, however, will be able to establish higher growth rates. This will depend on the increasing tendency to create large trunk lines between major hubs in various regions throughout the world. From these hubs, feeder lines will service container traffic demand in other ports in the region.

Written by: DRI Europe

Airports and other air transport facilities

NACE 764

Airports are a key component to air transport industry and to national and regional development. However, congestion in the EC's airspace and at some of the major EC hubs is causing problems for the operating economics of both airports and airlines as well as having an increasing impact on the environment. To overcome this, the EC is developing an improved air traffic management system, whilst some airports are actively investing in infrastructure improvements and additions. In the framework of the trans-European networks' programme, the Commission is presently developing guidelines for the airport network. The main objective of these guidelines is to ensure that the airport network can meet current and future demand for airport capacity while taking account of security and environmental protection requirements.
Competition between major Community airports for transit extra-EC traffic is heightening and this is allowing some of the national competing airports to gain share of traffic.

INDUSTRY PROFILE

Description of the sector

This sector comprises supporting services to air transport (airports and airfields). It includes units exclusively or primarily engaged in the activities essential to air transport, without actually transporting passengers or goods. Hence, units exclusively or primarily engaged in the operation of civil airports and airfields (public and private), radio beacons, radar stations, and units that manage air routes and air traffic control are classified in this group. This monograph will focus on airports.

Airports are the focal point of all aspects of the aviation industry. They are where passengers and freight concentrate before departure and after arrival, they provide bases for the airlines, air services related organisations and the physical means of providing air services - the aeroplanes.

Recent trends

Passenger growth at the major EC airports improved significantly in 1992 as the number of passengers handled grew by almost 11%, following a decline in 1991 of 5.2% caused by the recessionary pressures on the airline industry and exacerbated by the Gulf War. Cargo (including mail) also recorded growth in 1992 of almost 6%, which although less robust than passenger growth, was following a year of marginal decline of 2%.

The largest five airports in the EC for passengers are (in rank order) London Heathrow (45 million), Frankfurt (31 million), Paris Charles de Gaulle and Paris Orly (with 25 million each), and London Gatwick (20 million). In 1992 the individual growth in passengers handled at the major airports varied widely. In 1991 nearly all of the major airports suffered a decline in numbers, but the recovery in 1992 was positive for all of the majors. Amongst the top 20 European airports, ten managed double digit growth in 1992 and the fastest growing was London Stansted with 37%; this followed a 1991 result that bucked the average trend (+46%). However, some airports were unable to recuperate the loss of passenger loadings of the levels of 1990. London Gatwick, the sixth largest airport in the EC (and Europe), although showing growth in 1992, still had levels of loadings below those of 1990. Amongst the major EC holiday destinations, Palma de Mallorca was immune to the decline of 1991, achieving growth of almost 5%, but levels have remained almost constant with marginal growth in 1992 (1%).

The 1992 results for freight handled at airports in the major European cities provided a mixed picture. In the top 20 four recorded declines, three of which were marginal, but the most severe downturn took place at London Gatwick with a drop of 6% to 190 000 tonnes. A quarter of the top 20 had marginal improvement in the 0-5% range. The top three rankings in the EC for cargo growth were Milan Malpensa with growth of 24%, Barcelona with 15.5% and London Heathrow with 14.7%. Heathrow's growth was partially due to taking some of Gatwick's share of London freight. In terms of size, the largest airport for freight is Frankfurt with 1.24 million tonnes, followed by London Heathrow with 758 000 tonnes and by Amsterdam with 695 000 tonnes.

International comparison

When comparing volumes of passengers and freight handled in the three dominant world regions, the USA has the largest share (about 60% in passengers and about 50% in freight). In this country aviation has developed into the major transportation industry for domestic connections. The bulk of passenger and freight flows through USA airports are movements within the country. For freight, developments have been par-

Source: ACI

ticularly influenced by express freight services. The equivalent share of EC airports amounts to just over 23% for passengers and just under 23% for freight. A major portion of this is intra-EC or intra-European traffic.

The large South East Asian airports handle about 18% of passengers and 28% of freight. In Japan, traffic is dispersed among a number of regional airports due to capacity problems. In the future, some may become major hubs for both intra-regional and intercontinental traffic. Freight handling at Asian airports is important for high value electronics shipped to the European and American markets.

The 1992 growth of 11% for the EC major airports for passengers exceeded the rates of growth of both the South East Asia (+6.8%) and the USA (+6.7%). As a consequence the market share of the EC in these three regions increased slightly from 1991. The picture is different for cargo as the return to growth for the USA supported freight growth of over 9%, far ahead of the EC's 5.7% and South East Asia's 3.1%; this helped the USA increase its to almost half of the aggregate of the three regions.

The world's largest airport city is New York. Its three airports handled nearly 72 million passengers in 1992. However, a vast portion of this is domestic travel - some 73%. Of the New York airports the largest is J. F. Kennedy which handles most of the international traffic. New York is also the most important freight centre in the world with 1.8 million tonnes. Second in city rankings is Chicago with two major airports Chicago Midway and O'Hare, which between them handled 69 million passengers in 1992. O'Hare is the worlds' largest airport in total passenger numbers at 64.4 million, of which 92% are domestic. However, ranking on international traffic only, London Heathrow is the world's largest with 37.3 million loadings.

In South East Asia the largest airport city is Tokyo, which handled 65 million passengers and 1.8 million tonnes of freight in 1992. Its major airport for international flights (19 million international passengers) and freight (1.3 million tonnes) is Narita.

MARKET FORCES

Demand

The strong growth in demand for passenger and freight air transport during the 1980s was due to the increasing globalisation of trade, the growing internationalisation of companies and demand for leisure. This has led to increasing demand for rapid reliable air transport for business people and enabled leisure travellers to spend less time reaching both short and long distance holiday destinations. The growth in air freight has benefited from the growing requirement for express freight services, in particular documents, high value goods (of limited weight) like electronic products, and goods for which fast transport is important, for instance perishables such as flowers, and urgent deliveries such as parts required for mechanical repairs. The growth in the air industry has had a direct and proportional impact on the demand for airports.

The type of demand, whether business travel, leisure travel or freight, has tended to partially focus on some airports. Also, airlines, in particular the 'flag carriers', have tended to focus on particular airports. The 'flag carriers' have usually dominated the largest of their indigenous airports, with smaller hubs at the more important indigenous regional airports, due to the nature of the restrictions that used to be prevalent in the EC before liberalisation. The larger non-flag carrying airlines have also based their operations at the larger airports of their countries of origin and the smaller regionals are usually based at regional airport that has a sufficient catchment area to support profitable operations. In non-scheduled services, a number of airports in Portugal, Spain and Greece are largely dependant on charter flight handling. In Northern Europe, some airports have also tended to specialise in charter flights (e.g. Manchester, Maastricht). In some cases, however, this specialisation has been due to reasons other than commercial policy. For example, until 1991, charter flights from London were deliberately assigned to Gatwick in order to alleviate capacity problems at Heathrow: these non-scheduled services made up 44% of all traffic at Gatwick.

Supply and competition

Airport capacity is determined by several factors, such as runway layout, number of runways and gates at the terminal and number of positions on the apron. Also, within the terminal the check-in capacity depends on the access to the airport, the number of check-in counters, the capacity of the baggage handling system and the use of modern electronics. Further, juridical conditions are of relevance, such as restrictions on night flights, customs control capacity, etc.

One of the most significant current limitations on capacity, both for airlines and for airports is the present limitations of Europe's Air Traffic Control (ATC). At present, 23 countries of the European Civil Aviation Conference have 31 different air traffic control systems. These systems rely on 18 different types of computers and 30 incompatible programming languages. In 1992, almost 13% of delayed short/medium haul flights (over 15 minutes) in Europe were due to airport and air traffic control reasons. Although improvements to ATC are being provided, there is still a long way to go in terms of investment capital and time before a harmonised system of ATC will be available that is comparable to the one currently in existence in the United States. One fillip for international airlines, including those of the EC, is the Future Air Navigation System (FANS), which if approved by the 33 members of the UN International Civil Aviation Organisation (ICAO) will move much of the current ground-to-air based navigation and air traffic management to satellite-to-air. Estimates on the savings for airlines reaches as high as ECU 7.8 billion by providing more efficient routing and reducing delays caused by air traffic control.

A recent report from Airports Council International (ACI) on the Economic Impact of European Airports stresses airports are substantial contributors to regional development and public revenues. The airports contribute to employment through three mechanisms: the first is via direct employment in the airport by the airport itself and by the activities carried out by companies operating at an airport; the second is through an indirect impact of services related to the airport's business, for instance hotels and tour operators; and there is a third impact of induced employment which results from a multiplier effect from both the direct and indirect impacts. A case study on Copenhagen Airport showed that of total employment that could be attributed to the airport, 35% was direct, 27% was indirect but the balance of 38% was due to induced employment.

Production process

The services provided at airports form part of logistic chains. Passengers travel from one location to the other using air transport as one part, albeit major, of their total routing. Air transport involves adequate connections with other transport modes, lounges for waiting passengers, customs facilities for international flights. Further the passenger wants sufficient facilities such as bars, restaurants and shops in order to while away necessary waiting time.

Airlines also require services: they need weather forecasting services, fuel provision, flight catering services, and maintenance facilities. In particular, they need an adequate check-in procedure in which the passenger and its accompanying luggage is well administered and allocated to the correct flights. The market organisation of ground-handling services at Community airports is currently under consideration with a view to taking initiatives which would allow for a greater degree of access to the market.

The vulnerability of aircraft to terrorist devices has meant an substantial investment in equipment and personnel to supply adequate security monitoring of passengers and their luggage in the EC.

Local and national government has impacted the process through the provision of facilities such law enforcement, customs control and aspects of air traffic control.

Similar requirements exist for freight forwarding at airports. Services also form part of logistic chains in particular for industries. These more and more require modern logistic concepts like Just-In-Time and Door-to-Door transportation. Such facilities are comparable to those for sea ports.

INDUSTRY STRUCTURE

The major airports in the EC are competing with each other for passenger and freight traffic that is not destined for those particular airports, typically traffic that is using one of these airports as an intermediate staging post or hub. Estimates for London Heathrow indicate that about 30% of extra-EC traffic arriving are transferring to other flights, whether for intra-EC connections or even extra-EC connections. Hence airports such as Paris Charles de Gaulle or Amsterdam Schiphol can easily supply a similar routing. The major airports have been competing aggressively to take a larger share of the transfer market, and this competition has also been supported by the airlines that use these airports as their major hubs.

Strategies

Strategies to compete within national boundaries are less muted in the sense of hubbing; however, major (and minor) regional airports have been positioning themselves for a significant share of the potential market by offering direct services that negate the use of hubbing. An example is Manchester Airport, which is considering to expand capacity by adding a second runway and supporting infrastructure to attract additional airlines, passengers and freight for point to point services, to capture the traffic generated in a large catchment area in the North of England. In perspective, a significant portion of the potential traffic used to go (and some still does) via one of London's airports either by flight transfer or a combination of travel that would involve a train or car journey to a London airport, or via Manchester's regional competitors. The investment allows Manchester Airport to expand its market share at the expense of the other airport in northern Britain as well as taking some share of the London airports, and attracting new induced traffic. The success of Manchester's strategy is shown by the numbers of passengers, which have doubled from 6 million in 1984 to 12 million in 1992. The growth in freight for the same period is even more phenomenal, from 29 000 tonnes in 1984 to 81 000 tonnes in 1992. This development has also meant that Manchester has been developing a hub in its own right, with around 7% of passengers hubbing compared to around 2% six years ago.

Capacity problems are a major issue in airport strategies. Capacity problems arise on many air routes and in air traffic control and the number of aircraft that can be handled simultaneously at the airfields. Apart from improvements in air traffic control, airports' improvement of capacity availability takes many forms, including additional runways, additional infrastructure and improved equipment.

Capacity problems and safety provisions together with the need to keep ahead of competition have prompted airport authorities to invest in new facilities and service improvement. The attraction of additional traffic has also been achieved by offering higher quality services to all users of the airport. They also try, in co-operation with regional authorities, to attract economic activity. An example is Amsterdam-Schiphol. Together with regional and local bodies this airport drafted a strategic plan until 2000 for the development of both the airport and the region into a main complimentary port similar in concept to the port of Rotterdam.

There are many investment initiatives by airports, amongst which is the Italian Ministry of Transport's national airport

plan for the development of its airports. This plan not only envisages to invest in the large airports in Rome and Milan, but also in the small regional airfields. The Airport Authority of Copenhagen has drawn up a master plan for a substantial enlargement of facilities including a second terminal due for 1997 and co-operation in the Copenhagen Central to Kastrup rail link. BAA plc is still in the throes of the plan for a fifth terminal.

ENVIRONMENT

The conflict between air transport's major contribution to economic growth and its impact on the environment remains somewhat unresolved as policies (at both governmental and operator level) to minimise the environmental impact should also work hand in hand with growth in the sector.

The major negative environmental impacts of airports are air and ground pollution, substantial land use and noise. These impacts are both directly attributable to the airport itself and its users, and indirectly attributable to factors such as the external infrastructure required and other forms of transport used to and from the airport.

The major cause of air and ground pollution is the emissions from the engines of the aeroplanes and the land service transport. Advances in jet and turboprop technology has produced engines that are substantially more efficient than their earlier counterparts. However, congestion at the busy airports can lead to an excess fuel burn and hence emission that is 30-50% higher than would the case in the absence of congestion. The requirement by the end of the century that jet engines conform to Chapter III regulations will help reduce the amount of emissions (and noise), but the overriding issue that is likely to have a major positive impact in the short term is a reduction in congestion. Improvements in congestion can be achieved by improving the air traffic control system and expanding available infrastructure, but this will in turn for the major airports allow additional flights so that some of the gain will be used up.

Concerning noise pollution, estimates included in the Commission's Green Paper on The Impact of Transport on the Environment suggest that the percentage of the population exposed to aircraft noise above 55 db(A) varies from 35% in the Netherlands to 1.7% in Denmark, and above 65 db(A) from 1% in Germany to 0.3% in Denmark. Hence, the location of airports close to residential areas is a key factor in noise pollution. Estimates released by the AEA show that the modern jets generate about the same level of noise as a TGV, but for a comparatively minute distance (some 4 kilometres). However, the discussion about noise continues at full pace, and most services that land or take off at airports near residential areas have strict requirements about night flights and the levels of thrust that can be used. This has a detrimental impact on the airlines costs as it can take much longer for an aircraft to reach optimum cruising altitude and hence the fuel burn and the time taken for a particular stage length is higher, which in turn has negative implications for emissions.

Land use and noise tend to receive more public attention than air and ground pollution due to the direct and observable impact on people. Many applications to increase or change land-use go through a lengthy negotiation process at national and local governmental levels as well as public enquiries.

Both airport and airport services have become very aware of their responsibility to the environment. The service supplier are taking increasing responsibility to minimise pollution in maintenance and repair facilities for aircraft, fuel provision services and catering services.

REGULATIONS

In order to ease EC airport policy requirements, the Commission has categorised airports throughout the Community. Category 1 airports are the major hubs or capital airports such as London, Paris, Frankfurt and Amsterdam. Category 2 covers the larger regional airports, such as the airports of Marseilles, Hamburg, Shannon, Luxembourg, Barcelona and Manchester. Finally the category 3 airports are those remaining offering international services. Airfields for domestic services only will not be subject to EC policy.

On the problem of air traffic control, the European Civil Aviation Conference (ECAC) Ministers of Transport established the European Air Traffic Control Harmonisation and Integration Programme (EATCHIP) in 1990. In 1993, the Commission issued a directive (65/93/EEC) mandating the use of standards set by Eurocontrol throughout the Community. Eurocontrol is also responsible for implementing EATCHIP. These efforts will go a large way in improving the management of flows of aircraft in the EC (and Europe), as more cohesion and compatibility will be brought to the various national air traffic control networks. The gradual global movement towards a Single Air Traffic Management System and the introduction of the Future Air Navigation System (FANS), which if approved will move much of the current ground-to-air based navigation and air traffic management to satellite-to-air, will act as a fillip to Europe's air traffic control improvements. However, the EC will need to consider additions to its position to take full advantage of this global movement.

In January 1993, the Council adopted the regulation on common rules for the allocation of slots at Community airports (95/93/EEC). This regulation forms the basis for allocating slots on neutral, transparent and non-discriminatory rules for Community carriers. It aims to allocate slots among existing carriers as fairly as possible, given severe congestion at some airports, and it also allows new entrants a fair opportunity to slots. It has a caveat on provisions for third country relations, in that if a third country does not allocate slots to Community carriers on a similar footing, then Community allocation of slots to carriers from the third country can be constrained or withdrawn. The regulation comes up for review in three years from adoption.

In July 1992, the Council adopted the regulation on licensing of air carriers (2407/92/EEC). This regulation per se has marginal impact on most airports, but it does have an impact on the small regional airports that cater for international flights. It is these airports that will host some of the new entrant airlines operating small niche point to point services, and the regulation requires that new entrants operating small aeroplanes (less than 20 seats or under 10 tonnes MTOW) maintain a net cash at hand balance of at least 80 000 ECU. The regulation is designed to ensure the financial fitness of air carriers in a commercial environment that has been shaken by company failures. However, niche start-up airlines initial outlay of start-up capital is huge by most industry standards. This initial outlay includes plane purchase or lease, landing rights, purchasing access to computer reservation systems, hangerage and maintenance options, etc., and is estimated to be in excess of 350 000 ECU. The heavy initial investment coupled with the minimum requirements does not bode well for new entrants which in turn will severely reduce the small regional airports ability to attract additional business.

DUTY AND TAX FREE SALES

Duty and tax free (DTF) sales have become highly important for airports (and airlines) as a source of revenue. Also, passengers want to benefit from low-priced products available in the DTF shops on the airports. The Commission originally envisaged abolishing DTF allowances for passengers travelling within the EC with the advent of the Single Market. Estimates on the loss of concession income to airports concluded that landing and passenger charges would have to rise by 13 to

25%. In turn, airlines would pass these higher charges onto the traveller in higher fares, possibly causing a negative effect on traffic demand especially in the leisure market. The effect of DTF abolition would have been exacerbated by airline companies, especially charter airlines, losing revenues from on-board DTF-sales. This would cause a cost push on fares to overcome this. Due to strong lobbying from many sections of the international transport industry, the abolition of DTF has been postponed within the EC until the 1st July 1999. In the meantime the DTF industry has developed a system of vendor control, in which the vendor checks compliance with DTF allowances. This system is necessary as customs control for travelling within the EC will disappear, but it has increased the allowance to travellers within the EC, for each intra-EC stage is counted as one for DTF purchase. Previously, a passenger travelling from the UK to Denmark, then to Italy and returning to the UK was only allowed to import one allowance into the UK, however the equivalent for this route is now three times as purchases are possible and legal at each stage for importation into the UK.

OUTLOOK

The outlook for airports depends on the demand for air passenger and freight, which is expected to be fairly buoyant in the future. However, in the short term some of the larger congested airports will not be able to take full advantage of potential growth as congestion will be the limiting factor. As the EC's air traffic control improves, part of this constraint will disappear temporarily. Additional flights fill the vacuum

Table 8: Airports

at these airports, then the problem of congestion will return and will only be solved by adding additional infrastructure capacity - a thorny problem at most of the largest airports close to dense populations. The medium sized airports will continue to expand, especially those which have positioned themselves as competitors to the major hubs. The small regional airports will see some growth, but the major limiting factor for these will be the size of the catchment area.

Overview

NACE 81, 82, part of 83

The traditional boundary lines between sectors providing financial services are becoming blurred in Europe. Whereas in the USA and Japan, these demarcation lines still exist, in Europe deregulation and liberalisation stimulate the emergence of integrated markets. Disintermediation, securitisation, the growth of the market for derivatives, 'Allfinanz' mergers and alliances, electronic banking and electronic markets are examples of important trends in the financial services sector. Information and communications technologies are a major force for change in the evolution of the financial services sector. There are signs of a change in saving behaviour that will increase the supply of funds on capital markets. Regulation on credit and market risks provides an element of stability in the rapidly evolving financial markets.

INDUSTRY PROFILE

Description of the sector

The financial sector was traditionally, in many European countries, split up into various activities, which the authorities kept strictly separated, prohibiting diversification. However, distinctions between commercial banks (their role primarily being providers of short term credit to enterprises and individuals, financing enterprises and granting consumer credit), investment banks (which concentrate on the top line enterprises and engage in corporate finance, management of corporate assets and liabilities), and investment services firms were largely removed. Progressive liberalisation of the financial professions within the EC has allowed banks to play a direct role in the placement and brokerage of shares and bonds, as well as in related activities. At the same time, links between the banking and insurance professions have grown. Some insurance companies now offer credit services and payment facilities, while banks offer insurance products.

Although the demarcation lines between the providers of financial services has become fuzzy, the following classification is still valid:

- universal banks (can offer the whole range of financial services): most are joint stock companies, but in certain countries they are also savings, cooperative and public banks;
- specialised banks: among them are commercial banks (that offer a wide range of services), investment banks, mortgage banks, industrial banks, etc. (that offer only some types of financing according to their scope (industrial banks) and lending techniques (mortgage banks);
- finance companies (non-bank): consumer credit; industry credit; factoring; leasing; export financing;
- insurance companies and retirement funds: life assurance companies; non-life insurance companies; pension funds; social security funds; building societies; insurance brokers.
- other intermediaries: stockbrokers;; investment advisers; investment funds; exchanges; investment funds and other UCITS (undertakings for collective investment in transferable securities), clearing houses.

All these operate on all or some of the financial markets. These may be divided into groups according to various classifications. The most important distinctions are:

- money markets (short term instruments: call money, on-sight deposits, checking accounts) and capital markets (long term instruments: securities, loans, mortgage loans);
- primary markets (issues of securities) and secondary markets (dealing in already issued securities);
- regulated markets (like stock exchanges) and non-regulated markets (like over-the-counter markets, in which dealing takes place by dealers who may or may not be members of a securities exchange);
- spot markets, in which the operations and payments are carried out immediately, and forward markets, where the traded currency securities will be remitted later, and will be paid at the agreed time or upon remittance of those securities.

Recent trends

Difficulties in the European Exchange Rate Mechanism (ERM) affected the financial markets in 1992-1993. In 1992 the pound sterling, Italian lira and the Spanish peseta were withdrawn from the ERM. A period of relative calm followed, but in 1993, the tensions in the ERM increased again. This eventually led to the widening of the fluctuation bands in August 1993. This turmoil was reflected, and partly caused by, developments in the currency markets.

The real estate sector experienced a spectacular expansion during the past decade. Since the beginning of 1991, however, the sector is mired in a recession in several countries. This downturn is hurting the banking sector, as many banks are heavily involved in financing real estate.

The importance of the financial sector in the EC economy in terms of value added has been between 5% and 5.3% since 1985. Compared with 1980, this share has increased about 0.7 percentage points. The spread among most Member States is not large. Only in Luxembourg is the financial sector disproportionately important to the economy.

Four large EC countries, Germany, Italy, France and the UK, take account of 75% of gross value added in financial services. This figure is not very informative about the relative importance of each country on the different financial markets, since value added measures the contribution to the 'real' and not the 'financial' economy. To measure the latter, figures on assets, premiums written and stock turnover are more appropriate, and then a very different picture is revealed, with the UK clearly as the most important financial market.

Growth of the financial sector has resulted in a disproportionate growth in employment; indeed, employment in financial services has been growing at a faster rate than value added or profits.

International comparison

The leading financial centres are clearly New York, London and Tokyo. Although trade in financial products is to a large extent international, the international part of trade primarily originates from large (private as well as official) financial institutions or multinational firms. National regulations, conventions and culture still create distinct national markets. For instance, the consolidation of financial services in Europe - linking banking, insurance and other financial services - makes Europe the laboratory for new products and merged companies.

Japanese banks dominate the world market in terms of reserves, with Japanese banks on the first six places in the world. This is the result of a decade of exceptional growth during which Japanese banks pursued an aggressive policy of market share expansion that culminated in their moving into first place worldwide in terms of deposits. However, such a growth has been counterbalanced to a large extent by a significant devaluation of the yen vis-à-vis the dollar, all the European currencies and the ECU. The comparatively poor performance of US banks is the result of restrictive regulation, which limits the field of activity of the banks both geographically and commercially. The US banking system is fragmented and poorly diversified.

A substantial degree of internationalisation in the provision of financial services has been made possible by deregulation and the revolution in communication technology. The resulting integration of financial markets has broadened the choices of participants: issuers have increasing recourse to foreign markets to raise capital, while investors have tended to internationalise their portfolios.

The currency turmoil in 1992 (and in 1993) stimulated securities trading in so-called safe-haven currencies, at the expense of high-yield sectors. It also triggered a dip in bank credit. Lower long term interest rates stimulated demand for capital through financing and refinancing in longer-term instruments, to the detriment of short term paper. The greater risk involved with the variability of exchange rates and short term interest rates stimulated the use of derivative instruments, to hedge against these risks or to exploit opportunities to profit from these risks.

MARKET FORCES

Demand

Demand for financial services is determined by population and savings trends, deregulation and liberalisation of capital markets and changing patterns of consumption. In general, the population of Europe is ageing, which means that in the future a relatively smaller workforce will be available to generate the social security and pension benefits in pay-as-you-go systems. In anticipation of deficient social security payments, many people save in order to secure a sufficient pension. Till late in the 1980s, personal savings rates were declining in many countries, thereby constraining the financing of economic growth, and stimulating competition between banks, insurance companies, mutual funds and securities to attract savings. However, since then the fraction of saving in disposable income has taken an upward trend in several countries. If this trend continues, the supply of savings on the financial markets should increase. The question is then which financial instruments will be in demand. Households have changed their investment behaviour in the past decades. The high inflation years of the 1970s have made them fully aware of the phenomenon of monetary erosion. They have become more demanding about the yield on their savings, and look actively for the best investment opportunities. This has stimulated the success of more sophisticated saving instruments, like insurance products with a 'financial component' and mutual funds.

Retail banking, including investment of savings, portfolio management, consumer credit and mortgages, payment services and a wide range of advisory services, today constitutes one of the most important branches of the financial services sector. The retail banking sector has grown enormously since the

1960s, with the result that in many countries the market is saturated. This is demonstrated by the significant decrease in certain Member States of the number of banks branches. Banks can often only gain new business by directly luring it away from their competitors.

In the provision of financial services to the industrial sector three main trends can be identified. The first is an increasing demand for very specialised services for the management of assets and liabilities. Financial management increasingly relies on computer assistance and uses a wider range of instruments, for instance options and new fixed-term instruments. The supremacy of the banks is challenged by large companies, who have set up their own systems of financial management. The second trend is a growing intervention by banks in the management of businesses. Banks are increasingly asked to assist with financial restructuring and reorganisation, mergers and acquisitions, take-overs and leveraged management buy-outs. The third trend is the emergence of a capital market to finance small and medium-sized enterprises that have a solid track record but are unable to meet the criteria for an official market listing. These enterprises are served by risk capital companies, as well as by new segments of the official stock markets, such as secondary markets or over the counter markets.

Financial services linked to shares (especially the issue of shares, brokerage services, share transactions and portfolio management) have become on of the more important segments of financial markets since the beginning of the 1980s. Around 1982, when financial institutions were revealed as highly exposed to liquidity and country debt risks, they reoriented their activities towards stock-market based operations, in particular the underwriting of international bond issues and the intermediation of international transactions.

The market for derivative instruments has grown exponentially. The function of derivatives is to hedge against risks. Consequently, the trading of these instruments involves a degree of speculation. At present, there is a debate between banks and supervisors (e.g. BIS, Bundesbank, Federal Reserve) about the risk of the derivatives markets. The Group of Thirty asserts that these markets provide an important service and are not excessively vulnerable. Supervisory organisations however, emphasise the substantial undiversifiable market risks inherent in these instruments. These risks could materialise when the liquidity of the markets dries up.

Supply and competition

Since the mid-1980s deregulation has liberalised capital markets, thereby permitting the introduction of many new products, and has blurred the demarcation lines between different market players. In particular deregulation involved:

- an end to brokers' monopolies within stock exchanges and other organised markets accompanied by free negotiation between brokers and clients, which led to a reduction in commissions;
- reorganisation of the market for treasury bonds, with the appearance of specialists whose role is to stimulate the market and assure its liquidity;
- development of secondary markets;
- computerisation, resulting in improvements in market liquidity and in the precision and speed of information;
- creation of markets in derivative products, notably the United Kingdom's LIFFE and France's MATIF, respectively the fifth and sixth largest derivative markets in the world.

The result has been a more intense competition, but also a wave of acquisitions, mergers and alliances. While competition in new products and, to a lesser extent, price intensified, competition in territory (through building and extending a network of banking outlets) was less severe from the beginning of the 1980s as new organisational features such as home banking and automated banking facilities increasingly made the necessity of extensive branch networks less paramount. Product competition became particularly intense in the investment of household savings, with the appearance of a greater number of market participants. In addition to the traditional banks these included insurance companies and investment funds.

One of the major trends has been financing with securities rather than with (bank) loans. Examples are credit notes negotiable on the market in national currency, bonds issued by business firms, negotiable gilts issued by national treasuries and deposit certificates issued by banks. In line with this trend, financial disintermediation has spread. Increasingly firms bypass banks by going directly to the capital market (for an over-the-counter loan from for instance a life-insurance company, or the issue of bonds or commercial paper). As banks made less money out of 'normal' on-balance business, they had to look out for other income sources. These were found in off-balance activities thereby bringing commercial banks and investment banks into direct competition.

Foreign direct investment (FDI) has responded to the developments on the markets for financial services. The level of FDI has increased substantially when comparing 1987-89 with the period 1984-86. The share of insurance in intra-EC investment has increased considerably, but those of banking and real estate have lost a few percentage points. In banking and insurance, there is a redirection of direct investment flows towards other EC countries and away from the rest of the world. The intra-EC share of total direct investment flows in banking and insurance has increased significantly. In real estate

virtually all foreign investment by the EC remains in the EC. The strong decline in the ratio between outward and inward extra-EC FDI flows indicates that the EC has become an attractive location for direct investment from non-EC countries. Measured by this ratio banking and insurance appears much more attractive for FDI than the industrial sector.

Production process

The decade of the 1980s was marked by the liberalisation of financial markets involving the removal of brokers' monopoly, the authorisation of new products and the removal of credit restrictions. This triggered the expansion of markets and the introduction of innovative new products. Moreover, the distinction between brokers, banks, exchanges and electronic markets has become less clear, and in several instances even obsolete. All compete to provide services to the suppliers and demanders of capital.

An indispensable factor for the explosion in market activity and the proliferation of products permitted by deregulation, was the availability of enhanced information and communications technology. From the point of view of costs, computers as a mass processing tool permit significant increases in output per employee. Productivity related to administrative functions is growing in the banking sector in the order of 5% to 7% a year. At the same time, by minimising manual intervention, using real time operations, keeping customer files updated to the minute, reducing delays and making deadlines more reliable, computers are an important quality tool as well. Finally, technology is necessary for the provision of new services as remote banking.

Technology and competition have led to changes in the organisation of work. The most important are the overall responsibility of employees for good performance and cost control; the improvement of working conditions; the increased direct contact between employees and customers; and better internal control.

New technologies and methods presuppose new staff skills. Financial establishments that hired large numbers of untrained staff during the expansion race in the 1960s and 1970s are now faced with major investments in training and writing off redundancies. Furthermore, the additional costs of investment in computerisation weigh on profits of banks and insurers. Set against a background of growing competition, the way institutions handle these changes will be crucial for their future performance.

INDUSTRY STRUCTURE

Financial institutions

The fifteen major European banks, ranked by Tier One capital, include French, Swiss, UK, Dutch and German banks. Tier One capital includes common stock and declared reserves. In short, Tier One capital measures only the core of the banks' solvency. If banks are ranked according to their assets; German banks figure more prominently. There are over 10 000 banks in the EC.

In 1990, there were almost 4900 insurance companies in the EC, mostly active in non-life insurance. This figure includes approximately 750 reinsurance companies, as well as companies from former East Germany. However, the number of independently-controlled groups was only about 2500. This number will continue to decline as competition pushes the small and medium-sized insurers to merge.

Strategies

The large financial services groups follow two main strategies. The first is diversification: offering a complete financial service package ("Allfinanz"). The second is cross-border expansion or linkage (global player). Allfinanz (also named 'bancassurance', although there the emphasis lies on insurance products) offers benefits to banks and insurance companies, especially in the life insurance sector. The life insurance market offers banks attractive prospects for improving the return from their distribution network. Precisely the scope of the banks' networks is also attractive for the insurer, in that a larger volume of customers can be accessed at lower cost. The strategy of global player is pursued through acquisitions, mergers and alliances. However, figures from the CEC show, that in 1991, acquisition and joint-venture activity has slowed down.

Other financial intermediaries, like securities brokers, must first determine if they want to be an international, national or niche player. To be an international operator the successful strategy seems to be to invest in international networks of offices. Goldman Sachs, Credit Suisse First Boston and S.G. Warburg all have invested heavily and all are leading advisers.

A strategy of innovation can create competitive advantages for all players in the financial services sector, but especially for the stock exchanges. International capital investments increasingly use new financial instruments, simply because they offer a better performance.

REGIONAL DISTRIBUTION

In Europe, London remains the centre of the international financial market, both in terms of stock market capitalisation and volume of transactions. London's pre-eminent position can be explained by the extent of deregulation and the role of the SEAQ International transaction system, which deals in European shares. UK experience has speeded up the pace of innovation in other European countries. New ideas have begun to spread rapidly to the continent from the beginning of the 1980s and Paris and Frankfurt have significantly increased their market share.

REGULATIONS

The market for financial services is partly very internationalised, partly still nationally segmented. Several EC directives applying to banking, insurance and investment services, have the objective to create a single market in financial services. The latest directives have introduced three important principles to steer market integration:

- the home country control principle, by which the country where the main unit of a company resides, has the supervision over that company;
- the single licence, allowing a financial institution licensed in a single Member State to operate freely in all Member States
- the mutual recognition principle, according to which Member States must accept that financial institutions having their head office in another Member State, and operating on their territory, will abide by their national prudential regulations.

The Second Banking Coordination Directive came into effect as from January 1, 1993. It is supplemented by a directive on monitoring and controlling large exposures of credit institutions. A directive on the credit institutions' own funds, another one on the solvency ratio for credit institutions and a last one on deposit-guarantee schemes are in the advanced stage of the process that will lead to their approval by the EC Council of Ministers (common position on 25 October 1993).

In the context of the internationalisation of capital markets and the exponential growth of new financial instruments, new regulation on the functioning of markets is essential to maintain the stability of the system and reinforce investor protection. The entire supervisory process with respect to capital markets has therefore been expanded. Supervisory authorities have strengthened their prudential control on financial institutions through the application of solvency ratios and the elaboration of new international standards. In 1993, the minimum requirements laid down by the European banking directives came into effect. These require that total capital should be at least 8% of risk-weighted assets and that Tier One capital should be at least 4% of assets.

The insurance business in certain countries has traditionally been subject to stricter regulation than banking or other financial services. In those countries, regulations impose standardised policy clauses and, in certain sectors of the industry, set prices. The "third generation directives" of the EC have established the home country control and the single licence principles for the insurance industry and have phased out most of the foregoing restrictive regulations, leaving to the relevant Member States only the possibility to make some controls "ex post".

The Capital Adequacy Directive (CAD) of 15 March 1993 and the Investment Services Directive (ISD) adopted on 10 May 1993, introduce the same principles for investment services, however, this situation will be discontinued between 1996 and 1999.

OUTLOOK

The major trend for the future seems to be the integration of national financial services markets. Whereas wholesale capital markets have already been very liberalised and internationalised, the national boundaries between markets serving private customers and small and medium-sized businesses have remained intact. Economies of scale and scope, as well as deregulation have already driven financial companies into acquisitions and alliances. The new EC directives encompassing the single licence and the home country principle, provide the regulatory basis for further integration.

For financial services and insurance, the Single Market remains a concept whose impact will probably not be felt until around 1995. For major firms, savings, financial services and insurance are already global matters. Individuals, meanwhile, tend to remain attached to locally-available services provided by local companies.

However, a single European capital market could emerge, given the elimination of all barriers to cross-border transactions. This market will be characterised by a high degree of competition and financial innovation. It can be expected that financial firms will serve not only the large 'Blue Chip' companies, but also some middle-sized firms.

Disintermediation will continue to be important, and perhaps its importance will grow, given the regulatory changes and the changes in information and communications technology. It can be envisaged that e.g. electronic markets can perform both the function of intermediary and market, making stock exchanges, banks and other intermediaries in those instances obsolete. The main participants, however, will in the near future be precisely those stock exchanges, banks and intermediaries.

There is a caveat to disintermediation, which already has become apparent. In order to survive competition, banks were and are tempted to take on bigger risks with what business they still have. Recession has already forced many banks to build up bad debt provisions, but the situation is improving. The new solvency ratios and capital requirements must reduce these risks in the future. Economic recovery will be the biggest help though.

Written by: Netherlands Economic Institute

Credit institutions
NACE 81

Disintermediation, bad debt provisions, capital requirements, rising personal saving rates and technology are the important trends for the banking sector. Especially in wholesale banking there is a tendency of borrowers and investors to bypass banks and to go directly into securitised money and capital markets. This trend has been a challenge to banks already for a couple of years. Banks' reactions have existed partly in looking for higher-return investments, which however bear also a higher risk. During the long economic upturn of the 1980s this policy proved fruitful, but when the economy turned into recession, many banks had to make provisions for losses. Capital requirements imposed by the Basle accord and the EC try to put a brake on aggressive lending policies and to secure a greater level of financial stability. With respect to the other side of banks' balance sheets, rising personal saving rates may mean that they can fund their activities more easily in the 1990s, although competition from other players like mutual funds is strong. Fast progress in information and communications technology will continue to drive developments in the 1990s, as they have done in the 1980s.

INDUSTRY PROFILE

Description of the sector

Banking fulfils various functions: accepting deposits and converting them into loans and credit to enterprises, public authorities and consumers; managing payment systems and clearing mechanisms; providing services with capital transactions; performing various other services like the provision of guarantees and insurance agency. These functions are not performed by banks alone. Consumer and industrial credit are provided also by finance companies (many of which have links with banks) and mortgage loans also by life insurance companies and property developers. The special nature of banks is being eroded by the trend towards deregulation: some banks' activities are becoming increasingly similar to some of the activities of other financial institutions with which they compete.

In looking at the banking market, it is possible to distinguish the retail and the wholesale/corporate market. Each has its own characteristics and to some extent also different players. The retail banking market in Europe is still very national. The degree of concentration in most national banking markets is not high. Only in a few Member States the three main banks have together a market share of more than 20%. However, in every country there are a few banks that are the market leaders, and as such in every country there is to a certain degree an oligopoly. On a European scale, however, the retail market is fragmented. Entry in these markets is difficult, because of a high degree of customer loyalty and high set-up costs. Furthermore, managing a pan-European retail banking network faces the concerned organisation with many difficulties, not to mention the disadvantages of some approaches (see strategies). Wholesale markets are very competitive and margins are thin. Activities in this sector are more complex than in the retail market.

Credit institutions can be classified along the following lines:

- Universal banks: multi-purpose banks which can offer the whole range of financial services. Most of them are joint stock companies, but in certain countries also savings, co-operative and public banks are universal banks;
- Specialised banks: among them are the commercial banks, which offer a wide range of services, and the investment banks, the mortgage banks, the industrial banks, etc. which offer only some type of financing, according to their scope (industrial banks), or their financial techniques (mortgage banks).

There are also institutions which offer some type of specialised credit, but are not credit institutions according to EC directives, and which are called "financial institutions" because they do not attract their funding from the public; such institutions are particularly active in consumer credit, industry credit, factoring, leasing, car financing.

Mortgage credit plays a fundamental role in the EC economy. It comprises 80% of outstanding debt of households and is also important in bank lending to enterprises. Characteristic of this part of the banking market is the high concentration of mortgage credit in the UK building societies, as well as large Danish, German and Spanish specialised banks. Another characteristic is the importance of legal traditions. Every country differs from the other in this respect. Notwithstanding the second banking directive, the EC market for mortgage credit remains by and large the sum of twelve national markets. National differences in tax treatment of interest on mortgage loans and in preferences for renting obstruct effectively the international expansion of banks engaged in mortgage credit.

Finance companies specialise in providing credit to consumers and industry. Mostly, they are subsidiaries of larger financial (and insurance) institutions. Industrial credit (to be distinguished from leasing) is common in Germany, France, the United Kingdom and Sweden. Transactions with private customers represent in general more than 50% of the total volume.

The UK has the largest banking sector, measured by total assets, followed by Germany and France. The German bank sector employs the most people. The number of banks in Germany is overestimated because many of the cooperative banks are counted as different banks, whereas in other countries (e.g. France or the Netherlands) they are subsumed under the heading of their central or regional cooperative bank. The number of local units is informative about the presence of (retail) banking in the countries concerned. Cooperative banks figure prominently in Germany, France and the Netherlands, and savings banks in Italy, Portugal, Spain, Germany and Belgium. However, in every country except Germany, the (large) majority of assets is held by straight commercial banks.

Recent trends

In 1992 and 1993 banks were affected by the turmoil on the exchange markets, the economic recession and the capital requirements of the Basle accord and the EC. The unfavourable effects of the current economic situation in Europe have made themselves felt in the construction and property market sectors,

with a fall in output of 1.2% in overall construction activity in 1992 and a downturn in the volume of property related business. The construction of new housing is down in Europe as a whole . Some growth is still visible in the rehabilitation and maintenance of residential buildings. Non-residential building is very sensitive to fluctuations of the business cycle and is performing poorly in the current recession. Property markets across Europe have not escaped the fall in overall activity. ECMF figures on property transactions recorded a sharp drop in 1992, while nominal house prices showed a mixed performance.

In 1992 banks' assets registered an average growth of 6.4%, lower than the yearly average since 1986. Differences among the Member States were widespread, however, with the UK banks reporting a decline and Irish and Portuguese banks reporting strong increases. It is remarkable that, according to the Banker, the number of bank employees rose in 1992 in most countries.

The recession overall and in the real estate sector depressed the demand for credit by the private sector. It also resulted in increasing bad debt provisions, except in the UK, where it seems that the worst is over. Nordic banks, however, slumped even further. In the Scandinavian countries the real estate sector was hit particularly hard, and many banks were forced to make large provisions. Some of them had to be rescued by the government with the taxpayer money.

The European mortgage credit market was directly affected by the depressed real estate sector and lending figures fell in 1992. The situation varied greatly from country to country, however. Strong increases in residential lending were recorded in Germany, Belgium, The Netherlands and Portugal. The gains in these countries were more than offset by sharp decreases in France and the United Kingdom. Levels of outstanding loans against residential property increased by only 4.0% in 1992, substantially lower than the growth figure of 1991.

According to EUROFINAS's members, total credit of finance companies outstanding at the end of 1992 amounted to ECU 155 billion for the EC (excluding Greece and Luxembourg), a decrease of 0.5% compared with the previous year. The amount of new credit registered a drop of 8% to ECU 86 billion.

The recession combined with structural developments has resulted in lower profitability in many countries. Net interest income in particular has declined in recent years in all major banking markets of the EC (UK, France and Germany). There are, however, countries where the opposite holds, like Italy, Portugal and Ireland.

International comparison

Japanese banks dominate the world market in terms of assets, with Japanese banks on the first six places in the world. This is the result of a decade of exceptional growth during which Japan's banks pursued an aggressive policy of market share expansion that culminated in their moving into first place worldwide in terms of deposits. The fact that the volume of assets held by Japanese and EC banks is roughly equal shows that the Japanese market is much more concentrated than the EC market. Japanese banks have engaged in excessive lending in too risky ventures. In 1992 huge provisions against bad lending were needed. It is important to note that only two European banks are listed among the first ten in the world (Crédit Agricole and Union Bank of Switzerland) in terms of own funds.

North American banks figure less prominently among the rankings, with only 7 banks in the top 50, measured by assets. Banks' assets are also on average much smaller than those of Japanese or the European banks. However, interest margins are on average higher.

Foreign trade

The strong growth of international capital markets is a major feature of the past decade. The stock of net international bank credit at the end of 1992 amounted to ECU 3 022 billion. In US dollar terms (USD 3 660 billion) it was almost 21 times as high as ten years earlier. In 1992, the expansion of net international bank credit was 6%. Growth was inflated by in- and outflows of funds at the time of the exchange market turmoil, when the pound sterling and the Italian lira stepped out of the ERM. Taking this into account, growth has been very modest. Slow economic growth, which weakened credit demand and increased risk aversion, and perhaps also the new capital requirements, have taken their toll.

In the EC too growth of international bank assets has been on average very modest. However, when excluding exchange rate effects, the growth was probably higher. French banks recorded the largest increase, one quarter of which can be attributed to foreign affiliates.

MARKET FORCES

Demand

Demand for banking services derives from economic activity: savings and investment on the one hand and transactions on the other form the backbone for the volume of demand. The development of interest rates is of importance, especially the difference between long and short term interest rates, because a role of banks is to bridge the supply of shorter term savings (supply of capital) and the demand for longer term credit (demand for capital). Apart from the fact that interest rate developments determine the interest margin, they also influence patterns of supply and demand of capital.

Demand for international capital has originated partly from the growth of international trade, foreign direct investment and portfolio investment, and partly from the liberalisation of capital markets, which made it possible for investors to seek the best location to invest.

There is an increasing demand for more sophisticated and diversified financial products: flexible credit products, foreign currency financing, derivatives like swaps, options and futures. Innovation is very important in this area and plays a double role. It responds to demand, but by creating new products it also stimulates demand.

Supply and competition

The main trends in banking since the mid-1980s are deregulation, liberalisation and disintermediation. These trends pose challenges as well as threats to the banking sector. Disintermediation, involving securitisation (loans transformed into securities) and the operation of near-banking activities by large firms reduces interest income. Only when a bank succeeds in attracting new business with services (e.g. the issue of securities) can it compensate the loss with more income out of commissions. Up until now the banking sector has adjusted with some difficulties. Negative developments include declining profitability, financial fragility and increasing bad debt provisions. Competitive pressures, showing up in smaller interest income, drive wholesale banks to higher-risk and higher-return activities. The recession revealed the dangers of this evolution: bad debt provisions have grown considerably. In the 1980s set-asides had to be made against loans to heavily indebted developing countries, but in more recent years the provisions are primarily against bad domestic debts. Especially banks involved in financing real estate unsecured by mortgage credit and highly leveraged corporations were affected.

The pressures on interest income made banks look for other income sources: fees (e.g. for underwriting of security issues), commissions, advice for customers (retail and wholesale), arranging swap and forward exchange and interest rate contracts. As a result off-balance sheet activities have grown considerably, making the supervision by regulatory bodies more difficult. The search for other income has also spurred the drive towards 'Allfinanz'. Banks want to increase revenues from their customer base by selling them more products.

Pressures on profitability have pushed banks to higher efficiency. Cutting costs has become a major concern in the banking business. Many opportunities are still available in this field. One option is the reduction of the number of branches, especially in overbanked and overbranched markets. Technology (automated teller machines, telebanking) will preserve a wide access to banking services for the public. Another option is the merging of smaller banks to reap the benefits from economies of scale or scope.

The profitability of banks is also threatened on the deposit side on the tax treatment of deposits in the country concerned. Customers are more alert to invest their savings in high-yield deposits, or turn away from banks to mutual funds. In some countries, tax treatment of certain life insurance products lures savings away from banks. Banks can only compete by offering the same conditions, which means that the cost of funding goes up.

In the UK, the challenge of the building societies to the banks has forced the banks to move more strongly into the financing of residential investment. Furthermore, UK banks also faced competition on the credit card market by the development of store-based credit cards. In the 1980s and the beginning of the 1990s, UK banks were severely hit by bad debt provisions because of loans to the Third World and subsequently by the

impact of the recession, which affected particularly the real estate sector.

In Europe, but also elsewhere, one of the questions is how capital markets will evolve: with the emphasis on bank finance or on direct financing on the capital markets? Both have their own advantages. Bank-based systems are less crisis-prone, have a longer-term view in decision making and provide superior continuous monitoring of corporate performance. Market-oriented systems are usually more efficient, support more financial innovation and better resist conflicting interests between stakeholders.

Production process

Technology, especially computerisation, is of crucial importance to banking productivity and the development of new activities. Technological progress in information and communications technology has lowered the costs of collecting and analysing information. It also enabled to meet demand for more sophisticated products. Offering electronic banking services to corporate clients helps to generate fee-earning business.

First, large administrative processes were automated, by using batch processing in the 1960s and 1970s. This gradually evolved in spreading automation from back-office to front-office, together with the use of computers in office automation (e.g. word-processing). Finally, banking services itself became automated and electronic banking was born. As of the beginning of the 1980s, computerisation in banking activities accelerated, with marketing of specific services such as long distance banking by computer. In France a high degree of interbank compatibility and the spectacular development of a government sponsored video text system called minitel have allowed the development of one of the largest automatic teller networks in the world, with one machine for every 1 500 customers. On the other hand, customers are now familiarised with card services, and expect something new, such as genuine one-stop agencies featuring automated disc-storage, cheque printing, information and advice. Apart from automatic cash dispensers, telebanking now includes a variety of on-line videotext and off-line ASCII services. There is a definite trend towards more automation in transactions between bank and customer.

Computerisation is a processing tool that can produce major productivity gains. Estimates show that administrative productivity is growing annually at about 5% to 7%. However, investment in computerisation represents a heavy financial burden. In the decade 1980-1990, bank spending for computers rose by nearly 30%. Banks show an increasing tendency to centralise their technological resources, concentrating their information technology system in a limited number of centres, typically on a group or regional level.

The cost of acquiring a new customer is very high, at around 1 000 ECU according to a recent study. Adding one point of market share is estimated to cost between 1 billion and 2 billion ECU in investment.

INDUSTRY STRUCTURE

Companies

The fifteen major European banks, ranked by Tier One capital, include French, Swiss, UK and Dutch banks, and only one German bank. Tier One capital includes common stock and declared reserves plus (the increasing number of) perpetual, irredeemable and non-cumulative preference shares; it excludes hybrid forms of capital and extras as goodwill and revaluation reserves. In short, Tier One capital measures the core of a bank's solvency. The ranking would change if banks were ranked according to their assets. German banks would then figure more prominently.

The major retail banks in France are Crédit Agricole (a co-operative bank), Crédit Lyonnais, Société Générale and BNP. Banks in France have been subject to many political pressures. Many were nationalised in 1982 and then privatised again after 1986 when the political tide was reversed (e.g. Société Générale). Since the election of the new French government privatisation has again gained momentum, resulting in the privatisation of BNP in October 1993. Important wholesale and merchant banks are Paribas and Indosuez. French banks have invested heavily in new technology like automatic cash dispensers.

Deutsche Bank, Commerzbank and Dresdner Bank dominate the German banking market. German banks play a special role in the German economy because of two reasons. The first is that they hold stakes in many industrial enterprises and have influence on the companies' supervisory boards (Aufsichtsrat). This influence is usually thought to be beneficial, because banks tend to take a long-term view and provide valuable financial advice. The second is that they act as stock-brokers for the exchange (credit institutions own 80% of the new unified structure of the Deutsche Börse).

The UK banking market is dominated by Barclays, National Westminster, Lloyds Midland (HSBC Holdings) and Abbey

National. The banking oligopoly from some years ago has to face the challenge from building societies, of which one already has transformed itself into a public limited company and now shows up in the ranking.

The Italian banking market is more fragmented. Only two Italian banks figure under the first twenty European banks: Banca di Roma and Cariplo. Other important banks are the Istituto Bancario San Paolo di Torino and the Banca Nazionale del Lavoro. Many banks are state-owned and were under the influence of political parties. As a result the Italian banking sector is not very competitive. However, the adoption of the Amato law in July 1990 paved the way for major restructuring and modernisation. This law opened the way for publicly owned banks to become joint stock corporations with additional fiscal benefits. The Cassa di Risparmio di Roma acquired a 65% stake in the Banco di Roma and took over the Banco di Santo Spirito and created the Banca di Roma. This trend will develop in the near future with the privatisation of major public banks decided by the Ciampi Government in 1993 and which go beyond the Amato law which limited the private ownership to 49% of the capital. The process has already begun with the Credito Italiano which has become a "public company".

Strategies

The changes in the banking sector are numerous: removal of exchange controls, freedom to provide services, freedom of establishment, the Basle accord and the EC directives stipulating minimum capital requirements, the tendency for more and more companies to develop operations in Europe, the opening up of Eastern Europe. Banks must develop strategies to maintain competitive advantage and market share in a changing environment.

Large (retail) banking groups are following several strategies, of which two attract much attention. The first is diversification and includes: offering a complete financial service package like the sale of insurance products ("bancassurance"), acquiring shares in industry (merchant banking), offering a wider range of various financial services (leasing, factoring, forfeiting, etc.). This strategy is often named by the German term "Allfinanz". The most notable development over the past five years has been the emergence of bancassurance. This has led to numerous agreements between banks and insurance companies: in Germany, between Allianz (Europe's prime insurer), Dresdner Bank and Bayerische Hypothekenbank, and between DBV and Commerzbank; in the United Kingdom, between Commercial Union and Midland Bank (now HSBC); in France, an entity run by Groupe des Assurances Nationales (GAN) which brings together the Crédit Industriel et Commercial (CIC) and the Banque de l'Union Européenne (BUE); another development is that a number of French banks have opened insurance companies of their own, (e.g. "Predica" established by Crédit Agricole which within few years has become a leader in the life insurance business); and, in the Netherlands, the formation of the Internationale Nederlanden Groep (ING) out of Nationale Nederlanden and the NMB-Postbank. In many cases banks take over insurers, but in some cases the reverse occurs. The number of agreements is not a good indicator, however, of the penetration of bancassurance. For instance, French banks sell 35% of France's life insurance, whereas German banks only 5% of Germany's life insurance.

The Allfinanz strategy is a difficult one. To manage insurance companies with a life and a non-life division is already difficult, let alone a holding in which banking activities also play a role. The rationale of this strategy lies primarily in economies of scope (economies of scope exist when the joint production of a certain product mix is more efficient than the separate production of each product). One of the advantages (if not the most important one) is using each others distribution channels. However, differences in cultures between typical insurance distribution channels (agents, brokers) and banking distribution channels also pose a problem; in some cases each channel could see the other as a competitor. One way out of this is to use the banks for 'confection', simple products, and the agents and brokers for more complex and tailor-made products. The Allfinanz strategy usually directs attention to domestic markets and away from e.g. a European retail market. Indeed, most of the bancassurance alliances, mergers and acquisitions are domestic ones.

The second strategy is cross-border expansion or linkage (global player). This strategy can be developed along the following lines. First, a bank could opt for direct investment in a foreign country. However, this approach is not very attractive because of legal barriers and high consumer resistance in some countries. Second, a bank could acquire a foreign one (e.g. Barclays acquired Merck Finck in Germany, Deutsche Bank acquired the Banca d'America e d'Italia and the Banca Popolare di Lecco in Italy, the Crédit Lyonnais acquired the Credito Bergamasco in Italy, the Istituto Bancario San Paolo acquired the Banco Matutes in Spain, etc.). This approach has the advantage that the bank gets physical presence and

direct control, but the costs of this approach are high, let alone the organisational difficulties of integrating companies. Third, a bank could form a strategic alliance with a foreign bank (e.g. the Royal Bank of Scotland with Banco Santander in Spain). The advantage is that banks of similar size can develop links without threatening ownership of the company. Fourth, banks could agree to have a cooperation agreement which does not involve exchanging shares or developing joint European policies, but give the customers of one bank access to the other banks. An example is the agreement (1991) between Crédit Agricole (F), Rabobank (NL), Banco Ambrosiano (I), Lloyds Bank (UK) and Bayerische Vereinsbank (D) and the alliance (1992) between the Banque Nationale de Paris (F) and the Dresdner Bank (D). Banks that want to play a role in the wholesale banking market usually find the 'global player' strategy attractive.

In the single market prospect, and also in the broader context of a European cooperation strategy, in 1990 the savings bank members of the European Savings Banks Group signed a Co-operation Charter. That is now reflected in the more than 100 national framework or bilateral cooperation agreements (without exchanging shares) and in several multilateral initiatives (e.g. EUFISERVs.c., EUFIGEST, EUFINFORM-ADVERTISE).

Information on mergers and acquisitions from the CEC shows that in 1991 the number declined for the first time. With a share of 58%, national operations constitute by far the largest segment of these activities, followed by cross-border activities within the EC; banks from non-EC countries were only involved in 14% of the operations. More than half of all operations were mergers and acquisitions of majority interests.

Besides these two strategies other options are internal consolidation and innovation in banking. The aim of internal consolidation is to amalgamate or merge domestically in order to grasp economies of scale, so that the bank gets a competitive edge internationally. Several Italian banks follow this strategy, but also the Dutch ABN-Amro is an example. Innovations in banking include electronic banking, tailor-made loans, high-yielding deposits, financial products that link mortgage, savings and insurance. Through innovations banks can gain a competitive advantage and improve market shares.

Swiss banks figure prominently in the rankings. They pursue a double strategy: consolidation on their home market, with selective international banking in order to become a global player in the wholesale market. One of the differences with other banks is the small staff of their foreign and international divisions. These divisions contribute more than proportionally to their profits, resulting in a high ratio of income to costs.

REGIONAL DISTRIBUTION

The retail market is by its nature geographically dispersed. However, in the wholesale banking market, the activities are concentrated in the leading financial centres. There is a hierarchy of centres, based on the locational attractiveness. At the most global level there are the leading centres New York, London and Tokyo. These are followed by regional centres like Paris, Frankfurt, Amsterdam (and e.g. Sydney and Hong Kong), specialist centres like Chicago and Singapore and local centres like Madrid and Stockholm and Milan.

REGULATIONS

Banking has traditionally been sheltered by national authorities. In the context of the single market programme a regulatory framework is being built for the integration of the financial sector in Europe.

The Second Banking Coordination Directive no. 89/646/EEC of 15/12/1989 on the coordination of laws, regulations and administrative provisions relating to the taking up and pursuit of the business of credit institutions, came into effect on January 1, 1993. The directive establishes the single market licence, the home country principle and the mutual recognition principle. It is sufficient for a financial institution to be authorised to operate in one EC country in order to supply or establish financial services in any other EC country. Solvency and large exposures are under control of the home country. The practical application of the home country control principle is laid down in so-called Memoranda of Understanding (MoU's) between central banks and other supervisory authorities of the Member States.

The Council Directive no. 92/30/EEC of 6/4/1992 on the supervision of credit institutions on a consolidated basis applies to financial holdings also. Financial holdings are companies - not being credit institutions according to EC law - whose principal activity consists of holding shares in credit institutions or other financial institutions. The directive also applies to mixed holdings, which can be thought of non financial companies holding shares in credit institutions and insurance companies.

The directive on monitoring and controlling large exposures of credit institutions (92/121/EEC), accepted by the Council on December 21, 1992, has the purpose to spread credit-risks of the banks in Member States without distortion of competition. Main elements are a ceiling of 25% of equity capital for large exposures applying to a single borrower or group of borrowers, and a limit of 800% of equity capital for all large exposures together, a large exposure being an exposure corresponding to at least 10% of the equity capital of the relevant bank. The directive will be in effect from January 1, 1994. Requirements on large exposures should be flexible enough to take account of the unique structure of co-operative banks. Co-operative banks have a widespread decentralisation with autonomous management practices. A further point to be mentioned is that the Commission has proposed to the Council a Regulation for a Statute for the European Co-operative Society.

The application of the home country control principle requires some harmonisation of the different deposit guarantee schemes in the Member States. In 1993 the EC Council of Ministers has approved on October 25th a common position on a proposal of directive transmitted by the Commission on June 1992. The proposal specifies minimum guarantees (ECU 20 000, but with the possibility for the Member States to use a lower amount of ECU 15 000 until the end of the century), but no maximum guarantees. The latter has been left open, i.e. the national regulations apply. The guarantee does also apply to customers (with an account) of banks with headquarters in a different Member State.

In 1993 the minimum requirements laid down the EC directives became effective. These require i.a. that total capital should be at least 8% of risk-weighted assets. Furthermore, Tier One capital should be at least 4% of assets. Whereas Tier One capital can be depicted as core capital, Tier Two capital is made up from hybrid debt-equity instruments, revaluation reserves and from provisions available to meet unexpected losses.

The objectives of these capital requirements are to limit the exploitation of higher levels of leverage thereby putting a brake on aggressive lending policies, and to secure a greater level of financial stability.

OUTLOOK

The banking landscape is changing. Challenged by liberalisation of capital markets and technological opportunities, under pressure from smaller margins and customers who expect and are aware of new products and services in the financial sector, banks need to carve themselves a position in the competitive banking market. Especially the wholesale market is in a flux.

The European retail banking market is still very much made up of the national markets. In recent years there has been a spate of mergers, acquisitions, alliances and cooperations between banks, but many of these deals involved only domestic banks. Many national champions were created but few international ones. Cross-border activity has involved more alliances and cooperations than acquisitions. Furthermore, most international acquisitions targeted smaller banks. However, economies of scale will eventually be the decisive factor, and create a pan-European retail banking market. The reduced segmentation of financial markets due to the EC directives levels the way for a regional banking market. In the mean time, ameliorating cost structures will be important to banks to gain a competitive edge over their future rivals.

In the medium term, the slow economic recovery and decreasing interest rates will show up in the performance of the banking sector. Since recovery of commercial real estate is expected to lag behind, the volume of industrial and consumer credit and bank loans will increase first, followed by mortgage loans for residential property. On the other hand, lower interest rates and rising stock markets may lower intermediation margins and reduce the availability of cheap funds. However personal saving rates have been increasing in recent years so that the supply of funds may not become a problem.

Insurance
NACE 82

The single European insurance market is still in its infancy. Although financial markets have been liberalised and financial services are internationalising, the insurance business is still segmented in different national markets. However, the third generation directives of the EC will provide the regulatory framework for the integration of insurance markets. Stimulated by these developments, insurance companies have in recent years adopted strategies to strengthen their position. This has led to bancassurance, the linkage of banks with insurers and other financial services, and to take-overs and alliances within the insurance industry itself. For the customer this meant new distribution channels and new products; for the industry it meant more intense competition and faster growth in activities. Especially life insurance has developed quickly. Its growth has outpaced that of non-life insurance and of gross domestic product in recent years.

INDUSTRY PROFILE

Description of the sector

The NACE classification defines the insurance sector as embracing all units "exclusively or primarily engaged in insurance", i.e. converting individual risks into collective risks. Compulsory social security is not included.

Insurance is thus defined in terms of the economic function of converting and mutualising risks. NACE 82 distinguishes three classes of insurance according to the type of risk:

- life insurance, where the risk covered relates to the decease of the insured person;
- non-life insurance (health, casualty, injury and accident insurance), where the risk covered is defined as everything not included in the previous category;
- composite insurance, where the risk covered comprises life and non-life risks.

Reinsurance is not regarded as a separate category: it is assigned to one of the above three classes according to the type of risk reinsured. Not all countries allow composite insurance undertakings and the creation of new ones has been banned under Community rules. The breakdown is thus confined in some instances to two classes: life and non-life insurance. In non-life insurance, a further distinction can be made regarding the different types of customers and the competitive structure of the markets. Non-life insurance can be divided into individuals ("mass risks"), small- and medium-sized enterprises and large, multinational, firms ("large risks").

Although reinsurance is not considered as a separate activity by the NACE classification, its market share is an important indicator of insurance activity. It can be evaluated in two alternative ways: the rate of accepted reinsurance and the retention rate. The rate of reinsurance accepted is calculated by dividing the premiums on reinsurance accepted by total gross premiums. This measures the share of accepted premiums and provides an indication of the significance of reinsurance accepted in the national insurance market. There are few data, however, but the rare ones indicate a low and declining rate for life insurance (3.4% on average in 1990) and a higher and more stable one for non-life insurance (12.1% on average in 1990). These ratios are very variable between countries: for non-life they range from 2.5% for Portugal to 20.2% for the UK. The retention rate expresses the percentage of total gross premiums written that is retained by the insurers; the remainder represents premiums ceded. The retention rate is very high in life insurance, where reinsurance is very rare: 93.5% for the EC on average. In non-life insurance the retention rate is about 79%.

Within the Community three countries dominate the market: the United Kingdom (74 billion ECU in 1990), Germany (71 billion ECU) and France (59 billion ECU). These three account for 74% of total operations in the EC. In southern Europe insurance markets are much smaller. Premium income corresponds to 3.5% or less of the gross domestic product, whereas in northern Europe 5% or more is common.

The density of insurance, measured by premiums per capita, differs widely in the EC. Density of insurance is relatively low in southern Europe (Spain, Portugal, Italy and Greece), and relatively high in northern Europe (United Kingdom, the Netherlands, France, Luxembourg and Germany).

Recent trends

Total gross premium income in the EC was 303 billion ECU in 1991, of which 151 billion in life insurance and 152 billion in non-life insurance. The three leading European countries in terms of both overall premium income and premium income by sector (life and non-life) are Germany, the United Kingdom and France.

The non-life insurance sector represents around 50% of European gross premium income from all sources, life insurance makes up the remaining 50%. This division has been shifting over the past years, because the life insurance sector is growing at a faster rate than the non-life sector. In 1985 the split between non-life and life was 63%/37%.

The insurance sector (life and non-life) registers a considerable growth when using gross premiums written as indicator. Between 1985 and 1990 life insurance premiums tripled, and non-life insurance premiums grew with a factor 2.5. However, when this growth is compared with GDP growth a pattern more in line with overall economic activities shows up. Premiums as percentage of GDP increased only slowly in recent years, with a dip in 1990. The UK displayed a contrary picture with decline before 1990, and a rise in 1990. The UK market, as well as the German market, is mature and the only sources of growth are general economic growth and demographic trends. In recent years the UK market suffered from the recession.

In 1991 around 800 000 people were employed in the insurance industry in the EC. This figure applies to the insurance industry in the strictest sense, excluding intermediaries (brokers and agents).

International comparison

Compared with the two other large markets, the EC insurance market is larger than that of Japan (230 billion ECU in 1991) but smaller than that of the USA (363 billion ECU in 1991), which remains the world's biggest market. In terms of market share, in 1991 the USA had 34% of the world market (thought to be some 1 055 billion ECU). whilst the EC and Japan had 29% and 22% respectively.

Each of these three markets is also very differently structured. Whereas the American market is still largely dominated by non-life insurance (some 58% of all operations), the Japanese market is very much dominated by life insurance which accounts for 73% of all business. The structure of the EC market is thus somewhere between these two patterns.

Foreign trade

In the non-life sector, some 40% of insurance companies derive more than 5% of their premium income from foreign branch activities while in the life insurance sector only 25% of companies report similar export intensity. In both sectors, the importance of foreign operations is expected to increase in the years ahead.

The share of foreign-source premium income remains modest in most EC Member States. The United Kingdom is the leading exporter of insurance services in the EC: 44% of the non-life insurance business and 16% of the life insurance business in the UK derives from non-domestic sources. Lloyds of London (an ECU 15 billion insurance market) derives two-thirds of its premium income from non-domestic sources. The UK insurance sector is traditionally oriented towards the USA and former British colonies, while its continental European business is relatively small. French insurers have also expanded activities abroad. They focus on the EC and have consistently increased their market share in all Member States (26% in 1992). Finally, Switzerland has a very strong presence in the insurance markets of continental Europe.

Although they maintain a European presence, neither US nor Japanese insurance groups seem poised to acquire a substantial share of the European insurance business in the short term. They are active to any significant degree only in the United Kingdom.

MARKET FORCES

Demand

Consumer behaviour differs radically in the life insurance and the non-life insurance markets.

As far as the life sector is concerned, the ageing of Europe's population has played a decisive role in the growth of premium income. The need for comprehensive insurance coverage increases with advancing years, especially when social security benefits relating to pensions and medical treatment appear progressively inadequate. In an effort to compensate for the erosion of state benefits, the public is turning increasingly towards life-insurance products. Greater life expectancy and a lowering of the legal retirement age have had the combined effect of increasing the average length of retirement to a period equivalent to a quarter or one fifth of human life. The legal or accepted retirement age in every European country is now between 60 and 65 years (except Denmark, with a retirement

age of 67 years). The effective retirement age now tends to be the same throughout the EC and is below the age prescribed. In addition, there is a growing propensity on the part of retirees to insure themselves more comprehensively. Incomes of elderly persons measured in units of consumption now exceed the average income of the working population in certain Member States.

Improvements in living standards emerge as an essential factor in the shifting patterns of non-life insurance consumption. The population insures not only itself but also its growing number of possessions. In this respect, it is worth noting that the demand for passenger cars in the EC increased from 3 million in 1960 to more than 12 million in 1989, amounting to a stock of 128 million passenger cars (excluding eastern Germany). There are also now 150 million homes. Non-life insurance is coming to be regarded as a commonplace product. Here, a distinction has to be made between mandatory insurance coverage on the one hand (car insurance, workplace accident insurance, and so on) and other categories of insurance which are currently marketed. It is above all in the former category that price sensitivity plays a key role.

Supply and competition

There are broadly two models of insurance markets: the Anglo-Saxon model and the continental model. The models mainly depend on the extent of regulation in the respective countries. The first model is found in the UK, Ireland and the Netherlands (and in the USA). It is characterised by less prescriptive regulation, a wider range of consumer choice and a distribution dominated by independent brokers. The second model applies elsewhere in Europe (notably Belgium, Germany, Switzerland, Italy and France) and is characterised by strict regulations, less product innovation and tied company agents as the main distribution channel.

These distinctions are not the only ones, however. Usually, companies active in the continental model adopt more conservative reserve policies, often induced by favourable tax rules. Furthermore, shareholders put more pressure on insurance companies in countries following the Anglo-Saxon model, making insurers there more concerned about short term profits.

New players have entered the insurance sector. The most significant competitive challenge is coming from the banks. The countries that pioneered "bancassurance" are the United Kingdom, France and Spain, but in other countries banks are also beginning to enter the insurance market. Entry takes the form of alliances and cross participations and acquisitions or even creation of insurance companies. In all cases, banks operate as distributors of insurance services, in order to globalise the approach of their clients. The market share of the insurance market which is influenced by bancassurance has been increasing very quickly. It is estimated that by 1995, the market share influenced by bancassurance in the individual life insurance business will be around 10%, and a further 10% only as distributors of insurance. French banks sell 35% of France's life insurance; in Germany this figure is only 5%. However, deregulation in 1994 will increase the German figure. Deutsche Bank started its own life insurance company, DB Leben, in 1989; in 1992 it ranked among Germany's top 15 life insurers.

The non-life business appeared less vulnerable to entry by bancassurance, but there have been some recent and successful developments also in this segment. At the same time, major insurance groups have adopted a symmetric strategy, also known as "assurfinance", acquiring banks and other financial institutions in order to sell banking and other financial services, in addition to their own-made insurance services.

Insurance markets are still largely national. Increasingly, though, one can speak of a European insurance market. Freedom of establishment has not only facilitated market entry on the part of domestic groups, it has also boosted the presence of foreign insurers. The advent of foreign institutions has intensified competition in national markets.

Production process

In a unified and deregulated market, tariff structures increasingly reflect management and distribution costs. Management costs and tax prepayments can result in substantially increased insurance premiums. Keeping these costs down necessarily entails the introduction and development of administrative procedures that are as cost-efficient as possible. The various approaches open to distribution include:

- salaried employees (particularly in the life sector);
- tied company agents: an intermediary between the client and the insurance company, contractually bound to, but not employed directly by, a specific company, remunerated on a commission basis;
- independent brokers: mandated by the client, without any link to an individual insurer, remunerated on a commission basis;
- direct-writing by the companies themselves;
- banks: several distribution arrangements are possible (e.g. distributed under the bank's own name or that of the insurer, sold by insurance salesmen on recommendation by bank staff, sold partly by the bank staff and partly by the insurance salesmen);
- others (e.g. retail chain stores).

The preferred strategies vary from one country to another, depending on the regulatory environment, the companies' strategy, the influence of shareholders and the concentration of companies. Brokers dominate the markets in the Anglo-Saxon model (UK and the Netherlands), whereas agents are more common in the continental model (Germany and France). Banks are a growing distribution channel. As far as operational costs are concerned, marketing and distribution costs rank immediately after policy payments in terms of size. Not surprisingly, less expensive modes of distribution are being explored, like direct writing.

INDUSTRY STRUCTURE

Companies

In 1991 there were 4 246 insurance companies in the EC, the majority of which is active in non-life insurance. However, the number of independently-controlled groups is only about 2 500. This number will continue to decline as competitive pressure to merge occurs among the small and medium-sized insurers.

The average size of insurance companies is measured as total gross premiums divided by the number of undertakings. In the EC the average size in 1990 was 66 million ECU, 115 million ECU for life insurance companies against 45 million ECU for non-life insurance companies (both including composite companies).

The leading groups in Europe typically have a total premium income in the range of 3.5 to 10 billion ECU. However, the largest group, Allianz, had a premium income of 23.8 billion ECU in 1991, followed by UAP (15.1 billion ECU), Generali (11.3 billion ECU) and Zürich (11.0 billion ECU). The ranking differs a little when one compares the companies' market capitalisation, but Allianz remains the largest insurance group.

In some European countries, the state holds equity in the major insurers. Often the state finds it difficult to disengage from the insurance sector, which has an important influence on financial markets. In France, the newly chosen government has set a reprivatisation programme in motion, with i.a. the privatisation of France's largest insurance group, UAP.

Strategies

Insurance companies react in different ways to the desegmentation of insurance and other financial markets in Europe and the process of liberalising financial markets in general. One strategic route can be subsumed under the heading of bancassurance, another under the heading of concentration and internationalisation.

Table 6: Insurance

During the past decade several factors have stimulated the process of convergence between insurance and other financial services. Among them are: financial disintermediation, internationalisation and globalisation of financial markets, the development of new communication and information technologies and more competitive pressure. The emergence of bancassurance (or 'Allfinanz' or 'financial supermarket') offers benefits to banks and insurance companies, especially in the life insurance sector. The life insurance market offers banks attractive prospects for improving the return from their distribution network. Precisely the scope of the banks' networks is also attractive for the insurer, in that a larger volume of customers can be accessed at lower cost. While bancassurance is motivated in the first place by distribution concerns, the combination also offers advantages on the product side.

The convergence of banking and insurance can be limited by regulatory restrictions, specific features of market segments and the costs of functional linkages. EC legislation has kept the distinction between banking, the securities business and insurance. As a consequence, banks and insurance companies will continue to fall under different supervisory authorities. In order to get around the general principle of specialisation, bancassurance conglomerates are created in the form of holding companies. For instance, the Dutch ING group is a holding with Nationale Nederlanden as insurance company and NMB-Postbank as bank.

While bancassurance mergers, acquisitions and alliances have mostly been organised within national markets, cross-border mergers (between insurers only and between insurers and banks) also occur. Since 1987, there have been a number of cross-border takeover actions, and more are expected. Particularly the French companies (UAP, GAN, AGF, AXA, Groupe Victoire) have been active. Cross-border expansion has taken the form of take-overs rather than joint-ventures or minority stakes. This is explained by the preference of large insurance groups to exercise management control over their foreign subsidiaries in order to integrate them into their wider strategic and financial control system. Furthermore, establishing a new network in a foreign market is extremely difficult. Insurance is a product which is sold rather than bought, and the consumer usually prefers to deal with a local/national entity that he knows and trusts.

In the near future, the market share of national insurance companies should decrease to the benefit of international operators. However, recent figures indicate that European insurance markets are less international than all the cross-border merger activity might suggest. Penetration by foreign insurers is relatively high only in smaller markets, which have been the main targets for the recent acquisition activities. Southern Europe is likely to be a main target of acquisition activities, given the degree of relative under-insurance and the low level of competitiveness of local companies. Finally, it can be expected that cross-border activity will increasingly take the form of strategic alliances, because they are less costly. Attention is turning to improving operations. Acquisitions cut into the financial resources of the acquiring company, which can be applied better towards improving operations.

REGULATIONS

The European insurance sector belongs to one of the most heavily regulated sectors of the economy in view of its strong focus on consumer protection.

As a financial institution, an insurance undertaking is submitted by national law to stringent licensing and supervision regulations, which evolved into more harmonised approaches through the adoption, at Community level, of three generations of framework directives. The third generation of insurance directives (92/49/EEC for non life insurance services and 92/96/EEC for life assurance services), entering into force on July 1994, will provide the legal background for a real internal market for insurance services.

The original specific situation of the insurance regulations in each Member State heavily influenced the structure and practices of each individual national market. In most continental countries, "material" supervision regulations imposed prior approval of all contacts and tariffs, in addition to prudential supervision of the undertakings. In Anglo-Saxon countries, a "normative" approach of supervision has been focusing primarily on prudential supervision of the undertakings.

The achievement of the internal market for insurance has been described as a "deregulation process" due to the fact that Member States have finally agreed that systematic material supervision of products and tariffs might lead to certain excessive entrance barriers for cross-border activities and that the "European passport" could be provided to the undertakings through prudential supervision of their financial situation (normative approach), in combination with some additional rules to protect consumer rights.

The harmonised prudential rules, progressively adopted at Community level, consist of three basic prudential tests, applicable by the relevant supervisory authority to each individual insurance undertaking, at least once a year, on the basis of its annual returns:

- an adequacy test on the prudent calculation of technical provisions (introduced in the 1991 directive on insurance

accounts for non-life and, within general principles, in third directive for life insurance);

- a solvency test (introduced in the first insurance directives): selected items of the own funds are added together to form the solvency margin, which is required to equal a minimum percentage of the technical provisions (or business written), in order to provide a "safety net" to the policy holders with regard to pending claims;
- a test of diversification and spread rules over the assets backing the technical provisions, in order to ensure safety, yield and liquidity of these investments (introduced in the third insurance directives).

Considering the investment policy of an insurance undertaking, the third generation of insurance directives also introduces a matching test on the currency of the assets at 80% of the corresponding liability and prohibits Member States to impose any precise investment operation to their insurance undertakings.

The policy holder's interests are also safeguarded due to the fact that:

- systematic notification of policy conditions is maintained for obligatory insurance and health cover substituting for social security schemes (Germany, the Netherlands, the United Kingdom);
- the freedom of companies to establish policy conditions without prior notification is bounded by the need to respect Member State provisions designed to protect the "general good", insofar as such provisions are proportional and do not unnecessarily obstruct cross-border activity;
- extensive disclosure obligations on life insurance services and a cooling-off period after signature of the contract.

A further very important insurance issue concerns taxes. In general, taxes are a matter for Member States. The insurance directives are therefore based on the principle of "territoriality" for indirect taxation. Certain countries maintain specific fiscal measures to encourage the consumption of life insurance products. In Germany, for example, 80% of life policies are on a tax deductible guaranteed yield basis. In other countries, life premiums are still taxable (Belgium, Italy, Portugal). In Europe as a whole, premiums paid are as a rule partially deductible from taxable income. Exceptions are Denmark and the United Kingdom. Capital gains are generally exempt, ex-

OUTLOOK

The national insurance markets of Member States will slowly evolve towards an integrated European insurance market. The institutional framework for integration is set by the third generation EC directives, which will come into force in 1994. To prepare for the internationalisation of markets companies move to strengthen their financial assets and to look for new distribution channels and products. An important strategy in this respect is that of bancassurance, the marriage of insurance with banking and other financial services.

Market concentration will increase, not only because of the expansion of bancassurance, but also because of take-over activity within the insurance sector. Within the next decade, European insurance will be dominated by a small number of large pan-European groups like Allianz, UAP and Winterthur, while a number of parallel groups continues to be active as specialists in niche markets. Banks will capture more than 10% of the life insurance sector within the EC, and be responsible for a further 10% in terms of marketing and distribution.

Financial intermediaries
NACE 831

Financial intermediaries have become more important during the last decade. The large growth in demand and supply of funds on the financial markets (fuelled by rising saving rates and privatisation), as well as the spate of new financial instruments have stimulated demand for their services. In the future, intermediaries - brokers, stock exchanges, electronic markets and (investment) banks - will compete both on international and local markets. Knowledge of the local situation combined with international presence is an important source of competitive advantage. A global presence is required of banks or securities firms operating on international markets. National and regional stock exchanges will on the one hand compete to attract business, but on the other cooperate to create an efficient European market that can compete internationally with USA and Asian markets.

INDUSTRY PROFILE

Description of the sector

Financial intermediaries provide services for participants in the financial and insurance markets. They assist in the transformation of savings into investment and in the transformation of the portfolio of existing stock of capital. Their activities consist of brokerage, advice, research, dealing in securities, market-making and organising the "marketplace". Stock exchanges, brokers, but also large parts of investment banks operate in this industry. Partly the financial intermediaries perform functions that are complementary to banking and insurance activities, partly they provide financial services in competition with banks and insurance companies. The traditional clear distinction between various categories of financial institutions, each with its own activities, has become more and more blurred.

The activities of financial intermediaries contribute to a better allocation of resources, help ensure market liquidity of stocks and enhance negotiability. In general they bring greater efficiency to the financial system by stimulating competition and reinforcing market mechanisms. In particular they increase the number of competing enterprises in the various financial markets; extend consumer and borrower choice both nationally and internationally by launching a wide variety of new financial instruments; improve market transparency by using up-to-date information technology; improve overall financial system efficiency by exploiting deregulatory measures; attract foreign borrowers and investors; introduce efficient new technological infrastructures (such as new systems for payments, information transfers, negotiation and clearing); strengthen links with other international markets; contribute to market security and stability; and boost price competitiveness.

While providing services, financial intermediaries make the market for short- and long-term securities and, to a lesser extent, loans. Short-term securities include commercial paper (CPs), certificates of deposit (CDs) and repurchase agreements (Repos). Long-term securities consist of equity and debt, with the well-known examples of stocks and bonds. In the 1980s the market for derivatives or derivative securities has grown considerably. Derivatives are futures and options in stocks and stock indexes. Nowadays, a very large fraction, estimated to be a half, of the investment banks' public activities consists of advice and assistance with (cross-border) acquisitions and mergers.

The liberalisation of capital markets since 1986 led to the emergence of sizeable financial intermediary groups. These groups operate in corporate finance, in stock markets and in collective savings management. Banks also have a strong presence in these markets.

Recent trends

During the past decade financial markets recorded an enormous growth of volume. In the 1980s the economic recovery combined with the liberalisation of capital markets produced not only a large quantitative growth, but also a spate of new financial products.

The London stock exchange is by far the largest in Europe, followed by Frankfurt and Paris. This ranking, based on shares turnover, does not change when the exchanges are ranked according to capitalisation, or the number of companies listed (excluding investment funds).

Stock market performance, measured by stock market indices, has been negative from mid-1992 to mid-1993. However, stimulated by lower interest rates and perhaps by expectations of economic recovery, the stock market indices have been rising since then.

Stock market capitalisation of the three most important European stock exchanges increased sharply. In nominal terms, capitalisation in 1992 was three to nine times as high as in 1982. Even in real terms (taking into account the development of the stock market indices) growth has been impressive. Expressed as a percentage of gross domestic product, stock market holdings more than doubled in the German and the United

Kingdom markets between 1982 and 1991. In Paris, they were multiplied by six over the same period.

On the primary markets the volume of securities issues in five major countries (UK, F, D, NL, I) amounted to 560 billion ECU in 1992, more than double the volume of 1986. This means that the slowdown after the 1987 crash has come to an end.

Difficulties in the European Exchange Rate Mechanism (ERM) affected developments on the financial markets in 1992-93. In 1992, the pound sterling was withdrawn from the ERM. A period of relative calmness followed but in 1993 the tensions in the ERM increased again. This eventually led to a widening of the fluctuation bands. This turmoil was reflected, and partly caused by, developments in the currency markets.

In the 1980s corporate finance was a booming business, spurred by large take-over bids. The early 1990s, however, are characterised by low activity according to Securities Data Co, with less emphasis on large take-over bids and more on alliances, mergers and joint-ventures. It is estimated by Goldman Sachs that in 1992 around two-thirds of the European bids took place on the continent and a third in the United Kingdom. In five years, acquisition activity has thus shifted away from the United Kingdom (still accounting for two-thirds in 1987) to the continent.

International comparison

The most important financial market in the world is the New York Stock Exchange (NYSE). In 1992, its turnover was 2.6 times larger than that of London and its capitalisation 3.8 times. The Tokyo stock exchange has a turnover of shares comparable with Germany, but its capitalisation is almost 8 times higher. This is the result of the highest price-earnings (PE) ratio of the major stock exchanges.

In 1992, US financial markets were the strongest performers in the mature and large markets. The Morgan Stanley Capital Index rose by 4.2% over the year as a whole (end 1992 compared with end 1991), notwithstanding the economic recession. The PE ratio was 22.7. Japanese stock market performance was negative, with a decline of the MSC index of 22.1%. The PE ratio at the end of 1992 was 38.9. European markets were situated between these two figures. The London market decreased by 7.2% and had a PE ratio of 19.7. The German market decreased by 11.8% and had a PE ratio of 14.3.

Foreign trade

A substantial expansion of international activities has been made possible by deregulation and the revolution in communication technology. The resulting integration has broadened the choices of market participants: issuers have increasing recourse to foreign markets to raise capital, while investors have tended to internationalise their portfolios.

In 1992 the volume of transactions in foreign shares slipped back in Frankfurt, Paris and Amsterdam, but increased in London and New York. London is clearly the international financial centre. 43% of its share turnover originates from shares of foreign companies.

Indicators of activities on the international capital markets showed a remarkable growth of non-underwritten facilities, especially Euro Commercial Paper and Medium Term Notes programmes, in 1992, a growth that continued in 1993. Furthermore, issues of international and foreign bonds grew strongly in 1992-93 (1993 estimate based on the first four months). The growth was spurred by falling interest rates in a number of major markets and the large funding requirements of governments and corporations.

MARKET FORCES

Demand

Demand for services from financial intermediaries is a result from the demand and supply of funds on the financial markets, where the intermediaries are active. Especially the securities market is important, and the position of this market towards the banking market.

The supply of capital ultimately originates from savings. When the suppliers of capital desire a specific form for their portfolio investments, like bonds, shares or a savings account, the supply of capital is translated into a demand for those specific financial assets. Since 1987 the supply of capital has grown, due to strongly rising personal saving rates in several European countries.

The demand for capital ultimately originates from investment, and translates into demand for (bank) loans, and into 'supply' of securities (shares and bonds issues). In recent years the opening up of Eastern Europe, the preparation for the Single Market and the liberalisation of capital markets all stimulated the demand for capital and the supply of financial instruments, especially securities (and in the 1980s with the emphasis on debt instruments). Difficulties in the ERM increased volatility of exchange rates and interest rates. Against this background of expanding activities and increasing risk, the demand for the services of financial intermediaries grew, their role being to ensure market liquidity and spread, as well as advice on the risks and returns of different forms of investment.

Mergers, acquisitions and management buy-outs require services from financial intermediaries in various forms. The demand for services involving management of corporate assets and liabilities has increased, above all in situations involving financial and corporate restructuring. Furthermore, the need for advice and support for cross border alliances and take-overs has grown.

Supply and competition

Financial services can be divided into two groups according to their target markets: institutional and everything else. Institutional lenders and borrowers have different needs, and international competition mainly takes place on this market. Local markets will keep their role, however, because many private persons and companies prefer the home financial market to the foreign markets for borrowing and investing. Most domestic shares will be bought by the inhabitants of the country and not by foreign investors.

On the institutional markets, stock exchanges compete with each other to hold or increase their share of trading. An exchange's competitiveness is based on its technology and procedures for trading, clearance and settlements. In Europe, the London Stock Exchange has attracted much trade of shares of non-United Kingdom companies. The other European ex-

changes have been investing heavily to boost liquidity on their local markets. Although the London Stock Exchange was forced to abandon its investment in the computerised settlements system, Taurus, in March 1993, London's SEAQ International remains an important trading centre for many leading German, French, Dutch and Swedish companies. Regulation is very important to the competition between exchanges, both as an instrument or as a constraint in making exchanges attractive. Stamp duty, capital gains taxes, brokers' fees, trading hours and the delivery-clearing systems all determine competitiveness.

Large international brokers compete with the stock exchanges, and with each other, to gain the business of the institutional investors. They try to lure customers with the advantages of one-stop shopping. Instead of deciding whether to deal net (without commission) or agency (with commission), home market or off-shore, and then splitting orders among brokers, institutions can deal with just one large broker. Through the large broker investors can benefit from superior services, for instance 24-hour trading in stocks. Brokers compete with exchanges, because they can offer a customer to deal outside the exchange and directly through the broker with another customer. Only brokers with a sufficiently large customer base can offer such a service.

Electronic markets also threaten the more traditional stock exchanges. They allow investors and intermediaries to deal anonymously on an electronic system. Participants enter bid and offer prices directly into the system and can either trade instantly against these prices, or negotiate on screen on order size. Instinet (owned by Reuters) is a leading example of an electronic market. Electronic markets blur the distinction between brokers and exchanges. Instinet works like an exchange, but is registered and acts as a broker, being a member of several stock exchanges including London, Frankfurt and Paris.

The reorganisation of stock markets has also played an important part in stimulating the supply of financial services and the competition between financial intermediaries. Its aim was improving efficiency while ensuring stability and investor protection. Key elements include: an end to brokers' monopoly and liberalisation of commissions; a reorganisation of the market for treasury bonds, with the consequent adoption of a secondary market in such stocks to reflect the needs of investors; the creation of secondary listings, allowing medium-sized businesses, unable to meet the conditions for full listing, to improve their access to capital; and the computerisation of stock markets and market operations in all European exchanges boosted market liquidity by making information more rapidly available and accurate.

Following US developments, markets for derivatives (options, futures) have been created: the EOE in Amsterdam in 1978, LIFFE and LTOM in London as of 1982, MATIF and MONEP in Paris as of 1986, and the DTB in Germany as of 1990. They were modelled on the Chicago Board Options Exchange (financial options), the Chicago Board of Trade (financial futures) and the Chicago Mercantile Exchange (index futures). The aim of these markets is to afford investors hedging opportunities against fluctuations in interest rates, exchange rates and stock market prices. They have experienced rapid growth in terms of transaction volume.

Another important development is the securitisation of debt. To the detriment of banks, instruments designed to allow the transformation of loans into negotiable debt stocks attract more and more interest. This innovation, based on experiences in the USA and the United Kingdom, is new to France and still unknown in Italy and Germany. It offers financial institutions more flexibility in managing their assets.

Production process

Trade on stock exchanges can be order-driven or quote-driven. In Europe, the first is predominant on the continent and the second in London. In quote-driven trading systems there are broker/dealers and market makers, the latter being required to take positions to ensure liquidity. Order-driven systems depend on a confrontation of buy and sell orders, brought to the market by brokers remunerated by a commission. The market-makers' (or dealers') profit or loss is the difference between the price paid and the price received for the same security. However, the same firm or individual may function, at different times, as broker or dealer.

The progressive institutionalisation of share dealing suggests a shift towards a two-tier system, with order-driven, centralised national exchanges and a quote-driven, decentralised system outside the exchanges for block trades.

An order can specify to buy or sell a stated amount of a security at the most advantageous price obtainable after the order is represented in the trading crowd (market order); to buy or sell a stated amount of a security at a specified price, or at a better price (limit order, not possible in Paris); or to buy at a price above or sell at a price below the current market (stop order, or stop loss order, possible in Amsterdam, NYSE, Zurich, and to a limited degree in Frankfurt).

The settlement is the conclusion of a securities transaction when a customer pays a broker or dealer for securities purchased or delivers securities sold and receives from the broker the proceeds of the sale. Settlement times differ between stock exchanges, and tend to become shorter, due to competition and computerisation. Settlement times range from 2 working days (domestic shares in Germany) to once a month (in Paris, but for a fee it can be settled in less than 5 days).

INDUSTRY STRUCTURE

Companies

Competitors in this industry consist of different groups. Brokers are the most important. They can be divided into large, international brokers, small, national ones and niche players. The stock exchanges themselves are engaged in the competition, positioned either as an international player or as a domestic one. Private electronic markets are becoming significant, and in some instances (Instinet) already play a

leading role. Finally, the (investment) banks are also active in this industry.

In the past decade, large groups of financial intermediaries have emerged, consisting of combinations of brokers and banks. Monitoring these groups is a difficult matter, as they engage in activities that fall under different supervisory authorities in most European countries.

Stock exchanges can be compared by their performance. Merchant banks and securities firms can be compared by for instance their engagement in take-over deals. This measure reveals the dominance of Lazard Houses (UK), Crédit Lyonnais (F, a bank), and S.G. Warburg (UK). Brokers' ranking according to a Euromoney poll shows that in the different European countries local analysts are preferred to London-based pan-European teams for recommendations on the local market. Another interesting feature is the difference in rankings between research and execution. Investment banks can easily gain a top ranking on research, to be passed by others in the ranking on execution. Part of the explanation can be found in the possible conflict of interests between the research and corporate finance departments at the same bank or firm.

Strategies

Brokers must first determine if they want to be an international, national or niche player. To be an international operator, the successful strategy seems to be to invest in building up international networks of offices. Goldman Sachs, Credit Suisse First Boston and S.G. Warburg all have invested heavily and all are leading advisers.

The privatisation trend can warrant a local strategy, coupled with an international presence. Local knowledge is needed in order to successfully bring state enterprises to the market. International presence is needed to manage the typically large size of privatised companies.

Stock exchanges will compete with each other on market-making or order-routing trading systems, and with brokers and electronic markets by offering more linkages between exchanges (and possibly by offering market-making systems, like Amsterdam has done for wholesale investors). Eventually, European stock exchanges will be linked together. This can be accomplished through the following steps. First, barriers to market-makers in different markets must be eliminated. Second, mutual recognition of nationally-organised markets. Third, a single European exchange for the main trade stocks.

A programme to standardise listing requirements, Eurolist, is already being developed. A joint project of the FIBV, it is designed to produce one set of listing details for European blue-chip stocks that will apply in all exchanges. The Euroquote plan for a European exchange has been under review since the beginning of 1991.

REGULATIONS

The objective of the Investment Services Directive (ISD) which was adopted on 10 May 1993, is to create one single market for securities firms. The ISD must be transposed into national law by 1 July 1995 and be effective from 31 December 1995. A securities firm will then need a licence only in a single Member State to operate in all Member States. Investment firms and banks will however have to respect conduct of business rules on a host Member State basis. The directive provides that banks and securities firms may become stock

exchange members in their own name in each Member State, subject to a transitional period for France, Italy and Belgium until the end of 1996, and to Greece, Spain and Portugal until the end of 1999.

Furthermore, under certain conditions a Member State is allowed to force market participants to handle securities transactions on the regulated market. The investor, however, can demand that the transaction will be executed outside the regulated markets. A Member State can then require the investor to ask permission for such a transaction. This rule is a compromise between countries with highly regulated markets and countries with less regulated markets.

Together with the Capital Adequacy Directive (CAD) of 15 March 1993, the ISD regulates the EC securities market. The CAD stipulates minimum capital requirements, as well as a minimum starting capital. The ISD stipulates that securities firms and banks need to fulfil the CAD requirements.

OUTLOOK

The role of financial intermediaries is likely to gain weight in the future, due to the increasing relative importance of securities vis-à-vis bank loans. First, several privatisation programmes are going on in e.g. France, the United Kingdom, the Netherlands, Spain, Portugal, Italy. Second, demographic trends, falling birth-rates and rising longevity imply that in the future relatively more elderly people will have to be supported. Governments will then encounter difficulties to finance the growing volume of payments in unfunded systems. To alleviate this future problem, governments now stimulate private pension plans. Besides, the growing awareness of these trends also induces the public to look out for supplements to possibly deficient state pension and health care payments in the future. This stimulates saving through institutional investors and pension funds in particular, increasing the demand for securities.

The increased exchange rate risks, due to the suspension of the EMS, will stimulate the demand for products to hedge against these risks, and therefore the demand for related services. Falling interest rates, nominal as well as real, are likely to boost the demand for equities in the short term. Finally, the expected slow economic recovery will increase activities on the financial markets.

Real estate
NACE 833, 834, 835

The European real estate sector is going through a severe downturn, which has set in after a long period of strong growth in rental and capital values. The downturn started in London and spread over the continent. Now, German cities are also affected. The recession in the property market has partly been caused by the general economic slowdown and high real interest rates, and partly by rental and capital values that have overshot. The downturn is aggravated because many investments have been largely funded by bank debt, and as a result the high real interest rates are undermining the profitability and solvency of developers and investors. The withdrawal of Swedish and Japanese investors has also worsened the situation. Falling rentals and rising vacancy rates reveal the difficulties in the market. Nevertheless, in the medium term a recovery, although modest, is expected.

INDUSTRY PROFILE

Description of the sector

The various professions active within the property sector attest the dual nature of the industry, implicit in its primary and secondary markets. Certain activities relate to primary demand and the completion of property development, whereas other relate to the functioning of the secondary market. To the first category belong builders, developers and consultants specialising in feasibility studies. Real estate agents operate on the secondary market, with their expertise in surveying and valuation of properties, and their role in sales transactions and estate management.

In addition, the property market sector may be divided in two separate compartments: Residential property and commercial property, where the latter includes offices, retail shops and factories.

Recent trends

All over Europe a spectacular expansion occurred during the past decade, which peaked in the first quarter of 1991. Since then the property sector has slumped, due to economic recession, high real interest rates and sometimes too excessively increased office rents. The office sector has been hit harder than the retail sector; values have fallen by 23%, according to the Jones Lang Wootton property index. In other than prime locations, office rentals declined between mid-1992 and mid-1993 by on average 14%, hence less than the rental in prime locations. The industrial rental prices declined about in line with the decline of the prime office rents. Prime retail rentals experienced the sharpest drop. Finally, selling prices of residential property were in 1993 on average 10 to 15% lower than in 1992.

While the trend is mainly negative everywhere, there are large differences between cities and regions. London, Stockholm and South-European cities have been hit particularly hard; in London-City the office rents for prime locations were halved in three years time. Brussels, Amsterdam and some German cities show relatively modest declines in office rents and yields. Germany seemed for a long time invulnerable to the downturn in the property markets elsewhere in Europe, but in Frankfurt and München there is now an oversupply of office space and office rents are falling. Elsewhere in Germany office rents are stable. The German property market is highly regionalised, divided between west and east, and containing several cities that sustain important markets (e.g., Düsseldorf, Hamburg).

Paris's property market also saw a sharp downturn, with office rents falling in one year by 5 to 10%, and by 20-30% since the peak; capital values declined even more. Outside Paris, however, the office rents are much more stable. In Spain and Portugal the real estate sector will get a stimulus from the liberalisation of rent controls.

Not only prices are down, but volume is also. In London-City demand for offices in 1992 was 15% lower than the year before; London-West End showed a modest increase with 2%. In Paris the demand was 25% down and even Brussels registered a decline. These developments have resulted in a vacancy rate of 6% on average in 1992, compared with 2.5% in 1989.

The severity of the downturn has been aggravated by the extent of funding by bank debt. The downturn forces banks to make heavy provisions for their portfolio, and makes them more reluctant to finance new projects and investments. This in turn depresses the property market. This chain of events has mainly occurred in the United Kingdom, France and Sweden.

International comparison

The commercial property markets in the USA are very large compared to European markets. The value of transactions in the USA is estimated at USD 1 000 billion (ECU 800 billion) a year - nearly 7.5% of GNP. New construction accounted for half of the market until recently, but the structural oversupply has made funding of new projects almost impossible, resulting in less new construction. Only regional malls are considered relatively attractive by experts, although several retail chains have problems. The office markets are still characterised by high vacancy rates, due to structural oversupply. It will take a long time, seven years or more, before supply and demand will get balanced.

The Japanese market, confronted by problems of overpopulation and over concentration of activities in certain areas, has probably reached a saturation point. Rental prices in Tokyo's Central Business District are the highest in the world, being twice as high as in London.

Foreign trade

The increase in the proportion of international investment in the property market has slowed down in the economic reces-

sion. Potential investors focus on opportunities in their home markets. The relaxation of investment controls in the late 1980s caused a surge in geographical diversification, which was not always warranted. The London and Paris markets were both stimulated between 1988 and 1990 by Japanese, German and Swedish investors. Only the German investors have remained, and they concentrate on the United Kingdom.

Japanese real estate investments overseas were estimated at ECU 1.5 billion a year in the early 1990s. At the end of the 1980s, 75% of Japanese property investments were in office blocks, commercial properties and hotels. The remaining 25% was invested in golf courses, apartments and private hotels. Total real estate investment in the EC was evenly distributed between Germany, France and the United Kingdom.

MARKET FORCES

Demand

Property demand is of course largely determined by local factors. The most important are: economic growth, replacement demand, luxury demand (upgrading) and locational preferences. Economic growth creates a need for more space for offices, shops and factories. Replacement demand is the base for demand for commercial property. Its volume is dependent on the average lifetime of real estate. Upgrading will take place in a favourable economic climate and when the existing stock of real estate is estimated to be of poor quality (which applies to the building and the location). Finally, other factors can increase the attractiveness of a particular location and create an additional demand for property

The rental market is less dependent on economic fluctuations. Unlike the sales market, it is not bound by investment logic: rental is not investment in, but consumption of real estate. Therefore, interest rates are less crucial in the rental market than in the property market.

Transfer duties are levied at the time of sale of a property. At present, France has the highest such taxes in the world with 18.2%, compared to between 6% and 12.5% in most other European countries. The United Kingdom and Germany are the exception, with transfer duties of 1% and 2%, respectively.

The level of infrastructure provision and planning also influences demand. The three regions of Greater London, the Rhine-Ruhr and Ile-de-France comprise the principal focuses of wealth of the EC. When cities are ranked according to several attraction factors Paris and London stand out ahead of others. These cities have an outstanding infrastructure and benefit from a strong presence of multinational firms.

In the commercial property market, the shift in business demographics towards the services sector increases the demand for office properties to the detriment of industrial sites. In addition, the demand for offices is becoming more sophisticated, with the development of large luxurious American-style complexes, such as the Quartier de la Défense in Paris.

The domestic property market is still a sector that appears resistant to the kind of factors noted above. In this case, other factors are at work that are sometimes less pragmatic and more personal.

Supply and competition

National and even urban markets still have distinct evolutions. However, due to the growing activities of internationally operating firms, developments in the different national or urban markets are coming more in line with each other. The market in Brussels can be called a monoculture, based on the existence of international organisations as the EC and, to a lesser extent, NATO. The German market is very regionalised and has many centres. It is also characterised by the importance of owner-users of office-space. In the French real estate market, the south will gain importance, but Paris will remain by far the most important area. The United Kingdom market, with London at the forefront, is trend setting for the developments in office space. It is, however, underpinned by a relatively weak economy. The Dutch market is stable.

Currently, there is an oversupply in the property market. The boom in Europe's property values during the 1980s stimulated construction, often funded by large amounts of bank debt. Economic slowdown and high real interest rates hit these mar-

kets hard. Many countries have seen office vacancy rates rise. Overcapacity in property has been even more pronounced to the extent that foreign investors, notably from Japan and Sweden, have pulled out: Japanese investors because of too low rates of return and Swedes because of home market problems (the slump in the Swedish property market has even undermined the Swedish banking system). Sales agents were the first to be hit by the property recession. Having been drawn in by seven years of market growth, they counted on the rapid and highly profitable turnover of property and borrowed, in some cases, up to 100% from the banks. The recession brought major losses, aggravated by the withdrawal of the banks.

The evolution was different in central business districts and outlying areas. In central business districts, the recession initially only reduced shortages and rents were stable, whereas outlying areas were hit more severely. As the recession continued, however, rents in the central business districts also dropped sharply.

The property investment market has gone through the same developments, but in a more pronounced way. Investors have preferred to postpone their activities while markets are gripped by uncertainty. The degree of speculation that has characterised the investment climate in the 1980s and the early 1990s caused a severance of the link between supply and demand, exacerbating the current recession.

Production process

Supply of offices is fed simultaneously by the arrival on the market of new buildings (60 to 65% of supply) and the recycling of older ones. Few markets have a primary sector coexisting with a secondary sector to such a degree. This secondary market allows property to be used as an investment base, as it guarantees a measure of liquidity. (This role as an investment base is more pronounced in office property than in residential property. The latter has more of a community character, and is often the subject of regulation designed to preserve its social utility. This in turn holds down yields on capital investment.) This closed-circle structure accords particular importance to the role of intermediaries. They exist to help transactions (and ensure market liquidity), performing an essential role in affording investors continuity between primary and secondary sectors. Another consequence of this special configuration is that the various players in the marketplace can either simultaneously or successively adopt opposing roles: buyer and seller, provider and consumer.

Satisfying end-user demands presupposes activity by developers, investors, financial funders and consultants. Each is in competition with the next - both over the character of the product and the means by which it is acquired, i.e., purchase, rental, or leasing. Professional competence in this sector takes a number of forms:

- Local market knowledge; the ability to put a precise value on a site and its possibilities, and to define a product suited to the needs of the end-user. This factor can only be provided by local experts, and has acted as a brake on internationalisation of the sector as a whole.
- Manpower resource deployment: this activity is an integral feature of the sector. It should be pointed out that high levels of productivity are present: consultants achieve rates of ECU 150 million per employee in the larger firms within this sector, a productivity level comparable to that recorded in heavy industry. In terms of sales, volume exceeds ECU 350 billion at the level of 300 employees and above.
- Financial expertise: the professions in the property market are closely linked to the world of finance, which explains the presence of banks in the sector. Financing of the product, besides production and sale, presupposes management.

As in every service activity, communication capacity plays a major role. The profession is able to intervene rapidly, which is a key element for success. This is seen, for example, in the auction process, where investor reaction must be immediate. In such conditions, the larger institutions, with their hierarchical structure and their prudential constraints, are at a disadvantage in the race to obtain business.

INDUSTRY STRUCTURE

Companies

Within the EC, property professionals represent a workforce of around 120 000 authorised practitioners. Most agencies are small and operate at a local level.

There are two categories within the property profession: developers who construct buildings on land that they already own with a view to their sale or rental, and intermediaries who make markets in the product and counsel those involved.

Outside the property profession two other groups play an important role on the market: firms or persons who construct buildings for own use, and the government, often an important owner of land.

There are four types of developers. First, the independent developers. They make up only a small part of the sector. Secondly, the subsidiaries of banking or financial groups. Almost all have in-house development divisions, both as a channel for the distribution of credit and as a profitable activity in itself. Thirdly, subsidiaries of public works and construction authorities. Again, the large ones all have development arms. And fourthly, institutional developers. An example is the association of around 15 insurers and bankers in the Société Française d'Investissements Immobiliers.

At the intermediary level, the approach to the market is characterised by an increasing professionalism at the level of estate agents, an increasing role for consultants and progressively national/international structure. In this context, three types of intermediaries can be identified. The first type, estate agents and administrators, are specialised in marketing and renting to end users, as opposed to developers targeting institutional investors. Consultants are the second type; their numbers and importance increase as products become more sophisticated and the sector more international. These usually take the form of small, independent practices. Their role is important because decisions on development, investment and acquisition are wholly dependent on market conditions. The third type are the market-makers who buy to resell. These are the speculators who exploit market imbalances (notably when causing undervalued purchase prices) to their own advantage. In addition, however, they also act as a buffer, mitigating the impact of major differences between supply and demand. Their ability to play this role depends on their capacity to carry a property over a period.

Strategies

One current striking characteristic is the emergence of widely divergent strategies on the part of developers. Until recently, developers tended to adopt similar strategies; they were typically small-scale and unambitious, finding it difficult to operate on an international level in such a conservative profession. The current trend, however, is towards integration of upstream and downstream activities: development-proper upstream and commercialisation downstream.

One can also identify a growing tendency to extend the range of products offered in an attempt to reduce dependence on the vagaries of a single market sector, a case in point being developers originally specialised in housing who reposition to profit from the boom in office property. Two major strategic groups of developers can thus be identified. Some have elected to diversify into complementary development activities such as administration, hotel chain management or even insurance, which do not share the cyclic nature of property development. Others have opted to remain specialised, but have diversified their product portfolio and attempted to become more international in scope.

For several years now, intermediaries have tended towards the Anglo-Saxon model of consultancy. This strategic transformation, which is accompanied by an increased presence of banks in the marketplace, has facilitated globalisation of the property market. The main consultancy offices assume the role of go-between by opening up their domestic marketplace to foreign partners. This development also admits a larger volume of transactions, regardless of the size of the market. For instance, while the office markets in London and

Paris are almost the same by volume, there may be (depending on the period in question) between ten and twenty times more transactions in London than in Paris.

As far as estate agents are concerned, the present recession in property has revealed their inadequate financial resources. Developing these resources has emerged as a priority objective, and agents are working more closely with the banks to allow the development of projects for which no immediate client has necessarily been identified.

Despite growing globalisation of the property market and the increasing sophistication of products - both of which aim towards responding increasingly to demand along the lines of the Anglo-Saxon model - consumers tend to remain more attached to traditional national models.

REGIONAL DISTRIBUTION

Most real estate activity is concentrated in northern Europe, in an area that is bounded by Paris, London and Frankfurt and includes the Brussels area, the 'Capitals Centre'. This region has more than 30% of employment in the EC (excluding the new German Länder) and more than 35% of gross value added in the EC. London and Paris house the largest volume of office space in Europe, with a total surface area of around

32 million m^2. Other European capitals typically average around 5 to 6 million m^2.

As manufacturing activity moves increasingly out of the cities, European urban development is to a considerable extent influenced by the existing infrastructure and knowledge related to market services. These historically "locked-in" advantages create a significant element of rigidity in the economic ranking of European cities. London for instance has retained its prime position for financial services because of first-mover advantages (gained thanks to the early liberalisation of markets),

and because of the depth of the supporting financial and business services.

However, the opening up of markets, political and infrastructural changes provide all challenges to established patterns. The cities best positioned to prosper in the more competitive environment are those that have attracted unique international functions and that have a critical mass of activity and infrastructure sufficient to support the presence of specialised services needed locally by other activities.

REGULATIONS

The regulatory provisions that affect the real estate profession vary widely from country to country within the EC. Generally speaking, regulatory provisions apply mainly to estate agents. Certain countries - Denmark, Spain, France and Italy - have erected major barriers to entry into the profession; elsewhere, professionals are subject to the provisions of common law.

With the exception of Greece, Portugal and Denmark, each EC jurisdiction has a professional charter. Harmonisation of regulations on a European level is still pending.

OUTLOOK

The outlook for the property sector is one of modest growth, which means that in the medium term, the current downturn will be reversed into a moderate upturn. In the medium term, growth in the real estate sector will pick up, but will not achieve the high growth rates of the 1980s. This outlook is based mainly on the anticipation of a slow recovery of general economic conditions. Moreover, growth will differ strongly between cities. A distinction has been made between: growth cities - experiencing relatively high growth rates in production and employment; declining cities - experiencing relatively low growth rates in production and employment; high productivity cities - combining high production growth with low employment growth; low productivity cities - combining low production growth with high employment growth; and stable cities, which have neither high nor low growth rates.

Growth cities have the best prospects, since demand for real estate will be supported by the need for more space given the employment growth and by the desire to upgrade given the production growth. The current situation of excess supply might, however, delay the recovery. For Paris, no recovery is expected before 1995. Declining cities - of which many are in the United Kingdom - do not have these good prospects. Furthermore, there will be marked differences between central business districts and outlying areas; for the latter, development prospects appear less promising.

The industry is represented at the EC level by: Fédération Internationale des Professions Immobilières (FIABCI). Address: 23 avenue Bosquet, F-75007 Paris; tel: (33 1) 45 50 45 49; fax: (33 1) 45 50 42 00.

Overview

Business services experienced considerable growth and development throughout the eighties. The market has been powered by greater awareness of the benefits from increased externalisation of certain activities. Furthermore, the recent slump in economic activity did not hamper business services dynamism, which exhibited outstanding employment growth in comparison to the services sector as a whole.
The sector's prospects are rosy. As customers get progressively out of the depression, the sector's performances are likely to strengthen over the coming years.

INDUSTRY PROFILE

Description of the sector

The business services sector comprises a number of heterogeneous activities engineered by specialised companies, and aimed at assisting their customers in order to increase efficiency, productivity and competitiveness. The business services sector, as classified on the basis of the function performed on the account of the client company, includes the following sub-sectors:

- management and administration services (legal services, accountancy services, management consultancy, etc.)
- production services (architecture, engineering, operational leasing, repair and maintenance, packaging, quality control, etc.)
- research-related services (market research)
- personnel-related services (vocational training, labour recruitment, supply of temporary labour, etc.)
- information and communications services (software and computer services, advanced telecommunications services, data banks, etc.)
- marketing services (advertising, direct marketing and public relations)
- operational services (industrial cleaning, security services, linguistic services, etc.)

Recent trends

The business services sector employs above 6 million persons, that is well above 5% of total EC employment.

The business services sector was among the fastest growing sectors of the economy throughout the eighties. The economic recession which hit the EC in 1991 translated only into slower growth of business services activity, an outstanding performance which illustrates the relative insensitivity of some of the business services sectors to economic downturns.

This significant growth was the result of the increasing externalisation of this type of activities, coupled with the introduction of important innovations in service management. But the major factor that generated such growth was the strong demand for these services, sustained by the expansion of economic activity.

Moreover, unfavourable market conditions have often led industrial or financial organisations to get rid of in-house services such as economic services, legal or marketing services, and to use instead professional consultants. This has occurred particularly in 1992 and 1993, when companies were in the throes of a financial turmoil. Interestingly, their dismissal from industrial or financial companies led some people to either join existing business services firms or to establish their own company. This phenomenon has counted among the factors underlying the increasing externalisation of business services.

MARKET FORCES

The business services sector has thus been relatively sheltered from the economic downturn. Despite the poor financial position of the sector's customers, the business services industry reported continued growth of employment. This outstanding performance can be explained by the need for customer companies to meet such challenges as new technologies, emerging or plummeting markets, or new regulatory environments for example. Their determination to maximise competitiveness under changing and difficult business conditions have obliged firms to increasingly externalise functions requiring new or specialised skills that they either cannot afford or do not want to acquire for their own premises.

Furthermore, the economic downturn has led a significant number of industrial and financial organisations to try and

find new outlets, new forms of production organisation or production processes, in order to get out of the turmoil. This translated into increasing demand for business services aimed at supporting their clients' activity.

INDUSTRY STRUCTURE

The business services sector is characterised by considerable fragmentation and intense competition. The sector is composed of a large network of small companies, a size which give them the flexibility, quality and specialisation necessary to perform their businesses. In activities where economies of scale are important, the companies are usually larger; overall the sector counts a limited number of large, often multinational, firms. Consulting engineering, accountancy, market research, testing, inspection, quality control and some operational services are those sub-sectors of the business services industry where larger firms (i.e. companies with more than 50 employees) can be found.

REGIONAL DISTRIBUTION

As far as marketing or research services are concerned, the location of offices does not necessarily depend upon their demand. Furthermore, the development of information technologies gives companies active in these businesses increased flexibility and freedom in the location of their offices. Consequently, these companies are often found in large urbanised areas, and particularly around the national capitals.

For operational, production, labour-related, management and administration services, it is, in contrast, a real advantage (and sometimes even mandatory) to have offices in the places where high demand is expected. For example, vocational training is typically an activity highly correlated with population distribution and economic activity. This service is consequently quite evenly spread over the Community's territory, although a bigger concentration is observed in urbanised and more industrialised areas.

A glance at the country breakdown gives evidence of the preponderance of the European major economies as the largest employers in EC's business services sector. The United Kingdom is the largest employer, with 1.7 million employees in 1991, or 28.6% of EC's employment (excluding Italy). Such figures witness the peculiar structure of the British business services sector: the largest companies operating in business services are indeed primarily British-owned. This is particularly true in the legal services sector, where, contrary to any other Member State but Netherlands, law firms in the UK employ hundreds of lawyers.

Along with these differences in the size of the workforce, there are considerable differences in market growth between Member States. These differences mainly reflect the large variety of industrial market organisation that can be observed in the different Member States. With this respect, EC's southern countries have posted more rapid expansion in the second half of the eighties than the Big Four economies, in line with the process of integration of these economies in the European Community.

OUTLOOK

In the future, quality of service will constitute a key asset for companies to increase their market positioning.

For the time being, strategic alliances and mergers and acquisitions involving companies from different Member States are not very numerous. In the future, however, an acceleration of this concentration is foreseeable, thanks to the increased integration of EC's business services practices, and to the facilitation of the movement of services by the development of international communication and information networks.

As customers of the business services sector get progressively out of the depression, the performance of the sector is likely to strengthen over the coming years, leading to a further increase in employment.

Written by: DRI Europe

Advertising and direct marketing

NACE 838

Due to the deep recession in most EC countries, the growth of expenditures in both advertising and direct marketing slowed down in 1992. Nevertheless, growth was sustained although at a much lower rate than in the buoyant 1980s. Advertising expenditure as a percentage of GNP is still much lower in the EC than in the USA, which suggests that the sector has a substantial growth potential. The importance of direct marketing in total marketing communications' activities is increasing. Direct marketing techniques are replacing direct selling by sales representatives in some cases. New telecommunication and data processing systems have added to the effectiveness and application possibilities of direct marketing. In response to these new opportunities and to the demand of their clients, advertising agencies are expanding into direct marketing activities, often by acquiring an established direct marketing agency.

INDUSTRY PROFILE

Description of the sector

Advertising and direct marketing is classified under section 838 of NACE, called advertising. The turnover of the sector is approximately 75 billion ECU in 1992. This means it is one of the most important service sectors in the EC. Advertising accounted for approximately 64% of turnover, direct marketing for 36%. Both professions have one thing in common: an ability to deliver vital information effectively. The sector is engaged in communications services that promote ideas, goods and services.

Advertising

Advertising is the persuasive process by which users for goods, services or ideas are found through paid-for communications' media. It is an image oriented support for branded products. Its aim is to give the advertised product extra value over alternate products. Advertisements should be eye-catching, because people assimilate advertising messages in the same way as other information, both consciously and unconsciously. This is the reason why advertisements are placed in the main mass media: television, radio, cinema, newspapers, magazines, periodicals, outdoor.

Direct marketing

Direct marketing is a general term to describe a wide selection of techniques, using various media, that requires a direct response from the consumer (either the individual or business to business). Direct marketing can be used to sell products directly from distributors or producers to elicit information, promote ideas and information or to elicit funds for non-profit bodies, such as charities. In most cases, it seeks a measurable response from the consumer. Direct marketing techniques have been popular for some time in America, an recent elections in the USA have proved its potential both as a means to encourage funding of parties or candidates and to stimulate voting for candidates.

The main direct marketing techniques are: direct mail (mail order catalogues, addressed and unaddressed mail); direct response advertising in the printed press, broadcasting, including teleshopping systems and other mass media (cinema, outdoor and transport); marketing by telecommunications (telephone or fax); and interactive videotext (such as the French Minitel system).

Direct mail is estimated to generate 400 billion ECU of sales within the EC. No measurement of sales has been made for other forms of direct mail, however, the increase in their use would indicate that they are effective. Because they provide the user with a measurable response rate, they are ideal for product testing and for small and medium sized businesses which cannot afford expensive distribution systems.

Recent trends

Despite recessions in most EC countries preliminary estimates for 1992 show a slow growth of the total expenditure on advertising and direct marketing since 1991. Employment in 1992 was only marginally higher than 1991.

Advertising

Advertising agencies define turnover or 'billings' in terms of the amount of money they spend with the media on their clients' behalf. Normally the gross earnings are fixed as 15% of the turnover. The mass media with the highest billings by advertising agencies are newspapers and television. Both media together hold more than two thirds of the total advertising expenditure. Television is the only sector which expanded its share of total advertising expenditure in all mass media since

EC	13 970	8 730	4 060	26 760

Source: EDMA

1990. The billings per employee and year in advertising services are between 0.4 and 1 million ECU. Employment marginally increased from 1991 to 1992. Most of the bigger agencies expanded their staff. Roughly 10% to 15% of the total workforce is self-employed. Usually they are photographers, illustrators, designers, copywriters and translators. Average wage cost are higher in advertising than in direct marketing because more specialised people are working in advertising.

Direct marketing

Direct marketing is traditionally less expensive than mass media advertising because the creative and production costs are smaller. The importance of direct marketing will also increase as its customers have access to new electronic media such as E-mail, teletext, Minitel and other telecommunication systems. Direct mail accounted for more than 52% and direct response advertising for more than 32% of the total expenditure on direct marketing

Telemarketing accounted for less than 15% of the total direct marketing expenditure in 1992, because it is the most expensive form of direct marketing. Expenditure per capita on direct marketing in 1992 was only 56% of that in advertising, however, it should be noted that direct response advertising in the mass media (broadcasting, press, etc.) is double counted (i.e. calculated for both direct marketing and for media advertising). An increasing volume of direct marketing operations is included in the advertising sector, where direct marketing is replacing more expensive salesperson promotion.

International comparison

Since 1981 the EC shortened the gap in advertising investment compared with the United States. In 1981 the EC advertising expenditure was only 50% of the USA's expenditure for advertising. Due to exchange rate variations and the recession during the eighties, the EC was able to reach 85% of the US expenditure in 1992. The largest medium in the United States in 1992 was television with a 35% share of total expenditure.

Japan saw a fourfold increase from 1981 to 1991. But in 1992 expenditures fell more than 3%. The most important mass medium is still television. In relation to the GDP, Japan has a smaller advertising expenditure than the United States and the EC.

In Europe, Germany held the first rank in total advertising expenditure in 1992, followed by the United Kingdom, France and Spain. Concerning the expenditure per person, Greece is in the top position. Second are Denmark and Portugal. It is interesting to note that the importance of the mass media

varies enormously across the EC. Magazines are the most important medium in France, newspapers in Denmark and Ireland, and television in Greece and Italy.

Within the EC, Germany has the largest direct advertising expenditure, followed by France, the United Kingdom and Italy. The ranking of direct marketing expenditure per head is led by the Netherlands and Denmark.

MARKET FORCES

Demand

Advertising

The major products advertised are consumer products of the food and non-food sectors. The most important are: alcoholic drinks, food and beverages, baby care products, cosmetics, pharmaceuticals, tobacco products, sanitary products, toiletry goods, motor vehicles and car accessories as well as financial services.

Very few large international companies run their own advertising department. Most large companies working on a national and international level use advertising agencies. Advertising also plays an important role in promoting retail outlets.

Small and medium sized enterprises often cannot afford organised advertising campaigns. Their clients are usually located in the vicinity and they often advertise by conducting direct mail campaigns. But the increase of local TV and radio stations will probably induce more local advertising campaigns by medium and small sized enterprises.

Direct marketing

Direct marketing helps promote customer loyalty and supports sales activities It is a major means of providing sales promotion to the customer. Direct marketing is also extremely popular for local enterprises, and allows local retailers, service providers and producers to contact consumers directly by means of addressed or unaddressed mail, free newspapers and local newspapers, radio, local television and cable systems or by telephone marketing. Direct marketing is designed either by advertising agencies or in-house by the advertiser. Most telephone marketing is done in-house, although use of telemarketing agencies is increasing, bringing with it a professionalism of service and effective measurement data.

In larger enterprises and smaller chain stores, direct marketing is mostly conducted on a 'do-it-yourself' basis. This means the firms are using in house specialists. Smaller enterprises hire direct marketing agencies more often. Lately, direct marketing is increasingly replacing direct personal contact with the clients and demand for direct marketing services is increasing as a result.

Supply and competition

Within the EC, no regulatory barriers to starting an advertising or direct marketing agency exist. However, newcomers face difficulties entering the market, because client loyalty is one of the most important conditions for a good cooperation. Consequently, the market is dominated by large agencies, which often have worked for their clients for more than a decade. International companies mainly choose a single agency that has local offices in various regions for all campaigns. Small or new agencies accept lower profit margins to be more competitive.

Direct marketing should benefit most from the completion of the single market. Not only should small and medium sized enterprise be able to overcome the problems of setting up outlets in the regions or countries in which they identify their potential customers, but also overhead costs in terms of labour, printing, production, fulfilment of orders and media costs (post or telephone) can be reduced by using one country as a base rather than another. Unfortunately, these benefits are often

not available in practice. Postal regulations prevent companies from choosing the cheapest country to produce in, fulfil or mail from. Data protection and other national rules have also retarded the use of the single market. Except for business to business, there is little cross-frontier direct marketing except between the United Kingdom and Ireland, and Belgium and Luxembourg.

International competition between direct marketers is determined by differences in standards and costs, especially labour costs, between the various countries. Therefore, high volume printing tends to be produced in countries with the lowest production costs. Direct mail is often mailed from countries with lower tariffs. This offers a chance to freight and courier companies to enter the delivery market because they charge a calculated price depending on their costs, and not a fixed fee for each service like the national public postal services.

Production process

Closer international relations support an increasing number of international newspapers and magazines that are targeting larger international audiences. Electronic printing methods allow simultaneous publication in several countries.

The media for direct marketing are either telecommunication channels, the printed press, broadcasting or the public postal service. Modern computer networks automate the direct marketing process and the production and dissemination of inserts, flyers, catalogues, etc.. Consumer databases help to target the potential consumers.

INDUSTRY STRUCTURE

Companies

The sector is dominated by large advertising agencies, which include direct marketing services as well. Within the EC, 15 agencies have more than 1 500 employees. All of them are working on an international level. But there are still a lot of small to medium sized enterprises that are mainly serving regional markets.

Since 1990, the list of the most important companies has not changed much. If companies expanded, this was mainly caused by acquisitions and not by organic growth. The European top 20 agencies is still headed by Euro RSCG (F) with the greatest number of employees and the greatest gross income by equity. BDDO (UK) rose from 8th to 5th place, BSB (UK) from 10 to 7 and Saatchi & Saatchi (UK) fell from 4th to 8th place between 1990 and 1992.

Strategies

Advertising agencies are increasingly expanding into direct marketing because their clients are seeking to pinpoint their targets. For these jobs, they often acquire established direct marketing agencies. Running an advertising agency is not a capital intensive business. Human capital, in the form of a marketing, creative and media experts, is the essential asset. This differs slightly from direct marketing where computer technology and other expensive technical equipment is the main asset. A desire to increase efficiency and reduce costs is also reducing the environmental impact of direct marketing.

The sector tries to lower costs through the prevention of waste and the use of recycled material. In this context, more attention is given to the timing and the targeting of direct mailing. This means mailings are only sent out if they are likely to be of interest to the recipient and not discarded right away.

REGULATIONS

Regulations affect advertising and direct marketing to an important extent. Regulations still vary from country to country. Most Member States have self-regulatory as well as regulatory standards and various forms of codes of conduct.

Since TV broadcasting has been deregulated and a lot of private channels compete for advertising clients, TV advertising has expanded enormously in some EC countries.

At present, European directives exist on misleading advertising, pharmaceuticals, baby foods and food advertising. There are also advertising-related rules on various other product sectors, often related to labelling, such as alcohol, agricultural products, footwear, household appliances, financial services. Other notable EC regulations include credit, public procurement, copyrights, broadcasting, product safety, product liability, etc.

At present, a wide variety of EC initiatives of relevance to both advertising and direct marketing are in the process of being considered. These include tobacco advertising, comparative advertising, guarantees and after-sales services, time-sharing and claims in the advertising of foods.

Direct marketing has attracted considerable attention from the EC recently and has a variety of directives of relevance presently being considered, including data protection, data protection in the telecommunications sector, distance selling, environmental packaging waste and database protection.

The EC is currently preparing a discussion (green) paper on commercial communications which is intended to take stock of both national and European regulations for all forms of marketing communications, and propose a policy for the future.

OUTLOOK

The tendency towards cooperation between advertising and direct marketing companies will positively influence the total expenditure on advertising and direct marketing. In the near future increasing competition between clients for market share will keep the turnover of advertising and direct marketing agencies on a high level. New broadcasting channels will offer new markets for the advertising business.

Direct marketing is, for the most part, data driven. New media will increase its potential. The telephone, in particular, is becoming an important means of communications for direct marketing, however its development will depend on EC regulations. A European freephone number, ISDN (Integrated Systems Digital Networks), DNIS (Dialling Number Identity System), ANI (Automatic Number Identification) and ACD (Alphabetic Call Distribution) open many new possibilities for direct marketing strategies. But, these new technologies will also increase the costs of direct marketing agencies.

Public relations
NACE 838

Today a growing number of companies, organisations, public institutions and bodies are using public relations as an efficient technique of global communications towards the public opinion in general, specific targets related to a company or its products and services and the media.
In 1992, the number of public relations agencies and public relations firms decreased while the number of consultants increased. United Kingdom had the highest public relations turnover and also the highest number of public relations consultants within the EC. Germany, in both cases, was in second place.

INDUSTRY PROFILE

Description of the sector

At the end of the second World War the public relations sector started to develop in Europe in parallel with the re-establishment of democracy in politics and in social life.

The main objective of public relations is to establish and develop appropriate relation systems between a company (or organisation), its products or services and the public or other interested parties, according to the companies' target.

A relation system handles to gain, maintain and develop public confidence and acceptance of a company, its products or services.

In order to establish this appropriate relation system, public relations use their own methodologies which refer to the entire company's communication system.

Public relations can be considered as the combination of different, but not separable, elements as the application of Human sciences to individuals, a strong behaviour ethics, the analysis of the communication channels in a global network and the knowledge of technical elements related to the interests and the needs of the public.

The key publics, which are the key issues of the public relations profession, may be listed as follows: Consumers, traders, suppliers, shareholders, company managers, company personnel, competitors, local community, government authorities or officials, public servants, public bodies, media, unions, environmental groups and so forth.

From a technical point of view a public relations practitioner should have the professional skills to handle corporate communication, community relations, internal/employees communication, consumer relations, media relations, public affairs, financial relations, environmental issues, sponsorship, product publicity, house publications and audio-visual, special events, institutional advertising and crisis management.

The number of public relations agencies and consultancy firms has considerably grown in many European countries with a reduction of the number of public relations practitioners who operated as individual consultants. This is due to the need of better facing a more sophisticated and articulated service request by the client, but also the great difficulties that public relations consultants incur by working alone at high costs for the office, the organisation, the personnel, etc.

Very often, all over Europe, the responsibility for managing public relations in a company or in a public institution is shared between in-house practitioners that are public relations officers, and outside consultants, in order to merge their respective professional skills to face different issues and publics.

Public relations professionals are divided between those who are employed by and handle the public relations programs of a company, organisation or public institution by public relations agency or consulting firm and offer their services to a variety of clients.

The jobs in the public relations sector are equally shared between women and men who are 51% and 49% respectively.

Recent trends

CERP is a professional organisation to which belong professional public relations Associations representing 17 European countries with a total of 15 789 full members who are in-house public relations practitioners or individual consultants.

According to CERP's European 1992 public relations survey, the total public relations investments in the twelve EC countries were estimated to 5.3 billion ECU while the figure amounted

to 6.2 billion ECU in 1991. This 15% decrease confirms that the recession of the economy is also affecting the service sector, as well as the public relations sector.

Considering the public relations consultancy sector only, a total of 16 333 individual consultants did their job in 1991, while in 1992 18 909 consultants resulted to serve their clients in the twelve EC countries.

Therefore more professionals are active within the public relations sector, but in the same period the total investment has been reduced with more marked reduction of consultancy fees granted to each individual.

The same investment reduction affecting the public relations sector is stronger in advertising and sponsoring all over Europe.

The above situation shows that when there is economic crisis or recession in some European countries, companies reduce communication investments in parallel with their own minor capability to develop the business in the respective market.

INDUSTRY STRUCTURE

The current situation

A common standard, accepted and applied in all European countries, considers only the turnover from consultancy fees related to a time sheet, with different level of fees according to the various positions of consultants working for a client (for instance the project coordinator, the Executive Project Head, Clients Account, Media Specialists, Executive Assistants and so forth). Therefore, in keeping with the previous criteria, the 1992 CERP survey considered the consultancy fees and not the operational costs related to the execution of a public relations program, which are not included in the public relations turnover. This aspect must be particularly stressed, as it is really different from other professional activities conducted within the communication area, such as advertising and sales promotion.

The public relations consultancy sector is made up of public relations agencies, public relations firms and individual consultants.

A public relations agency is normally a registered firm, a small company formed and managed by some consultants providing companies and organisations with full service in public relations. A public relations agency consists of a group of consultants, on average from a minimum of 3 to a maximum of 10, assisted by executive and secretarial support, handling for instance public relations services in specialised areas as media relations, public affairs, sponsorship, in-house publications and so on, but not covering the whole of the issues and publics related to the global corporate communication.

The individual consultants normally provide their professional service in two different ways:

- some of them operate on an annual contract basis for two or three clients covering a very wide part of the whole client's communication needs;
- other operate on the basis of contracts related to specific short term public relations projects referred to single issues, public and client needs.

All above considerations are today generally applicable to the twelve EC countries, even if the development of the public relations sector is not consolidated due to the different economical and social conditions and to the fact that public relations firstly started to be considered as a separate profession in some countries, as in the United Kingdom, France, Belgium, Germany, The Netherlands and Italy.

Only in the last twenty years a certain consolidation has been achieved in all the twelve countries through professional National Associations and CERP itself.

In 1992, in the EC countries, the number of the public relations agencies and public relations firms amounted to 4 016 with a 15% decrease in comparison with the 4 730 public relations agencies and firms estimated in 1991.

In the meantime, the number of consultants employed in public relations agencies and firms in 1992, increased 4% and reached then 5 680.

As far as the turnover of public relations agencies and firms is concerned, an amount of 489 million ECU was estimated for the twelve EC countries with a reduction in comparison with the 512.5 million ECU in the previous year.

The situation is improving for individual consultants, as the data showed an increase of their number and their respective fees were estimated to 1.16 billion ECU compared to the 953 million ECU in 1991.

The total consultancy fee turnover of the public relations sector was estimated to 1.46 billion ECU in 1991.

Public relations consultancy is strictly connected with the same sector directly handled by in-house practitioners and therefore it is important to note that CERP's survey evaluated 28 911

Table 3: Public relations

public relations officers working as a company or organisation employees in the twelve EC countries, with a modest increase in comparison with the 28 507 in the previous year.

A classification of the EC countries with the highest public relations turnover assigns the first place to the UK (153 million ECU), the second place to the BR Deutschland (122 million ECU), the third place to The Netherlands (54 million ECU), the fourth place to France (48 million ECU) and the fifth place to Italy (42 million ECU).

For the number of the public relations consultants, including those operating for public relations agencies, firms and individuals, the first country is the United Kingdom again (6 960), the second is BR Deutschland (4 836), the third is Italy (2 388), the fourth is France (2 033) and the fifth is The Netherlands (1 134).

Legal services
NACE 835

The advent of the European Union in 1993 has focused attention on a number of large-scale changes which are reflected on a much smaller scale within the legal professions. These trends are characterised firstly by a process of "harmonisation" or reconciliation and simplification of common elements; and secondly, by a recognition of the need to compete in a supra-jurisdictional marketplace. The process of simplification of the legal professions is occurring in both common law and civil law jurisdictions, both inside and outside of Europe. Over the past few years, international legal practice has been growing rapidly. Within Europe, the growth of economic integration and trade has strongly challenged the traditional jurisdictional restrictions that characterised legal practice. Multinational (also referred to as cross-border or trans-national) partnerships are permitted within the EU and function to varying degrees within a number of EU countries. These developments are likely to continue.

INDUSTRY PROFILE

Description of the sector

The legal services sector described within this report covers all professional staff working in the liberal legal professions within the states of the European Union. This report does not relate to lawyers undertaking legal work as employees of central or local government, the judiciary, the prosecution service or commerce and industry. This report was written primarily on the basis of statistics supplied by Eurostat supplemented by information held in the International Database of the Research and Policy Planning Unit of the Law Society of England and Wales.

The EC Directive to facilitate lawyers' effective exercise of freedom to provide services (77/249) included the following professions within its definition:

- Belgium: Avocat - Advocaat
- Denmark: Advokat
- Germany: Rechtsanwalt
- France: Avocat
- Greece: Dikigoros
- Ireland: Barrister, Solicitor
- Italy: Avvocato
- Luxembourg: Avocat-avoue
- Netherlands: Advocaat
- Portugal: Advogado
- Spain: Abogado
- United Kingdom: Barrister, Solicitor

Table 1 compiled from a number of sources shows the number of registered lawyers within the definition in EU member states and available data on the structure of their practices. The number of registered lawyers in some cases conceals those who may be registered but not currently practising as lawyers. For example in Greece, where there are an estimated 20 000 lawyers (not including notaries) - 14 000 of whom are located in Athens - the Athens bar association estimates that between a quarter and a third are not practising. In Spain, over 22 000 of the registered advocates are non-practising.

In addition to the above, the analysis in this chapter includes the work of notaries, where appropriate, whose function is principally the preparation of deeds and legal documents. Table 2 from Eurostat shows the latest estimates for the number of notaries and their practices in the European Union.

The services provided by the legal professions - described as "lawyers" within this chapter - fall within the following general categories:

- negotiation on behalf of a client;
- the preparation of legal documents;
- legal advice; and

- representation of clients before Courts, Tribunals and administrative bodies.

Within these broad categories, lawyers perform a wide variety of tasks such as:

- practising in court (civil and criminal), including preparatory advice and investigation;
- preparation and negotiation of contracts between parties;
- the purchase and sale of properties (domestic and commercial);
- company law including mergers and acquisitions;
- intellectual property law;
- consumer and social security law;
- preparation of wills and settling the estate of the deceased client;
- tax planning and investment advice;
- company formation and statutory change; and
- translations of legal documents.

It is important to note that many of these functions are also performed by legally trained professionals employed in government or commerce and industry but who fall outside our working definition of lawyer.

Recent trends

As there are no management statistics uniformly collected on the legal professions throughout the EU, it is difficult to identify with a high degree of certainty specific economic factors which have affected the providers of legal services throughout the Union.

Table 3 from Eurostat shows estimates for five European countries indicating the total gross income for legal service providers. However, gross income figures should be treated with some caution. They are at best a rough estimate of the fees paid to lawyers within a particular jurisdiction before salaries and other overheads are deducted. They are not a measure of profits or the net earnings of lawyers. They also mask a high degree of variability within jurisdictions - such as the higher overheads and costs of legal practice in urban centres like London or Paris and those of more rural practices. The figures do suggest that lawyers in Germany, Netherlands and the United Kingdom have the highest fee income, although the figures for Germany pre-date reunification.

A key factor that characterises the professions which provide legal services is that - in the absence of a distinct limit to their size (numerus clausus) - they have been growing rapidly. Figure 1 compares data from the CCBE on the numbers of registered lawyers in 1989 with figures supplied for 1993. Professional providers of legal services have increased on average by over a fifth across the EU over the last four years, with the largest individual increases in Luxembourg (from 346 avocats to 510, an increase of 32%), Portugal (30%) and Belgium (29%). In France, the 40% increase is largely attributable to the amalgamation of the legal profession of avocat with that of conseil juridique which took effect from 1 January 1992.

The advent of the European Union in 1993 as outlined in the Treaty of Maastricht has drawn attention to a chain of large-scale trends reflected on a much smaller scale within the legal professions. These trends are characterised firstly by a process of "harmonisation" or reconciliation and simplification of common elements; and secondly, by a recognition of the need to compete in a supra-jurisdictional marketplace. These two characteristics dictate a third development which is the building of international regulation to codify and structure behaviour within the new system (see Regulation section below).

The process of simplification of the legal professions is occurring in both common law and civil law jurisdictions, both inside and outside of Europe. The legal professions in England and Wales, Scotland, Germany, France, Greece and Spain have and are currently undergoing substantial structural and legislative changes. The overall effect is one of simplification and regulatory harmony. In England and Wales and in Scotland, the traditional specialisation of the profession and legal restrictions on rights of audience have been relaxed, with the first Scottish "solicitor-advocates" now beginning to practise.

Within the European member states, the question of whether the large macro-economic structural changes initiated by European institutions will or should result in a complete harmonisation of law within the European Union is one that is still

the focus of debate. However, there is clearly a growing awareness of a wider market for legal services outside traditional limits.

In Germany, reunification forced the pace of the re-orientation of the domestic legal market from a focus on small firms working within court-delimited practice limits to trans-local firms with up to 80 partners with offices in cities throughout Germany. This larger focus, in turn, has provided the basis for the internationalisation of the German legal profession: a number of the new trans-local firms have opened Brussels offices and then moved on to enter alliances and networks with other European law firms.

Another possibly important factor in relation to the provision of legal services has been the considerable shifts in policy toward the public funding of legal aid in a number of countries. Although many areas of the law and legal practice are becoming more European in character, legal aid appears to have remained primarily defined by national policy. Given the national parameters, no national government with the exception of France (whose expenditure prior to the 1992 reforms was one of the lowest in Europe) expects to increase central expenditure on legal aid. A common experience amongst a number of countries is that the State wishes to control the steady increase in legal aid expenditure, while legal professionals have indicated that the provision of legally-aided work is becoming increasingly un-economic for them to carry out. In some jurisdictions, legally-aided work accounts for up to 12% of the estimated gross income of the legal professions.

International comparison

Reliable data on the patterns of development of the United States and Japanese markets for legal services are also difficult to obtain as each state and the District of Columbia is considered to be an individual jurisdiction and there is little information available on Japanese lawyers in private practice.

However, preliminary analysis of the little comparative information available yields startling contrasts between the two legal markets. In 1986, there were 12 500 licensed lawyers in Japan with about 9 000 in active practise. The ratio of lawyers to population was about one practising lawyer to every 14 000 people. In the same year, there were approximately 650 000 lawyers in the United States, with an estimated 325 000 in practise; this was equivalent to one practising lawyer for every 700 Americans. In other words, there were about 20 times more practising lawyers in the United States than in Japan. Some of the available American figures are shown in Table 4 with examples of the contrasts in the number of lawyers per population in a number of individual jurisdictions.

One commentary noted that in Japan in the 1980's, when litigation was increasing in the United States and in parts of Europe, the use of litigation was both uncommon and on the decrease. However, lawyers in Japan play a different role than that played by lawyers in other civil and common law jurisdictions. They do not have a monopoly on the provision of legal services, although the license allows them to appear in court. Most of the top corporations in Japan have in-house legal departments staffed by non-licensed law graduates. A licensed lawyer would be retained only when a court appearance is necessary.

The output of law graduates from Japanese universities is high - between 65 000 and 70 000 a year. Approximately 30 000 to 35 000 per year sit the examination to continue their training to become advocates, judges or public prosecutors - less than 500 per year pass the examination. Thus, the number of lawyers in private practice is low.

Foreign trade

Over the past few years, international legal practice has been growing rapidly. However, it is important to note that international legal practice is numerically a minority undertaking in relation to the bulk of most legal work. As one commentator notes:

"Even in the American legal profession, generally characterised as the most aggressively competitive and internationalist, foreign branches contain fewer than 2 000 lawyers - or less than a quarter of a percent of the profession (and many of them are foreign qualified lawyers practising local law). The only country that even approaches that proportion is the United Kingdom. Elsewhere no more than a handful of firms have even the barest toehold outside their borders".

However, it seems clear that this is changing. In 1989 there were no foreign law firms in Spain; in 1991 there were nine representing three countries. This trend is all the more striking in a recessionary climate that has resulted in cut-backs on the expansionist impulses that characterised the 1980s; since 1989, there has been an estimated 25-30 % shrinkage in the number of American lawyers in London.

Within Europe, the growth of economic integration and trade has strongly challenged the traditional jurisdictional restrictions that characterised legal practice. Multinational (also referred to as cross-border or trans-national) partnerships are permitted within the EU and function to varying degrees within Belgium, France, the Netherlands, Spain, Denmark, Germany, Portugal, Ireland, and England and Wales. The mechanisms through which these practises function are numerous: delivery of occasional services in another country; becoming a fully integrated member of another jurisdiction's legal profession; establishing oneself in another jurisdiction but retaining only one's home state qualification; and through an association with other firms, groups, networks or through European Economic Interest Groupings (EEIGs).

Lawyers in the Netherlands have recently been the most overtly active in developing international links. A 1989 survey by the Netherlands Bar Association found that 85% of Dutch advocates had some arrangement - formal or informal - to

facilitate international co-operation. The firms that seem the most successful at forming international associations or offices are those that truly international in focus. As one lawyer recently noted: "Firms that open offices abroad to practice only the law of the jurisdiction from which they originate find it difficult to make money,".

MARKET FORCES

As consistent statistics across all the member states are not collected, it is difficult to fully assess the effects of market forces on and within the legal professions through the EU.

Demand

Table 5 and Table 6 from Eurostat provide crude measures of the demand for legal services by showing the number of representations before the European Court of Justice over a period of years and the estimated number of notarial acts for 1992-93, respectively. This is only a small proportion of the advocacy and legal documentation work undertaken by the legal professions within EU jurisdictions.

Table 7 from Eurostat provides an indication of the number of legal businesses in each jurisdiction in 1990 where available and the estimated turnover in millions of ECU. These figures are also difficult to compare because of the emphasis on in-house lawyers in some jurisdictions and their inclusion in the figures (e.g. in Italy and France) and not in others (e.g. Germany).

Supply and competition

Table 8 from Eurostat provides an overview of the market share of lawyers and notaries in terms of a range of legal services in five EU member states.

In Belgium, the Belgian Order of Advocates announced a "joint declaration of rapprochement" between advocates and notaries, stating that it is advisable to allow lawyers and notaries to work together, provided clients are informed of such collaboration. A survey of Belgian advocates asked them to comment on the value of co-operation with other legal professions and yielded interesting results. Although 61% of the respondents favoured collaboration with notaries, they did not feel that such co-operation was necessary. Some advocates were concerned that there would be a loss of specialisation, possible ethical conflicts, threats to the independence of the profession and to attorney-client privilege. However, analysis of the figures in Table 8 show that in some areas of law such as property and real estate and company law including mergers and acquisitions, arrangements between notaries and advocates would result in the capture of a large proportion of the market share.

In the Netherlands, partnerships between advocates and accountants had traditionally been forbidden, however local bars now allow joint partnerships between advocates and public notaries, tax advisors and patent agents. A recent decision by the advocates' professional body recommended not to expand the existing possibilities for establishing joint or multiple partnerships to other groups, specifically banning partnerships between advocates and accountants. It felt that many areas of legal practice could be endangered by allowing partnerships with those outside of the legal profession. As in the Belgian context, co-operation between legal professionals would account for a considerable share of the domestic market for legal services.

Although not featured on the table, in Germany partnerships between attorneys performing advocacy work and patent attorneys, tax consultants/auditors, and notaries are allowed in regions which permit attorneys to be notaries. The success of this arrangement is widely attributed to a common code of ethics which protects the secrets of clients with their lawyers and accountants.

However, Germany is certainly the exception as most lawyers' professional bodies have resisted any move toward formal acceptance of partnerships between lawyers and their rivals in the foreseeable future, although some commentators maintain that there is at least some "cross-fertilisation" taking place, notably between lawyers and accountants. One commentator suggests that in its desire to control the legal work generated by an increasingly global marketplace, the legal profession throughout Europe has rebuffed any formalised co-operation with accountants. Paradoxically, lawyers in Europe are trying to learn as much as they can from accounting firms: some law firms in Spain, for example, send junior lawyers to train with accountants. This has been linked to the resulting favourable position Spanish lawyers as gaining skills necessary to a new breed of European lawyers. An interesting contrast to the Spanish image is the approach of the Italian legal profession, which traditionally shunned not only co-operation with accountants, but business matters in general as a "vulgar" dilution of the proper work of the legal profession. A number of studies maintain that one result of such a stance has been to isolate Italy's lawyers in the global marketplace for legal services, as Italian lawyers are just now struggling to come to grips with the knowledge which Italian accountants have been mastering since World War II.

The legal professions are not the only ones struggling to forge a place in the European market for professional services. Arthur Andersen, one of the "big six" accounting firms, has established a legal arm in London much the same way it has in France and Germany - by associating with a newly-created law firm which will rely on Arthur Andersen as a prime source of business.

Fees and prices

The extent to which fees for legal services are regulated is not standard between different countries. There appears to be a continuum with total control of pricing and billing for legal services on the one hand (through the profession and/or the state) and complete non-regulation on the other. The one shared element appears to be the high level of control over legal fees for cases in which the State is the indirect client, i.e. for legal aid work. Many countries fit somewhere in the middle of this range, and reviews suggest that they are far from static.

However, it can be argued that civil law jurisdictions exhibit greater level of control over fees for legal services and most European Union member states have adopted and maintain more institutional mechanisms for regulating legal costs. One result of regulating legal fees is that it achieves a level of standardisation not found in jurisdictions where lawyers are free to set their own fees. Fee standardisation is of some benefit to users of legal services because it allows for some predictability of legal expenses and affords some peace of mind on the "reasonableness" of the fees charged. The great disadvantage for users is that it does not allow for competitive pricing, and possibly reduced cost of some standardised legal services, and does not necessarily reflect the amount of work actually done by the lawyer dealing with their individual case.

Price competition has some obvious implications on the cost of legal services and the cost of justice for clients. However, it is important to note, however, that the cost of the litigation process involves more than lawyers' costs. Price competition does not apply equally across all jurisdictions as some legal professionals comply with fee scales set by government or the professional bodies, while in other jurisdictions professionals set their own prices and fees. For example in Germany, it is possible to predict fees for any type of work very near the initial consultation period which defines the nature of the matter and the level of judicial activity required. In common law countries such as the United Kingdom, charging on an hourly rate is used extensively. It is sometimes used in civil law jurisdictions for international legal work.

INDUSTRY STRUCTURE

Companies and practices

There are thirty-four legal professions within the European Union arising from the unique histories and social structures of each member state. The structure of legal professions and the limits it imposes on how lawyers work - for example what legal work they can do or where they can practise - also defines at least in part, the type of legal service which lawyers provide. As one commentator notes: "there are considerable differences between countries in the extent to which legal work is concentrated on a narrow range of functions and substantive areas or broadly diversified... Representation in court is the functional core of all legal professions, at least historically, but they differ greatly in the extent to which they have diversified into counselling, drafting, and negotiating... Within the range of functions that legal professions have carved out for themselves and defended against competing occupations there are further differences in the degree to which particular lawyers specialise".

Taking the British jurisdictions as an example, the legal profession's formal specialisation and separation into solicitors and barristers may entail the use of more than one lawyer for a single legal problem. Another example is provided by countries that operate a limited geographical or local system of jurisdiction. Again such divisions of legal functions, this time based on geography as opposed to specialism, may lead to involving more than one set of lawyers for a particular case. An obvious case is that of "localisation" in Germany which prevents individual lawyers from practising outside their court-delimited jurisdiction. Before the legalisation of trans-local firms in the last year, a "correspondence system" had evolved with two or more lawyers working on a shared case in each of their jurisdictions.

There are numerus clausa controlling the number of notaries in operation in the Latin notary countries. Notaries occupy a unique position in most of the jurisdictions in Europe of being both an independent practitioner acting solely on behalf of his/her client, as well as an official of the state from which his/her notarial power to act is derived.

Table 9 from Eurostat showing the largest 15 law firms in Europe, illustrates an important point about the traditional structure of legal practises throughout the world: the large law firm is a phenomena particular to common law jurisdictions. Of the 10 largest firms in the world, there are 7 American firms and 3 British; of the 40 largest, there are 25 American firms, 10 British, 4 Australian and 1 Canadian. However, there is evidence that a direct challenge to the common law hegemony may be emerging within Europe where of the 30 largest firms, 25 firms are British and 5 are Dutch firms.

However, size is not the best indicator of the quantity or quality of the legal services provided, it is simply the only one available. In jurisdictions with relatively low population concentrations or with smaller economic centres where large firm arrangements might not be appropriate, the legal needs of the jurisdiction could be best met by smaller collections of practitioners. For example, French notaries are acknowledged as one of the most profitable legal professions in Europe, yet their numbers and size of their practices are relatively small when compared to other legal professionals. International associations, co-operation and EEIGs as described above give smaller groups of practitioners access to the international legal marketplace. However, the economic impact of such groupings compared to that of the large firms is currently invisible due to their relative informality and the lack of any means of measuring or quantifying their effects.

REGULATIONS

EC regulation

A number of EC Directives circumscribe and define the activities of legal professionals within the European context.

One of the most basic was '[t]he Council Directive to facilitate the effective exercise by lawyers of freedom to provide services' (77/249/EEC) also known as the EC Services Directive of 1977. It requires each member state to recognise lawyers from another member state for the purpose of providing occasional services. It specifically does not address the issue of the rights of establishment or the mutual recognition of qualifications. It does allow for the right of home title and encourages lawyers to abide by local codes of conduct as well as those of his/her home state. This Directive has been implemented by all the member states.

A second Directive of importance is the EC Directive 89/48 on the Mutual Recognition of Qualifications. The so-called "Diplomas Directive" provides for full integration into the legal profession of a host member state, upon that state's recognition of home state legal qualifications. Recognition can take one of two forms: the host state may require an aptitude test, or it may subject lawyers to a waiting period before becoming fully-qualified members of the host state profession. The deadline for implementation of the Directive was 1 January 1991, but all states still have not yet implemented it into national law. As of 1 January 1992, six states had implemented the Directive: Germany, Ireland, the United Kingdom, Luxembourg, Spain and France. All have opted for an aptitude test, although the practical organisation of the tests has not yet occurred in all states. Since then, some member states have introduced legislation to implement the Directive.

In Belgium, although the Directive has not yet been implemented into Belgian law, the National Order of Advocates has accepted the temporary organisation of an aptitude test pending implementation. The Brussels French Bar adopted on 21 January 1992, a resolution organising the aptitude test given once a year, in French, Dutch or German.

Implementing legislation is under preparation in Denmark. The General Council of the Danish Society of Advocates recommends a waiting period; a lawyer from another member state must work in the profession in Denmark for three years before becoming fully qualified as a lawyer in Denmark. The Council foresees few applications from lawyers of other member states, and thus sees the preparation of an aptitude test for so few applicants of little practical value. Should the recommendation of a waiting period be adopted, Denmark will be the only member state to allow applicants to become fully qualified members of the profession without passing an aptitude test.

The Directive has been fully implemented in Greece and was transposed into Greek law by a Presidential decree. The general legal machinery for the provision of aptitude tests has been specified, however the details are not yet fully developed for the administration of tests. Current laws restricting lawyers in Greece from having foreign offices are expected to be lifted in regard to offices in EU countries.

The Directive was implemented in Italy on 27 January 1992, and provides for an aptitude test. However, the practical organisation of the test has not yet been arranged.

In the Netherlands, the Directive has not yet been implemented into Dutch law, however the Dutch Order of Advocates has recommended that the government require an aptitude test. Draft legislation has been promulgated to this effect, and awaits the advice of the Council of State to the government.

The general provisions for enacting the Directive have passed into Portuguese law stating a requirement for an aptitude test. However, the additional machinery for the administration of the tests has yet to be developed.

EFTA countries have been changing their laws in anticipation of accession to the Treaty. In Finland, for example, the Act of Advocates has, from early 1993, allowed lawyers from other EFTA and EU member states (which now make up the European Economic Area) to be admitted to practice in Finland. The Finnish Bar Association plans to develop an aptitude test as a requirement for admission to the Finnish Bar.

Another important development in the regulations affecting the legal professions in Europe is the Council of the Bars and Law Societies of the European Community (CCBE) draft Directive on working in another member state under home state title. Responding to the feeling that the Services and the Diplomas Directives alone do not adequately respond to the real needs of the market for international legal services in Europe, The CCBE developed a Draft Directive on Rights of Establishment for Lawyers in 1992.

The draft Directive allows a lawyer of one member state to be established in another member state under his or her home state title, without integration into the legal profession of the host member state (which would have to be acquired under the Mutual Recognition Directive 89/48), and without necessarily having the right to perform all of the activities reserved to the lawyers of the host state. Such an agreement would allow, for example, the establishment of branch offices in other member states, or setting oneself up as a "foreign law consultant" without integrating oneself fully into the host member state's profession.

The draft Directive provides that all EC lawyers have the right to be established to practice under their home title in another member state. It provides for a registration process with the competent authority of the member state in which a lawyer wishes to practice; and it provides that lawyers must practice under the professional title of the home state, not the host state. Special areas which could be reserved for host-state lawyers include conveyancing and estate administration; there could also be requirements that lawyers appear with a host state lawyer in court. Lawyers would be subject to the disciplinary authority of the host member state, but special procedures would ensure fairness and a final right of recourse to the European Court of Justice.

The draft was agreed upon by a 10-2 majority (Spain and Luxembourg opposed). Since the CCBE obtained the required majority of member states to agree, the draft has gone to the Commission. The Commission has held meetings with member state governments throughout to ensure that all approve the draft.

The draft Directive on Establishment as proposed would greatly facilitate associations between lawyers of different member states. It will allow greater numbers of lawyers to remain established in their home member states but provide legal services on a greater than occasional basis (currently all that is permitted by the Services Directive) in another member state, without having to become qualified in the host member state's legal profession.

International regulation

To cope with the issues raised by the numerous changes brought about by the developing European market for legal services, a number of supra-jurisdictional organisations have attempted to lay down some agreed ground rules to regulate the new scope of the professions. The CCBE has been at the forefront of organisations trying to address the issues and has issued an international Code of Conduct for European Community lawyers. The code recommends approaches to the regulation of fees, how to deal with lawyers belonging to more than one bar or law society by providing a "choice of law" rule.

These provisions have been adopted by most professional bodies in Europe; where the local bar has a regulatory function, the national bar has suggested the adoption or incorporation of similar rules. On a lesser scale, the International Bar Association has been working on an international code of conduct along the lines of the CCBE provisions.

In addition, one of the key negotiating groups involved in the discussions around the General Agreement on Tariffs and Trade (GATT) has been working a parallel General Agreement on Trade in Services (GATS) covering the international provision of services such as legal work. The central aim is to liberalise services by dismantling barriers and opening markets to foreign competition. GATS would set up agreed rules to regulate international transactions to ensure that, a) the GATT principles of non-discrimination against foreign providers of services were followed; b) that established foreign firms should be treated as domestic firms; and c) that the rules are published and available to all should be applied to the provision of legal services. These provisions have yet to be fully agreed and established.

As one commentator notes: "The local and regulatory framework at world-wide, community-wide, national and local levels, must continually adapt to this [growing competition] process by facilitating the changes which are necessary while maintaining essential safeguards for professional standards and the protection of the consumer."

OUTLOOK

As comparable information on the legal professions throughout the European Union is not available, it is impossible to make any concrete forecasts as to the anticipated market for legal services.

However, it most likely that the overall trend toward the growth of the legal professions throughout Europe and the increasing internationalisation of service provision will continue. One indication of the possible new forms this trend could take is embodied in a new challenge to the previously unassailable national parameters of legal aid provision. In 1993, in response to a "written question" to the European Commission by an MEP, the European Parliament resolved to investigate the establishment of a pan-European Legal Aid Bureau. The resolution has been referred to the Legal Affairs Committee of the European Parliament. The central concept underpinning the establishment of such a body would be to ensure all EU citizens equal access to national courts.

If the trends of cross-border co-operation, simplification and the creation of pan-European organisations continue, the legal professions in each jurisdiction are likely to grow and cross-border legal activity is likely to increase. Co-operation between the providers of legal services within jurisdictions as well as between jurisdictions is likely to grow rapidly over the next few years, especially within the European market.

In addition to more co-operation, another likely result is that of more direct competition on both a national and international basis. Competition on a national scale between specialist providers of legal services within jurisdictions is likely to occur as all attempt to promote themselves within an increasingly international business context. This is likely to be circumscribed by increased competition between jurisdictions as legal service providers learn from the German experience of reunification to regard legal advice as a vital export. Already this has lead to a climate of intensifying struggle between lawyers from Europe and North America for the adoption of their systems of law as the primary system to govern commercial contracts in the new markets opening in the East.

Accountancy services
NACE 836

Accountancy services providers, like all those providing external services to businesses, experienced decreased turnover due to the general economic downturn.. The industry is dominated by several major accountancy firms: six large firms accounted for 78% of the fee income of the top 20 EC firms. There remains, however, a vast number of smaller firms providing vital, local services to small and medium sized enterprises. Despite efforts at the EC level to eliminate barriers to cross-border practice by professional accountants and accountancy firms, national differences in business and accounting practice, as well as oversight of the accountancy services industry, still prevent a truly open border situation for this sector.

INDUSTRY PROFILE

Description of the sector

"Accountancy services" is a generic description which embraces a number of services. The accountancy profession dominates most of these markets and competes with other professions on certain other markets. Consequently, there is no strict correspondence between accountancy services and the scope of practice of the accountancy profession, the latter being much wider than the former. The situation varies, however, from country to country and is still strongly affected by history. Some EC countries have a long tradition in these areas of the economy, whereas these markets are somewhat new in others.

Accounting services have long existed in Europe, but it was not until the mid 19th century that some specialists started to organise themselves on a professional basis. These developments took place in the United Kingdom which has since kept its tradition of a self regulated profession and services. As a result, the British and Irish markets are nowadays the most developed in Europe in terms of both accountancy services and the profession. Similar developments later spread through continental Europe, where the market has been organised and structured according to local traditions, with a greater use of laws and regulations.

Financial information is at the heart of accountancy services. Accurate, relevant and timely financial information has been a key success factor since the beginning of the market economy. Accountancy services have logically followed the development of the European economy, in terms of volume, variety, sophistication, etc. With the expansion of capital markets, financial information has even reached the status of a public utility. Given the many possible ways of accounting for one single economic reality, public authorities have felt it necessary to intervene in order to protect the public interest. As a result, accountancy services and the accountancy profession are heavily regulated in all EC countries, which gives a specific character to the market.

The rules and regulations governing the profession and the services it provides, have so far been developed from a national perspective in order to respond locally to national problems. It is no surprise that significant differences between the EC Member States have resulted from the process.

The range of services accountants can offer is very wide, although it can vary from country to country. It is, however, fair to state that the core activity of accountants remains centred on financial information and hence, on accountancy services. These cover mainly accounting and auditing. Accounting includes the production of financial information which involves the analysis of economic transactions, the selection of a relevant accounting treatment and some data processing or computing. Auditing consists of the expression of an objective opinion on a given set of financial information, according to a given set of standards, in order to improve the reliability of that information.

The competence developed by accountants to be able to produce, process, analyse or audit financial information can be used for other purposes, too. Hence, according to national business cultures, the activities of accountants have been expanded far beyond accountancy services. As it is, for example, not possible to produce financial statements without having properly addressed the fiscal liabilities of the enterprise, accountants have developed an expertise in the tax area. This can obviously be used outside an accountancy context. In the same way, accounting or auditing activities require a sound knowledge of the enterprise, its activities, its structures, etc. On that basis, it is easy to develop management consultancy activities, and many accountants do.

In addition to accounting and auditing, the range of services provided by accountants in most of the EC countries can be grouped into seven broad categories.

Merger audit, which consists of the expression of an objective opinion on a merger in order to guarantee fair treatment of the shareholders of all merging companies.

Contribution audit, which consists of the expression of an objective opinion on the value attributed to assets (property, inventories, trade mark, etc.) contributed by a shareholder to the capital of a company in order to guarantee a fair treatment of the other shareholders of the company.

Insolvency services consist of acting as liquidator, receiver or administrator. It may even cover advising clients on strategy before a critical or irredeemable stage is reached in its financial position.

Expert witness accountants can act as experts before most courts.

Tax advice includes tax planning or tax compliance. The former consists of advice on the application of taxation law. Tax compliance relates to the preparation and presentation of the various returns and declarations required by law, and assistance to clients in their dealings with the relevant authorities.

Investment services include advising clients on potential investments, performing financing studies or even acting as trustee.

Management consulting includes, inter alia, information technology (IT) consulting, internal control and procedures review, organisational review, etc.

This large range of services varies from country to country according to local rules and regulations. Accountants can even be prevented by law, in some countries, from offering some of these services. In France, for example, accountants cannot offer insolvency services or tax advice, except in very limited circumstances, as these activities are restricted to other professions. In other EC countries, though, accountants are leading providers of such services. As a consequence, the NACE classification of services does not correspond to the division of the market between the various professions. Therefore, only general data are so far available on turnover, number of persons employed and the number of firms of the accountancy profession, and for income of a given category of professional services offered by accountancy services.

Foreign trade

More than 35 years after the signing of the Treaty of Rome, 12 national markets still exist for accountancy services and the accountancy profession in the EC. Many factors work towards retaining the existing barriers between national markets. Four main factors work towards this reality.

- The dependence of the profession on law. Many of the activities of accountants require an extensive knowledge of law in a number of areas (accounting, tax, company law, social law, etc.). As most of these laws diverge deeply from one Member State to another, the investment necessary to bridge these differences in order to be capable to practice in another Member State remains substantial, although the professional know-how would be almost the same in a large number of cases.
- A number of services provided by accountants are supplied within a limited distance, because of the close relationship which should exist with the client. This is especially true for small and medium sized enterprise (SME) clients, which constitute the bulk of the market. Cross-border competition on these markets is very limited so far.
- The implementation of the general system of Mutual Recognition of Diplomas has not led to large movements of accountants across borders. It is estimated that only around 10 professionals benefit from the system each year. The system is indeed not designed to get rid of the existing barriers, but is rather a device helping people to establish themselves abroad despite those barriers. All initiatives taken at the EC level in the recent past have put a strong emphasis on the keeping of the current legal status quo. This is why, despite the provisions of the EC Treaty, the cross-border provision of most accountancy services and the mutual recognition of professional firms is still not possible.
- International networks of firms of accountants have long developed their own solutions. They mainly rely on locally licensed professionals to supply their services and refer the work to their corresponding members in the relevant countries, as soon as any international service is needed.

Although no figures are available on the matter, it is very likely that intra-EC trade in accountancy services remains marginal.

MARKET FORCES

Demand

Although individuals may, from time to time, use the services of accountants, the bulk of the market is accounted for by enterprises, whatever their legal form (sole practitioner, partnership or corporation) and ownership (private, public, state, etc.). Professional accountants could therefore be defined as professional advisors to the business world. The demand is potentially very wide and can be segmented according to many indicators. One is the size of a business, as the needs of sole-practitioners, SMEs and big companies are definitely not identical. Others could be the economic sector, the legal form of the business (as some legal obligations are associated with corporate forms for example), quotation on a stock exchange, etc.

As for many other markets, the scope of the demand varies with the size of the client, big multinationals requiring very

sophisticated and diversified services, and SMEs having generally more basic needs. However, it is fair to state that big companies can afford several consultants, and have strong enough internal structures to get each service from the best specialist in the area. On the contrary, SMEs appreciate that the same consultant, in whom they have "invested", can provide them with a large range of services to limit both costs and waste of time. In small firms, for example, it is frequent that the professional accountant be the sole external advisor to management.

Legal requirements oblige many companies to have their annual financial statements audited. A properly approved auditor or firm of auditors must state whether the financial statements they have audited give a "true and fair view" of the results of the company's activities and its financial position, and whether accounts comply with the relevant legal provisions.

The purpose of the independent external audit is to lend credibility to financial information, thereby enhancing the effectiveness of economic decisions made on the basis of it. In addition, many companies and other entities not subject to the statutory audit requirements voluntarily request contractual audits, in view of the benefits that accrue from this service. Finally, there is growing demand for audit-related services, which involve the issuance of special-purpose reports and opinions on the application of certain defined procedures.

In the past, many small companies, self-employed people and other small businesses were unable to do any of their own accounting and bookkeeping and therefore depended on the services of accountants. However, because computer hardware and accountancy software programmes have fallen so much in price, nearly every business can afford the investment required. Nonetheless, many businesses continue to use accountancy service firms in order to make better use of their own resources and to have access to specialist expertise.

Another source of demand can be the public authorities. Courts allocate insolvency work and require expert services; governments require audits and evaluations should they decide to privatise State owned businesses. With the development of the so called "social economy", a market has recently emerged in the non-profit making organisations as their requirements tend to get closer to those of the rest of the economy.

Supply and competition

In order to offer certain accountancy services, it is often a legal requirement that the provider holds a professional qualification and belongs to a recognised accountancy body. This is especially the case for statutory audit, which can only be performed by a properly qualified and approved professional. For the other activities of the accountancy profession, the requirements in that respect vary from country to country, some imposing conditions similar to statutory audit. In any

case, all the professional titles of the members of the main professional bodies in the EC are protected.

The process of qualifying as a professional accountant is a long one, requiring both theoretical knowledge and practical experience. The entire process can last from six to seven years, or even up to ten or fifteen years in some countries. Many of those working in lower positions in accountancy firms are doing so to gain the practical experience necessary to qualify as a professional accountant. Most people working in the accountancy services sector are not professional accountants. They include support staff and technical staff as well as trainee accountants.

The accountancy profession is mainly practised through collective entities in almost all EC countries. Only Italy still prevents the use of such entities by liberal professions, and even in that Member State, professional associations without legal personality are very popular in the accountancy profession.

Production process

IT has already been integrated in accountancy services for a long time. However, some further developments can be expected in that respect in the near future. EDIFICAS is the latest initiative of the accountancy profession which intends to tailor EDI (electronic data interchange) to accounting and auditing needs. Although accountancy services are not technology driven, these evolutions, which should help accounting data circulate more rapidly and accurately, will impact on the way the services will be supplied within a few years.

Given that professional standards have long existed in the sector, ISO 9000 has not yet had any real impact on accountancy services. Things are developing, however, and the British profession recently took steps towards its implementation on a voluntary basis. It is too early, though, to state whether this will constitute a precedent for the other Member States.

INDUSTRY STRUCTURE

Companies

Supply segmentation almost parallels that of demand. The most visible part of the profession is the big international firms, which attract much public attention, the most famous being the so called "Big 6".

These firms mainly serve the big national and international companies in each EC country as they do all around the world. One of their major features is indeed to be able to provide the same services with the same quality wherever their client is located. These big firms dominate the market of large quoted companies, banks and insurance companies.

As well known as these big firms may be, the bulk of the accountancy profession is made up of small and medium sized firms which are often better suited to serve the many SMEs of each Member State. Altogether, these smaller firms cover the same range of services, although each firm separately may supply a more limited range of services to its clients.

Unlike the 1980s, the beginning of the 1990s has not witnessed any more mega-mergers at the top end of the sector. Small and medium sized firms in the EC are currently developing regional networks to gain national or even international coverage. That evolution follows the trend set by a number of enterprises which use the internal market to expand their activities abroad.

The general economic slowdown affects the accountancy sector as all others. Pressure on fees is growing, and the growth rate of the profession's turnover, which in the past has averaged 10 % in most EC Member States, now barely shadows inflation.

Strategies

The structure of the accountancy profession in the EC is very contrasted, and one can find a different national model in almost each country. The existence of independent professional bodies or institutes is actually the only common feature. These bodies have either been established by the profession itself as in the United Kingdom or the Netherlands, or created by law as in France or Belgium, or combine structures of both origins as in Germany or Spain. However, even in those countries where the profession took the lead, governments have become more and more involved in the regulation of the profession over the recent past, partly as a result of implementing EC directives.

The profession is generally structured with several tiers corresponding to the segmentation of demand in terms of sophistication of services. The differences between the various tiers is a matter of: level of education, measured in terms of university education, practical experience, etc.; the scope of practice, the less qualified members of the profession having, in principle, more limited rights to practice; ethics, the code of conduct of some bodies being looser or less stringent than others; and international recognition, as some international professional bodies like FEE only have first tier members, etc.

There are, however, some exceptions to the several tiers rule. In France, Greece and Luxembourg, to a lesser extent, although several professional bodies exist, they all belong to the first tier. In these countries it is consequently not possible to get a less sophisticated service from a less qualified professional, at least for the many regulated activities restricted to accountants.

In addition to the ordinary functions of any professional body, the accountancy bodies are heavily involved at the national and international level in the development of accounting standards or reporting standards, of auditing standards and other standards on professional activities and finally of ethical codes. They have an important role to play in overseeing their members.

The structure of the profession has been rather stable over the years. Any evolution is rare but may be significant given its potential impact on the market (on the supply side at least). The implementation of the Eight Company Law Directive and the mutual recognition directive (see regulation section) has had a major influence on the structure of the profession in a number of countries like Germany, Spain, Italy, etc. Over the last year, two countries, Greece and the Netherlands, have seen dramatic evolutions in that respect. In Greece, the former state agency charged with statutory audit, SOL, has been replaced from 1 May 1993 by an independent institute, SOE, modelled on the professional bodies of the other Member States. As a result, statutory audit is now supplied in Greece on a market basis by auditors independent from the state. In the Netherlands, the second tier profession acquired with the law implementing the 8th directive the right to practice statutory audit.

In the EC, approximately 300 000 persons are members of the professional organisations belonging to the Fédération des Experts Comptables Européens (FEE). About one-third of these persons work in the accountancy services sector. Most of the remaining 200 000 members of professional bodies represented in FEE, are employed as accountants in industry, commerce, education and the public sector. Obviously, the size of the profession in one country does not mirror the size of its economy. This derives from the conception of the profession in countries like the United Kingdom, Ireland, the Netherlands, Italy, etc., where all those having the relevant educational profile are permitted to be members of professional bodies, be they in practice, in industry, retired, or whatever. Belgium, France, Germany or Greece, restrict the membership of the professional organisations only to those in public practice. The membership of the institute is then associated with a given function, and no longer with a certain education.

REGIONAL DISTRIBUTION

As the provision of accountancy services usually requires a degree of geographical proximity to clients, the regional distribution of accountancy services providers throughout the EC closely mirrors the regional distribution of economic activity. However, special concentrations can be noted in major financial and administrative centres. Another determining factor is the scope of practice permitted to the profession, with a relatively greater concentration of providers in those Member States with a broad-scope profession.

ENVIRONMENT

There is a clear and definite growth in the importance given to environmental accounting and auditing. The number of companies disclosing environmental information in their annual reports is growing although the information is in most cases limited to qualitative information with no assessment of the financial impact. Companies in a number of countries are moving in the direction of producing "greener" financial statements; however, the development of an accounting and management reporting framework which specifically deals with environmental issues is some way off. The environmental audit requires knowledge and experience which go beyond that of a financial auditor. The financial auditor does have a role to play in this field, but only as part of a multi-disciplinary team of experts. The accountancy profession, with its considerable experience in carrying out financial audits and in reporting the results of such work, may provide the starting point for the creation of a new form of profession comprised of individuals from different professional backgrounds.

REGULATIONS

Accounting and auditing services are highly regulated in the EC. Regulations are both numerous and complex and vary from one country to another, despite the attempts made at EC level to bring them closer together. These regulations fall into two main categories: regulation of the services themselves including rules governing the manner in which the services should be provided and regulation of the accountancy profession and its members working in this sector.

Regulation of services

Many of the services provided by the accountancy profession have been regulated for a long time in most European countries, often in different ways. These services include statutory audit, accounting, public sector audit, contribution audit, insolvency practice, etc. National regulations define the type of work to be carried out, when, under which conditions and by whom.

Statutory audit is the only service provided by the accountancy profession which is regulated in all EC countries in the same way. It is also the only service which has been subject to specific EC directives. As a result, all companies above certain minimum thresholds must now prepare and file financial statements audited by an independent expert. All the other services have, until now, kept their own national specifities. Certain services are regulated in some countries, but not in others; some services are reserved to one profession in certain countries but are shared between several professions in other countries, or even forbidden to the accountancy profession in others. Consequently, the range of services provided by the profession varies significantly within the EC as does the degree of competition which exists in each of these markets between the accountancy profession and other professions.

Regulation of the profession

In addition to the services it provides, the accountancy profession itself has been regulated for a long time in European countries. Because the economies of the Member States developed in different ways, the regulation of the profession differs from one country to another. The degree of self-regulation, which historically has been very significant in the profession in many countries, has decreased in the recent past, mostly as a result of the implementation of EC directives.

In a majority of Member States, the profession has been created and organised by law or by public authorities. Even in those countries where the profession has been privately organised, it enjoys official recognition by the State, which entitles its members to carry out regulated activities. Regulation, be it

Table 5: Accountancy services

public or private, applies to a number of areas such as the definition of professional titles, protection of the titles, membership requirements, minimum levels of education and training, continuing education, ethical standards or codes of conduct, technical standards, additional licensing requirements for specialised areas of practice, rules for establishment of professional firms, etc.

In the EC, only limited attempts have been made to harmonise these rules. This has resulted in the Eighth Company Law directive on "the approval of persons responsible for carrying out statutory audits of accounting documents". The directive established minimum education and training or requirements for statutory auditors, be they individuals or firms. However, Member States remained free to impose more demanding requirements, and many did.

Another directive applying to the accountancy profession is the First Mutual Recognition directive which, when implemented, allows professionals from other Member States to seek recognition of their qualifications so as to be able to carry out regulated activities without having to re-qualify. In the case of the accountancy profession, Member States can require applicants to pass an aptitude test on local laws and ethical requirements. Although such a regime previously existed in some countries such as Belgium, France, Ireland, Luxembourg and the United Kingdom, it is new for others. This new system should have come into force early in 1991, but its implementation has been delayed in a number of countries. However, it is already obvious that it will not generate significant flows of accountants across EC internal borders. Despite making it easier for professional accountants to establish themselves abroad, differences remain between national laws and regulations with which accountants must be familiar. These differences will continue to restrict the free movement of accountants within the EC.

OUTLOOK

Growth of the accountancy services market is dependent on the general economy's health, and the current downturn is affecting the accountancy profession as all others. However, the shape of the economy does not seem to be the main challenge accountants face at the moment, as it is very likely that their activities will sooner or later resume with double digit growth.

The recent wave of financial scandals, and the litigation which followed, have had an effect on the whole profession. Some now question its credibility. Even if one can argue that accountants are easy scapegoats for business failures at a time of economic recession, the challenges ahead of the profession now include, in addition to the increased financial pressure resulting from the huge claims made against its biggest members, the evolution of laws and regulations that may limit its freedom to act, and the strengthening of its public standing. Considerable work on these issues has already started, both inside and outside the profession, and will no doubt lead to a satisfactory response.

The industry is represented at the EC level by: Fédération des Experts Comptables Européens (FEE). Address: Rue de la Loi 83, B-1040 Brussels; tel: (32 2) 231 0555; fax: (32 2) 231 1112.

Market research
NACE 839.1

The EC accounts for 40% of the world market for market research. Four of the top ten world market research companies have their headquarters in the EC. 53% of all EC market research is bought by manufacturers, 12% by the public sector and 11% by the service sector; 67% of research is for consumer products and services. The market research sector employs nearly than 24 900 permanent employees and over 76 000 interviewers as well as freelance researchers and other self-employed consultants and sub-contractors.

INDUSTRY PROFILE

Description of the sector

Marketing research is covered by NACE category 839.1 and is distinct from management consultancy. Market research analyses the markets for products and services of all kinds and provides a channel of communication between consumers and the product or service supplier with a flow of information on what people want and why they want it. It is used by decision makers to:

- identify and define opportunitics, threats, competition and emerging concerns
- initiate, modify and evaluate marketing activity
- improve understanding of marketing processes

Marketing research enhances economic efficiency by enabling companies and other organisations to provide the goods and services that customers want, by investigating their needs, attitudes and behaviour. This helps companies avoid wasting resources in developing unwanted products and services, or communicating the benefits of their goods and services inadequately. Marketing research provides the information required to address these issues, designs the method for collecting information, manages and implements the data collection process, analyses the results and communicates the findings with recommendations for action. For instance in recent years, marketing research has highlighted to both manufacturers and governments increasing public concern about protecting the environment and associated health issues.

As an activity based firmly on the application of aspects of scientific method such as hypothesis generation and testing, experimental design and the use of statistical and sampling methods, market research combines many elements of academic rigor with the characteristics of both a profession and a key sector of the business service industry.

In 1992, the market for market research amounted to 2.516 billion ECU in the EC. This total includes research conducted by research institutes but excludes in-house research by companies, advertising agencies or governmental and academic bodies and work by consultants. In 1992, Germany had the largest marketing research expenditure in the EC of 637 million ECU (25%), ahead of France at 571 million ECU (23%) and the United Kingdom at 565 million ECU (22%). Italy was in fourth place with 290 million ECU (12%), followed by Spain at 148 million ECU (6%) and the Netherlands with 144 million ECU (6%) in sixth place.

If market research expenditure is compared with population, Gross Domestic Product and advertising expenditure in 1992, the significance of market research in France, the United Kingdom and the Netherlands is apparent as well as its more limited use in Italy, Spain and Portugal.

Recent trends

Rapid growth in market research since the 1950s was interrupted by the economic recession triggered by the oil crises

of the 1970s. While hard figures are difficult to produce (particularly since the distinction between marketing research/information, marketing consultancies and related disciplines is increasingly blurred), the 1980s saw an annual real growth in excess of 10% with particularly strong growth in South Europe, albeit from a low base. Since 1989, growth in marketing research expenditures has slowed considerably because of the worldwide recession. Nevertheless the market research industry has outperformed the advertising business in this recessionary period and grew by 6% in both 1991 and 1992 in the EC.

International comparison

As shown in Table 1, the EC market research market of 2.516 billion ECU accounted for 40% of the total world market for market research in 1992. The USA accounted for 36% (2226 million ECU) and Japan for 8% (713 million ECU). The 1992 EC growth rate of 6% compares to 3% in the USA and 3% in Japan but when estimates are based on local currencies the picture looks somewhat different with the USA showing a growth rate of 8% and Japan a growth rate of 2%.

Many US major corporations have disbanded or downsized their market research departments in the past few years and this trend has also been observed in other countries. This has given research institutes the opportunity to develop new and often closer forms of relationship with clients whilst the client also benefits in a switch from a fixed to a variable cost. In Japan, client marketing management rather than research companies tends to collect marketing information, and there is greater integration of survey based data with other market information sources such as dealer visits and interviews, store

observation and personal contact with customers at retail outlets. This may account for the lower total turnover quoted for Japan.

Foreign trade

In 1992, 84% of market research conducted in the EC was commissioned by domestic clients. The proportion of international research grew from 10% in 1990 and preceding years, to 14% in 1991 and 16% in 1992. Foreign clients are particularly important for Germany, Belgium, Italy, Greece and Luxembourg. Of total European research expenditure in 1992, 8% went on multi-country survey research where an institute in one country coordinates studies and subcontracts fieldwork abroad. United Kingdom research institutes handled about 40% of such work with French institutes handling 20% and Italy 14%.

MARKET FORCES

Demand

Traditionally, manufacturers of consumer packaged goods were the main buyers and users of market research and this remains the case with 53% of research within the EC being conducted for manufacturers. In recent years however, a broader range of business and non-commercial organisations have used market research to aid their planning, decision making and policy formation. The public sector is a significant client with 12% and research is becoming more important in providing feedback to governments, both local and national, about public reactions to policies implemented or planned. Taking 11% of research spent, service industries are also important and growing clients and hospitals, banks and airlines are amongst those who use market research results to improve

the quality of their services. Advertising agencies (7%), wholesalers/retailers (4%), other research organisations (5%) and other clients account for the rest. In the EC, approximately 65% of the total expenditure stems from research for consumer products/services while the non-consumer studies (including business-to-business and government research) amount to 35%.

There have been considerable changes in the information needs and priorities of marketing companies. A key factor is the globalisation/regionalisation of many businesses and their branded properties with an increasing number of major companies now being run on a European basis, rather than as separate national units. This increased demand for market information resulting from client companies addressing the Single Market is strengthened by the growth in pan-European media and underlines the need to remove statistical barriers created by different national definitions to improve the comparability of survey findings. Clients are demanding that research companies have a wider geographic spread of resources but also a strong local presence and perspective so the national insight is not lost in the global picture.

Another change is the growth of profitable new markets in South East Asia and the emergence of markets in East and Central Europe. In the short term, demand for market research in East and Central Europe will only grow gradually because of the high cost of studies and the lack of expertise but as the demand for market research relates to the productive investment rate, the potential demand is significant in the long term. The growth of demand will also depend on variables such as qualification standards, and will be strongest in countries where the labour force is highly qualified. Business opportunities for market research are increasingly apparent with studies made by public institutions and a number of cooperation agreements between EC and East and Central European private companies.

Another change is that top management increasingly views brands as a company's key asset. A greater emphasis on building and maintaining strong brands has a major influence on the types of market research in demand as companies strive to understand brand elasticity and the measurement of brand relationships, positioning and brand equity.

Changes in technology, growth in the information industry, diversification of life-styles and proliferation of media has made marketing research ever more necessary to monitor changes in the market place. However, increased computer power, the advent of scanner data and the associated area of single-source information has meant a greater detail and frequency of reporting which has produced a sense of data overload amongst many users. This has led to an increased need amongst marketing management for researchers to provide diagnostic, interpretive and predictive services and specialisation and expertise in the client's business sector. It also implies that clients will demand an on-going strategic counselling relationship rather than one characterised only by a string of projects.

Growing areas are research into customer satisfaction, branding and corporate image and research for the business to business, finance, retail, utility and legal sectors- sectors that have only recently started using market research systematically. Studies suggest that expenditure on most types of market research is likely to increase rather than decline over the next five years. This will be markedly so in the case of main areas of research activity such as usership and attitude studies, product testing, advertising and concept development and evaluation, and advertising campaign tracking, particularly with the proliferation of different types of media, new publications and TV stations.

Supply and competition

With the diversification of sources for marketing data, companies will have smaller marketing research departments, if they have one at all and it will be increasingly necessary for researchers to provide an interpretative service to help marketers understand the implications of data for marketing strategy. This trend is already evident with an increasing number of researchers acting as consultants to companies.

There is considerable cost and price variation among the EC countries, largely reflecting differences in salaries and social costs. For instance, freelance and part-time interviewers in France and certain other countries are eligible for benefits and large social costs for employers include income tax and social security contributions as well as holiday entitlements, redundancy pay and pension provision. In other countries they are employed on a very different basis which affects pricing and competitiveness.

Other factors in pricing include the degree of competition in the local market, the enhanced efficiency that comes with greater experience in certain types of research, the mix of research and data collection methods and geographic dispersion of populations.

In an E.S.O.M.A.R. survey designed to discover how research prices vary from one country to another, research institutes were sent detailed specifications for six different surveys and asked to state what price they would quote to a client for carrying out each of these six studies. Averaging across all six projects, France and Italy emerged as the most expensive countries and Belgium, Greece and Portugal as the cheapest. In 1991 the rank order in terms of average research costs from the most to the least expensive was as follows: France, Italy, Germany, Ireland, United Kingdom., Denmark, Spain, The Netherlands, Belgium, and Greece with Portugal the least expensive. Research prices in Germany and Denmark were relatively much less expensive in comparison with three years before. These are relative changes and they should not be taken to mean that research prices in Germany and Denmark had necessarily fallen in absolute terms.

Recent developments in exchange rates of various EC countries will also have made the prices of certain countries such as the United Kingdom increasingly competitive and Germany more expensive.

The structure of the market research industry is remarkably similar across the Member States. Generally, the market can be split into three parts:

- Media market measurement.
- Audit shops or scanning (the analysis of consumption from computerised tickets shops).
- Specialised market research by multinational research companies and local unaffiliated companies. They include specialised quantitative research, ad hoc research and qualitative research.

Ad hoc and continuous research have traditionally accounted for about two thirds and one third of global research expenditures respectively. Continuous research, involving audits and panels for market and media measurement, has always demanded higher investment than ad hoc research.

However, over the past decade, more EC research companies in the ad hoc sector have begun to emulate US. research firms in the standardising and branding of research products. This, too, involves investment, although typically in the time of first-rate research technologists and innovators. Significant investment in designing, testing and validating new research techniques, and subsequent marketing investment in communicating the benefits of these techniques to customers is only possible if the costs can be amortised by the application of the same techniques across many countries and over time.

In the continuous research sector, the advent of scanners in stores and homes that record product purchase, peoplemeters recording television viewing, growing computer power, and single-source data services have added further to the high technology and investment that characterise this sector of the research business. Data thus derived, as well as from other sources, increasingly from part of database management information systems (decision support systems) - a further significant investment. Computer-aided interviewing especially by telephone (CATI) has involved the commitment of substantial sums to the installation of facilities typically comprising 20 to 100 telephone booths with appropriate telecommunication and computing equipment.

These costs, and the protection afforded to the research suppliers by time series data, have created entry barriers that have led to a limited number of very large players. Corporate guidelines for research buyers worldwide for preferred research suppliers or techniques and a demand for increasingly sophisticated international coordination of research projects have all led to a concentration of ownership, the formation of international research chains or networks of national agencies.

Table 7: Market research
Number of research organizations in EC member countries, 1992 (1)

	1992	1992/91 (% change)
Belgique/België	30	3.4
Danmark	15	15.4
BR Deutschland	105	6.1
Hellas	18	0.0
España	38	26.7
France	77	0.0

Italia	75	0.0
Luxembourg	3	50.0
Nederland	42	0.0
Portugal	9	0.0
United Kingdom	117	2.6
EC total	534	3.9

(1) The figures refer to the numbers of research organisations with a full listing in the ESOMAR 1993 Directory which reflects the market situation in the year 1992; comparison has been made with the listings in the 1992 Directory (1991 market situation).
Source: ESOMAR Directory 1993

Parallel to this has been the emergence of more specialist research companies dedicated to CATI omnibus services, advertising tracking and research into particular business sectors, for instance pharmaceuticals or automobiles. Larger research businesses have also broken down into separate operating divisions or subsidiaries focusing on specific areas of market information need or research techniques. Clients can now choose among a wide spread of suppliers from large full-service research companies to specialist research boutiques and consultants.

Market research has always been highly competitive and subject to intense price pressure with very few entry barriers to ad hoc research. Recession exacerbates this tendency with a growing number of research professionals leaving research institutes or client corporations to set up their own consulting businesses.

An estimated total of 24.870 people are employed in the EC market research industry with about a further 76.000 as freelance interviewers. Over the past year, several countries have seen a fall in numbers of permanent employees, for instance Germany and the United Kingdom. mainly because of automation and downsizing for greater efficiency.

External competition is emerging with other business services firms also offering marketing and management information including management consultants, accounting firms and database marketing organisations.

Production process

Research methods can be divided into ad hoc and continuous research and qualitative and quantitative research. In 1992, 55% of research was ad hoc and 45% was continuous research (30% on panel research, 5% on omnibus research and 10% on other continuous research). About 85% of research expenditure in the EC is derived from quantitative research, 10% from qualitative research with the balance coming from desk research and secondary activities.

Data collection methods in quantitative research are divided between mail survey, telephone and face-to face interviewing. Despite the higher costs involved, face-to-face studies continue to account for the majority of quantitative research expenditure in the EC: 30% compared to 12% telephone studies and 5%

Table 8: Market research
Top 10 market research companies in the EC, 1992

Research Company	EC market research turnover (1) (million ECU)	EC countries with office (incl. associates)	Current ownership/Acquired/ Merged with
1. A.C. Nielsen	399	11	Dun & Bradstreet, USA (acquired 1984)
2. IMS	188 (2)	11	Dun & Bradstreet, USA (acquired 1988)
3. GfK	164 (2)	10	Public Company, D (ex public association)

mail studies. Smaller countries with a highly developed infrastructure tend to make more use of telephone studies (21% of all research expenditure in Denmark) compared to South European countries where, for example, they account for only 2% of total research expenditure in Greece, 4% in Portugal and 8% in Spain. The proportion of telephone studies is rising because of cheaper costs, higher telephone penetration and problems associated with some inner city areas. For qualitative research, group discussions account for the majority of the research expenditure in EC (approximately 5% of total research expenditure) compared to 4% for in-depth interviews, with variations among countries depending on socio-economic factors.

A major problem for the research industry is falling response rates caused by a range of reasons. People now have minimal time available with work, family and social commitments and do not have the time or motivation to respond to interviews without monetary incentives. Rising crime levels in urban areas and a distrust of being approached by strangers also affect response rates. There is also growing concern about invasion of privacy and about what happens to personal information given during an interview and who has access to it thereafter. This is particularly the case when respondents have difficulty in distinguishing between a sales call and a research project.

INDUSTRY STRUCTURE

Companies

There are well over 1500 market research companies and consultancies in the EC, including the headquarters of several of the world's largest. Four of the top 10 world market research companies including two of the world's three major market research chains (networks of independent companies) have their headquarters in Europe. Although there are a number of major players in the EC, the industry is, nevertheless, characterised by considerable fragmentation and intense competition. Barriers to entry are low except in the high tech/high investment areas of market and media measurement (around 35% of total market research expenditure). Many of the major research organisations are represented within the E.S.O.M.A.R. membership.

Pre-tax margins have historically been modest (an average of around 5 to 6% on turnover for ad hoc research organisations) though perhaps a little higher in recent years. Substantially higher margins are earned by research companies with multiclient services and a contractual customer base.

As can be seen from Table 8, the US-owned A.C. Nielsen Company, which mainly provides store audit data on a regular and continuous basis, is by far the largest operating research organisation in the EC and has been so for many years. IMS, specialising in pharmaceutical research, is the second largest company. Both these organisations are owned by Dun & Bradstreet Group (USA).

The German GfK Group is the third largest research company in the EC and the largest EC-owned company. The French Sofrès/Cecodis Group is fourth with the EC-based Research International Group ranking fifth. Among the top ten EC research organisations there are four based in the UK, two in Germany, two in France and two in the USA.

Strategies

Several companies have restructured their services to survive in the rapidly changing market. A number of mergers and acquisitions have taken place, often as part of the creation of major marketing services corporations. One effect of this development has been to reduce the level of American ownership of EC research businesses. Another effect has been to increase industry concentration and to produce seven major research holding companies in the EC.

Parallel to this is the growth in automatisation and technological developments evidenced by innovations such as television audience meters and scanners developed by the largest research chains. This trend and the growth of international research chains, have made it possible for buyers to go to one head office to commission a research project in many countries or several regions. A variant on this is the licensing in other countries of particular research techniques or brands. This is practised most commonly by American research firms which license elsewhere their techniques in advertising pretesting, simulated test market, brand position and customer satisfaction/service quality.

The other major structural change process is horizontal specialisation. Increasingly, market research organisations throughout the EC are setting up specialist divisions or operating subsidiaries that concentrate on key business sectors (e.g. media, health care, automotive, travel, finance) or research specialisations/problem areas (e.g. qualitative, advertising, customer care).

The rapidly growing interest in international research has also led some research suppliers into setting up multi-country syndicated services on a regional or global basis.

Vertical integration has always been a feature of the European market research industries. All but the smallest companies have combined a client service function with a data handling facility (data collection, preparation, processing and printing). However, there are signs that this vertical integration is beginning to be questioned by some companies, especially where personal interviewing fieldwork is concerned. The US. market for instance has long been characterised by an ownership separation of research companies from fieldwork suppliers.

The client-research company relationship is likely to be affected by growing Total Quality Management (TQM) and Service Quality demands and the associated measurement needs. Many companies are adopting TQM and cultivating service quality and so research organisations must also expect to do the same to offer consistently high and reliable quality in their services.

REGIONAL DISTRIBUTION

The 1993, E.S.O.M.A.R. study on the size of the research industry in 1992 showed an 6% growth in the size of the market within the EC from 2364 million ECU in 1991 to 2516 million ECU in 1992 (ignoring inflation). The prominence of Germany can be attributed only partially to relatively strong growth in this market since the fall in the United Kingdom. exchange rate has undermined the monetary value of equally strong growth in the United Kingdom. Together, the three major countries continue to account for over two thirds of the EC market research turnover.

Whilst the definition and collection of this information is gradually improving over the years, detailed trend data is not yet available. Thus whilst all EC markets show an increase in the monetary value of their market research turnover on the previous year, this does not take inflation into account and so may or may not represent real growth. Of the three major countries with quotations in local currency show that Germany and the United Kingdom both had healthy growth rates of 10% for 1992, where France shows slower growth at only 3%. This represents an improvement on 1991 for the United Kingdom which had only moderate growth and France which remained static. The Netherlands continued its relatively high growth rate of 12% whilst smaller growth rates for 1992 are shown in Italy (7%) and Denmark (4%) compared to 10% to 11% growth in 1991. The Spanish market growth of 7% in 1991 slowed down to 4% in 1992.

When a market reaches a certain stage of maturity, an equilibrium is established, in which continuous research captures about one third of total expenditure. Other regular services (e.g. advertising tracking, quality of service monitoring) add a further semi-contractual sector, partly substituting for ad hoc studies and partly reflecting overall growth in the information market. Other geographic variations stem from broader economic and marketing influences. In smaller countries, less research on new product development is undertaken as the major R & D activities and corporate headquarters are located elsewhere. This leads to more research involving the screening of concepts, products or communications approaches that have been developed and more thoroughly researched in the larger EC markets.

Market research tends to be relatively less widely used in those countries where the emphasis is more on industrial products. There have been different patterns in the post-war evolution of markets and of marketing. Restrictions on television advertising (and hence, related research) in a number of countries have also contributed to this differential use of market research across the Community as have the varying levels of retail trade concentration (broadly, more concentration in the North than in the South).

REGULATIONS

Market research is like many service industries dependent on self-regulation. For instance, the ICC/E.S.O.M.A.R. International Code of Marketing and Social Practice is applied by all E.S.O.M.A.R. members and the national marketing research societies and societies in all the 12 EC Member States. This Code guarantees the respondent's anonymity and specifies responsibilities towards respondents. the rights of respondents, relations with the general public, the mutual responsibilities of clients and researchers, and reporting standards. The Code is particularly relevant in the light of the EC Directive on privacy of personal data. For the time being, such restrictions based on the protection of personal data vary from one EC Member State to another, without preventing marketing research in recognition of the fact that it deals with aggregated and anonymised data and not personalised data.

Another Directive which can also have an effect on the industry, in particular telephone research, is the proposed Directive for the protection of personal data in the context of

Table 9: Market research

digital telecommunications networks in particular ISDN (Integrated System Digital Network) and digital mobile networks.

The proposed EC Directive on Temporary Employment will affect most free-lance interviewers and ultimately will drive up market research prices. At the moment, legislation on social security and benefits varies widely among EC member states.

Other restrictions which vary from country to country can affect the right to conduct and publish public opinion polls, particularly in the run-up to an election. Although political opinion-polling constitutes only about 2% of the entire market research industry and actual pre-election polling less than 0.3%, it naturally attracts a lot of media and public attention.

OUTLOOK

The adoption of TQM by many major corporations brings the need for measurement to monitor its degrees of success, both initially and over a period of time. This will involve behavioural measures of business control monitors in efficiency and quality, satisfaction studies amongst internal as well as external customers, the effectiveness of their communication and studies amongst personnel. Apart from major corporations in the commercial sector, research companies will increasingly be working with central and local government, including education, health and crime prevention services.

Another trend will be the enhancement of tracking services with a demand for more multi-country tracking on a comparable basis, more emphasis on various types of brand equity measurement, and a wider scope for tracking studies including business control monitors, advertising effectiveness, business efficiency and environmental and other issues of public concern.

Downsizing has already been seen in the USA and the United Kingdom and will be a continuing trend because of recessionary pressures. In Europe, a major change will be the move towards pan-European data collection where the region is treated as an entity. One-stop data collection through integrated European data handling companies will move the research industry further along the road of international research co-ordination and steps in this direction have already been taken with computer assisted telephone interviewing.

The outlook for the marketing research is good provided that proposed European legislation takes into account the needs of legitimate marketing research. Furthermore, the marketing research industry will need to ensure that it can convert to being predictive rather than reactive, and that services continue to develop from providers of techniques and data to on-going strategies for management in industry and service.

Management consultancy
NACE 839.1

New technologies and market globalisation have strongly pushed demand for management consultancy services in the 1980s. The current economic slowdown has placed the industry in a difficult situation. Many companies have cut-back very significantly in external services directly affecting management consultancy firms. Turnover of the sector has fallen in 1992 compared to 1991. Many firms have stepped out of the market completely, also causing employment in the industry to fall rapidly.

INDUSTRY PROFILE

Description of the sector

Management consulting consists of providing information, advice and expertise on a whole range of specialised management functions in an independent, objective manner. Services are performed by specialised personnel with considerable experience in the specific branches in which they work. Consultants include people with backgrounds in banking, computing, economics, general management, accounting, law, management communications, management planning, marketing and sales, market research, personnel selection, quality assurance and control, stock markets and technology transfer.

Management consulting is a diverse industry comprising very diverse subsidiary business services including: corporate strategy and development of organisations; administrative and financial systems; management of human resources (including recruitment of executives and temporary management staff); management of production and services (including technology, organisation support management, research and development and quality control); marketing and corporate advertising and promotion; information and management technologies and systems; project management; and economic and environmental impact studies. The most relevant sector of management consulting is information technology. This service is very similar to the computer-based management schemes developed by computer software houses. Management consultancy firms are increasingly involved in helping companies develop information technology and apply computer tools.

Management consultancy services also often overlap with other services. A main area of overlap is contract research, particularly ad hoc market studies which often form part of strategic analysis projects. Accountancy companies offer management consultancy services in the European market and many US firms are among the major suppliers of this service.

This overlap occurs, to a lesser extent, with consulting engineering firms concerning production or computer-based production, organisational support, project and programme management and also economic and environmental impact studies.

(1) Figures for EC cover members of FEACO
Source: FEACO

Figures in this monograph are taken from an EC-wide study carried out by EAG, as well as figures from FEACO (Federation of European Consulting Associations): members of these groups account for between 40% and 70% of the activities of the sector.

Recent trends

Total EC turnover (10 FEACO members) reached 4 185 million ECU in 1992; nevertheless other sources (EAG) estimate that the total market for management consultancy in Western Europe (including, but not restricted to the EC) is worth about 6.4 billion ECU in early 1993 prices.

Germany, United Kingdom and France were the countries with the highest 1992 revenues among the EC members, with 2 053, 1 012 and 455 million ECU, respectively. In 1992, the country with highest number of consultants was Germany with 9 000, followed by the United Kingdom and France with 6 321 and 3 175, respectively. At the same time, Belgium was the country with largest turnover per consultant, 167 000 ECU, followed by the United Kingdom and Germany with 160 000 and 156 000 ECU, respectively.

The field of activity that has been accounting for the largest segment of the industry is information technologies. In 1992, the average EC turnover in this field represented 25% of the total turnover of the industry. Denmark and United Kingdom

showed the highest percentages of activity in this field compared to the other fields in the industry, with 46% and 40%, respectively.

The second largest field of activity was corporate strategy and organisational structure, reaching an average of 21.5% of total EC turnover in the industry. The highest percentage of turnover in this field of activity, 33%, occurred in Germany; Denmark had the second highest with 23%.

MARKET FORCES

Demand

Specific factors such as technology development and market globalisation have introduced a higher level of complexity in entrepreneurial and economic activities. Therefore, demand for expertise and advice has increased since the early 1980's (with slowdowns due to the general economic crisis).

Private industry is the main user of management consultancy according to FEACO. Private industry accounts for more than 60% of its member's commissions. The private business services sector accounts for roughly 20% to 25%, and trade between 5% and 10%. The public sector is very small (civil, services, public authorities and governments) although the importance of public authorities as buyers of management consulting services is higher on average in France and the Netherlands. There is also a growing demand for consultancy by certain public services (in particular, health, education and transport).

The development and introduction of information and management systems remains the main area of activity. Strategy definition is a very commonplace management consultancy activity. An important part of strategy studies recently have focused on the single European market. Others concern strategies for developing business in the East European countries, or the wider global market.

Management consultancy revenues from intra-EC cross-border activity approximately doubled over the period 1986-1991.

For some specialised markets, experts from outside of the EC might be used. Exports, varying 5% to 25% according to country, are mainly to developing nations.

Three trends are predominant within the management consultancy sector: (1) recourse to management consultancy is becoming increasingly common practice, at least among companies with more than 500 employees; (2) the use of strategy or systems consultancy is becoming increasingly recognised as an intangible/strategic corporate investment; and (3) consultants who formerly intervened from time to time concerning improvements of performance and productivity are being used to promote quality and the optimisation of resources in all corporate functions: key factors in finding the competitive edge.

The break-up of the Soviet Union has had an important effect on the development of East European business consultancy. These include political risk studies, industry infrastructures analyses, legal system assessment, investment analyses and market analysis. A smaller market exists for consultants to work directly for East European authorities. These public authorities demand advice and expertise to establish foundations or to consolidate their new market economies. The former East Germany currently provides over 15% of the turnover of German consultancy firms. To a large extent, this growth has compensated for cutbacks in consultancy assignments in markets such as the United Kingdom. A number of West European firms have established "test" offices in, or sent consultants to, Eastern Europe, mainly Hungary, Poland, CSFR and Russia. Consultancies based in Northern Europe tend to be far more active in the region than those based in Southern Europe. The Anglo-American consultancies associated with multinational accountancy practices tend to dominate.

Supply and competition

The majority of management consultancy in the EC is carried out by local consultants. Foreign companies often use the services of EC based consultants to provide them with information rather than hiring consultants from their own locality.

Table 3: Management consultancy

Source: FEACO

There are no formal regulations that directly constrain cross-border activity. Following the study of the industry carried out by EAG for the European Commission, the most important constraint on the growth of cross-border activity is the client attitudes. These attitudes range from the desire to have local knowledge and understanding to "xenophobia". During the survey for the above mentioned study, industry representatives stated the preference of the public sector for either national or truly multinational consultancies, both of which have local offices. This leaves medium sized consultancies based in other countries at a competitive disadvantage. A second important constraint for cross-border activity, is low fee rates in certain markets (especially Eastern Europe).

INDUSTRY STRUCTURE

Companies

There are five broad categories of consultancies within the industry; high level strategy consultants (usually US in origin), EC multinationals (often developed from accountancy practices), large information technology system groups, consortia and nationally based consultancies. The development of consortia or EC networks appears to be growing, partly because they require lower levels of investment than the establishment of branch offices, while allowing the partners to compete against the multinationals. There is a fairly high level of concentration in the industry with the top 20 firms accounting for at least 50% of total revenues, most of these large firms are also audit companies. There are, however, thousands of independent practitioners, or partnerships of specialist consultants which means that the industry is "polarised" between the large and the small players. Large practices are growing more quickly than medium-sized ones. Some medium size, nationally based consultancies, have expressed concern over this polarisation.

In the top auditing consultancy practices, KPMG (NL), Price Waterhouse (USA) and Arthur Andersen (USA) in particular, have strengthened their market positions by developing management consultancy services.

Strategies

The EC integration process as well as market globalisation have given priority among the industry, in many cases, to establish cross-border strategies. Current cross-border strategies can be grouped under three headings; export, association (via network or consortium) and establishment. The export strategy is recognised by most consultancies as limited since some local representation is usually important. The growth of associate networks and consortiums however, is an important phenomenon, specially among medium sized national firms that are trying to cope with the competition from large firms and networks. Associate networks or consortia may ultimately retard cross-border strategies since such associations are based on referred rather than exported business. The third

Source: FEACO

heading, establishment of a branch offices in a host country, is generally regarded as having to be staffed largely by nationals.

Medium-sized, and especially large firms, are increasingly offering multidisciplinary services to gain competitiveness.

REGULATIONS

There are no regulations specifically affecting management consultancy or regulating the type of persons engaged in the profession. There is also no requirement for consultants to be a member of any professional association. In fact, the EC market is currently open to all consultants wishing to work internationally. The only force stopping non-EC consultants from carrying out assignments in Europe would be their failure to gain travel visas.

The legal/regulatory framework is one of self-regulation via a number of national industry associations, membership of which is voluntary. Harmonisation of the standards, certification or codes of conduct applied by these associations is being examined by the FEACO and the International Council of Management Consulting Institutes (ICMCI). However, a harmonised international system of accreditation had not yet been developed, and in practice, there is little mutual recognition between the national associations.

Qualification and certification procedures are being developed in France, the United Kingdom, the Netherlands, Denmark and Italy. The attempts to comply with international standards (ISO) confirm the way in which the industry is maturing.

OUTLOOK

Since mid-1990, market growth has weakened, reflecting the economic downturn. However, the development of market economies in East European countries, following the virtual collapse of communism, will present further opportunity for new growth. The management consultancy companies already involved in meeting East European demand may grow by up to 200% between 1991 and 1994 (based on data on EAG report). Development in the East European countries will need to be largely supported by international finance from developed market economies before more EC consultants will be affordable to developing businesses in those countries. The slowing down of demand and the maturity of the EC sector in the medium-term should lead to more competition and possibly further mergers and alliances between the major consultancies.

Owing to the nature of this service sector, it is very difficult to predict growth rate values for the next five year period. A great deal of management consultancy is ad hoc and often cannot be planned for until firm contracts are made. There are plenty contradictory moves in the sector. Many management consultancy practices have been increasing staff levels in the third quarter of 1992; this comes from more than just optimism. Most already have a clear idea of what lies ahead of them in the next year. Some clients that have retained consultants for a range of management services, including financial auditing, have written management consultancy into their budgets.

Among industry members, there is moderate optimism regarding increases in sales in the next 2-5 years. A survey developed by EAG for the Commission stated that 39.2% of the management consultancies companies interviewed think that sales will increase in a range of 5-10% over the next 2-5 years.

The sectors with largest expected growth are: manufacturing, human resources, project management and information technology. Corporate strategy will experienced a lower rate of growth than in previous years, nevertheless, it will still have, together with information technology, the largest growth over the next 2-5 years. The industry believes that future growth will be mainly driven by the public sector demand rather than private sector demand.

Revenues in the industry will increase in 1993 and 1994, mainly as a result of a higher EC private demand and exponential growth in the East European countries.

Personnel hiring will probably show steady increases. However, the number of non-EC personnel in the industry who are located in EC member states is expected to decline up to 1994.

The earlier mentioned forecasts were made in early 1993 and were the only existing and reliable forecasts. Based on a later evaluation of the general economy, P&G believes the prospects for the industry are slightly more pessimistic than those stated in EAG report. Growth in sales for 1993 will probably reach 0.5%; at the same time, expected annual growth will be around 1.8% from 1994 to 1997.

Architects
NACE 837

Undertaking the analysis of professional activities led by European architects from an economic point of view is not an easy task. This difficulty is due not only to the lack of systematic and unbiased data available, as is the case in most service activities, but mainly because of the extreme complexity of the actual environment in which the profession of architect is being practised in the twelve countries of United Europe. Although the term "architect" is commonly used worldwide, it doesn't have the same meaning in all countries, especially from a legal point of view.

The European architects' common scope of activities is quite broad and, even though their economic significance is quite poor in the light of consolidated GNP, European architects as a whole have a powerful impact on the evolution of the building industry.

As a matter of fact, considering the huge scope of their tasks from a social and cultural point of view (environment, heritage, well-being...) and considering their high skills, both general and specialised, architects are to be found everywhere in the process of development, design and management of real estates.

The difficulty to represent the outlook of this profession is further enhanced by the fact that the architect is less and less an isolated professional. He is more and more implied in highly complex combined professional teams that require all sorts of complementary features to meet the requirements of complex building or development programmes requested by the various sleeping partners.

In order to make-up for the highly fluctuating effects of the economic trends in the building and real estate markets, many "architects' firms" endeavour to diversify their activities in related fields such as the management of real estates, surveying, programming, planning, home design, landscaping, city planning, etc.

As all objective data likely to usefully further complete the economic statistics related to the profession of architect have not yet been collected, it seemed necessary to have an outlook of the profession by considering the actual situations that vary from one country to another.

INDUSTRY PROFILE

Training

Generally speaking, the training of architects at a university level covers five academic years. However, in many countries, there are variations in the educational networks that are characterised either by specific options offered by the educational institution or by the nature of the training. There are for instance options in the technical or scientific field or other options in the field of art and creativity. Situations vary with the type of institution considered, whether they are Higher Vocational Training Institutes, Higher Institutes of Architecture, so-called "Polytechnical" Institutes or Universities.

The training of the architect takes place at the highest level of education thanks to highly diversified curricula composed of core syllabuses and specialised courses. It makes it possible for those who have been granted their diploma to enter highly diversified careers that are often far from the practice of the profession of architect. Some countries require a one-year or two-year training period, reserved to those fully qualified professionals who intend to specifically practise the profession of architect.

The architects' title

Institutions teaching Architecture deliver a diploma that stipulates the qualification or skills and bears with a title: namely the title "Architect". This title does not necessarily provides the right to practise the profession and, in some countries, it is not required to have been granted the title of "architect" to practise the profession. Moreover, the title "architect" itself is not protected everywhere so that in some countries like Denmark for instance just anybody can claim he is an "architect" and can practise the profession, although in reality only qualified architects are ever employed. In some countries, the title or diploma required to practise the profession of

architect may vary: (civil or construction) engineer, architect-engineer, architect, certified architect, etc.

Missions and services provided

Within the large scope of architecture, missions carried-out by architects are highly diversified. In most cases, this mission consists in developing a space framework in which human activities provided for in the programme developed by sleeping partners will take place. In some cases, this mission is also extended to the follow-up or the supervision of the building works up to their completion (a mission which is mandatory in Belgium).

More and more, the mission of the architect covers the whole building process, from the development of the programme and the pre-feasibility study to the completion of the file required by the administrations and by those who will carry-out the works through all the coordination and works planning services, the follow-up, the supervision of works, the advice and assistance to be provided to the sleeping partner and, finally, specialised services in real estate management of completed buildings. This process also applies to refurbishment and rehabilitation operations.

Therefore the activity of architects' firms covers significant and diversified services that require a structure and an organisation adapted to the scope and the diversity of tasks that result from the architectural missions which they have been entrusted with.

REGULATIONS

Legislation and liability

One of the most significant factors determining the cost of services provided by the architect is the burden of civil liability which this activity involves. Again, there are large differences in the twelve countries of United Europe. In most countries indeed, the legislation requires an architect for the delivery of a building licence. In some countries like Belgium, Spain or Germany such legal obligation is not limited to the development of the building plans, it also applies to the follow-up of the works themselves.

Civil and professional liability may also vary a great deal from one country to another. In the Netherlands, for instance, the damages which an architect may have to pay are limited to his fees for the task he has carried-out and shall in no case exceed one million guilders. The cost of such damages is unlimited in France and in Belgium and damages may be claimed any time during a ten-year post-building period (ten-year guarantee) while this period is limited to five years in Germany.

Professional risks are so high that architects take an insurance to cover such risks, even in the countries where such an insurance is not mandatory. The cost of such insurance may vary a great deal here too. Such an insurance is for instance mandatory in France and in Belgium.

Of course these factors have a significant impact over the cost of services. This important matter is now being tackled in depth at a European level.

Professional rules and regulations

In most countries in which the title of architect is protected and required to be able to practise the profession, in which an architect is required in some cases and in which legal liabilities are defined, the practice of the profession is placed within a specific regulatory framework. Professionals have then to be registered and are submitted to strict codes of ethics.

Controlled professions are also ruled by an Official Institution or a Professional Chamber having widespread powers, namely in the field of ethics.

The rules included in the codes of ethics are also quite diversified though we note, in all European countries, an ethical streamline towards independence and social service that is inherent to the aspect of public interest in architectural creation.

Professional status

From the viewpoint of social legislation, the profession of architect may be practised in very different ways:

- as a liberal professional (self-employed and working on his own behalf);
- as a free-lance worker, working for an employer but bearing himself the cost of social security and retirement;
- as an employee in the private sector (architect, engineering firms, industry etc.);
- as a civil servant in a public administration.

In some countries, architects are not allowed to practise their profession under various statuses that may be incompatible. In Belgium for instance, an architect who is a civil servant is not allowed to practise as a self-employee.

The status that corresponds to the most widespread concept of architect is the liberal profession or the independent employer. As a matter of fact, they are those architects who have most often been entrusted with the mission of developing buildings on behalf of public or private institutions and some of these architects are famous and are recognised for their great skills.

More and more architects' firms or agencies are now setting-up EEIGs (European Economic Interest Groupings) to pool and promote their cross-border activities. They do so pending a European legislation that would make it possible for them to set-up more adequate associations that would be European legal entities.

Structural framework

The evolution of the legislative and economic context obliged professionals practising their profession under the status of liberal professionals or independent employers to look for the most adequate legal form of practice in order to separate their personal assets from those of their professional activity. Many of them have placed their professional activity within the framework of a company. This structural framework also varies to a large extent from one country to another, since some countries accept that the architect has a profession with a commercial nature while others forbid such commercial practice or limit it, probably in order to maintain the personal liability of the liberal professional.

To make-up for this inconvenience, architects have adopted structures that have the "form" of a business company without actually being one, keeping its "civil" object. Others have set-up a company whose object consists in carrying-out a specific professional action that does not involve their personal civil liability. In other cases, the architect is employed by his own company.

The establishment and the registration of a legal entity in order to practise the profession is not authorised in several European countries. The choice of the structural framework does not only have an impact from a tax point of view, it also has an impact over the management of the assets or over the inheritance of the latter.

EUROPEAN HARMONISATION

Competition

Competition can be felt both within the field of architecture and beyond. As a matter of fact, parts of the missions are entrusted by some sleeping partners to professionals who do

not practise the profession of architects, namely real estate and city planning surveyors or engineers specialised in specific techniques, in programming, in coordination, in planning or in real estate management or quantity and quality surveyors and project managers or building consultants, or even interior design architects or designers.

Many building companies and real estate agencies, both in the public and in the private sector, tend to work with multidisciplinary consultancy firms composed of architects and other specialists.

Harmonisation through EC directives

The main directive aimed at the harmonisation of the practice of the profession of architect is Directive 384/85/CE. It aims at harmonising the rights for architects to establish themselves and to provide services in the 12 Member States. It lists the education institutions that are authorised to deliver the diploma and the title of architect as required by the cross-border practice of the profession. The profession of architect is the only profession in the building and real estate industry that rests on a European Directive which is specific to it. This European Directive has been included in the national laws of most of the 12 countries and does not raise many difficulties in its application.

Voluntary harmonisation of the profession

The architects of the EC have set-up an Architects' Council of Europe whose objective, among others, consists in endeavouring towards a harmonisation of the practice of the profession of architect in Europe as a whole. The various commissions within ACE are working actively and in a concerted way to draft reference documents, regarding, namely, the missions, the fees, the principles of professional ethics, etc. in a spirit of harmonisation. Regional cross-border relationships between professional organisations are also making efforts with a view to harmonise the practice in the field, while respecting national specific characters.

OUTLOOK

The architects are conveniently placed at a cross-roads that makes it possible for them to observe, as from the start, all the trends in the building and real estate markets. We note that large architects' firms that are linked to multinational sleeping partners are more significantly hit by these movements.

On the other hand, smaller or middle-sized architects' firms seem to adjust themselves to economic fluctuations in a more flexible way. The number of large firms with an international scope seem to get smaller or seem to keep the same size while the number of small-sized or middle-sized firms is increasing and is better adapted to the needs of local markets in terms of savings and personal credits.

One of the factors in the evolution of the profession is the contribution and the more systematic use of new tools such as CAD (Computer-Aided Design) in the field of design and in the management of projects.

Generally speaking, beyond the issues of the evolution of professional ethics, the most significant problems which the profession of architect will be faced with in the short term is its fundamental approach towards a commercialised nature of its activities and structures. In some countries, this approach could have an impact both on the way to use management and marketing techniques and on the way to meet some rules of professional ethics. This evolution is not specific to architects only, it is specific to all professions.

The various Architects Conventions in Europe and throughout the world now emphasise the need to highlight the architect's mission of public interest by taking into account environmental concerns. There is no doubt that most European architects are open to these options but that these will be clearly translated into architectural production only once such European architects have a reliable information on all building products and techniques from the environmental point of view.

Construction economists
NACE 837

The construction economist - traditionally known in various countries as the quantity surveyor, the metreur-verificateur, and the geometra - is a professionally qualified expert who assists the client/owner/building promoter in contractual, financial, managerial and economic matters, to optimise the value of a construction project over its lifetime.
Building surveyors and construction experts are closely associated with construction economists and are included in this monograph.

Table 1: Construction economists

INDUSTRY PROFILE

Description of the sector

The services of the construction economist encompass :

- project development;
- project and quality management;
- feasibility studies, including the environmental impact;
- risk analyses;
- cost information and estimates;
- drawing up bills of quantity;
- drawing up project specifications;
- planning of time scales;
- preparation of documentation and analysis of tenders;
- contracts between client and technical consultants and between clients and contractors;
- planning of site and security measures;
- logistics to and on the construction site;
- planning of building maintenance and operation;
- facilities management;
- arbitration and related services.

In France, and Ireland, construction economists are trained as quantity surveyors. In the United Kingdom they are trained as quantity surveyors as well as building surveyors. Traditionally quantity surveyors deal mainly with new construction while building surveyors specialise in facilities management, building pathology, maintenance and refurbishment. In other countries the services of construction economists are provided by several professions. In Germany construction economists are either architects or engineers by training. In Spain and Portugal they are technical architects - Apraejadores y Arquitectos tecnicos. In the Netherlands and Finland they are architects and engineers who have specialised in construction economics. In Belgium the construction economists are predominantly engineers and in Denmark they are architects, construction technologists and engineers who have specialised in construction economics and participated in a post graduate training programme.

As the professional training and the role of the construction economist varies from country to country - only in the United Kingdom and Ireland is the situation very similar - a European Association of Construction Economists, CEEC, was founded in 1979. The aim of CEEC is to harmonise and promote the profession on a Europe wide basis. In particular the organisation works to:

- establish guidelines for the definition, contents, practice, and supervision of construction economics;
- coordinate working methods;
- facilitate the exchange of information and experience;
- promote basic and continuing education of construction economists;
- promote the use of qualified construction economists.

So far the CEEC has organised a system for the exchange of information and experience - especially on costs, time scales and tender actions.

In Ireland and the United Kingdom quantity surveyors are traditionally occupied in new construction, while 10 000 building surveyors specialise in facilities management, building pathology, maintenance and refurbishment. To recognise the distinct profession of building surveyors a special European Association for Building Surveyors/Experts, AEEBC, was founded in 1991. Its statutes and work programme are very parallel to those of CEEC and it also maintains close links with the CEEC.

Recent trends

In 1993 close to 50 000 construction economists were registered in the national, professional associations in EC countries, excluding Germany, where presently no figures are available. In addition more than 20 000 building surveyors operated in Italy, the United Kingdom, France, Belgium, the Netherlands and Ireland.

Building surveyors realised a turnover of about 1.4 billion ECU in the six Member States mentioned above for which data are available. In the United Kingdom the turnover of quantity and building surveyors combined amounted to about 2.7 billion ECU.

The activity of this sector mainly follows general economic developments, and in particular developments in the construction sector.

MARKET FORCES

Demand

Capacity of the EC construction industry exceeds demand for construction. This will be the case for years to come, except in eastern Germany. Demand here refers to effective demand reflected by the resources actually allocated to construction, not to the obvious need for improvement of older dwellings with poor sanitary installations, inadequate heating systems and in poor repair. Only a large-scale, determined EC effort to obtain a substantial reduction of CO2 and CFC pollution within a short span of time might be able to redress the balance between supply and demand in the building in-

(1) Estimates for 1989
Source: CEEC

dustry. The resulting demand for the modernisation of existing buildings could lift construction demand to full capacity level for an extended period.

The number of construction economists in the various EC countries reflects the degree of competition and the stage of professionalism in the particular property market. Until now the decision to start a construction project has been motivated almost everywhere by a direct need for production infrastructure, or for dwellings for a growing population in the cities, and not by considerations on the internal interest rate of the project. The exception is the United Kingdom where professional developers of construction projects emerged as early as in the second half of the last century. Furthermore, until recently the major part of income from investment in property has originated from increases in value. Consequently the incentive for improvement of productivity in construction has been small. However, overcapacity in industry and high vacancy rates in existing buildings have depressed the value of real estate substantially. The unoccupied space is not primarily a result of economical recession but a consequence of increasing cost competition in many economic sectors. Increases in productivity are often accompanied by a decline in the need for labour and space.

The response to increased competition in the construction sector is likewise an increase in productivity, which must be achieved by an increasing specialisation of the various construction activities. This creates a need for the services of the rapidly growing number of construction economists. Their function in the construction process is to optimise the contractual and financial interests of the client.

The need for construction economics is amplified by the EC Directive on Procurement of Services. Public procurement contracts with architects, consulting engineers or design teams exceeding 200 000 ECU can be awarded only after an open or limited tender. Criteria for awarding contracts are either lowest price or the economically most favourable bid. The EC directive on services only deals with public procurement but in reality the principle of tendering is expected to be applied to almost all procurement of services. For these reasons there is a growing demand for the skills of construction economists even though the demand for construction is declining. Their skills are needed by purchasers of construction services in planning the procurement of services and in evaluating the bids, as well as by those bidding in formulating a competitive proposal.

Production process

The nature of the services provided by construction economists evolves over time. The following elements are becoming increasingly important:

- assistance with bidding for construction services;
- quality management;
- use of information technology;
- optimising the financial interests of the client;
- care for the environment.

The salient characteristic of tender and bidding for immaterial services is the difficulty of specifying the exact nature and quality of services wanted. The present classifications of services in the construction industry, often drawn up as part of fee scales, are rather general, and consequently not very suitable for tender or bidding. In response to these problems the CEEC has started to formulate a Code of Practice. It is based on a standard model for project management and includes standard formats for all kinds of documentation. The aim is, through consultation within the AEEBC and the CEEC, to produce a European Code. This Code will be implemented in the various countries over a period of time. Initially it will merely serve as a structure for decision making, and gradually it will prescribe general contractual conditions.

Quality management according to EN 29 001 is expected to be included in all contracts. The primary aim of quality management standards is not to improve basic services but to reduce time spent on negotiation of contracts, time wasted on misunderstandings, inter professional friction, and judicial disputes. For the client the main advantage will be the reduction of these indirect costs, as the safeguarding of the interests

Table 3: Construction economists

Source: CEEC

of the consumer in the case of design and construction defects may be provided by an EC directive on liability.

A thorough and intelligent use of information technology and exchange of data offers a possibility for substantial cuts in production costs. Furthermore as a service to the client a database can be constructed with all data relevant to facilities management - structured in a functional way. This database is handed over to the operator of the completed building, and helps to cut costs in facilities management.

The financial interests of the client are optimised by evaluating the expected payback of the project over the next 20-30 years before the project is started, and by the efficient management of the design and construction process. Income from property mainly derives from the difference between income/rent obtained and costs of running and maintenance. The evaluation of the payback must thus focus on life cycle costs, location, indoor climate, design and the various 'green' issues, in that order.

INDUSTRY STRUCTURE

Companies

Construction economists are engaged as employees by governmental institutions, local authorities, architects, contractors, and in consulting companies owned by construction economists. The total number of construction economist companies operating on a business service basis is about 7 500 in the EC. In most Member States the majority of construction economists is employed in private consulting companies. However, in some countries, notably the Netherlands and Spain, a substantial majority works as employees within contracting organisations. In all countries a smaller number of construction economists works for the public sector.

The total number of private companies within the EC Member States varies from 10 in Belgium to 3.000 in Spain. The average number of qualified staff in such firms is less than 10, except in the United Kingdom, where the average is 20. However, there is a small number of firms, particularly in the United Kingdom, with a total worldwide staff in excess of 100, and in some instances in excess of 500. In Denmark only five private companies work exclusively in construction economics. The other are predominantly architectural firms owned by or employing construction economists.

ENVIRONMENT

About half of CO2 emissions in Western Europe results from the use of energy in buildings for heating, lighting and air condition. In addition, air condition accounts for about half of the CFC emissions. Consequently major changes must be implemented in the design of new buildings as well as in existing buildings.

Along with other environmental objects this presents an enormous challenge to building owners - and a need for services rendered by construction economists in order to arrive at optimal solutions.

REGULATIONS

No formal regulations exist for construction economists but professional training is based on the directive on Mutual Recognition of Diplomas.

OUTLOOK

In general, the outlook for the construction industry is bad. However, as a result of increased competition among building owners, the directive on Procurement of Services, and the need for a variety of measures to protect the environment, the outlook for construction economists is quite good. Their services will be in demand in construction as well as in civil and heavy engineering. Further demand will originate from the need for new construction and extensive rehabilitation in Eastern Europe and the absence of local know-how concerning project management and other fields of construction economics.

Engineering consultancy services
NACE 837

In 1992, engineering consultancy and related services affiliated to EFCA accounted for more than 8 000 firms for both the EC and the EFTA countries and for about 200 000 persons employed within the same area. However, compared with 1991, turnover has increased when staff is reduced in favour of more free lance consultants hired by large companies.
Competition is mainly between in-houses and private services. 1992 showed public demand decreased in favour of private demand in almost all EC countries. The Single European Market, however, appears to promote cooperation.
The outlook for 1994 is brighter than for 93 as the general economic situation improves.

INDUSTRY PROFILE

Description of the sector

Engineering consultancy services are defined as the intellectual services which aim at optimising investment projects in, inter alia, industry, construction and infrastructure, at all stages of a project from its conception to its actual functioning. These services are provided either by engineering consultancy firms, consulting engineers, engineers employed by construction firms, design firms or public agencies which employ engineers and design consultants, or by individual engineers and consultants. All of them are equipped with highly specialised technical knowledge and provide comprehensive multi-disciplinary neutral services, independent of any supply or manufacturing interest. Their main objective is to optimise investment projects by proposing the lowest cost - highest investment productivity engineering solutions, consistent with the particularities of the specific markets. The broad range of these services includes pre-feasibility studies, preliminary designs, cost-benefit analyses, working drawings, efficiency investigations, building management and supervision of construction, commissioning technical management and advisory services, management, overall planning, project supervision and logistics. Engineering consultancy services include engineering design and construction services. An engineering consultant could be responsible for part of a project or for a whole project from the inception itself to the final inspection. The latter projects are known as turn-key-projects.

Engineering consultancy services apply to residential and non-residential buildings, to civil engineering like transmission lines, power plants, transportation facilities, public work facilities, environment, telecommunication, industrial plants and other technical services (e.g. geology, hydrology, ship-building and marine engineering).

Engineering consultancy services can be traced back to the 18th century when they first emerged in the United Kingdom construction sector. Before the second world war, the international market was dominated by British companies. Since 1946 the United States became more and more important. In the sixties and early seventies the market changed significantly to an international market. Large projects financed by international aid programs especially in third world countries influenced the market situation enormously.

Engineering consultancy services are, to a large extent, part of the construction industry but are not separately reported in public statistics. Thus there are only data available for the EFCA and national association members.

Recent trends

In 1992, an increase of the turnover and of the total of registered firms was accompanied by a reduction of staff compared with 1991. Thus the average turnover per employee in 1992 is significantly higher than in 1991. The total turnover in the EC countries increased more than 8%. This increase was due to the domestic markets. Foreign markets showed a downswing in 1992. The average number of employees per firm decreased from 34 persons in 1991 to 30 persons in 1992.

Though engineering consultancy services represent only about 8% of the construction industry, their economic significance is far more important, because the sector is causing a large turnover in the production industry for equipment and material. The sector is always moving. The markets for engineering materials, new technology and equipment are always producing new ideas. Engineers are the users of these new ideas. They are responsible for the diffusion of new processes, materials and technologies throughout the economy and constitute an important link between research and development and production. The determining factor for these processes is the search for more efficiency, productivity and competitiveness to the benefit of the client.

Exports still play an important role in the engineering consultancy services sector, because these services use well known domestic technology, there is an important demand for material and equipment caused by engineering consultancy services. This fact influences the balance of payments of exporting countries.

International comparison

During the eighties the US was steadily loosing market share in favour of Europe and Japan. Demand decreased until 1987. The opening of east European markets and the necessary reconstruction of war damaged countries caused increasing demand. This is the reason for the increasing importance of the international markets.

Foreign trade

Foreign trade is of significant importance for the engineering consultancy services sector, which is still dominated by a flow from developed to less developed countries. The majority of exporting engineering consultancy service companies is registered with international organisations which play an important role in the awarding of contracts to consulting firms. The most well-known are the World Bank, The Asian, Inter-American and African Development Bank, the EC, and some organisations of the United Nations like the EBRD, FAO, WHO and UNDP.

An increase of the intra-EC trade, due to the start of the Internal Market evolving increased mobility for engineering consultants across the borders, is still to be measured.

In 1992, Germany holds the first rank within the EC concerning the number of companies and turnover. In Germany, the service structure is dominated by many SME's, with an average number of employees per firm which is under the EC average. Although the largest enterprises have their headquarters in the United Kingdom, it is interesting to note that the greatest average size per enterprise is in Italy. The firms with the smallest average number of employees are located in Ireland. Concerning exports as share of the total turnover, the United Kingdom is on top of the rank followed by Italy and The Netherlands. Denmark is the only EC country that shows substantially increased exports in 1992. In comparison with that, the exports as share of turnover fall from 27% in 1991 to 24% in 1992. The largest average turnover per employee is calculated for France and Spain.

MARKET FORCES

Demand

Demand for engineering consultancy services is closely related to the general economic situation and activity. Three main factors are of important influence: public and private investment, technological progress and the availability of finance. Engineering consultancy services derive most of their turnover domestically. In the export market, demand from international working organisations has the greatest importance. There are still contracts for consultancy in third world and less developed countries offered. But also some large European projects (e.g. the channel tunnel) increased the intra-EC demand for engineering consultancy services during the last decade.

In 1992, from the domestically generated turnover, public demand decreased in favour of private demand in almost all EC countries. The reason therefore was a lack of funding for infrastructural investment in most EC countries.

Supply and competition

The recession seems to make price as a selection criterion more often used. This creates concern by engineering consultants: the scope of work in a commission of engineering consultancy is often necessarily ill-defined and must itself be developed by the engineering consultant working with the client. When it is known that a commission is to be awarded on the lowest price, there is inevitable pressure on those, submitting offers to base their tenders on using less experienced and cheaper staff. This will tend to minimise the scope of work offered to meet no more than what the client specifies. Furthermore an apparent saving in the initial stages will seldom provide the best value for money for the implemented project as a whole. However, most international lending agencies select engineering consultants by using the combined criteria of quality and price. On public projects, private engineering consultancy firms are often in great competition with in-house engineering consultants. Especially the public sector is using its own in-house consultants. This is an other competitive disadvantage for the profits of private consulting engineering companies. The externalisation of in-house services could prove decisive factor for the development of EC engineering consultancy services sector. Today small enterprises which are only covering part of the services required by the clients, are facing strong competition from large enterprises. Such are firms with own planning offices and firms which offer the complete management and coordination of projects. This means for smaller firms or independents that they have to specialise in fields where the larger enterprises are not working in or to cooperate more with larger enterprises as it was the case in the past. The Single European Market is assumed to enhance cooperation. In cases where foreign enterprises are commissioned with work abroad they will need local experts who know the specifics of the national markets and their regulations. 1993 shows already a tendency towards an externalisation and to a reduction of staff in favour of more free lance consultants who are hired by large companies.

INDUSTRY STRUCTURE

Companies and strategies

In the 1960's, engineering design services were closely related to trade in engineering equipment. Due to the externalisation process engineering design companies are now more independently operating. However, engineering consultancy is still causing exports of material and equipment.

The engineering consultancy sector is highly concentrated. Besides a great number of small, sometimes even one-man firms, there are giant companies existing as well. According to employed persons the largest engineering firms in the world are Canadian, American and Finnish. The world Top 30 1991, shows 13 US, 2 Canadian, 7 English, 2 Dutch, 2 Swedish, 1 Finnish, 1 German, 1 Japanese and 1 Egyptian company. Within the EC and EFTA countries the largest companies have their headquarters in The Netherlands, Finland, the United Kingdom and Sweden. Swedish and Finnish companies are of great importance in the European market. During 1991 and 1992 most of the large companies reduced their staff due to the recession. The last few years some larger companies merged. The trend to create international alliances is still continuing. The reason therefore is to gain market positions in foreign continents and countries. Since 1990 the list of the most important companies within the EC has not changed much. If companies expanded, this was mainly due to acquisitions and not by organic growth.

On the international market firms often cooperate with domestic firms, which have knowledge about the domestic market.

REGULATIONS

The title consulting engineer is not protected by an official EC regulation. Nevertheless regulations are influencing engineering consultancy services to an important extent. However, they are still varying from country to country. The following EC regulations are mainly influencing the sector: the Council Directive 92/50/EEC of 18 June 1992 relating to the coordination of procedures for the award of public service contracts (Public Procurement) and the Council Directive 92/57/EEC of 24 June 1992 on the implementation of minimum safety and health requirements at temporary or mobile construction sites.

The Directive on Services allows every professional to offer his services in a foreign EC country. The aim of this directive is to promote price competition on the markets for services. National laws were to be brought in compliance with this directive as of July 1993, however some countries still have to do so.

The EC Directive for Public Procurement is relating to the coordination of the procedure for the award of public service contracts. Studies with fees exceeding 200 000 ECU fall within this directive. They are to tender on the EC level. This directive is already adopted into national law in Denmark, Germany, Greece, Ireland, Italy, Luxembourg and the United Kingdom.

The Directive about the minimum of safety and health requirements is still in discussion in most EC countries. This directive is only adopted in Luxembourg.

OUTLOOK

In spite of the bad economic situation also influencing engineering consultancy services in most EC countries in 1993, a small improvement of the general economic situation is expected for 1994. The development of the financial situation of public authorities will be of great influence for the short and medium term perspectives of the engineering consultancy services sector. At the moment the demand for engineering consultancy services by public administration is at a standstill in some EC countries.

Some factors will probably improve the situation of the engineering consultancy services in the near future. But this will be different from country to country. The harmonisation of environmental regulations, stricter environmental control and technological progress in Europe and the USA, and the reconstruction of the infrastructure in the former planned

economies in Central and Eastern Europe will cause additional demand. Moreover planned large projects in Asia (e.g. a huge dam at the Jangtse river in China), Africa and Latin America and the construction and completion of a European transport network will cause additional demand for engineering consultancy services.

These facts imply that most of the services are needed in Europe. This will increase the market of EC engineering consultancy services during this decade but the Single Market is expected to cause keen competition among domestic services and foreign services.

Written by: V. Stabernak Consulting
The industry is represented at the EC level by: European Federation of Engineering Consultancy Associations (EFCA). Address: Avenue de Cortenbergh 79, Bte 7, B-1040 Brussels; tel: (32 2) 732 4990; fax: (32 2) 732 5126.

Geodetic surveying
NACE 74.2

Due to the economic situation and the wide spread market saturation, the industry will in the near future show no growth, with the exception of Germany. The long term prospective is, however, promising. The number of people employed in the industry will remain stable, but qualitative demands will become higher. There are over 65 000 professionals working in the industry of which more than half are in France and Germany, and about half are working in the public sector. There is a trend towards larger companies offering a more diverse range of services.

INDUSTRY PROFILE

Description of the sector

Geodetic surveyors measure the size, position and three dimensional shape of the earth surface and the objects upon or in it. The following areas of expertise come within this broad description: cartography (national and international, small or large scale, plans, navigation charts, etc.), measured building surveys; tunnelling and mining surveys; measurement and location of underground structures and services; cadastral and boundary surveys; industrial and engineering surveys; preparation for construction; monitoring and deformation surveys; land and geographic information systems; ocean bed, coastal and river surveys; measurement of marine resources; and other surveying services.

In many Member States, urban and regional planning, land and building valuation, soil testing, land management, and management of development can also come within the scope of the geodetic surveyor, although not necessarily as part of a traditional definition of the geodetic activities. Measurement systems can be land, sea, air or space borne. Examples of these systems are remote sensing (land, air or space), Global Positioning Systems (space), hydrography (sea) and tachymetry (land). Much of the geodetic surveyors work, however is in the management, analysis and structuring of the acquired data, in order to create information (e.g. maps, plans, positions, size etc.) from this data.

Recent trends

In many Member States, the geodetic surveyor is traditionally a public servant as in the Netherlands, Germany, France, or the access to the profession is legally protected as in Belgium and Germany). Only in some Member States, like the United Kingdom and Ireland has the profession been open to competition. In the last decade this has changed in some Member States (e.g., the Netherlands). The number of people employed in the private and the public sector together, is given in Table 1. In total over 65 000 surveyors and technicians are employed in the countries of the European Community. If this figure is recalculated over the number of inhabitants in each country, the level of penetration is highest in Denmark, Greece and the Netherlands and lowest in Spain and the United Kingdom. The high level of penetration in Denmark and the Netherlands can be explained by the legal situation in these countries and the demand for high accuracy. In Greece the penetration level is high because there are many other activities which involve geodetic surveyor.

The penetration in the United Kingdom is low because of the large number of other types of surveyors, who are not included in the figures, and the fact that the land registration system in the United Kingdom is essentially descriptive. In Spain it is expected that the number of surveyors will grow in the coming years.

Table 2 shows the sector in which the geodetic engineers and technicians are employed. Clearly visible are the large differences between the countries: it varies from over 80% public sector employees in Italy and Germany to the opposite in Belgium and Denmark who have 80% private sector employees. In the near future no major changes are to be expected which could significantly alter this.

The turnover in the private sector in each Member State is given in Table 3. About three quarters of the estimated total turnover in the private sector is generated in just three countries: France, Germany and the United Kingdom. There is widespread market saturation within the EC, with the exception of Spain and Germany.

MARKET FORCES

Demand

Geodetic surveyors provide a service to developers, builders and contractors, architects, planners, lawyers, engineers, geophysicists, oil companies and government bodies.

The list is a growing one as more people, for instance in earth sciences, start to benefit from the services and skills of the profession. Satellite positioning systems have opened new markets where conventional techniques would not have been considered due to cost. However, the apparent ease of

operation of such systems means that often for low precision work the geodesist is involved more in the role of a consultant than a practitioner.

Market differences exist between Member States in the amount of workload derived from the private and public sectors. Belgium, Denmark, France, Greece and the United Kingdom have a larger proportion in the former and Italy, Luxembourg, Germany, the Netherlands, Portugal and Spain a larger proportion in the latter. Generally, cadastral surveys and other public sector works show a fall in demand balanced by an increase in engineering and industrial surveys and large scale mapping.

Supply and competition

Within each country profit margins have been reduced considerably due to the economic downturn, which has its affect on government spending and the construction industry.

In certain sectors of the industry, especially in the areas of land and geographic information systems, computer software companies are competing for work. These companies are also competing for qualified geodesists at a time when most predictions are of a shortage of suitable personnel.

Geodetic surveying is a national business and in many countries even regional. In surveying there is hardly any international competition. Generally over 95% of the turnover is generated in the home country. Only companies in Spain and, to a lesser extent, Luxembourg and Portugal meet serious competition in their home market. The main disadvantages for outside competitors are the regulations necessitating membership of professional bodies and educational requirements.

The focus of some specialised areas, notably aerial photogrammetry and hydrography is almost by nature international. The largest photogrammetry companies have their headquarters in Germany, France, Belgium and the Netherlands, and the major hydrographic companies are located in the United Kingdom and the Netherlands.

The distribution of geodesists is highly correlated with the population distribution overall. The service provided is strongly tied to the land itself and hence the industry polarises where land or real estate is being exchanged, monitored or developed.

INDUSTRY STRUCTURE

Companies

The number of private companies in each Member State is given in Table 4. In total the number of companies is well over 6 000. Most companies (over 90%) are small, less than 10 persons employed. Belgium, Germany, Denmark, Greece and Ireland all have a high proportion of very small companies and in Belgium self-employed status is the normal situation. The United Kingdom and the Netherlands have a more equitable spread of company size. Most larger companies are either technically specialised, for example in aerial photogrammetry and remote sensing (Hansa Luftbild, Eurosens and KLM Aerocarto (NL)) or part of a bigger group such as civil engineering, offering geodetic surveying within their operation (Oranjewoud, Heidemij Advies (NL)). Some larger companies do offer a range of services purely within geodetic surveying (Engineering Survey/Clyde Surveys, Inpark).

Because many of the larger companies form part of a company with activities in other fields, it is hard to rank with any certainty the largest companies operating in this sector.

However, the following companies are amongst the largest operating within the EC. They are listed in order of the estimated size by number of employees: Inpark (NL), Racal Surveys (UK), BRS Grontmij/Geogroep (NL), Oranjewoud (NL), Hansa Luftbild (D), Starkstrom Anlage Gesellschaft (D), Engineering Surveys/Clyde Surveys (UK), BKS Surveys (UK), Mason Land Surveys (UK), Egle Vermessungsbüro (D) and Eurosense (B).

Strategies

The most general strategies especially for larger companies point towards diversification of services offered and collaboration with associated professionals, particularly in the field of information technology and aerial photogrammetry. Some smaller companies tend to specialise, offering niche marketing solutions to specific problems (e.g. monument measuring). Most companies try to attempt to keep abreast of the latest technological developments, since many professional customers also use these technologies. Lesser themes include efforts to achieve quality accreditation, and a change in personnel structure.

REGULATIONS

The most important regulations are those concerning cadastre. Most countries recognise boundaries based on survey measurements. These measurements are carried out by specialist organisations (e.g. the Administration du Cadastre et de la Topographie in Luxembourg), by public servants (cadastral surveyors in most countries) or by licensed geodetic surveyors (e.g. Öffentlich Bestellter Vermessungs Ingenieur (ÖbVI) in Germany). In the last case, this work often forms a substantial part of a geodesist's activities. Ireland and the United Kingdom have an essentially descriptive system of land registration. The geodesist's role in these two countries in cadastral work is, therefore a minor one. The difference in cadastral law between countries (and also between regions within one country such as exists in Germany) mean that this sector of the market sees little competition across borders.

EC regulations concerning recognition of qualifications for migrant workers are being addressed by the Comité de Liaison des Géomètres-Experts Européens (CLGEE). A detailed report of education for geodetic surveyors within the EC was published in 1988. A second update to this report is being prepared. The CLGEE is striving to harmonise qualification standards and mutual recognition of diplomas. Some cross border commissions have already resulted from these initiatives.

EC directives concerning public service contracts have had no significant effect to date.

In Denmark, Germany, France and Italy the profession is afforded legal protection. In the Netherlands, Ireland and the United Kingdom no such legislation exists. Elsewhere there is a position between these extremes.

OUTLOOK

The outlook in the short and middle long term is strongly linked to the economic situation in the countries of the European Community. It largely depends on the activities of the construction industry, public utilities, off shore industry and the cadastre. Since the construction industry shows in most countries less economic activities, the turnover of the geodetic surveyors in this sector will in general remain stable at best. The off shore activities in the North Sea and the Continental shelf are limited, thus affecting the hydrographic activities in a negative way. This is partially offset by the increase in activities in the far east.

In most Member States, government or semigovernment bodies are facing budget constraints. This too will have its effect on the activities of geodetic surveyors.

In Germany the near future looks brighter, especially for the ÖbVI's. All five new "Länder" (former East Germany) have accepted the ÖbVI's. The market in these five "Länder" is growing with the regulation of land property.

The long term future for geodetic surveyors is good and will rest largely with their ability to adapt to change. Many of the traditional skills in data acquisition are becoming less relevant with the advance of automated systems. However the processing, structuring and manipulation of these data within land and geographic information systems for resource management, planning, route guidance systems and other projects is becoming increasingly important. Collaboration with information technologists will be essential to be able to provide such services.

In general there is a tendency towards fewer and larger companies offering a more diverse service, but there is also a place for small sized companies who offer simple low tech services with low overhead or who invest and can offer state-of-the-art products.

It is estimated that the number of people employed in the industry will remain stable. The qualitative demands will become higher as more and more knowledge is required for the manipulation of data and the user requirements of this data become broader.

Industrial metrology is a growth area where the surveyor's measurement skills are competing with long established methods. It is to be expected that some surveyors will choose to specialise here and increase their market share.

The industry is represented at the EC level by: Comité de Liaison des Géomètres-Experts Européens (CLGEE). Address: 40 Avenue Hoche, F-75008 Paris; tel: (33 1) 45 63 24 26; fax: (33 1) 45 61 14 07.

Landscaping

The landscaping, gardening and sports ground construction industry is finding increased demand with the growing urban population and a concern with a green environment. The sector is dominated by a large number of small to medium sized firms who operate labour intensively. The future for landscaping companies anticipates increased activity in renovation and maintenance of existing parks and gardens along with more complete biological and ecological environmental projects.

INDUSTRY PROFILE

Description of the sector

This sector includes the installation, renovation and maintenance of gardens, landscaping and sports ground construction in private and public gardens, parks and leisure centres. Specific activities like tree maintenance/transplantation, landscaping of public works, installations for noise prevention, creation and construction of ways and places within parks fall within this sector. Less traditional activities are gaining importance, biological engineering and natural landscaping are examples. The former is landscaping by using living plants and inanimate materials like wood, stone, and geotextiles; natural landscaping is the creation of "almost" natural spaces or ecological niches not typically intended for public use.

Data for Member States are incomplete for this sector. In 1990/91 a structural survey was taken among some national associations, however it was non-conclusive, as not all EC Member States participated. Limited data did indicate that in 1991, employment in member companies of national associations in gardening, landscaping and sports ground construction for eight Member States totalled 69 250 individuals. Thus, overall employment figures for the sector clearly exceed 100 000 persons. Germany employs the largest number of landscape gardeners, approximately 31 000, while the United Kingdom, the second largest employer, accounts for 13 000 gardeners. Clearly Germany has the largest turnover per enterprise, with France and the United Kingdom following far behind. The majority of garden, landscape and sports ground construction companies are small and medium sized firms.

Recent trends

Traditional landscaping work such as construction, laying out and maintaining, gardens and parks is the core sector. However, due to the current recessionary business climate, landscaping companies have seen the construction of new gardens, parks and sports grounds facilities decline. In response, firms have been seeking out new fields of work such as: gardens in the backyard, on the roof, or facade and even indoor gardens. Ecological and biological works are also new areas of expansion. Thanks to the increased concentration of urban population, municipal and state projects have been areas of growing interest, for example: landscaping in traffic-restricted zones, natural landscaping of roads and highways, city redevelopment, new private and public parks, play grounds, and leisure centres. Renovation of pre-existing sites and ongoing maintenance is a significant field of work for landscape contractors.

Foreign trade

As most companies are small to medium sized, they depend on a small regional market. Intra-EC projects do take place when the landscaping firms are located close to national borders, or decide to collaborate efforts for a specific contract, or if the firm is highly specialised and is able to fill special requirements i.e. transplantation of larger trees, roof planting.

MARKET FORCES

Demand

The concentration of the population in extensive housing estates, the construction of highways and increasing pollution have made stronger demands for a healthy environment for the public. As a result, the requirements for the construction of gardens, landscapes and sports grounds have not only increased, but are also undergoing a big change.

The data available shows that the landscaping demand is closely divided between privately funded clients and public and semi-public clients. This division is not consistent throughout all Member States, for example, 30% of Denmark's demand comes from private clients, while private clients account for 60% of Belgium's demand. In the United Kingdom and Italy public demand represents the highest portion of sales.

Landscaping often deals with various projects of recultivation (reclamation) and renaturalisation. In general, these projects are a result of a legal condition. An example would be the renaturalisation of gravel pits or quarries, greening of mounds or slag heaps, recultivation of industry fallows or areas under recent construction, and the restoration of damp areas.

Supply and competition

State companies, most particularly, road construction and civil engineering, are currently main competitors for garden, landscape and sports ground construction companies in the EC. Government initiatives such as employment programs, social rehabilitation, and even agriculture programs compete with private landscaping firms. State financed employment and social programs employ untrained persons to maintain parks and public places. These programs are especially prevalent in Denmark, Germany and the Netherlands. Competition is growing from farmers as government agricultural programs are reducing the amount of cultivated acreage by paying farmers to leave their fields untilled. Another objective is to maintain and beautify the land. Although farmers are not landscaping the countryside or building parks, some of the activity of maintaining uncultivated ground competes with landscaping companies.

Production process

The industry is labour intensive. The average salary per employee per hour varies between approximately 6 and 11 ECU with an average estimated work week of 39 hours. Within the EC, traditional construction machines i.e. wheel loader, excavator and tracked vehicle make up, on average, 45% of equipment used. Transport vehicles are the second largest capital expense followed by machinery and equipment for speciality use e.g., compressors for building paths and squares. The use of special machines varies dramatically among the individual Member States and their needs. Winter equipment is a good example of this.

Professional qualifications are treated differently by public authorities throughout the EC. In the Netherlands, and outside the EC, i.e. Austria and Norway, a professional certification is required in order to manage a landscaping company; whereas, in other countries no certification is necessary to open a landscaping company although professional certificates do exist and membership in national associations require an adequate qualification.

INDUSTRY STRUCTURE

Companies

The industry has a low concentration. Available data indicates that 90% of garden, landscaping and sports ground construction companies operate with less than 50 employees. In fact, in Belgium, France and the Netherlands, most firms have five or less employees. There are only larger garden, landscape and sports ground companies with more than 50 to 100 staff in Germany, France the United Kingdom, the Netherlands and Switzerland. Firms frequently collaborate across national boundaries to expand capacity and expertise in larger projects. At present the market for landscaping services is very price sensitive.

ENVIRONMENT

The push for environmental quality in and around urban centres continues to benefit the industry. As land gets more expensive, gardens and green spaces become smaller. This encourages creative and intensive use of gardens. Reurbanisation projects such as Parc André Citroën in Paris are another example of the urban need for green space.

REGULATIONS

An important area for currently developing EC regulation is the standardisation of quality and safety norms. Lawn quality and maintenance for sports grounds alone is subject to several different norms depending on the use and need for safety of the different facilities. Another concern is the contract bidding process. Public works projects, now must be offered for tender on the EC level instead of a national or local level as before.

Other areas of public policy like social legislation, industrial law and the safety and security directives for work place and machines affect the industry.

OUTLOOK

Landscaping is a growing sector, but as mentioned above, it is linked to general economic development, above all the construction of houses, business facilities and public projects. Although the general economic outlook at the moment is not the best, landscapers are confident for its future development. The 1990/91 survey of participating national associations indicates that recultivation and renaturalisation, leisure centres, natural parks and maintenance work will become increasingly important. Biological/ecological and other more comprehensive environmental works will also grow in many Member States.

Linguistic services
NACE 839.3, NACE 935

This sector includes translation services, interpretation and foreign language instruction. Demand remained high for these services due to the internationalisation of economies both within the EC and worldwide. Registered professionals in this sector increased 13% from the 1991 total of 11 500, although the actual number of practising interpreters, translators and instructors is much higher. Competition is strong among the major EC languages but less so for others, such as East European and Asian languages. This sector is seeing a greater demand for expertise in specific business or technical fields and experience with computer automated translation programs.

INDUSTRY PROFILE

Description of the sector

Translation and interpretation services, as well as language teachers, belong to the linguistic services. Translators and interpreters are included in NACE 839.3. Language teachers are part of NACE 935 (private tuition).

The translator has the duty to translate texts from one language to another. Translation covers an extremely diversified market. In all realms of human activity, translation is required ranging from commercial and industrial affairs, scientific matters, legislative, press and audio-visual subjects to literary works. In fact, there are two different types of translators. The literary translator who translates only literary texts and the techno-scientific translator who is responsible for all other required forms of translation. The technical translator must keep pace with innovative specialised terminology. This knowledge needs to be more than verbal. Literary translation is extended to encompass fiction, such as plays, essays and poetry. It demands subjective involvement - often identification - with the original author.

Interpretation also covers a wide range of subjects. Interpreters translate spoken words directly from one language into another. Three different types of interpretation exist. Simultaneous interpretation is done instantaneously, mainly during international conferences and with the help of modern communication technologies. Similar to this form of interpretation is whispered interpretation: the interpreter whispers the translation of a foreign language into the ear of his client. This form of interpretation is normally used for speeches or statements, which are directly translated for a second person. The third form is consecutive interpretation. In this case, a person stops talking after a few spoken sentences then the interpreter translates what was said. Then the speaker continues with the speech. The interpreter translates again after some more spoken sentences. This continues until the end of the conversation and is mainly used during face to face conversations.

Language teaching covers language courses provided by public institutions, private enterprises and individual teachers. Besides normal language education during public school time, language teaching, in the form of advanced vocational training, takes place in private language schools or public high schools and in the in-house language courses of big companies.

Professionals in all three groups work mainly as independents or for the public sector. Only a few are employed by private enterprises.

Recent trends

The total number of translators and interpreters registered in the national professional associations within the most important EC countries was around 13 000 in 1992. Compared with 1991, this was an increase of about 13%, mainly caused by a large increase in the BDÜ produced by new memberships of translators and interpreters located in the former German Democratic Republic. Around 70% of all members are women. Most professionals work as free-lance translators. For example, free-lance translators make up almost 100% of the total in France, about 90% in the United Kingdom and about 85% in Belgium. The largest group of employed translators is registered in Germany with around 50% of the EC total; Italy is second with around 40% of all registered translators. The national professional associations estimate that their registered members cover only a quarter of all persons working as a translator. However, in each reporting country the figures for registered translators are slightly increasing year by year.

The literary translator is normally paid in a lump sum and/or royalties, while the technical translator tends to be paid by the word, line, page or hour. In some societies, technical translation is financially more rewarding than literary translation, in others the reverse is true. Considering that a translator has a full-time job, his average yearly turnover is likely to be between thirty-five and fifty thousand ECU. This is a wide range because translators are mostly paid according to the lines translated, and the prices per translated line vary from country to country. Another reason is the experience of a translator. More experienced translators are able to translate more rapidly than beginners and obtain better contracts. Sometimes, remuneration also depends on the degree of difficulty and demanding deadlines. Since there are no figures available on the number of interpreters and language teachers, there

Table 1: Linguistic services

(5) Only literary translators
Source: National professional associations, F.I.T.

can only be an estimation for the average yearly turnover of a full-time working interpreter and a full-time working language teacher. The estimated yearly turnover is dependent on the labour costs which vary from country to country and on the specific needs of the user. Considering this, the yearly turnover of a free-lance interpreter is probably between fifty-five and ninety thousand ECU. For a free-lance language teacher the turnover will be between thirty and sixty-five thousand ECU a year.

International comparison

Germany is the country with the highest number of registered professionals among the Member States, followed by the United Kingdom and France. Translation and interpretation within the EC is more important than in Japan and the USA because more countries which work together in the EC which has no fewer than nine different official languages. But since Japan has close trade relations with the EC, and as cultural relations become more and more intensive, literary and technical translation from a European language to Japanese are assuming increasing importance.

MARKET FORCES

Demand

In general, demand for linguistic services has grown with the increasing number of international relations in the private business and with the closer cooperation of national governments in international organisations like the EC, the OECD, UNESCO and the other United Nations agencies based in Europe. Private undertakings with international relations also require the services of translators and interpreters from time to time. But decreasing budgets for translation, especially in international organisations, are limiting the demand for linguistic services.

Presently, more than 50% of the demand for translation comes from the commercial and industrial sector, about 20% is scientific and less than 30% is legislative and miscellaneous translation including press, audio-visual and literary translation. During the 1980s, only the demand for literary translation was decreasing or stagnant in a few EC Member States. The demand of large companies for exotic languages has recently increased because in-house translation offices mostly employ translators of the four major languages English, German, French and Spanish. Large companies consequently tend to hire free-lance translators for translation into exotic languages. In general, the employment status of registered translators is the following in most EC countries: one third work free-lance, almost half are employed by private enterprises and the remainder are engaged by public administrations or private translation offices.

Interpretation is mainly necessary for conferences on an international level and required by the public sector as well as by private enterprises. These conferences are not regularly scheduled and take place in various places. This requires a great deal of flexibility on the part of the interpreters and is the reason why most of the demanding institutions and enterprises do not have an in-house staff of interpreters, and why most of the interpreters are independent. Employed interpreters mainly work for international organisations like the EC, the United Nations and the OECD.

The demand for language teaching services differs from that for translation and interpretation services. Large enterprises of the business sector or national and international institutions need language teachers for the vocational training of their staff. Usually, however, they have their own teachers for in-house training. Smaller companies tend to use private language schools. These schools employ their own staff. Demand for independent language teachers mainly comes from private persons who need to learn a foreign language in a short time.

In general, demand for linguistic services is not dependent on the general economic development of a country. But it is interesting to note that private enterprises tend to reduce their in-house staff if their economic situation is bad. In this case, there are greater possibilities for independent translators and interpreters to obtain free-lance work awarded by large public or private enterprises.

Supply and competition

With a distinction between the private and the public sector, there are different types of translators, interpreters and language teachers: free-lance workers and salaried workers.

Traditionally, free-lance translators are members of a professional association. They work on their own premises, dealing directly with the client or through the mediation of agencies or translation businesses. These agencies normally have no in-house translators, but subcontract free-lance professionals. Employed translators are mainly hired by international institutions or large enterprises involved in international business. The typical free-lance translator normally works for smaller private enterprises which cannot afford their own translating staff. But in recent years, even government agencies and international organisations increasingly award translation con-

(1) Including former East Germany
Source: UNESCO Yearbooks 1990, 1991 and 1992

tracts to free-lance translators because they have too much work which requires detailed knowledge and specialised skills in translation. A new trend is interesting to note: for free-lance translators as well as for employed translators alike, a combination of translating and commercial skills are an advantage for obtaining jobs and contracts.

In reality, free-lance translators generally have sufficient work because a majority of them only work part-time. Nevertheless, quite a few translators in most of the EC countries are registered as unemployed. For example, more than one thousand unemployed translators were registered in Germany in 1992. But the number of unemployed translators has been decreasing in almost all EC countries since 1988.

Although the unemployment rate of translators is quite high, competition between free-lance translators with specialised knowledge is not very high. There is, however, great competition for well-paid positions on a permanent employee status offered by international organisations. Only larger volumes of translation which require multilingual knowledge are mostly done by translation enterprises employing translators with different native languages. Free-lances specialise more in exotic languages, smaller projects and in specific subjects. Compared with in-house translation, the free-lance translation is cheaper in most of the EC countries. This is a small advantage for free-lance translators competing with in-house translators. Strong competition between single independent translators is mainly concentrated close to the borders of countries where the official languages are the same. This is the case along the borders between Belgium and France and between Belgium and the Netherlands.

Normally, the number of free-lance interpreters is sufficient within the EC. Though more interpretation into English, French and German is required than into other languages, competition for interpretation into these languages is larger than for interpretation into exotic languages. This is mainly dependent upon the huge number of interpreters for these three languages. Specialisation in certain sectors (especially in the technical field) and the knowledge of exotic languages enable the free-lance to avoid competition. But in general, the free-lance interpreter is always in competition with the in-house interpreting staff of public administrations, like the EC and the OECD.

Language teaching services are offered by individual professors, private schools of all sizes and free-lance teachers. Competitors for these three are enterprises which offer telephone tutorials or training programmes in the form of books, videos, records, tapes and compact discs. This method of learning foreign languages is cheaper and offers more flexibility to the pupil than scheduled courses.

INDUSTRY STRUCTURE

Companies

Employed professionals are mainly employed by large companies or the public administration, having their in-house translation, interpreting and language teaching services. The EC Commission is the most important public employer of translators and interpreters. Private translation, interpretation and language teaching enterprises are usually large. Most have more than one hundred full-time translators or interpreters and award contracts to independent free-lance professionals. The largest European companies in the translation sector are located in the United Kingdom. These include Interlingua T.T.I. Ltd., Randall-Woolcott Services Ltd. and the Longman Group UK Ltd. The most important company offering interpretation services in the world market is the German company Brähler International Congress Service whose share in the world market was almost 30% in 1992. This company also provides all the technical equipment and experienced technicians necessary for interpretation services. In the language teaching sector, Linguarama Ltd., London, and Elsevier Languages of the Netherlands are the largest European enterprises. But two other language schools are important within the EC: Berlitz, with headquarters in Princeton, USA, and E.F. with headquarters in Lund, Sweden. Both run schools in many different countries.

Strategies

Considering the growing market for linguistic services, free-lances and enterprises working in that business will face stronger competition in the future. In this context, stronger competition means shorter deadlines, more translation into East European languages, more detailed texts in technical languages and more translations with specific software demanded by the clients. In this context, there is a trend to recognise, that small companies or free-lances offer comprehensive services, e.g. from the translation to the printout of a manual and desk-top publishing.

These facts require great flexibility on the part of the professionals. In particular, the technical standard of translators must be raised. Computer assisted translation is already being used. This means the translated texts are typed with specific software and provided on diskettes. The use of translation machines, work with certain systems like "Systran" (used by the Commission of the EC), and access to terminological data bases like "Eurodicatom" make the work of the translators faster and more efficient. But the creation of such a modern infrastructure is expensive. Only large institutions and enterprises are able to create such translation assisting tools. Furthermore, computer assisted translation is only possible with less emphasis on quality. This places the free-lance translators who do translations of good quality at a disadvantage. However, they have the chance to specialise in certain subjects which require fundamental software and computer knowledge. Since increasing numbers of specialists are required, firms with modern equipment offer free-lance translator contracts for certain periods and projects; contracted translators work with the machine and on the premises of the clients.

REGIONAL DISTRIBUTION

Professionals working in the linguistic service sector are concentrated in regions where large enterprises or international organisations are located. Inside the EC, the OECD and the European Commission have the largest staff working as translators and interpreters. This means that a great proportion of all employed translators and interpreters work in, or in the vicinity of Paris, Brussels, Luxembourg and Strasbourg. Since the EC and the OECD cannot translate everything in-house many free-lance translators have their premises close to these institutions. The same is the case for interpreters; they also settle very near to these cities. Regarding private industry, translators and interpreters concentrate in areas where international, export-related companies are located. This is the case in most capitals of the EC Member States, and in a few other cities of international importance such as Berlin, Hamburg, Düsseldorf, Frankfurt, Munich, Milan, Barcelona, Amsterdam and Rotterdam.

REGULATIONS

The role of translators and interpreters is only manifested by two international documents:

1. The UNESCO Recommendation on the Protection and Improvement of the Legal and Social Status of Translations and Translators, adopted in Nairobi in 1976.

2. The relevant provisions and recommendations regarding translators and translations set forth in the Final Act of the Conference on Security and Co-operation in Europe, signed in Helsinki in 1975.

Both documents recognise translators and interpreters as members of important professions which play an important role in the interest of international understanding, the promotion of culture and the furtherance of science, technology and economic progress. But they neither include any regulations for the professions themselves, nor for education related thereto.

In most EC countries, there are either absolutely no or only unsatisfactory regulations governing the legal status of translators and interpreters, apart from international or national copyright laws that apply to translators. Only a few EC countries have laws regulating admission to the practice of translation and interpretation. There is no professional job profile. Professional training is not necessary. There are no examination and qualification criteria that protect the title "translator" and "interpreter", codify the rights and duties of the profession, or provide for regulation of the practise of the profession of translator and interpreter. In most of the other EC countries, the legal situation is the same as in the United Kingdom: civil law is decisive in such matters as negligence, liability and performance of contract. Some countries such as Germany, have already enacted various legislative measures to regulate interpretation and translation in legal and administrative proceedings. But in general, the public has no guarantee that every person offering and discharging his or her services as an independent interpreter and/or translator does in fact possess the requisite skills. Only interpreters and translators registered in the national professional associations of some countries must have a university degree. More and more EC countries are offering an education for translators which leads to an academic, legally protected title. The already existing EC Directive on the acknowledgement of academic education is the only regulation which would be valid for the interpretation and translation professions, has not yet been adopted as national law in all EC countries. Consequently, at the present time, any person without any specific education as interpreter or translator is able to work in these professions within the EC.

OUTLOOK

The demand for the so-called "traditional languages" is almost satisfied within the EC. But the opening of Eastern Europe and closer relations in the world economy offer new possibilities for the profession. Therefore, a good knowledge of East European languages and other "exotic" languages is increasingly being sought. Greater professionalism, specialisation and comprehensive services will be required by clients. The use of artificial intelligence is becoming necessary. Free-lance translators and interpreters will face more competition from translation companies which are well equipped with computers and different in-house specialists. But the market remains large enough for free-lance translators and interpreters who are able to speak at least one "exotic" language and have special knowledge in a certain branch.

Publishing services
NACE 839

The publishing services sector is growing very rapidly, influenced by the pace at which technology is advancing. The customer base of publishing services is broadening. They range from non commercial concerns such as hobby clubs to major international commercial enterprises. This sector overlaps into other service sectors, which include computer consultancy, below the line advertising consultancy, and secretarial support services. The sector employs almost 50 000 persons in total.

INDUSTRY PROFILE

Description of the sector

Publishing services are services which help people prepare documents for publication. This help can take various forms from consultancy to the actual preparation of print ready documents. Companies and individuals providing publishing services include Desktop Publishing (DTP) consultants, DTP shops, pre-press companies and printing companies. Because of its diversity, no reliable statistics are available on the publishing services industry.

Recent trends

In recent years, the publishing services industry has been revolutionised by the introduction of computerised methods, and in particular by the growth of DTP. DTP equipment has replaced phototypesetting equipment in many printing companies. DTP shops have been established throughout Europe. It is thought that there are now at least 5 000 such shops in the EC. Finally many companies in all fields and of all sizes have found it worthwhile to establish their own in-house DTP facilities. A few years ago, working drawings and slides were the input for the graphic reproduction process, now in the Netherlands, for example, it is estimated that 60 per cent of the input of printers and pre-press shops is in the form of floppy disks.

Most DTP software is of American origin, notably PageMaker and Ventura. As a result, it was first available in English, which gave the United Kingdom a lead in the use of DTP in Europe. Nowadays, the major programmes are available in all European and many other languages, and the UK's lead in this field has been much reduced.

International comparison

It is difficult to estimate the size of non-EC markets for publishing services owing to a lack of statistics. The USA has a sophisticated publishing service market. The EC lags behind the USA in desktop publishing and design services. Japan despite being a developer of very hi-tech equipment is trailing a long way behind the EC in the development of DTP companies.

Foreign trade

There is very little trade in publishing services. The service companies involved sometimes have production carried out in a country with lower costs, such as Singapore or Thailand, especially for regular large production volume publications. Extra-EC imports and exports are very small. Taking data for the whole printing sector these are less than 2% of the internal market turnover. Cross border business within the EC is also minor, amounting to less than 5% of the turnover of the sector.

MARKET FORCES

Demand

Many printing press businesses have now computerised their production processes. Relatively inexpensive and more efficient computerised systems have helped many to make the decision to convert. There is a polarisation in the demand for final finish of documents. For some customers printing on a laser printer (300 dots per inch) gives an acceptable quality. Often this demand comes from persons and companies not using this type of promotion or communication tool before.

Those professional customers converting from the older technology often require the best possible finish and have 2 540 dots per inch bromide films made before printing. Professionals also enhance pictures in documents, often to give them a crisper look, using specialised desktop publishing program extensions.

Customers often require the flexibility of the electronic publishing system which allows documents made at the pre-printing stage in several formats so that they can choose the one they think is best. The text for a document, nearly always generated by word processor, is transferred to DTP software to enhance the way it looks. Style sheets, automatically set, present information in a given style. Very few key strokes are necessary to change style sheets. In fine tuning a document font types and character sizes can change to achieve the most suitable result.

The introduction of "in-house" DTP facilities in many companies reduces the potential demand for outside publishing services, especially if the company thinks it can handle the whole job itself, perhaps with the help of a colour photocopier. However, really high standard work still requires, sooner or later, the help of a professional pre-press or printing company. Moreover lack of graphic knowledge can cause trouble and extra cost at the next production stage.

Supply and competition

The traditional pre-press and printing companies are to a certain extent in competition with DTP shops and in-house DTP departments. Printing is a highly skilled profession, and in most countries the industry is a well organised, high wage industry often with strong trade unions. In competition with the new DTP shops, traditional companies must compensate their higher labour costs with higher productivity resulting from their skilled workforces and more sophisticated equipment.

There are no major pan-European DTP service companies. Most companies in this relatively new market sector only serve a limited locality in their own country.

Companies offering a full professional service are fewer than those offering processing and production at 300 DPI. Increasingly the latter subcontract pre-printing to printing companies, if they have to produce a high quality document.

Prices of publishing services offered by both pre-press and printing companies, and DTP shops have been falling, partly due to increased competition in the present economic climate, and partly because of falling hardware and software prices leading to improved productivity.

Production process

Computer technology is rapidly replacing technologies involving manual techniques prevalent in the mid-1980s. Most of the companies in the sector are new. Many only started business in the mid-1980s. Some business service companies with longer histories have altered business plans to get into the flourishing DTP services market. Many computer consultants have become more involved in DTP than in other activities.

Other professionals attracted to DTP include those that were previously involved in translating, printing, typing, word-processing, copy-writing, and proof-reading. Publishing production professionals, photo composers, page layout specialists and photo engravers, have had to move with the times by making investments in electronic printing. Most have now converted from manual to computerised page layouts. These include PC picture publishing, PC art, computer aided design (CAD), and DTP.

Most DTP companies are very small enterprises. Their main work is to layout documents from manuscript or electronic text using professional DTP packages, and subcontract the production. Many use only four main tools: an Apple Macintosh, IBM compatible or other PC, a scanner, computer software including DTP programmes, and a laser printer.

Some have made investments in higher or additional cost pre-printing equipment. This includes film making and bromide, and Cromalin proofing equipment. Often DTP involves incorporating pictures, graphs and tables into a document, and this sometimes needs special scanning or filming equipment and software to create files in tagged image film format (TIFF).

PageMaker has offered colour picture DTP software for several years. This has meant that Apple Macintosh has been the computer system chosen by many printing companies for DTP. In 1991, Xerox's subsidiary, Ventura, launched some very professional colour printing products for its IBM compatible PC customer base.

Specialised computer programs are available for making multi-coloured pictures. These programs allow PC users to make colour separations and retouch images. Examples are Ventura Separator, Ventura Photo Touch and Ventura ColorPro.

Professional picture publishing programs and scanners are expensive. For example, the normal retail price of Picture Publishing Plus software plus Scanner is about 8 000 ECU. The unit price of some sophisticated drum and flat bed scanners is about 100 000 ECU. Less effective hand held scanners serve the other end of the market.

Although scanning photographs or drawings has been the main method of making electronic pictures, programs now exist to make picture films from video films. "Multimedia" computer programs provide pictures by the latter method. An editor can also buy picture files. Many electronic picture libraries and software companies sell electronic pictures. Documents containing line drawings, data tables and graphs must merge files or parts of files from other PC programmes.

Big professional printing companies generally produce the final documents because they have the equipment for high resolution film or bromide production and large print-run capacity. Higher resolution desktop printers have recently become available. Eventually this may change things for small print-run printed matter, such as newsletters.

Moreover, photocopy machine technology has developed to the extent that the newest generation of professional photocopiers integrate printing and binding of documents. This process involves a computer terminal linked to the photocopy machine.

There are many DTP programs. They range from programs designed to make single page layouts to those for long documents. Printing professionals mostly use Ventura Publisher and PageMaker.

Companies not requiring so much sophistication or text adjustment can use other programs. These programs include Timeworks Publisher, Express Publisher, Newsmaster, Avagio, Finesse and Page Plus. Most programs are available for use in the DOS, Windows and Mackintosh operating systems. Some are also available on Unix and OS/2.

IBM compatible computers are now becoming the standard for the computer industry and users are changing from the DOS operating system to Windows. Apple Macintosh was the major computer system for DTP until recently.

PC art and picture publishing packages to create layouts are newer products for desktop publishers to work with. Some of them have existed for several years. PC art computer programs such as Artline, Illustrator, FreeHand and Corel-DRAW, many in fourth generation versions are relatively inexpensive (about 750 ECU per single user software in 1993). These programs help operators, lacking flair for drawing, to produce very professional drawings.

Printing companies that have resisted the conversion to the higher technology are unable to offer much flexibility or radical last minute changes. The DTP market is growing organically as trade associations, clubs and various companies begin producing magazines, newsletters and other printed material for their members.

REGULATIONS

There are no EC regulations governing this sector. National regulations which concern the computer and printing industries apply to publishing services. Companies involved in DTP must observe copyright and trademark laws.

OUTLOOK

As the cost of DTP hardware and software continues to fall more and more, "non-professionals" will be able to afford the equipment necessary to prepare their own documents for publication. Professionals such as DTP shops and pre-press houses will find their market increasingly restricted to, on the one hand, clients who do not have in-house DTP facilities, and on the other hand, to the final preparation of high resolution documents, already in electronic form, for printing.

As costs fall, the overall volume of pre-press undertaken both in house and by independent professionals, will increase. More newsletters and publicity material will be produced and catalogues will be updated more frequently. This will create increased demand for ancillary services such as electronic picture libraries. It is generally estimated that the pre-press market is growing at about 10% a year in the EC as a whole.

Temporary work services
NACE 839.2

Over the past four decades, temporary work services have progressively changed into a sophisticated, professional service industry providing instruments for labour management. The industry has been the main tool for helping businesses fill temporary shortages in their workforce. Since temporary workers often find permanent employment through their temporary assignment, this has turned the industry into personnel recruitment advisors. Temporary work businesses are now widely accepted in most countries and have flourished in the recent past. Currently, however, the sector is experiencing a period of stagnation or even recession in some countries. This is largely due to a general economic recession, and in part to the fact that the sector has reached a maturity phase in several countries.

INDUSTRY PROFILE

Description of the sector

Temporary work businesses hire temporary workers putting them at the disposal of a third party, and forming a triangular relationship. Key to this relationship is the fact that they receive their salary from the temporary work business but their workorders on assignments from the third party. Client firms call upon the services of temporary work businesses when they have temporary shortages of labour. The hourly cost of temporary labour may at times be higher than that of permanent workers, but since temporary labour is usually resorted to for short, well defined periods or for specific tasks, the cost is borne only for effectively supplied hours of labour. The alternatives, overtime or a permanent reserve of extra manpower, would be more expensive. Temporary work businesses bear the cost of recruitment, selection, pay rolling, statutory social security insurance, etc.

For temporary workers, temporary work businesses satisfy particular individual needs and preferences. However, a growing number of jobless workers also resort to temporary work businesses to find a temporary occupation with the expectation of finding permanent positions at a later stage. It is estimated that on average well over one third of temporary workers find permanent jobs as a result of temporary contracts. The actual proportion varies widely between different EC countries.

The ageing of the European workforce and the increase of the female component also have an effect on the temporary work services sector. These developments have been associated with a greater desire for more flexible and temporary working arrangements.

It is important to note that temporary work is very strictly linked to the level of economic activity: therefore, like advertising or transport services, it constitutes a useful conjunctural indicator.

Recent trends

The importance of temporary work can be shown by the number of people who are active in the sector each working day. In Table 1 it can be seen that France, (West) Germany, the Netherlands and the United Kingdom are the largest employers of temporary workers in the EC. On the whole it is estimated that in the EC well over a million persons a day work through temporary work businesses. In the United States, a country with a comparable workforce, this figure was lower for many years. But the past few years have shown a quickly increasing market penetration, so that employment per day is now higher than in the EC. For a correct comparison, however, it should be taken into account that the temporary work services sector is nonexistent in Italy and Greece, and still not very developed in for example Luxembourg and Ireland.

Most of the turnover in this sector is generated in Belgium, France, Germany, the Netherlands and the United Kingdom, as can be seen in Table 2. The sector in general has shown double digit growth in recent years, in countries where temping was already developed and in countries where it has been developing rapidly. The arrival of the current recessionary period in many countries, however, has resulted in a zero or even negative growth in 1991 and 1992. The sector is still growing in importance in Spain and Portugal. In these two

countries, temporary work businesses have only recently been legalised, or tolerated in the case of Spain (the sector has not yet been officially legalised). The market potential is, therefore, still large. Most Member States indicate that 1993 is not bringing signs of recovery. Improvement in the market situation is generally not expected until the second half of 1994.

International comparison

Total turnover in the EC was approximately ECU 19 billion in 1992, down from almost ECU 20 billion in 1990. Turnover in the USA, in comparison, was approximately ECU 17 billion in 1990 and is now estimated at ECU 21 billion. While the sector is clearly stagnating in the EC, it is a large growth market in the United States. Market expectations there are still positive. The sector has also grown in importance in Japan and was estimated at over ECU 9 billion in 1992, although market forecasts are now comparable to the EC. In EFTA countries, the sector is still not very developed, though it must be noted that the figures given are incomplete due to a lack of statistics from several countries. The world market is estimated at approximately ECU 50 billion currently. All estimates given are based on statements made by national federations, since no regular statistical surveys are held in this sector in the EC or other countries.

Foreign trade

Basically, temporary work businesses operate on a local scale, whether they are a small, independent oneoffice company or an office of a larger multinational temporary work business enterprise. "All business is local", is a saying which applies very directly to this sector, with the possible exception of highly specialised businesses. Furthermore, it is difficult to send temporary workers across borders due to contradictory national legal regulations. Therefore, cross border activity takes place only on a very small scale. Temporary work businesses wishing to operate in foreign countries generally do this by starting a local branch or by buying into a local company.

MARKET FORCES

Demand

The enormous growth in demand for temporary work services in the past clearly stemmed from the growing need for more flexible labour contracts. The favourable economic climate, also helped boost growth. The current situation is somewhat reversed. The more developed temporary work markets show saturation tendencies, and the stagnation of economic growth or recession in most EC countries have caused zero to negative growth. Markets which are heavily effected by these trends are, for example, France and the United Kingdom. In general,

it is expected that growth will remain more in line with general economic activity in the future.

The fields in which temporary workers fulfil their assignments tend to differ between countries. In France and Germany, for example, the majority of temporary workers are blue-collar workers. In the United Kingdom, Denmark and Spain temporary workers are primarily active in the administrative or commercial fields, as is the case in the United States and Japan. In some countries this is due to restrictive regulations. The differences are further illustrated by Table 3.

The length of the contract that is desired by clients varies. This is usually dependent on the function which the temporary worker will fulfil for the client. If the temp is called for to replace someone who is, for example, ill or on holiday, contracts are usually fairly short: from a day to several weeks. However, if a temp is called for because of an unfilled vacancy, or because the client is not certain whether the development of his business will allow him to hire an extra worker permanently, contracts can be extended to months or even a year or more. Contract duration is usually limited by national regulations, but the maximum period varies per country. Client companies often treat temping contracts as if they were trial contracts. They increasingly tend to offer a permanent contract to workers who have worked for them through a temporary work business.

Supply and competition

The number of branch offices per enterprise can serve as a basis for market coverage calculations and concentration figures. The fourth column in Table 4 shows quite clearly that the sector is the most concentrated in Belgium and the Netherlands. Market coverage in terms of active population per establishment is highest in the Netherlands and the United Kingdom. In these countries, there is one office for every 3 500 to 4 000 potential temps. Differences in market coverage are large, as can be illustrated by comparing this last figure to that of Spain: where the number of persons one branch office serves is many times higher. These differences will diminish with the further development of the sector. Naturally, the market coverage figures also give an indication of the degree of competition in the different EC markets. In general it can be said that competition is fierce in well developed and/or stagnating markets, such as the United Kingdom and moderate in less developed and/or growing markets, such as Spain. In comparison to the EC, Japan especially has a high number of offices per enterprise. The workforce served per office in Japan and the United States indicates temporary work markets which are fairly developed.

The degree of differentiation in supply varies from country to country, depending on market demand and regulations, but does not seem to differ very much within any particular country. An exception which regularly appears, is a specialisation in client markets, like intermediating for medical staff for example,. Prices and other terms offered are more or less the same, competition takes place through elements such as response time to a client request, distance between client office and temporary work business, past performance of temps hired and other client services offered.

INDUSTRY STRUCTURE

Companies

Some of the largest temporary work businesses operating in the EC and their home countries are (in alphabetical order): Adia (CH), BIS (F), ECCO (F), Manpower (USA), Randstad (NL), and Vendex (NL). Their estimated total market share in the EC is 35%. In the United States the four largest companies are estimated to hold 30% of the market. Temporary work businesses of EC origin account for over 80% of the EC market (above percentages based on 1989 data). Many temporary work businesses operate under more than one name in the same market. Some have the same management, others operate more or less independently. Franchising is known to be practised by, for example, Manpower and Adia. The market leader differs per country; regularly, the leading position is held by a business with its home base in that country. Examples are Randstad in the Netherlands, ECCO in France and Interlabor in Belgium.

A notable phenomenon is the existence of cost-based government temporary work businesses in Belgium (T Interim) and the Netherlands (START). They have gained a considerable share of the market. At the same time their operation has proven to be beneficial to the acceptance of organised temporary work in these countries, and thus to the market size.

Strategies

In the past years temporary work businesses, particularly the larger enterprises, have diversified into less related services such as security, contract cleaning and maintenance, language services, business information and financial services. The present trend is more focused on efficiency and upgrading, while expansion is strongly geared to services related to personnel management and internationalisation. In their efforts to improve the efficiency of their operations and the quality of their services, temporary work businesses are investing heavily in computer systems and networks. The second trend is to upgrade, illustrated by the fact that some temporary work businesses are shifting towards temporary workers with higher educational qualifications and more experience. The major temporary work businesses have expanded their businesses internationally. Internationalisation not only takes place in EC countries, sometimes by acquisition but also, outside the Community, notably in the USA and the Far East including Japan.

The expansion into personnel management areas is to be found in services such as personnel management for small and mediumsized enterprises, recruitment, including head-hunting and training of personnel. This is triggered by the fact that the distinction between permanent and temporary employment is becoming less pronounced.

In those countries with a liberal regulatory regime a shortage of qualified temporary personnel has shown to be an obstacle to growth. This shows the importance of education and training now provided by an increasing number of temporary work businesses. Typing courses, word-processing training and low-level technical courses are forms of training that figure regularly in their programme. Specific training tailored to the job or the individual is also common.

The issue of quality accreditation has also made its entrance into this sector. The countries in which the sector is well developed have recently started efforts in this direction. It is a result of a more competitive market situation, combined with the trend in business in general towards a higher level of client service. Companies try to offer quickly available and flexible services, while still complying to the high quality standards demanded.

REGIONAL DISTRIBUTION

Basically temporary work business is local business. Most companies operate through a network of local offices. Offices are located either in the near vicinity of potential clients or in the near vicinity of potential temps. This differs for each country.

REGULATIONS

Organised temporary work is widely practised in the majority of the Member States. There are, however, considerable differences in regulation between EC countries which is clearly explained in "Temporary Work and Labour Law of the European Community and Member States", edited by R. Blanpain, Kluwer Lavv. Several countries prohibit temporary work altogether. Other countries accept temping, either with or without specific regulation. Two countries, Greece and Italy, absolutely prohibit the operation of temporary work businesses and the conclusion of temporary work contracts. In these countries, illegal practices are known to exist. In Italy, the social partners are becoming increasingly aware of the benefits of temporary work and the negative effects of the illegal practices at this moment. The Prime Minister has announced the intention to publish a new draft law in 1994. In Spain the estimated 200 temporary work enterprises are still officially forbidden, although they are tolerated in practice. The local branch federation GEESTA is recognised as a partner in the discussions which take place about the legalisation of temporary work. A draft law is expected to be accepted in 1994.

Denmark, Ireland and the United Kingdom accept the existence of temporary work without applying specific regulation. This leads to a relatively protected status of the temporary worker in Denmark, as he is considered to be an employee and therefore enjoys normal labour standards and social security. In both other countries, however, the temporary worker is not necessarily considered an employee.

Belgium, France, Germany, the Netherlands and Portugal have regulated temporary work. Some restrict the use of temporary workers in one or more business sectors. For example, the Netherlands and Germany prohibit temporary work in some areas e.g., blue-collar workers in the building and construction industry. Belgium has the same rule for that industry as well as for furniture removal and storage. A number of other restrictions and requirements are common to regulations in Member States as well, the most important being: requirements for the contract between the user and the temporary work business; registration and/or licensing of temporary work businesses; limitations to the conditions under which temporary work is allowed; limitations to the duration of contracts, varying from 3 to 24 months or no restriction; requirements for wage levels and social security conditions.

An indicative summary by the national branch federations of the degree of regulation is shown in Table 5. The statements 'liberal' and 'restricted' should be seen relatively; they are meant to compare the EC countries to one another. The United States considers its regulatory regime liberal, while Japan characterises its regulation as restricted.

Three Commission labour law proposals, enacted in 1990, apply to temporary work. They mainly consider working conditions, specific regulation for contracts involving distortion of competition and measures regarding health and safety. This last proposal was accepted in 1991. A fourth proposal which also affects this sector, accepted in 1991, regards the posting of workers across borders and considers, among others, pay and working time. Implementation of the proposals could cause difficulties in several countries, as this can imply significant changes in the current regulations. Also, problems arise because of different conceptions of key aspects such as "employee" and "employer".

OUTLOOK

The expectations for growth vary from country to country. However, unlike the growth figures mentioned in earlier Panorama editions, the 1993 growth figure is expected to be zero e.g. Belgium or negative e.g. France, the Netherlands, Germany, with the exception of the growth markets in Spain and

Portugal. In general it is clear that the industry is dependent on the growth of the economy. Economic recession and full employment both tend to reduce turnover. The sector seems to thrive best in a climate of moderate or brisk general economic activity. Prospects are expected to improve in the course of 1994.

In those countries where temporary work businesses are well developed, competition is strong. In the countries where the sector is less developed or as yet illegal, measures leading to a more liberal regulatory regime could still provide large growth impulses for the sector. Competition there is much weaker.

The industry is represented at the EC level by: Confédération Internationale des Entreprises de Travail Temporaire (CIETT). Address: 1214 Denman Street, London W1V 7RN, United Kingdom; tel: (44 71) 323 4300; fax(44 71) 255 2878.

Industrial cleaning services
NACE 923

The EC market for industrial cleaning services reached 19 billion ECU in 1992, a 5.35% increase in real terms over 1991. The three main users of industrial cleaning services are government, private businesses and hospitals. The rate of penetration of industrial cleaning services is still fairly low at about 50%, indicating that the sector could continue to enjoy rapid growth in the coming years. Client demand is increasing for quality standards and a broader range of services. This industry is labour intensive and thus very sensitive to changes in the regulatory environment.

INDUSTRY PROFILE

Description of the sector

The service activity presented in this chapter is the cleaning by specialised firms of buildings whether they are used for administrative, industrial or commercial ends. Services provided by cleaning contractors are the following: inside cleaning of buildings such as offices, factories and workshops, inside cleaning of transportation vehicles (buses, trains, planes, metros, trams, ships), tanks, and simple building maintenance. The following activities may also be provided by cleaning firms, but are not covered here: security services, waste management services, evacuation of asbestos, laundry, dry cleaning, and pressing. In some EC Member States, chimney sweeping, facade cleaning (not including restoration), the maintenance of areas around buildings and general sanitation are also part of industrial cleaning services.

In 1992, overall turnover of cleaning contractors in the EC was over 19 billion ECU. This growth can be explained not only by an upturn in European market for industrial cleaning services, but also by an increase in the level of market penetration by cleaning firms. All the Italian data for 1992 remain the same as 1991 due to lack of new data and the current difficulties in Italy.

The degree of market penetration, extremely important for business services, measures the share of the total potential market that is actually subcontracted to specialised service contractors. The rate of market penetration by cleaning contractors is calculated based on several estimates, one of which is the sales of cleaning products and materials to cleaning companies. At present, the rate of penetration in Europe is estimated at 51%. The rate of market penetration differs between Member States, in Belgium and Germany it remained the same from 1991 to 1992, but it grew in France from 46% in 1991 to 48% in 1992. The low rate of market penetration in Denmark and in the United Kingdom explains the relatively low turnover achieved in those countries, compared to other countries with a similar level of development.

Recent trends

Office cleaning is traditionally more important in terms of turnover than other market segments. It is also the segment of the market where in-house cleaning is estimated to be the most significant, and it is also estimated that there is still a significant potential for growth. Indeed, many private or public companies do not yet contract out the cleaning of their premises, except perhaps for some exceptional work like, window cleaning, cleaning of carpets, floors, etc. In-house cleaning may, however, be limited to certain segments of industry with specialised facilities or controlled environments such as nuclear power stations, agri-food industries, dust-controlled rooms, etc. In the public sector, the rate of market penetration is higher than in the private sector e.g., for Spain with 70% penetration in public markets and 60% penetration in private markets.

Hospital cleaning must be separated from the other market segments since the requirements are very specific. It entails both, the cleaning of common spaces, and rooms, quite similar to hotel cleaning (in terms of day-time work, full-time and with longer average working time) and the disinfection of more sensitive areas such as operation rooms. This latter task generally requires specific techniques and skills. Frequently rooms and public spaces are still cleaned by the hospital's own staff.

MARKET FORCES

Demand

Two trends have recently appeared on the cleaning market : the demand for quality and a broader range of services. It is, however, still difficult to either quantify or measure their impact on the industry.

Cleaning service customers are more and more demanding in terms of quality. These customers often ask that objective criteria be used to establish the price for a defined level of quality. This raises serious problems in the case of industrial

cleaning services because of the high subjectivity attached to the concept of cleanliness. It is, indeed, extremely difficult to measure quality in the cleaning sector. Some projects towards the establishment of quality measuring systems have been carried out. A Dutch cleaning institute, VSR, has developed a relatively sophisticated system which can be applied to approximately 25% of the local market. It consists of establishing, with the client in advance, a precise list of criteria based on a range of possible errors. The level of quality, according to this list, is checked periodically. This quantitative account is used to define what is an acceptable level of quality for the client and is then registered with the contract. In France, the International Technical Centre for Cleanliness (CTIP) is also trying to define a means of quantifying cleanliness and the technical means to achieve the desired results.

The client's natural requirements for high quality are in contradiction with the widespread tendency of systematically choosing the lowest priced tenderer. The process "low price/poor service quality/dissatisfaction of the client" is thus engaged, seriously damaging both the quality of the services performed and the profession's image. A first solution comes from the contractors themselves, who try to make their clients aware of the problem as the contracts are being drafted. Another solution is provided by the professional organisations who organise communication campaigns, and promote establishing minimal professional requirements necessary for market entry and performing cleaning services.

Another trend that seems at present to be limited to the British market and, to a lesser extent, the Dutch market, is the extension of the contractors' activities to the provision of broader support services. These may include, security services, catering, building maintenance, and the care of surrounding areas, etc. This trend is the consequence of the requirements expressed by some big clients, especially the British public sector, who are seeking to simplify subcontracting by limiting the number of contractors. It is, however, not yet possible to measure the impact of this trend on the market or on the profession. It is also impossible to appreciate whether it will extend significantly to other EC markets.

Supply and competition

Structurally, the sector is characterised by a large number of small companies, employing less than 20 workers. Broadly speaking, more than 90% of the cleaning contractors in the EC employ less than 100 people. The number of employees is still increasing, but the augmentation was less important between 1991 and 1992, than it had been in the past.

There is still a large proportion of women in industrial cleaning services. One should note moreover the constant prevalence of part-time workers, with an average working time which is about 4.5 hours/day. Cleaning services are performed outside the usual working hours, when the clients buildings are relatively unoccupied.

Contractors must, therefore, concentrate their workforce on two relatively short periods: in the morning and in the evening. Full-time work is quite atypical in the cleaning industry, as the "work day" is frequently split into non-consecutive periods : morning and evening.

Wages are close to 6.2 ECU/hour. Except in Portugal and in the United Kingdom which are in fact estimates, the minimum hourly wage for unskilled workers in the cleaning industry is quite homogeneous. The gross wage appears to be quite high in Denmark, but this results from the fact that the social contributions are distributed differently between employees and employers. The total cost of labour including both the wages and employer contributions, varies significantly from one country to another. This mainly reflects differences in national and professional contributions which are required by the government and guaranteed by the collective agreements for social protection systems, across countries. However in Spain, the devaluation of the peseta must be taken into account when comparing the 1991 data and the 1992 data.

In order to promote greater professionalism in the cleaning industry, employers are aware of the necessity to increase work time. At the same time, they intend to develop vocational training initiatives especially for the lower levels of professional qualification. Beyond its direct affects on the quality of the services, this strategy hopes to keep workers in the

company, or at least in the industry, and stimulate their professional motivation by offering them the opportunity to have a professional career in this industry.

INDUSTRY STRUCTURE

Companies

Apart from Spain and Luxembourg the number of firms within EC Member States is still increasing, for example in Germany the number of cleaning companies increased 33% between 1991 and 1992, while in Portugal the number of firms grew 22.16% from 1991 to 1992, the largest increase occurred in Denmark with 73.91%. The EC cleaning industry in 1992 was made up of nearly 40 000 companies, this number is constantly increasing as a consequence of the dynamism of the industry.

Strategies

The trend towards a greater concentration of the market through mergers or acquisitions is evident in all EC countries. It is hard to put numbers beside this trend since there is usually only a change in capital ownership as the establishments often retain their previous name after the transaction, which usually only affects the capital ownership.

More frequently the larger groups are seeking to diversify their activities by entering the cleaning services market and taking over existing companies. This has particularly been the case with large temporary work service companies, and of companies such as the French Compagnie Générale des Eaux. The big groups are also growing in importance in terms of employment and turnover. In France, more than half of the workers are employed by firms with more than 500 employees which represents less than 100 firms and 40 companies with over 1 000 companies account for one third of the turnover of the sector.

REGIONAL DISTRIBUTION

Cleaning contractors are naturally located in industrial and urban areas, close to their clients. The industry is in effect characterised by the necessity for the contractor to be established very close to the clients. This results in a high fragmentation of the industry. The firms which develop activities in several regions usually operate via a network of local agencies, linked to the mother company through regional or national subsidiaries. Most of the big groups are established in several countries EC and non-EC. The internationalisation of these groups, however, is hard to measure since, they often enter new markets by taking over national companies which remain essentially national establishments. The cross-border provision of cleaning services is quite rare and limited to neighbouring regions or to very specific contracts.

REGULATIONS

The cleaning industry is highly labour intensive, which makes labour-related costs an extremely important factor in the determination of the price of the service. Labour costs represent between 75% and 85% of the companies' turnover. Companies are therefore directly affected by social regulations. The organisation of work is unique to cleaning activities and often requires the adaptation of social laws to its features. For instance, any regulation limiting part-time work would have a major impact on the cleaning service sector. The social statute of workers in the cleaning industry is generally defined by sectoral collective agreements, at the national or regional level, except in the United Kingdom where agreements are made at the company level.

One of the most constraining social regulations for cleaning contractors is the obligation in most EC countries to keep all or part of the workers at a given site in the case of a change in ownership and contractor. The terms of this transfer of employment vary across the Member States. By taking away the contractor's manoeuvrability, this regulation tends to decrease competitiveness.

Except in Germany, the access and the exercise of the profession are completely free in the EC Member States. Because

the sector is a fairly dynamic one, many new cleaning companies are created every year. Most of them are small (less than 5 employees), and managed by people who neither have a basic knowledge of management rules nor basic professional skills. This makes the "life expectations" of these firms quite short, and many do not survive beyond one year.

Most small companies have a tendency to tender at unrealistic prices which are sometimes lower than the local cost of labour. Furthermore, they often do not have a sufficient financial capacity to be able to face the difference between the date at which they are paid by their clients and the monthly payment of their social obligations. This explains why so many companies go bankrupt after only a few months of existence. Beyond its social consequences, this problem damages the whole profession and often results in a return to in-house cleaning by the client who initially out-contracted these services. The profession has tried to react in most of the European countries, and national organisations of cleaning contractors are trying to impose minimum standards with which firms must comply to be allowed to enter the market. The solutions adopted by the industry representatives differ from one country to another, depending on the national legislative system and habits. Some systems have been established by the profession itself as in France: "Marque Professionnelle", and in Germany "Guterschutzgemeinschaft"; but the labels are granted by independent authorities.

OUTLOOK

From an economic point of view, the completion of the single European market offers good opportunities for the companies in this sector. Beyond the opening up of public procurement of services and the complete liberalisation of service provision, cleaning companies should benefit from the cooperation tools offered by the EC law, especially the European Groups of Economic Interests, a body which aides in formulating legislation. The creation of a European company statute should also facilitate the internationalisation of cleaning companies in the near future. One major concern must be mentioned: the distortion of competition that can result from differences in labour costs. The current situation shows large differences in unit labour costs across countries. This may result in an artificial delocalisation of companies, eager to benefit from lower labour costs in certain regions. This could seriously damage the regional, economic and social landscape of these regions. However, because of the proximity requirements, this phenomenon would be limited to cross-border regions, and to a limited number of long distance or very specific contracts.

Written by: FENI
The industry is represented at the EC level by: Fédération Europeénne du Nettoyage Industriel (FENI). Address: Avenue des Nerviens 117, bte 48 bis, B-1040 Brussels; tel: (32 2) 732 1601; fax: (32 2) 735 0787.

Security services
NACE 839.3

The security services sector in Europe had a turnover of approximately 7 billion ECU in 1993, employing 424 550 people of which some 314 410 persons were employed by the 4 635 private security companies operating in the EC.
About three quarters of security activities are subcontracted with the remaining quarter handled by corporate security divisions.
Many Member States are working hard to improve the quality of the services provided. Some individual firms have already been certified in accordance with ISO standard 9000.
Quality improvement in the education and training of employees has in some Member States resulted in forms of co-operation with the regular police in the field of preventive supervision. Against previous expectations, no real growth took place in the security services sector. Due to the recession, the private security sector stabilised on the level of 1992. Also a lot of companies had to cope with an increase of direct costs, such as staff salaries, social premiums etc., which have put the net results of many companies under pressure.

INDUSTRY PROFILE

Description of the sector

The term "security" comprises a variety of specialities within the sector. This monograph is mainly based on data concerning the "manned guarding" sector, but also provides some information on transportation of valuables and other related and ancillary specialities.

The sector of the production of electronic and technical equipment, for example, manufactures detection systems offering a variety of possible security applications, as well as exchange units capable of handling many types of signals and forwarding these to central alarm stations via telephone or permanent lines.

We are witnessing the dawn of the "electronic age". Wireless transmission from detection systems to a central alarm station may mean lower installation costs and can in some cases positively affect the risks of sabotage etc.; it may also prove the best solution in case of objects needing temporary protection (as in the building sector).

Even the technical advantages of the space age are noticeable in the security services sector. Today, tracing systems are being applied which can, by using satellite communication, accurately trace any object on earth equipped with a signal code emitter to within a few metres. This represents a great step forward in combating crime, (e.g. in the case of VIPs taken hostage). Furthermore, this development can also play an exceptionally useful role in improving the security of, for example, shipping traffic after a calamity has occurred.

Satellite tracing systems also contribute to the improvement of efficiency in international land, sea and air transport by allowing continuous spotting of the transports. This helps to coordinate the deployment of materials and/or ensure proper monitoring.

As an extension of the production sector of security equipment, the technical installation sector constitutes a logical speciality. It ensures the installation of security equipment in buildings, on grounds and to an increasing degree in private homes. This sector is developing very fast.

In the construction of new office and industrial buildings, a clear increase of so-called "smart buildings" can be observed where building automation plays an essential part. Often the technical installation comprises not only the security equipment: elements like air-conditioning, automatic access control, lift service programs etc., are also included in the technical infrastructure.

The central alarm station forms a vital link in the above-mentioned sectors. Equipped with state-of-the-art security equipment and usually manned by a team of at least two, it receives the signals from technical systems installed at the clients' premises and handles them according to a scenario agreed previously with the client. Depending on the type of occurrence, assistance is called in from the police, fire units,

technical emergency services or the alert verification team of a private security organisation.

The central alarm station is also increasingly seen to give active response to certain signals because today's data network infrastructures allow remote control of technical processes. Systems can be switched on or off at a distance, the degree of distance being basically irrelevant. Visual images can also be transmitted via this method.

In the EC over 1500 central alarm stations are operational with an estimated 4.5 million connected installations. This sector has a considerable growth potential. It appears likely that middle-class households, too, will increasingly decide to purchase professional security equipment linked to a central alarm station. Considering technical developments, the purchase of "domestic equipment" will in principle suit all purses.

MARKET FORCES

Demand for manned guarding services

All over Europe, the beginning of the nineteenth century saw the advent of night security services, usually on a small scale, active locally and often established in industrial areas. Not until after the Second World War did a substantial growth occur due to a number of factors: increasing industrialisation and the prosperity it brought, increased crime, weakened social supervision by the environment (family, church etc.); increased awareness by entrepreneurs of the necessity of protecting their own belongings instead of considering the mere responsibility of the authorities or the police. Preventive security activities were carried out by security staff employed by the company itself as well as by employees of the contracted private security organisation.

The growth of the private sector was greatly enhanced because businesses frequently chose to concentrate on their own field and hive off disparate tasks. After industrial cleaning maintenance and catering, security activities were also increasingly subcontracted. Besides subcontracting, we find the birth of the "externalisation" concept meaning that "corporate" security guards are transferred to a security organisation specially selected for a particular purpose. In this new form the existing security activities are continued on a contract basis. This tendency may be compared to the process of privatisation of government tasks.

Annual growth in the security services sector over the previous year is 10% on average. This growth is occasionally the result of incidents, such as the Gulf War (1991) when heightened threats of terrorism compelled entrepreneurs to take additional security measures.

The existence of an extremist terrorist group in a country can strongly affect the level of prevention within companies. But security is also seen to contribute to the continuity of the production or labour process and as such represents important support for a company's continuity criterion.

Preventive security has become a profession. The duties have grown more complex. Where in the past they were mostly concerned with porter services, mobile surveillance and the like, present day security guards perform extremely useful and critical tasks within the framework of the total management of extensive projects involving a wide range of crucial security functions.

In large industrial plants and exhibition operations, security guards are in charge of not just access control but also fire prevention and sometimes fire protection; they perform tasks in traffic control and parking supervision on the grounds and provide First Aid. For all these purposes, they man control rooms from where the security of the production process in the widest sense is monitored.

Another reason for the growth is the diversification of the security services sector. The uniforms (often an element of identification), recognisibility, mobility and up-to-date communication equipment represent an infrastructure that allows private security organisations to explore new fields of activity such as operating bridges and locks in water-abundant areas, management of nature reserves or preventive supervision in the recreational sector (campsites, beaches). Other activities

include environment-screening in cooperation with companies or public authorities.

In many countries there is some form of cooperation with public authorities. For example, budget inadequacies of the police have contributed to the development of cooperation in which the police play a supervisory role. A common example is the security check of passengers in many international airports where private security guards screen passengers under the supervision of the regular police force. Less familiar are forms of cooperation (e.g. the overseeing of detainees, traffic control, parking supervision in city centres and intendancy in public transport particularly in large cities) where drug abuse has especially caused criminal acts to multiply. Security guards are also used to protect military objects and to perform preventive activities in prisons.

Supply and competition

In many EC countries, much is being done to improve the quality of the service. Quality is increasingly becoming a measurable element which relates to:

- quality/expertise of the company management;
- quality of the organisation, procedures, etc.
- quality of the performing staff (education/training);
- quality of the terms of delivery.

In the countries where relevant legislation exists these rules are often seen to contribute to the quality aspect. Indeed, competition among security firms is first of all a matter of quality aspects and much less a question of rates and on-charging. In those countries where competition has focused on the cost price of the service, we also find that this policy leaves no room for financial investments in quality improvement. Although no unequivocal standard has as yet been established, it seems likely that the international quality standard for services (ISO 9000) will be applied as a certificate of quality assurance.

Several security firms have so far been certified according to this standard and no doubt more companies will follow their path.

INDUSTRY STRUCTURE

Manned guarding services

A survey held in 1992 among the members of CoESS (Confédération Européenne des Services de Sécurité) showed that this service sector employs 424 550 people.

The subcontracting percentage in the EC Member States averages 74% (314 410). The remainder (110 140) employed in a corporate situation. In the EC an average 124.9 out of each 100 000 inhabitants work as a security employee. The turnover of the 4 365 private security firms in the EC amounts to 6 684 million ECU, with an average annual turnover of 21 259 ECU per employee.

There are 4 365 security firms in the EC. The average work force is 72 employees per firm. In non-EC European countries, the average company size is 74 employees in the 457 security firms established in these countries. An overview of the company size of security firms can be given for the following EC countries: United Kingdom, Germany, Spain, The Netherlands and Italy.

In addition, about 33 600 security employees are being employed in non-EC countries by a total of 457 security firms. Their total turnover is 1 014 million ECU which means an annual turnover per security employee of 30 164 ECU.

Transportation of valuables

In 1993, this sector of activity employed 44 600 persons in the EC, for a total turnover of 1.6 billion ECU. The sector of transportation of valuables consisted of 197 companies, with 8 900 armoured vehicles of all types. The average work force in the sector is 226 employees, and the annual turnover per employee was 35 830 ECU.

Table 4: Security services

Source: ESTA

The activities of armoured car transportation of valuables are diversifying to include services such as: coin processing, cash note processing, cheque encoding, and Automatic Teller Machine servicing.

New technology is progressively introduced to protect the crew members from hold-up attacks. The principle used is the self destruction of the transported valuables in case of robbery.

REGULATIONS

In various ways there are considerable dissimilarities in the laws and regulations. These laws and regulations are, of course, subject to change. The information supplied below was valid in late 1990 and early 1991. It describes a number of marked differences in laws and regulations. Since then, two EC countries have adopted new statutes, namely Spain (1992) and Portugal (1993).

Most European countries have some form or other of laws or regulations. One noticeable exception is the United Kingdom where no government rules exist whatsoever. Germany too, considering the extent of the sector there, takes a position of its own. This country does have some incorporated legislation but no specific legislation.

A number of duties are performed on a standard basis. In some countries the array of duties is quite wide. In Sweden the tasks include the production of identity cards and assistance in fire-fighting. In Germany a considerable amount of activities are connected with the maintenance of public order. In Spain part of the duty is to pursue and arrest lawbreakers.

All European countries (excluding the UK) have mandatory licence and practical requirements which are generally the same. Although such harmonisation exists, a number of countries enforce special requirements, including:

- compulsory third-party liability insurance (Belgium, France, Portugal, Spain and Switzerland);
- Belgium and France apply restrictions for those who have previously been employed professionally in the police force or have been in the military. Italy and Spain, on the other hand, make it a requirement to have accomplished one's military service to be allowed to work as a security guard;
- in France it is not possible to enter the security services sector after a bankruptcy.

The requirements and the duration of the various types of schooling in Europe are quite diverse. In Germany there is no unified concept. In The Netherlands, however, schooling is organised quite thoroughly as compared to the other European countries.

Laws and regulations with regard to equipment (uniform, weapons, identification and the use of dogs) are on the whole similar in all countries. Wearing a uniform is compulsory in most countries, but is optional in four countries. The uniform shall not resemble the police uniform.

Carrying arms is permitted with the exception of Denmark, the United Kingdom, the Netherlands and Norway. In some countries, the laws and regulations with regard to arms are contained in the Fire Arms legislation of the country in question. In other countries, a separate article is included in the Security legislation.

In most countries employees in the private security services sector are obliged to carry an identity paper; Austria is an exception. In Spain security guards can easily be recognised by a badge that each guard is required to wear.

As for government supervision, Belgium, the Netherlands, Portugal and Spain stipulate annual reporting to the Ministry in charge. In Sweden and Norway supervision is in the hands of the police.

The amount of possible sanctions varies widely. In the Netherlands there is only the possibility of withdrawing the licence. Belgium, Denmark, France, Norway, Portugal, Spain and Switzerland have, in addition to that sanction, the possibility of imposing fines and/or imprisonment.

Other noticeable clauses include:

- security firms are not to concern themselves with or intervene in political or labour conflicts (Belgium and France);
- in case a person offers resistance against removal a certain amount of violence may be used (Finland and Sweden);
- the wages of a security guard must not be lower than the starting salary of a police officer (Greece);
- in Austria approval from the Prime Minister is required if someone wishes to exercise other activities simultaneously with security activities;

- in Spain each private security organisation is assigned an exclusive number. This number must be mentioned on any document and in any publication the firm produces.

OUTLOOK

Late 1993, the Directorate General V organised a social dialogue on the security sector in Brussels. The dialogue was attended by representatives of trade union (Euro-Fiet), branch organisations such as CoESS, IPSA and DGIII.

The basis is created for structural debate in future on a variety of important themes, such as: legislation, vocational training, screening and licensing. In general the meeting found agreement for setting up a minimum of standards throughout Europe in relation with the mentioned subject.

Although, at this moment, no direct improvement of the economy is in sight, the security sector hopes that it will maintain the actual size and volume and by improving quality to be able to grow again in future.

As for the security transportation sector, it will continue to grow as it did during the 1988-92 period, when it nearly doubled its turnover. At present the contracting of the security transport services to private companies is reaching the top of the potential market in some EC countries and will stabilise in the years to come to the actual values.

Car rental
NACE 844

The EC market for short term and long term car rentals is dominated by five large companies. These companies are able to offer competitive prices for business and leisure travellers. Small and medium-sized companies tend to service other market segments, but regularly do not have car rental as their major activity. It is, however, likely that the large companies will gain market share at the expense of small and medium-sized firms. Market developments strongly correlate with economic activity and air travelling. With the slowdown in economic growth the increase in car renting in 1992 was only 2%; in 1993 and 1994 growth will not be much higher. After 1994 an improvement of the growth rate is expected at about 5% per annum.

INDUSTRY PROFILE

Description of the sector

The car rental branch deals with the commercial rental of motor vehicles (passenger cars, vans and trucks) without driver. Distinction can be made between short term rental (a few days) and long term rental (contract hire and leasing). Car rental with driver is not included, as this belongs to the taxi business classified in NACE 722.

Commercial car rental is provided by companies either exclusively or in combination with other business activities. The majority of the big companies are in the car rental business exclusively, in part also in combination with car leasing. The small and medium-sized companies, however, combine the car rental business with other activities, especially with gasoline stations, motor vehicle dealerships and repair in garages. Mostly, in such companies car rental is not the major activity.

Another distinction which can be made is between car rental for business purposes and for tourism purposes. The former relates to short term car rental by business travellers and long term car rental; the latter basically is short term car rental by tourists.

The largest short term car rental markets can be found in Germany, France and the United Kingdom. In 1991, the United Kingdom accounted for 25% of the EC total of short term passenger car rentals. Germany, with 24%, was of more or less equivalent size. France took 20% of the EC total.

Germany is by far the largest market for long term car rentals. In 1991, the German fleet amounted to about 2.2 million passenger cars and 300 000 light vans. The United Kingdom ranks second with 1.26 million passenger cars, 73 600 light vans and 90 800 trucks.

For short term car rental the average rental period for a passenger car has increased from 3-4 days in 1989 to 4-5 days in 1991. For light vans the average period was 2-3 days; for trucks it was 3-4 days.

Long term car rental periods vary considerably. In Greece, the average period for passenger cars is the lowest with 6 months. The longest period is identified in Switzerland with 38 months. For vans the lowest is also 6 months, but the highest is 29 months. Long term truck rental periods vary from 12 months in France to 42 months in the United Kingdom.

The average distance per short term hire amounts to about 150 kilometres, with the exception of Italy where it is at 450 kilometres. The demand for one-way rentals varies substantially, from 33% of all rentals in France to 3% in Italy. Rental activity is the strongest during the summer months (May to August), whereas it is markedly weaker in the winter months (January and February).

Vehicle utilisation indicates to which extent demand meets supply in the car rental business. In long term rentals the norm for the utilisation rate is 100%, as there is usually one customer using the car on a permanent basis. In short term rentals the utilisation rate is lower. For cars it varies from 55% to 70%; for light vans it is between 48% and 70%; for trucks, utilisation ranges from 50% to 80%. Higher utilisation rates in short term rentals are considered counterproductive, as too many clients have to be turned away without a vehicle.

Recent trends

Over the 1989-91 period, the EC market for short term car rental has grown considerably. The fleet expansion, for passenger cars, increased on average 8.5% from 449 000 in 1989 to 528 000 in 1991. For light vans, the increase was lower: 5.5% on average; for trucks the growth was more substantial: 10.9%.

Long term car rental also shows high growth rates. The market for passenger cars in the EC has increased by 17.4% on average during the 1989-91 period. Growth in light vans was of a similar percentage: 15.8%. Long term renting of trucks has increased by 10.8%.

Source: ECATRA Statistical survey 1991

The high growth rates were not only caused by favourable market conditions. The opening up of Eastern Germany has resulted in a strong upward movement of units rented. This can be clearly seen from the data on Germany, which show high growth rates. However, the effect of reunification could not be isolated.

In 1992, the European car rental industry grew by only 2% according to budget. This was due to low economic growth and slow growth in the airline industry. In 1993, the growth rate could be harmed by the economic slowdown.

MARKET FORCES

Demand

The three most important factors affecting the growth of the European car rental market are general economic growth, airline traffic growth, and customer attitudes. According to the "Budget report on Car Rental in Europe", a 1% increase in disposable income leads to a more than proportional growth in demand for car rental, namely 1.8%.

Most short term car rentals (20 to 30%) occur at airports, where business travellers and tourists arrive. Business travellers are more and more in need of flexible transportation to use their time as efficiently as possible. Further, in view of European integration, there is a growing need for mobility as business deals are more and more concluded internationally instead of locally, which benefits car rental demand. Furthermore, the European tourist is becoming increasingly independent and enterprising, a tendency which also benefits the car rental industry. The greatest benefit will accrue to South and East European travel markets where transport systems have not been fully developed yet.

The long term car rental business benefits from a growing demand for advantageous financing constructions, whereby fleet owning companies sell their fleets and lease them back from a rental company. Further, companies want to concentrate on their core businesses, and leave the maintenance of their fleet to the rental company.

Supply and competition

In general there is extraordinarily strong price and service competition in the car rental industry. It is led by the big companies. They court the business sector as well as the leisure sector with a very flexible pricing policy based on partial cost thinking. At the same time the performance standards (car plus service) have been expanded and improved substantially.

The Budget Report confirms that average rental fees per day for a Ford Escort declined by 12% from 1988 to 1991. Comparing the cost of owning a car with the cost of renting one on weekends shows that up to a utilisation rate of 44 weekends per year renting the car is cheaper or at least not more expensive than owning the car. The Budget Report lists additional advantages of car renting, namely higher quality and reliability, time saving, petrol costs saving by using the shortest route, and adaptation of the rental car to special requirements.

The partial-cost oriented pricing policy of the big car rental companies is possible because of the effects of rationalisation and declining costs resulting from the size of the companies, and also and importantly because of the strong financial and/or contractual ties to the automobile industry. Vehicles are bought from the European car manufacturers at large discounts. Selling used cars yields high revenues, further enabling low rental rates. However, there are indications that the automobile industry is limiting discounts, leaving opportunities for Japanese manufacturers. Moreover, the prices on the used car markets have recently come down, causing a rise in rental prices.

Companies in short term rentals compete for the customers by offering all kinds of services. Express desks, self-service returns and reward schemes for frequent clients (e.g. Avis's

Source: ECATRA Statistical survey 1991

Club, Hertz's Gold Club and Eurodollar's First Choice Card) entice the business clients. Also, modern computerised reservation systems (e.g. Avis's worldwide Wizard network) have become an essential competitive edge.

For the leisure traveller rental companies have organised all kinds of arrangements together with airline companies and tour operators. Fly-drive arrangements have become a popular product. Recently, rail-drive arrangements and rail-sail-drive arrangements (e.g. to Ireland with Sealink, British Rail and Hertz) were added to the product range.

A new development in the industry is the rental of electric cars. These cars contribute to reducing air pollution and to promoting cleaner and quieter roads. In Geneva, Switzerland, a pilot project has started with Avis, Hertz and Sixt-Alsa. Clients can rent an electric car for SFr 50 a day.

INDUSTRY STRUCTURE

Companies

The five big car rental companies in Europe are Avis, Budget, Eurodollar, Europcar and Hertz. Avis, Budget and Hertz operate worldwide with international networks in many countries. Eurodollar and Europcar are trying to establish a global presence through cooperation. Eurodollar is the major licensee of the American Dollar group and Europcar has marketing agreements with National in the USA, Tilden in Canada and Nippon in Japan.

Hertz, the largest car rental company worldwide, is owned by Park Ridge Corporation, in which Ford Motor Company holds a majority equity share. After Hertz, Avis is the second biggest car rental firm worldwide. Avis Europe, in which the Belgian Lease International and to a lesser part General Motors and the American parent company Avis Inc. hold shares, is the market leader in Europe, ahead of Europcar. In 1991 its pure rental turnover amounted to 175 million ECU.

The largest companies are also leading in the various national markets in the EC. Avis is the market leader in the United Kingdom, Italy, France and Denmark, Budget in the Netherlands and Austria, Hertz in Sweden, Switzerland and Belgium and Europcar in Germany and Finland.

Strategies

Avis relies primarily on its extensive agency network at airports and train stations in Europe. Exclusive contracts exist with the French, Belgian and Luxembourg railroads. In addition, there are cooperation agreements with most of the big travel agencies, many airlines e.g. Lufthansa (D) and hotel chains. Avis, like the other big companies, provides a number of special services for the business customer, the major client. A computer system supports fast and flexible management decisions. With its "super value" programme in 1991, Avis was the first of the major car rental firms in Europe to offer leisure travellers special discount rates.

Hertz relies primarily on its strong airport presence; it has 2 000 airports locations worldwide. Travel from the USA, where Hertz is market leader, is a cornerstone of its business. In the United Kingdom Hertz also has an exclusive agreement with British Rail and a cooperation agreement with the national railroad of The Netherlands. Hertz has specialised in the business segment of the market. The company has numerous fly-drive agreements with airlines, e.g. its "Business-drive"-programme in partnership with British Airways. In combination with British Rail Hertz introduced its "Intercity-drive" programme. In 1991, a number of products were introduced for the leisure traveller, like the "Holiday-saver" programme. Since 1991 Hertz has been selling its used cars directly to the final consumer or user rather than to wholesalers.

Europcar was created in 1989 by a merger of InterRent, a 100% Volkswagen subsidiary (until then market leader in Germany) and Europcar, the leading car rental firm in France and the United Kingdom, a subsidiary of the Belgian-French travel firm Compagnie Internationale des Wagons-Lits et du Tourisme. Reorganisation, rationalisation, and network adjustment took place in 1990 and 1991. With counters in about 260 airports in 79 countries, Europcar's market share is around one third. Europcar has cooperation agreements with National Car Rental of the USA, Tilden rent-a-car of Canada and Nippon-rent-a-car of Japan. Further, it is extraordinarily active in East European markets. It entered the Soviet market in 1989, and the East German market in 1990. In addition it has licensees in Czechoslovakia, Hungary, Yugoslavia and Bulgaria. During 1991 the non-airport segment of the market was more intensively courted by Europcar with the programmes "Cost cutter", "Business-drive" and "Super drive".

Source: The Budget Report on car rental in Europe 1991

Especially for the visitors of Euro-Disneyland the company started the pan-European promotional campaign "Join the countdown to Euro-Disney".

Budget is the third largest car rental company worldwide with a fleet of 250 000 vehicles and 3 600 outlets in 140 countries. It operates its own network, in Belgium and in France, as well as a franchise network. Despite difficult market conditions, its own network grew at a rate of 15% in 1991. Franchise partner in Germany is Sixt AG, which in recent years achieved second place with low-price strategies and a rapid pace of expansion. A new segment which Sixt believes promising is the rental of heavy tractors and trucks (in excess of 9 tons). Budget was the first company to introduce all-inclusive rates. Within this all-inclusive rate it is the only company to offer personal insurance. Budget must also be considered the price leader among the big car rental firms. Budget's fast pace of expansion was based on the mix of corporate and licensed operations. Especially, the various local market segments could be reached with franchise partners. One specialty is the provision of luxury cars. Of all car rental firms Budget maintains the largest Mercedes fleet and is the biggest customer of Mercedes in the world.

Eurodollar International is the European franchise of the American group Dollar Rent A Car Inc. Dollar in turn belongs to Chrysler Corporation, which also owns Thrifty Rent A Car. Eurodollar has own and franchised outlets in 20 European countries. In 700 locations in Europe it offers more than 70 000 vehicles (worldwide this figure is 125 000 in 1 800 locations). In 1991, the French, Dutch and Italian franchisees were taken over by Eurodollar International. Through cooperation with Autohansa in Germany the franchise network was expanded there. An extension of the network is planned to Eastern Europe, the Middle East, and Africa. In early 1992 a new franchise started in Poland. The sharp expansion, especially in the business segment, has diminished the originally strong dependence on the UK market.

Together, these five large companies represent over 50% of the market in Western Europe. the remaining share of the car rental market is accounted for by a great number of small, medium-sized and larger firms of local, regional and nationwide importance, which frequently enter into horizontal cooperation arrangements in order to improve their efficiency.

A clear pricing policy and a constant high level of service are becoming increasingly important. This trend favours the big car rental companies with evenly high performance standards and large agency networks. Economies of scale and financial and/or contractual interrelationships with the automobile industry create additional structural competitive advantages for the large car rental companies. They use these advantages consistently and efficiently in order to safeguard and expand their market shares. The beneficiary is the car renter who enjoys very low rental fees.

In this way the airport business has fallen almost entirely into the hand of the big car rental companies. The numerous small and medium-sized car rental firms focus on the non-airport segment of the market. This consists of the rental of substitutes for accident damaged cars (turnover share approximately 50%), the rental for business purposes (app. 30%), the rental to tourists (app. 15%) and the rental for other private purposes (app. 5%).

Price comparisons suffer from the very low degree of standardisation within the individual EC countries. The sector is in the process of providing a solution for the standardisation of services and quality levels. This should render the market more transparent and more competitive.

The sales prices of the small and medium-sized firms are not always based on exact cost calculations, but are oriented on market prices. As this frequently results in prices which fail to cover costs, the car rental division is often being subsidised by other activities of these smaller firms. There are still local supply monopolies or oligopolistic constellations, especially in the countryside, which make cost-covering prices possible. The increasing regional expansion of the large companies' networks, however, results in increasing price and service competition here, too.

ENVIRONMENT

The car rental activity has positive and negative effects on the environment. Positive environmental considerations include the use of train for long distance travelling, the smaller size of rented cars compared to owned cars, and the use of relatively new cars in rental fleets.

The combination train and rented car can replace the use of one's own car for long distance travelling. The rented car is then used at the point of destination. The environmental damage and the resource use of the railroads, in terms of person-kilometres, is much lower than that of one's own automobile. Besides, the substitution of the train for the car ride results in less traffic on motorways, contributing to a decline in accidents and emissions. The economic costs of car accidents, in particular, are considerable.

Another environmentally beneficial effect relates to the use of rental cars versus the use of private cars. Generally, rental cars are smaller, leaner and younger than privately owned cars. Further, car rental fleets get regular maintenance and inspection, which contributes to energy efficiency and the minimisation of harmful exhaust gas emissions. However, in southern EC countries car rental firms frequently have older, poorly maintained cars in their fleets.

Environmentally damaging factors include the use of aeroplanes for long distances and increased car use in holiday resorts. Exhaust emissions of aeroplanes, in terms of person-kilometres, are much higher than that of automobiles. In holiday resorts tourists using car rental services cause a far higher transport demand resulting in higher exhaust emissions.

REGULATIONS

One of the most important problems in the car rental industry is vehicle theft and conversion. Theft by juveniles accounts

for the majority of vehicle crime. Enormous losses are involved and the abolition of custom control at national borders has aggravated the problem. The industry is spending considerable efforts on prevention. These include a call for improvement of car security systems by car manufacturers, a microchip security system on rental cars and car security cards.

In the long term rental business companies encounter refusals by car manufacturers to supply vehicles. They justify this using an EC Directive for selective distribution in Europe. This Directive will expire in July 1995, but it could be renewed or amended by that time.

Truck rental companies have requested the EC to examine the EC Directive on Truck Rental. It deals with the proposed liberalisation of truck rentals. The application of this Directive seems to differ in the Member States, which is considered harmful to the industry.

The envisaged harmonisation of VAT and excise duties is important for the industry as well. Currently, large differences exist in the Member countries causing rental companies to charge different prices. For the consumer, who regularly comes from another country, prices are by no means comparable due to these differences, causing less clarity in the market. It also creates annoying inflexibilities in international car renting.

Finally, the proposed directive on unfair clauses in consumer contracts is of importance. Rental agreements by companies need to comply with this directive.

OUTLOOK

Car rental will most likely register strong growth in the years to come. Mobility in all EC countries is rising and this trend is expected to continue in the medium and long term. Growing business travel in the wake of the completion of the EC internal market, economic growth in Eastern Europe as well as continued expansion of Europe-wide tourism will stimulate the car rental market in the future.

Car rental has become a true alternative to the use of a self-owned automobile or truck. Short term car rental is stimulated by an increasing tendency to use rail or aeroplane services in combination with a rental car for both business and tourism passengers. Long term car rental benefits from the increasing need for flexible financing of car and truck fleets.

In view of the above growth in the car rental industry is expected to be relatively strong. In 1993-94 a slowdown can be expected and therefore growth rates may not exceed 2% on average. For 1994-97 a real expansion of close to 5% is expected.

Leasing
NACE 84

The idea of equipment leasing was imported from the USA and quickly gained general acceptance throughout Europe in the 1970s and 1980s. It became particularly popular in the service sector. Hence, leasing became a strong growth industry and currently is responsible for around 20% of investments in equipment. National legislation in the various Member Countries has dealt with leasing in very different ways. As a consequence, the leasing business varies considerably from one country to another. Harmonisation of regulations is difficult and is likely to take a long time. Due to the economic recession the high growth rates have come down and even turned into negative figures. However, when the economy recovers new investments will lead to a new upward trend.

INDUSTRY PROFILE

Description of the sector

NACE 84 covers renting, leasing and hiring of movables, of which leasing is the most important. The leasing of real estate is excluded. Consequently, figures only refer to the leasing of movables, or the so-called equipment leasing. More specifically, the following types of equipment leasing will be discussed, leasing of agricultural machinery and industrial equipment, NACE 841; leasing of construction machinery and equipment, NACE 842; leasing of bookkeeping and office machines, electronic data processing equipment and cash registers, NACE 843; leasing of cars NACE 844; leasing of other means of transport without driver, including aircraft and ships, NACE 845; and leasing of other movables, NACE 847. All these categories do not include permanent staff or chauffeur as part of leasing.

The definition of leasing is not exactly the same in the different Member States. Comparisons across Member States therefore have to be interpreted cautiously. Commercial and civil laws in most Member States were developed at a time that leasing did not exist. Consequently, no legal definitions of leasing exist (except in France for 'crédit bail', the French system for leasing). Instead ministerial decrees and court rulings are regulating the leasing business. This hinders the formation of a single market for leasing.

Broadly speaking, leasing refers to the transfer of a good from the lessor (the owner) to the lessee, who is able to use the good with regular payments. While leasing concerns an operation on medium or long term, renting refers primarily to a transfer of a good in the short term (hours, days, etc.) between two persons on payment of a fee. The differences in regulation between Member States and the existence of intermediary forms (e.g. hire-purchase) clouds the distinction between leasing and renting. A large proportion of English and French leasing contracts for example would be classified as hire-purchase in Germany.

Recent trends

With leasing being a relatively new operation, the market for leasing in the different Member States showed huge growth figures in the 1970s and the 1980s. However, because of the economic recession, this rapid development came to an end recently, with even negative growth figures in several Member States.

The US was the first country where leasing operations were set up and further developed. Within the EC, leasing is relatively more widespread in the UK and Ireland, two countries which are traditionally more affiliated with the US. Leasing operations in these countries make up around 30% of total investments, the same level as in the US.

The growth in leasing activity affected also the number of companies. In the first years of leasing, the manufacturers of capital goods dominated the leasing market: they used leasing operations mainly as a marketing instrument in order to stimulate the sales of their 'core' products. Attracted by this booming market, independent leasing firms established themselves and gained a firm position. These independent firms, mainly bank subsidiaries, overtook producer leasing in new business generation, in part because of the introduction of

new innovations. The present economic recession which has caused a major decrease in investments, and increasing competition between leasing companies has resulted in the shake-out of companies in some Member States.

Principally, there are two major categories of leasing contracts: the financial lease and the operational lease. Financial lease refers to a contract with full pay out (full amortisation). It is in principle irrevocable and does not provide for maintenance and service as the legal ownership stays with the lessor, but the economic ownership shifts to the lessee. Furthermore, in several Member States the financial lease includes an option to buy for the lessee at the expiration date.

Operational lease refers to a contract with non-full pay out (partial amortisation): the lessee only uses the capital equipment for a portion of its normal service life, and there are normally one or more additional users. The leasing rates and payments are calculated at a fraction of the purchase value. Furthermore, an operational lease can in principle be cancelled. This form of leasing may or may not call for the lessor to maintain and service the leased equipment, and the costs of this maintenance are either built into the lease payments or contracted out separately as the legal and economic ownership stay with the lessor.

International comparison

The leasing market in the US is relatively well developed, with a leasing ratio (share of leasing in total investments) above 30%. Japan has lagged behind, but is now making up for it with growth rates in leasing activity ranking among the highest in the world. Within Europe, the leasing market is far more developed in the EC than in Eastern Europe. In countries such as Poland, Czech Republic, Slovakia and Hungary, leasing becomes more prevalent and the prospects are very optimistic.

MARKET FORCES

Demand

The structure of the European leasing market in the 1990s is different from the structure earlier. The European leasing market has gradually undergone significant changes in terms of suppliers, customers and products.

In the beginning, leasing operations were mainly focused on office equipment. Through the years however, leasing has come to encompass all kinds of goods, such that almost everything can be leased. Machines and industrial equipment, in several Member States, are now almost as important as office and computer equipment. Lately, leasing commercial vehicles

and cars has rapidly developed. Confronted with a slowdown in the world demand for cars, the major car producers offered, via their own leasing company or via independent leasing companies, extremely favourable leasing conditions in order to stimulate their sales.

The growth of car leasing is partly reflected in the shift of customers. In some Member States car leasing to private persons has been made possible, especially in France and Germany where private customers account for a considerable share of the leasing market. Private households are attracted by the favourable leasing conditions offered by the car manufacturers; conditions are in many cases much better than the conditions for personal loans from financial institutions.

The service sector remains however, the largest customer of leasing products, within some Member States it has a share of 50% or more. The expansion of the services in the 1980s has caused a shift from the industry to the services as the main customer.

Supply and competition

As said earlier, originally, leasing companies were mainly manufacturers trying to stimulate their sales by offering additional services for customers. A second family of leasing companies was formed by financial institutions which in several Member States overtook the manufacturers because of their financial expertise. In reaction, a lot of manufacturers founded leasing companies with an independent legal status and adopted some of the contract ideas of the independent competitors. Recently however, the observation in most Member States is that leasing companies are becoming more independent of large corporations, as well as of bank and insurance companies.

The shift in suppliers has also led to a growing specialisation of leasing companies. Leasing activities are increasingly realised by independent leasing companies, which are less and less dependent on manufacturers or financial institutions. This evolution and the introduction of new innovations results in a stronger profile of leasing companies vis-à-vis pure financing. Furthermore, because of the economies of scale in some stages of the leasing process, newcomers entering on a relatively small scale face serious drawbacks.

REGULATIONS

EC Member States not only define leasing differently, but also have a wide variety of civil law, fiscal and accounting rules. In addition, there is no standardised supervision by governments or central banks. Differences include clauses to civil liability, maintenance of the leased good, insurance, tax rates for depreciation and the accounting rules for capitalisation. So far, this did not cause major problems, but in view

of the Single Market this may lead to unfair competition between leasing companies of different Member States.

The European Commission would like to come to a harmonisation in the fields mentioned. However, this has appeared to be a difficult process as Member States consider these fields as part of their sovereignty. Special working committees have been installed in order to come to a breakthrough. Especially with respect to accounting rules, major differences between Member States exist. Accounting operates according to two methods: the economic approach or the legal approach.

The economic approach neglects the legal content of a contract and interprets the economic content ('substance over form'). This interpretation is decisive for the capitalisation of the leased good: the economic owner is allowed to capitalise and depreciate the leased good. This means that with financial leasing, the lessee (economic but not legal owner) can enter the leased good on his balance sheet, while with operational leasing the lessor (economic and legal owner) is allowed to capitalise and depreciate the leased good. This approach is also called the Anglo-Saxon method, and is advocated in Europe by the UK, Ireland, the Netherlands and Belgium.

The legal approach gives the right to the legal owner to enter the leased good in his balance sheet. Consequently, no distinction with respect to accounting rules is made between financial and operational leasing, since the lessor stays in both cases the legal owner. This approach is used in most countries of continental Europe which includes France and Germany.

In France, financial leasing is indicated by 'crédit bail', while operational leasing is called 'location financière' or 'location simple', although some intermediary forms exist. A 'crédit bail' transaction is only present when at the outset the renter is granted an option to buy. Furthermore, the law stipulates that the purchase of goods for the purpose of renting is the precondition for a 'crédit bail' transaction. The law thus specifically excludes manufacturers from leasing. Manufacturing companies in all kind of sectors have therefore set up special finance companies in order to comply with these requirements.

Companies who offer exclusively 'crédit bail' operations are subject to other regulations than companies which offer also other forms of leasing. 'Crédit bail' companies are aided by legal regulations that guarantee market entry limitations, refinancing advantages, etc. On the other hand, these companies are subject to strict government controls and rules on advertising.

In Germany, the lessor is accountable as legal owner of the leased good and not the lessee. Operational leasing is understood to mean short and medium term leasing contracts in which the lessee has the right to cancel the agreement at any time. Financial leasing is irrevocable and includes an option to buy for the lessee at the expiration date of the contract. Because conditions for leasing are considered to be relatively favourable in comparison with other operations, hire-purchase and other rental forms are less widespread.

In the UK, leasing is not subject to any specific regulations or restrictions, as in some other Member States. In contrast with Germany and France, the lessee can capitalise and depreciate the leased good in financial leasing, an element taken from US law. Finance leasing contracts are those agreements transferring all the major risks and advantages inherent to ownership of the leased object to the lessee. If the minimal payments made by way of leasing are equal to 90% of the market value of the leased good, the contract is considered as a financial lease contract. All other leasing contracts are treated as operational leasing contracts. In the UK, operational leasing is considerably more widespread than in other EC Member States, which is partly due to the differences in definition.

The characteristic feature of the leasing market in Ireland is the relatively favourable fiscal situation and diverse subsidies. Just as is the case for the UK with financial leasing, the lessee can enter the leased good in his balance sheet.

In Denmark there is no specific legislation. Leased goods are capitalised and depreciated by the lessor, but special tax codes for leasing are non-existent. In the beginning, leasing in Denmark faced considerable acceptance problems and had to adjust to frequent changes in treatment by taxation legislation. In the Netherlands and Belgium, in the case of financial leasing, the lessee is allowed to capitalise and depreciate the leased good. Leasing to private households is not allowed in Belgium.

Spain and Portugal have, like France, introduced laws and relatively tight regulations for leasing. Spanish law obliges firms to operate as stock companies and comply with minimum equity provisions. These regulations partly explain why financial institutions have absorbed their subsidiary leasing companies.

No specific rules on leasing are present in Italy, although preparatory work is done in working groups. The current trend concerns the incorporation of leasing firms within financial institutions; as such leasing companies expect an improvement of their long term refinancing.

The conditions for leasing in Greece are relatively disadvantageous. The leasing of buildings, buses and trucks is not allowed and the depreciation rates are unfavourable. Although the country has shown considerable growth, leasing is still unimportant, which is partly explained by the unattractive conditions.

OUTLOOK

The economic recession had a considerable negative effect on the leasing market, causing negative growth figures for leasing operations in several Member States. In 1993 and 1994 leasing will face difficult times, due to the unfavourable economic developments. On the longer term however, an upward trend is expected, mainly because of the economic growth and the accompanying increase in investments in the second half of the 1990s. Furthermore, the forming of a single market for leasing with adequate solutions for the differences between Member States, can form an additional impetus for the development of leasing within the EC.

All types of assets are expected to show a growth with respect to leasing operations. Investments in office machinery and computer equipment are expected to grow because of the increasing penetration of these goods and the increasing importance of services in most Member States. The decline of hardware prices however, reacts as a counter effect to this positive evolution.

Investments in machinery and construction equipment, which show a relatively high conjectural character, are expected to increase because of the favourable economic climate. Furthermore, the build up of the former East Germany will result in a significant growth of leasing activities in Germany. Also the evolution in East European countries like Hungary the Czech Republic, and Slovakia can offer new opportunities for EC leasing companies.

Car leasing has shown in recent years the highest growth figures and is expected to do the same in the short term. In this segment, leasing should be able to increase its market share. For the moment, car leasing is hindered by the fact that in some Member States leasing to private households is not allowed. Should this situation change, leasing growth will accelerate considerably.

The industry is represented at the EC level by: European Federation of Equipment Leasing Company Associations (LEASEUROPE). Address: Avenue de Tervueren 267, Bte 9, B-1150 Brussels; tel: (32 2) 771 2108; fax: (32 2) 770 7596.

Franchising

Franchising is a means of adaptation to local conditions without losing the benefit of global concerns, ideas and scales. Within the EC, franchising has become the most dynamic business development strategy. France is by far the European leading country and the second after USA at the world level. The outlook is bright as franchising has an important role to play in the promotion of EC trade and has the tools for that purpose.

INDUSTRY PROFILE

Description of the sector

Franchising is a strategy of business development that has a remarkable success all around the world. Nevertheless there exists a very specific European form of franchising because the European culture has given this strategy a specific colour, a clear concern for balance and transparency.

Franchising is a means to achieve adaptation to local conditions without losing the benefit of global concerns, ideas and scales. Therefore, if in its actual realisations Italian or Belgian franchising is quite different from German or French franchising, the basic definition of franchising contained in the Code of Ethics is accepted by all members of the European Franchise Federation and by the EC Commission itself.

Franchising is a system of marketing goods and/or services and/or technology, which is based upon a close and ongoing collaboration between legally and financially separate and independent undertakings, the franchisor and its individual franchisees, whereby the franchisor grants its individual franchisees the right, and imposes the obligation, to conduct a business in accordance with the franchisor's concept. The right entitles and compels the individual franchisee, in exchange for a direct or indirect financial compensation, to use the franchisor's trade name, and/or trade mark and/or service mark, know-how, business and technical methods, procedural system, and other industrial and/or intellectual property rights, supported by continuing provision of commercial and technical assistance, within the framework and for the term of a written franchise agreement, concluded between parties for this purpose.

Guiding principles of franchising

1. The franchisor is the initiator of a franchise network, composed of itself and its individual franchisees, of which the franchisor is the long-term guardian.

The obligations of the franchisor: the franchisor shall

- have operated a business concept with success, for a reasonable time and in at least one pilot unit before starting its franchise network;
- be the owner, or have legal rights to the use, of its network's trade name, trade mark or other distinguishing identification;
- provide the individual franchisee with initial training and continuing commercial and/or technical assistance during the entire life of the agreement.

The obligations of the individual franchisee: the individual franchisee shall

- devote its best efforts to the growth of the franchise business and to the maintenance of the common identity and reputation of the franchise network;
- supply the franchisor with verifiable operating data to facilitate the determination of performance and the financial statements necessary for effective management guidance, and allow the franchisor, and/or its agents, to have access to the individual franchisee's premises and records at the franchisor's request and at reasonable times;
- not disclose to third parties the know-how provided by the franchisor, neither during nor after termination of the agreement.

Recruitment, advertising and disclosure:

- Advertising for the recruitment of individual franchisees shall be free of ambiguity and misleading statements.

A specific organisation

In 1972 the European Franchise Federation (EFF) was created. This international non-profit association assembled all national Franchise Associations or Federations established in the Member States. The members of the national Associations are franchisors settled in the country.

The aims of the EFF are:

- the promotion of franchising in Europe;

Source: National franchise associations and federations

- protecting the franchise industry by promoting the European Code of Ethics;
- influencing and encouraging the development of franchising in Europe;
- representing the interest of the franchise industry in international organisations such as the European Parliament;
- the promotion and representation of the European franchise industry and its members worldwide;
- the exchange of information and documentation between national Associations or Federations in Europe and in the world.

MARKET FORCES

The last 20 years have seen quite an evolution in the channels of distribution. Stronger competition resulted in increased specialisation and the emergence of new ideas. Franchising is one of them.

ithin the EC franchising has become the most dynamic business development strategy. More than 2000 franchisors and more than 110 000 franchisees achieve an annual turnover of over 55 billion ECU.

In Europe franchising was first adopted in the retail sector, where with some exceptions the traditional forms of cooperation were not much used, and in completely new business sectors, like the do-it-yourself shops, fast food restaurants and car rentals. Although North American franchisors found their way to Europe, many national franchise networks were developed. Despite a growing internationalisation most of the national markets are still held by national networks.

France

France is by far the leading country in Europe and comes second in the world after the USA. 600 franchisors and 30 000 franchisees realise a turnover of 21 billion ECU, which represents 7.5 % of French retail turnover.

Franchising appeared in the north of the country, where the major wool manufacturer Pingouin led the way in 1929. It then spread to the confection sector, giving a strong impetus to the growth of product franchising, which today represents 70% of all franchising in France. Personal equipment represents 30% of the franchise market, food 20% and home equipment 20%. The remaining 30% consists of service franchising, at present achieving annual growth rates of 20% in areas such as fast food, hotels, instant printing and car maintenance.

French franchising networks sell world famous brands as Chanel, Yves Saint Laurent or Cardin. Product franchising is mainly aimed at the promotion of the trademark and image of the network, while know-how is relatively unimportant.

Franchising in France is moving towards increasingly innovative and performance-oriented forms in services for the individual consumer or business. In these areas a new trend is appearing: Franchisors consider franchisees more and more like partners with an increased freedom in their actions as long as the network's image is preserved.

95% of the franchising networks present in France are French. The remaining 5% are mostly American fast food chains.

The success of French franchising is best measured in terms of employment. In 1992, 10 000 jobs were created or saved by franchisors and franchisees.

United Kingdom

373 franchisors and 18 100 franchisees realise a turnover of 6.8 billion ECU. In recent years, the growth of the turnover was 25%; this was mostly due to expansion in services and specialised retail businesses. The characteristics of the United Kingdom are

- the absence of confection franchises. In 1989 the United Kingdom had 7 confection franchises, when France at the same time had 150.
- the great influence of American franchises. For US firms the United Kingdom has always been the natural gate to Europe, most of them started their European strategies with an English subsidiary. Consequently almost 30% of the franchise networks in the United Kingdom are American, and the United Kingdom is the leading country for Master Franchise.

Germany

70 franchisors and 15 500 franchisees realise a turnover of 8.2 billion ECU.

Germany has become one of the important franchising countries in Europe although, because of its cooperatively structured retail industry with strong "Buying Groups", franchising did not really take off until 5 years ago. It mostly developed in food distribution, with very large groups like Spar or Eisman, and in pottery and household equipment, followed by personal equipment and services.

Service franchising is largely made up of fast food chains. The growth of German franchising will receive extra stimulus from the development of the eastern Länder and countries.

The Netherlands

With 331 franchisors, 12 640 franchisees and a turnover of 6.5 billion ECU, franchising represents 12% of retail turnover in the Netherlands.

Except in the fast food sector, developed like generally in Europe by American franchisors, most of the franchisors are Dutch.

Belgium

Belgium counts 3 200 franchisees sponsored by 90 franchisors. Franchising has revealed itself as a successful strategy since 15 years, and expands according to the French model: product franchising is preponderant, while service franchising is developing since only recently.

50 % of the networks settled in Belgium are Belgian. The GB Group is the largest franchisor.

Italy

Italy has 318 franchisors and 16 100 franchisees achieving a turnover of 8.5 billion ECU.

A sudden expansion started in 1987 and lasted two years until 1989, with an important development in personal equipment. In the number of franchisors and franchisees Italy is the third country in Europe. Franchising seems perfectly adapted to the need of the country, experiencing at the same time a severe recession and a rapidly spreading culture of individual entrepreneurism.

Still, franchise turnover is very low compared with total retail turnover, representing roughly 1.2%. Very few foreign franchisors, mostly American and French, have settled in Italy.

Spain

Franchising is a rather new distribution channel in Spain. Taking off only in 1988 it did expand very quickly: until 1991, the annual growth rate was almost 70%. Today Spain has 117 franchisors and 14 500 franchisees realising a annual turnover of 2.1 billion ECU.

The expansion is mostly due to foreign franchisors. In 1991, only 58% of the franchisors were Spanish. The trend is now changing. An important number of national networks has been established, and as a culmination the Spanish Franchise Association was founded in October 1993.

The traditional business areas are personal equipment, confection and food distribution. Service franchising is still not developed, but the needs are obvious in sectors like car services, hotels, restaurants, as well as in specialised retail business.

Portugal

In the past four or five years, Portugal has experienced the same evolution as Spain.

Today 55 franchisors and 800 franchisees are operating.

Eastern Europe

In Eastern Europe franchising may be a way to import managerial know-how and an efficient retail structure.

Countries like Hungary have grabbed this opportunity and have today a successful franchising sector.

REGULATIONS

While franchising occurs in many forms in the various Member States, its regulatory framework is very homogeneous, mainly ruled by two texts:

- the block exemption
- the European Code of Ethics

The block exemption

Before 1986 no specific national laws existed and jurisprudence was poor, with the notable exception of France.

In this context a French company, Pronuptia, provoked the first judgement of the Court of Justice of the European Communities favourable to franchising. Article 85 (1) of the Treaty of Rome, establishing the European Economic Community, prohibits cartels between suppliers of commodities. However, the Pronuptia ruling took for the first time into account both the interest of the consumer and of a 'new economic being': the network in which franchisor and franchisee fight together against their competitors, and whose identity and image need a real protection.

It was the first step towards a global exemption for franchising from Article 85 (1), in recognition of the fact that consumers benefit from the combined purchasing power and higher service level that franchisees are able to offer in comparison with independent, individual entrepreneurs, and even that franchising does not in itself harm competition.

After four other individual exemptions, Yves Rocher, Computerland, Charles Jourdan, Service Master, the block exemption for franchising was passed in 1989.

The EC regulation covers product and service franchising (Art 1) only if the interest of the final consumer is taken into account (Art 4). Franchising was at last recognised as a distinct form of business, establishing a common legal basis for the development of franchising in EC Member States.

The European Code of Ethics

Since the very beginning of franchising in Europe there has been a real concern for ethics and self-regulation. The first Code of Ethics (1971) created by the French Franchise Federation, followed by a European Code in 1972 has permitted a smooth development of franchising, becoming a reference for all the partners of franchising: franchisors, franchisees, lawyers and consultants, administrations, governments, being even increasingly used by courts throughout Europe as the benchmark of franchising standards.

Since 1992 a new European Code, drafted in close consultation between the European Franchise Federation and the Directorate-General XXIII of the European Commission (which has responsibility, inter alia, for Trade and Distribution), is promoted in all the countries where the EFF has members.

The absence of specific laws in EC Member States is a proof, if one is needed, of the power of a self regulating effort, a code of ethical conduct and fair behaviour in an economic environment.

The franchise agreement

extracts of the Code of Ethics)

The Franchise agreement shall comply with the national law, European Community law and the European Code of Ethics and any national extensions thereto. The essential minimum terms of the agreement shall be the following:

- the rights granted to the franchisor
- the rights granted to the individual franchisee
- the goods and/or services to be provided to the individual franchisee
- the obligations of the franchisor
- the obligations of the individual franchisee
- the terms of payment by the individual franchisee
- the duration of the agreement, which should be long enough to allow individual franchisees to amortise their initial investments specific to the franchise
- the basis for any renewal of the agreement
- the terms upon which the individual franchisee may sell or transfer the franchised business and the franchisor's possible pre-emption rights in this respect

- provisions relevant to the use by the individual franchisee of the franchisor's distinctive signs, trade name, trade mark, service mark, store sign, logo or other distinguishing identification
- the franchisor's right to adapt the franchise system to new or changed methods
- provisions for termination of the agreement
- provisions for surrendering promptly upon termination of the franchise agreement any tangible and intangible property belonging to the franchisor or other owner thereof.

OUTLOOK

Franchising has more than ever a role to play in the modernisation of commerce, not only because the existence of the network allows a rapid diffusion of technological discoveries (for example the computerised cash register that can treat and analyse sales data), but also because franchising is a means of making alliances for the sake and benefit of the franchisor, the franchisee and the consumer.

Franchising is adapting to a new environment and may be showing the way to a new and better model of European distribution. It should then be a means of standardisation.

Franchising is a strategy that makes it possible to keep the advantage of scale economies, while respecting the identity of all the partners. Thanks to its centralised and flexible structure, thanks to the clear common interest which is preserving the network's image, franchising makes it possible to redistribute the decisions at the right level.

Now more than ever franchising has an important role to play in the promotion of trade within the EC. And indeed, it has all the relevant tools for that purpose. It is certainly a way to grab the opportunities of a changing market. The present evolutions promise a radiant future.

Written by: EFF
The industry is represented at the EC level by: European Franchise Federation / Fédération Européenne de la Franchise (EFF). Address: c/o FFF, Bd des Italiens 9, F-75002 Paris; tel: (33 1) 42 60 00 22; fax: (33 1) 42 60 03 11.

Fairs and exhibitions

Fairs and exhibitions are one of the most important business service sectors. They are the product of a long European tradition, they currently represent a direct value added of more than 18 000 million ECU and 520 000 employees. 300 major cities house 3 500 fairs per year of which 300 can be regarded as international. They are a growing factor for the European economy thanks to the 450 000 direct exhibitors and 63 million visitors in 1990.

INDUSTRY PROFILE

Description of the sector

Fairs and exhibitions (F&E) are trade activities linked to specific and extraordinary spaces and times with the objective of connecting, supply and demand, of those interested in knowledge, market expansion. The sector is built around the exhibition centres and organisers. They try to attract exhibitors and visitors interested in increasing sales, opportunities, image, contacts and market knowledge. There are different types of fairs, and currently trade and professional exhibitions are the most successful ones.

The content of the sector includes a wide number of exhibition activities mentioned in other Panorama chapters: stand constructors, catering and restaurants, hotels, security and cleaning services, other business services, etc. They all co-produce the service which benefits a broad number of enterprises: marketing and publicity firms, tourism and hotels, as well as manufacturing and service firms. All these contribute to increasing the consolidation of the European market. Figure 1 represents the fairs and exhibitions and their impact on the surrounding environment.

Although economic statistics are not available for this sector, it is possible to estimate the overall importance of the sector by taking into account the number of fairs existing in each country and the average spending coming from exhibitors and visitor costs. The fairs and exhibitions sector covers over 3 500 fairs throughout the entire EC, of which 1 200 have national relevance and 300 have an international scope. Sited in 300 exhibition centres, in 1990 exhibitors and visitors generated around 18 000 million ECU. The estimates of employment reveals 70 000 direct full time equivalent employees and more than 500 000 total jobs. These amounts do not include the profits coming from the contracts and additional business transactions at a fair or as a result of a fair, nor the benefit on urban and regional development.

Table 2 shows the overall relevance of the sector through its specific indicators: around 20 million sq. metres of net rented exhibition surface, 450 000 direct exhibitors, and 63 million people visiting fairs per year. This grouping strives to give the maximum comparability regarding the number of biennial fairs, the irregularity of normal activity and the lack of available data. Figures included in tables are taken from the professional association coverage. Most large fairs are included, while local / rural fairs are not.

In absolute terms, there are five main countries: Germany, France, the United kingdom, Italy and Spain. Germany is the leader with the 11% of foreign exhibitors, 16% of foreign visitors, and the highest number of exhibitors and net rented surface, 121 000 and 6.6 million sq. metres respectively. France is the second most important country for fairs and exhibitions, and Paris is the leading trade fair city. Italy, the United Kingdom, Spain and the Benelux countries follow. They have been growing very fast. Compared to these, Denmark, Portugal, Ireland and Greece have minor relevance.

Recent trends

The evolution of fairs and exhibitions seems to be more linked to the service cycle than the manufacturing cycle. During the petrol industry crisis in the 70s, fairs were not significantly affected. However, in the current crisis, the recession is affecting fairs, especially since late 1991, and up to 1993. Exhibitors and visitors cut marketing budgets including exhibitions. They spend less at fairs, they rent smaller areas and some decide not to attend. This latter situation does not seem to be a rule, but an exception. Enterprises still go to fairs trusting in their counter cyclical effects. Some firms use fairs to their own advantage, as a tool against recession.

International comparison

The relatively strong position of the European trade fair sector is also due to its comparative superiority over the USA or Japan. Fairs are a typical European phenomenon. No historical tradition of fairs and exhibitions exists in the USA or Japan, so fifteen to twenty years ago, this was a purely European sector. However, in recent years some cities such as Tokyo, Atlanta, Los Angeles and Chicago are augmenting their possibilities with some major fairs. Regardless, the EC is still different in terms of marketing strategies and business approaches. A major factor explaining these differences is the diversity inside European markets.

Foreign trade

The wide fairs and expositions market all over Europe involves a great volume of intra- and extra-EC trade. Unfortunately, the lack of statistics keeps data on foreign trade from being revealed. However it is possible to estimate some part of trade by looking at the following variables: direct spending, percentage of foreign exhibitors and visitors and percentages belonging to the EC. Supposing the percentages of foreign exhibitors and visitors to be 20% and 3% on the average, and that exhibitor spending is around half of the total, we estimate that 12% of the total spending in one country is made by foreign countries. In overall terms, that is more than 2 000 million ECU. It is mostly intra-EC trade since more than half of foreign exhibitors and visitors come from EC countries. The rest should be divided in two parts, spending done in country of origin (20-25%), and spending in Europe. If so, extra-EC exports may be estimated at 500 to 800 million ECU. EC spending in other countries cannot be estimated.

MARKET FORCES

Demand

All kinds of markets, from local to international, are propitious to fairs. However, the relative importance of the sector varies sector by sector. General fairs have been decreasing to the current 22%. Their growth has stopped, reducing the coverage to local markets and waiting for new functions more related to basic sales, leisure and attraction The most important and fast-growing sector in specialised fairs is "Other industries and services." That is not because of commercial and business services, but because of other manufacturing industries such as machinery, electrical equipment and cultural services. The relative importance of fairs and expositions sectors is revealed in Table 4.

Most large enterprises participate in fairs. A large and increasing number of small and medium size enterprises (SME) do as well. A considerable proportion of the marketing budget is spent in this sector e.g., 30% in Italy, 20% in France, 10% in the UK [Tenth Anniversary of PARIS-NORD Villepinte]. There are three main factors explaining this success: commercial advantages, marketing and communications. Commercial advantages are not only sales, but also in the creation and extension of trade distribution networks. Marketing refers to fairs as a marketing tool: an alternative channel to traditional publicity, a laboratory for testing strategies and a comparison with the competition's marketing. Lastly, the communication factor is important when competition is fierce, and market knowledge is necessary. At fairs it is possible to very quickly obtain and transmit information on clients' opinions and desires, the competition, and one's own position, new product tests, the opportunities of one's own current prices, etc. Fairs contribute to the market's transparency through quick feedback. A summary of these functions is shown in the Figure 3.

Supply and competition

The supply has a multiple number of agents operating at three levels. Level 1 is organisation: organisers, exhibition centres (also known as hall owners) and professional organisations. Level 2 is exhibition services firms: stand constructors, consultancies, business services, auditors and the whole set of internal services such as catering and restaurants. Level 3 is city reception services: local administration, hotels, transport, communication services, etc. These three levels' supplies have different problems and situations.

The EC supply has to compete at all three different levels, especially in order to host international fairs. Cities, exhibition centres and organisers try to attract exhibitors and visitors in a narrow market segment. For example, in a wide number of subsectors, no more than 2-6 major international fairs can be held successfully in the same year. For instance, in Germany competition affects mayor cities; in UK there is competition between London and Birmingham and among organisers; particularly in France, international fairs and exhibitions vie especially with one another. However, the more local the fair, the less the competition. There are many forces which have heightened competition in this sector: the current demand requires a fuller complement of services, information, quality, and prices; the general internationalisation of markets, and the arrival of new movable organisers, and some state interventions (which may sometimes generates a relative market saturation and duplicity of events).

Prices play an important role in deciding which fairs are interesting for participation, especially for small and medium-sized fairs. For demand, the cost of hiring each square meter of space involves calculating stand construction costs, staff expenditures and promotion. For visitors personal expenses are the only direct costs. For supply, price policy varies between considering the investments and maintaining costs, and the results they can offer in terms of visitors. This second factor has been increasing in importance as a tool for evaluating

the quality:price ratio. The real prices of fairs and exhibitions services are not only direct costs but the opportunity cost a firm must pay if it does not attend.

Production process

Due to the increasing competition and the unique features of this sector, innovative processes are highly important. First, new technologies are being used in an attempt to provide technical facilities for stands and transportation. Second, new spaces are being used to house complementary activities such as conferences, product demonstrations, special meetings, etc. Third, exhibition services are improving in quality and quantity. In addition to these three factors, the crucial innovation requires the creation and implementation of new ideas. One of these is new computer systems, used to help establish contacts between visitors and exhibitors.

The rise of specialisation is also relevant. Specific training for trade fairs and exhibitions staff is on the increase with some workers becoming professional specialists (e.g., training courses are emerging). This is happening, not only inside enterprises, but also outside enterprises. Certain degrees of out-sourcing are being reached, specially in countries like the UK or France.

INDUSTRY STRUCTURE

Companies

The number of companies operating in this sector is difficult to estimate. At least 1 200 organisers exist in Europe since most regional fairs organise only one or two major fairs. Major international and national major fairs (1 200) are organised by 300 organisers in only 100 cities. Major cities are able to organise between 15 and 140 events. There are two ways of organising fairs: the hall owners are in charge of organisation; or the hall owners let the space to organisers. The former case is more prevalent in Germany, the Netherlands and Denmark. Separation of functions dominates in the UK, France and the United States.

Most organisers are state-run companies, semi-public companies or public institutions, but an increasing number of non-state for-profit companies are entering the market in competition with traditional organisers. They are exponents of a more professional way of organising fairs. Further from traditional organisers are groups like sectors' professional organisations. Technical competence and specialisation are reforming the industry outlook.

Organisers' details can be estimated since their turnover may be multiplied by a factor of 5 to generate total spending [AUMA report]. Then, 3 600 million ECU could be the overall turnover of organisers. The average turnover is 9 million ECU thanks to 250 direct full time jobs.

The leaders throughout the industry are well represented by the major exhibition parks in Europe, most of them members of European Major Exhibition Centres Association (EMECA). Overall employment in a mayor exhibition centre can create 5 000 - 6 000 full time equivalent jobs. Table 5 shows the main available indicators for these centres.

In considering fairs and exhibitions of greater than regional size, concentration is quite important. The total exhibitors given in Table 5 represent 55% of the total showed in Table 2 (41% in terns of visitors). However, these percentages are less revealing, since a true measure of market share should consider the market subsector by subsector. The large number of exhibitors going to general and culture fairs distort the results.

Strategies

All industrial concentration processes are affecting fairs and exhibitions, particularly organisers. As has already been men-

tioned, some of them operate in narrow markets where competition is high. Major international fairs fight to win the first or second position (the pole position is often held by Germany). Organiser's strategies are based on the innovation. Dynamics in the sector are very high, so restructuring must be made continuous.

The changing factors push organisers and hall owners to look for more careful strategies, to make investments in services and facilities, to search for a balance between making fairs open to the public and limiting entrance to professionals only, and to professionalise the service, stimulating efficiency, quality and innovation. Investments inside exhibition centres are still continuing while some organisers are testing investments abroad (Messe Frankfurt in the USA and Asia).

One strategy which will be seen in the future is the forming of alliance networks between organisers so one exhibition can become movable instead of fixed. That means not setting up fairs and exhibitions in one city each year or each two years, but going one year to one city, the next to another and so on. This kind of rotation system already exists for some fairs. Textile equipment and tools and machinery (ITMA and EMO) are good examples. They have been rotating between Paris, Hannover and Milan.

REGIONAL DISTRIBUTION

Some estimations say that in terms of exhibitors, the leading city is Paris followed by Frankfurt, London and Milan. However the leader country continues to be Germany since 5 of the top 10 first cities are German and their figures for foreign participation are extremely high. The figures indicate that the sectors' regional structure varies greatly from country to country. While in Germany the location of fairs and exhibitions is not concentrated, in France activity is very concentrated around Paris. In the United Kingdom most exhibitions are distributed between London and Birmingham. In Italy, there is a broad group of cities of national importance, but Milan is the most international. In Spain, Barcelona and Madrid hold similar positions, and in the Netherlands, so do Amsterdam and Utrecht. In Belgium, Brussels is the only relevant city.

Fairs and exhibitions are a major instrument for regional and urban development. Although increasing competition is cutting down the number of events, local and regional fairs can maintain their market position in association with local "niches". Most of them are protected from strong international competition.

ENVIRONMENT

Fairs and exhibitions are also an instrument for environmental policies. New exhibition centres are a sort of pilot cities in which new methods of organisation are tested. These are the main items in which fairs and exhibitions tend to contribute to a better environment: spatial distribution, helping to clear congested areas; arrangement of buildings low-rise buildings, with modern lines and safe structure; transport systems with intensive electric transportation, close to airports and traffic hubs; waste treatment, new processes for ecological waste treatment; green areas and reforesting. All these conditions depend on the exhibition centres' policy in coordination with local administrations. A major effort should be made in this direction. In old exhibition centres, these elements are very difficult to obtain.

Once an exhibition centre organises its own urban development, it begins generating positive external economies. Tech-

nological nuclei, enterprise investments and infrastructure can arise, improving economic growth rates and local living conditions.

REGULATIONS

The state has a serious influence on the sector. Local, regional and national administrations have certain instruments to regulate, control and promote fairs and exhibitions activities. The use of these instruments varies country by country, but in general, there are two levels of participation, the legal and the economic.

Regulation of general activity and the granting of rights (specific laws); Concession of licenses and permits for developing activities; Restrictions on product imports, soon to end due to the Single Market; criteria of recognition e.g. internationality.

Support for exhibition centres (investments in infrastructures, exhibition centre improvements); economic aid for supply (subsidies for organisation, subsidies for invitations and participation, special fiscal treatment); economic aid to demand (export policy instrument, subsidies for enterprise's participating).

Most of these regulations are not important, considering the general activity of the sector. The current situation is heading towards deregulation, so the current level of regulation and state aid does not substantially affect the hierarchy of fairs and exhibitions and fair competition. In some cases, regulation does pose obstacles to Single Market consolidation, and causes saturation of exhibitions, price distortion, and discrimination. However, a certain kind of economic support can be considered positive for the whole sector and normal regarding the current situation in the European industry.

The sector is also heading towards a self-regulating system explained by the emergence of national and international professional organisations. They are very active giving prestige and training, and trying to guarantee certain standards of quality (e.g. security regulation, technical standards in stand construction or electronic material, statistics through control and data auditing). The Commission of the EC can play an important role in these processes by reinforcing this self-regulation.

The role and coverage of professional associations is growing, especially in major fairs and exhibitions centres. EMECA represents 25% of the total market in terms of number of fairs hosted by centres, but considering only major exhibitions, it covers the 65% of fairs. The other two major international organisations in fairs and exhibitions are UFI ("Union des Foires Internationales") and IFES (International Federation of Exhibitions Services), grouping mayor organisers and exhibition services firms respectively.

OUTLOOK

The future evolution of the sector depends on two factors. On one hand, it is contingent on economic evolution and the eventual end of the recession. The current situation makes it impossible to project forecast estimates. The agents do not even know how the sector will evolve over upcoming months. Some time ago, it was possible to predict the volume of activity for the next two-three years. Nowadays, the visibility margin has been reduced. Even exhibitors do not decide on participation until a few months in advance.

On the other hand, the demand situation will coincide with increasing competition in the sector, especially at the international level and between organisers. The near future can be set by restructuring measures, forming strategies through alliances, intensifying innovation processes, and looking for better service quality. Specialisation and more professional processes will continue. Customisation is also more and more important; supply and demand are called on to work more closely.

What seems certain is that in any scenario produced in the near future, fairs and exhibitions will continue to play a central role in European economic development.

Overview

The advanced industrial economies are entering the so called information age where information services are very important and they deeply impact the overall efficiency and innovation of the economic system. For this reason, information services can be considered the essential infrastructure of the most competitive countries. In the information technology sector, in spite of the crisis in the hardware market, information services (including telecommunications services), software and computing services and electronic information services are very dynamic and fast growing; the EC information services market was worth about 154 billion ECU in 1992.
The most important segment of the information services in 1992, telecommunications, amounted to about 93 billion ECU, whereas software and computing services were worth 57.4 billion ECU and electronic information services 3.6 billion ECU.
Telecommunications remains a tightly controlled market in most of the EC; state-owned monopolies maintain control of the most basic telecom services. Liberalisation of the market is a growing trend, particularly in emerging telecom markets such as mobile communication, value added services (VAS) and data communication.
Software, computing services and electronic information services are comparatively less regulated and are very open markets.

INDUSTRY PROFILE

Description of the sector

Information services include three distinct but linked segments:

- telecommunications services such as local and long distance telephone calls, fax and data transmission, value added services, mobile communications services and satellite communications;
- software and computing services such as system software, application packages, custom software, office services, system integration, consultancy, and training; and
- on-line and off-line electronic information services and products such as on-line data bases (real time or not), and CD-ROM (off-line).

Recent trends

The EC information services market amounted to 155 billion ECU in 1992. The largest segment of the information services market was telecommunications, which reached 93 billion ECU (60% of the total market); software and computing services were worth about 57.4 billion (37%) and electronic information services were worth just 3.6 billion (2.4% of the total market). The overall growth rate from 1991 to 1992 was 5.8%, but growth in the three market subsectors varied: growth in telecommunications was about 4.5%; in the software and computing services market it was 8.7% and that of electronic information services was about 12%.

It is estimated that in the EC, the information business (inclusive of hardware, software and telecommunications services all included) is already more than 5% of the GDP. This percentage will surely increase in the future due to the quick development of information services which will grow faster than the overall economy. It is forecasted that by the year 2000, telecommunications alone should be more than 7% of the EC GNP.

These data show only the direct contribution that the information services sector contributes to the general economic growth. In the information age, the advanced networks services (mobile communications services and digital networks) are becoming more and more strategic and are becoming the 'nervous system' of the whole economy. Real time communications and distributed information are a must either to increase individual and social productivity and efficiency or to quickly innovate products and processes.

Foreign trade

Generally speaking, USA and Japan are worldwide leaders in information technologies and consumer electronics, Europe has an increasing trade balance deficit for hardware products (computers in particular). Most computer hardware imports into the EC come from the Four Dragons countries (Korea, Taiwan, Singapore and Hong Kong).

But, as far as the trade balance for services is concerned, estimates are questionable as reliable data are difficult to find because the flow of services is not easily measurable. However, services still represent a point of strength of EC countries, especially the telecommunications and computing services.

Presently, the EC has a surplus in relation to the American telecommunications services, though it is decreasing because of the lowering of long distance tariffs. In fact, telecom carriers have agreed to a cooperative mechanism to share revenues for international calls and incomes of each carrier depends not only on the usage of the networks but also on the level of the tariffs fixed by each country. Because the EC countries usually have higher tariffs than the USA for international calls, they benefit from a trade surplus.

As far as the computing services are concerned, about 95% of the EC market is supplied by EC companies (while just 75% of hardware systems are produced by EC based companies). The trade balance is also negative with regard to software because very innovative American companies, Microsoft (USA), Novell (USA) and IBM (USA), control the worldwide standards and the largest share of the market (just 45% of the software market is supplied by EC firms). The trade balance is also negative concerning electronic information services because many on-line data bases are supplied by American companies, although some European companies, Reuters (UK) for instance, have a worldwide leadership.

Another big trade balance issue concerns the reciprocal free access to the domestic markets for EC and extra EC companies. This problem has been recently discussed before Oftel and FCC (the telecom regulatory bodies in the United Kingdom and USA) by AT&T and British Telecom, each of them claiming a lowering of the cntry barriers of the other competitor's domestic market.

For many years, extra-EC suppliers of software and computing services have been operating in the EC market through subsidiaries or associated firms; more recently, because of the opening of European telecom markets, many extra-EC telecom firms opened their branches or made partnerships in Europe, thus contributing to the generation of employment and value added in the EC. Nevertheless, it is very important for the EC to face the problem of the growing trade deficit.

MARKET FORCES

Demand

In the information services sector, demand of the business users has a major influence on the market because of the sophistication of their needs and their purchasing power. Also, residential users are important, either in using telecom basic services (telephone, audiotex and videotext) or as customers of easy to use application software.

Broadly speaking, business customers need more customised and sophisticated solutions (for example outsourcing in the telecom sector, financial and technical databases, or custom business software), have a growing bargaining power (particularly in the telecom sector because of the introduction of competition) and are very performance sensitive.

Residential customers are more price sensitive, requiring more standard products and user-friendly services. Demand is strong for entertainment services and cheap information services and products that prove to be useful in daily or professional life. In fact, working at home is becoming more and more important and is facilitated by advances in the computer, software and telecom sub-sectors .

Beyond the great difference between business and residential users, the whole market is segmented into niches because of the increasing differentiation of end user needs: penetration of the market requires being closer to the customer and increasing investments in marketing research and promotional efforts.

The information services market is also becoming more globalised and, therefore, it is increasingly necessary to have international distribution channels to reach the customers.

Supply and competition

There is a very important difference between the telecommunications sector, on one side, and software, computing services and electronic information services on the other. The telecommunications market, in fact, is basically still nationally based and strictly regulated, whereas the others have always been very competitive and usually global.

The main telecom players are the national public carriers that maintain a monopoly on the telephone services; the telephone market is the largest one in the telecom sector providing about 85% of the total revenues. However, emerging services like mobile and data communications are, in many EC countries, becoming more competitive as they are in open markets not dominated by the national monopolies. Newcomers in the liberalised markets can be private telecom operators, foreign or extra EC telecom carriers, computer and professional services companies, specialised companies (for instance in the VAS market or as providers of outsourcing services) and large customers who have data networks and the possibility to sell the extra capacity on thc free market.

EC carriers have never faced an open and competitive market. So the public carriers are deeply involved in improving efficiency, providing flexible and timely market services and becoming closer to their customers. They are forming many partnerships with other telecom carriers to provide global services to multinational companies, and with VAS vendors and other operators such as computer vendors to be able to acquire complex knowledge in the data network and services arena.

The market for professional and computing services is mostly country based because of the necessity to offer specific solutions to specific problems. Many firms are in the market, but there is a trend towards concentration. This market is coming under strong competitive pressure from groups of different origins such as computer manufacturers, end user organisations or consortia and audit firms.

The packaged software market is definitely global but because of many historical reasons, the EC players have a marginal role, whereas the American companies are leaders.

The electronic information services market is both international and country based. In fact, some markets, like those related to scientific and financial information, are global while some other markets are national, such as those concerning information about local laws or domestic companies. Moreover, the international flow of information is still constrained by linguistic barriers.

OUTLOOK

The information services market will be one of the largest and fastest growing business sectors in the EC. According to some estimates, the total market will reach 244 billion ECU in 1997. The telecommunications market will amount to more than 136 billion ECU, remaining the largest subsector of this market, and will grow at a compounded average annual growth rate of 8% from 1992-1997. Software and services will grow

at the annual rate of about 7% during the same period, exceeding the 80 billion ECU level. Electronic information services will have a 12.4% growth rate and, in 1997, will amount to 6.5 billion ECU.

The convergence of the telecommunications, data processing and media industries is finally happening and is beginning to keep its promises. New ranges of service are underway such as intelligent telecom services; high speed digital networks; intelligent mobile services spurred by the forthcoming introduction of PDA (Personal Digital Assistant, a computerised mobile telephone); and multimedia services like those that will be offered by video on demand, Cable TV or CD-ROM players. All these services require the integration of different activities of the major information industry companies, so new waves of partnerships, technological and commercial agreements and joint ventures are highly probable. The EC industries are well positioned to take advantage of the opportunities emerging from this sector. In fact, the EC has some of the world's largest companies in the market, like some of the most important telecom carriers, international publishing companies and computing services companies. To meet the challenge, however, the EC industries have to use more aggressive strategies on a worldwide basis.

Software and computing services
NACE 839.2

The software and computing services sector continued to experience positive growth, confirming its strategic role on the overall EC economy with a growth rate of 8.7% between 1991 and 1992. The industry is a heterogeneous group of companies, products and services making it difficult to provide comments that are applicable to the entire sector. In terms of growth in market value, however, the areas of software and system integration/networking can be identified as the most important.
Industry concentration is still low but there is a rising trend towards technical collaborations and alliances that tend to create higher market entry barriers. This encouraged the presence of few large European groups and many small, niche-oriented companies: alliances and cooperative arrangements between these two categories of firms could be important means to face the competition of American industries in the European market.
Nearly every area of activity still has room for development as the saturation of the hardware market brings new demands on software and services by more highly sophisticated end users.
Threats, coming from increased competition and constantly falling prices, will quickly shrink profit margins and accelerate industry concentration. However, more opportunities will arise as a consequence of new technologies and infrastructures (multimedia, data highways, personal electronics, etc.) and expansion into new markets such as Eastern Europe.

INDUSTRY PROFILE

Description of the sector

This sector provides different categories of information technology (IT) software and services and includes various kinds of suppliers. The broad areas of the sector's activities can be classified into the following four categories:

- software products, including application packages, system software and tools;
- professional services, including consultancy, technical assistance, software customisation , training, education, auditing, etc.;
- processing and network services such as the traditional service bureau, new IT services like facilities management, disaster recovery, etc. and value added network based services (VANS); and
- hardware maintenance and support services, including hardware installation, site preparation, etc.

System integration and turnkey systems delivery, often cited in the literature as individual segments, would be better considered as a combination of most of the above mentioned services for supplying complete IT solutions (systems integration or solution integration), sometimes with hardware and software included (turnkey systems). This kind of service can be provided both as main activity itself by specialised companies, or in addition to other products or activities by non-specialised companies, such as hardware vendors or telecom services vendors.

Recent trends

The area of services as a whole accounts for 70% of the EC software and computing services market, out of which the professional services are the most important (36% in 1992). The remaining 30% is accounted for by software products.

In 1992, Germany had the highest percentage of EC revenues with 22% (12 billion ECU), followed by France with 17%, the United Kingdom with 16%, Italy with 13% and Spain with 3%. Revenue breakdown by country is expected to be about the same in 1993 and 1994.

Since 1990, the EC market for software and services has been increasing, both by total market value, from 48 058 million ECU in 1990 to an estimated 61 378 in 1993, and by product category. A positive but slower trend is also expected for 1994, with a market value that is expected to reach 65 933 million ECU.

The increasing complexity of end user requirements, combined with heavier demand for organisational and application consultancy and training, has maintained strong growth in software products and professional services categories. They registered growth rates of 11.6% and 10.3%, respectively, from 1991 to 1992. Processing and network services had a respectable 7.6% rate of growth during the same period, but the 1993 figure is expected to dip slightly before climbing to near 1992 levels during 1994. The hardware and maintenance subsector experienced a 3.5% growth rate in market value in 1992, but expectations are for its growth to level off at around 2% per year for 1993 and 1994.

Network services are anticipated to grow at a compound annual rate of 16.1% per year from 1992 to 1994. The slower growth segment in that period will be processing services with a 5.2% compound growth rate (CGR). Growth will be faster in countries where software and computing services are less widespread and the actual markets are still far from their potential size. Spain, for example, will see a 14.1% CGR from 1992 to 1994. Even though the German market is already in the forefront, its revenues are predicted to increase by 9.1%.

Applications, systems and network operations (facilities management, outsourcing services, disaster recovery services, etc.)

will record the highest growth in the 1992-1994 period (16.5% CGR), while lower rates are foreseen for education and training (8.6% CGR), contract programming (8.1% CGR), IT consulting (7% CGR) and staff delegation or temporary personnel services (4.9% CGR).

International comparison

While the demand for services is essentially satisfied at a local/domestic level, the demand for software products strongly depends on extra-EC suppliers. Overall, the European packaged software market is the largest in the world, followed by that of USA and Japan. For USA software developers, Europe is the second largest market, accounting for 10.8 million ECU (33% of total USA production) compared with their domestic market worth 16.2 million ECU. The European industry's share of the world packaged software market is 16%: USA packaged software dominates the market with a 78% share and the rest of the world controls only 5%.

Foreign trade

The European industry share of the domestic packaged software market is less than 35%, compared to 63% for USA vendors. Most of the packaged software produced by European vendors is directed to the European market (6 million ECU on a total production of 6.7 million ECU), the rest is sold to the USA (0.4 million ECU) and to Japan (0.3 million ECU).

American companies are present on the European markets through local subsidiaries or, at a lower degree, through distributors: the number of companies directly present has recently grown very fast in proportion to the growth of the European market.

So far, the European software industry has not been able to control its own internal market or expand into other industrialised markets. Recently, software export activities to Eastern European countries have become more important as a consequence of the growing consultancy work, technology supply and investments in that region.

The custom software business is characterised by a stronger presence of local firms who are specialised and focused on vertical markets by being nearer to the end-users and aware of their specific requirements. EC firms dominate the local markets for custom software development.

The professional services category also has a high percentage of locally based companies. Only Cap Gemini Sogeti (F), Andersen Consulting (USA) and EDS (USA) have global and international structures, but many other American consultancy and service companies are contemplating expansion of their business by entering the European market. The presence of Japanese and Southeast Asian companies in the EC market remains weak and is not foreseen to become a substantial threat in the future.

MARKET FORCES

Demand

The impact of the economic recession on IT expenditures has affected the recent upward trend of software and computing services, but to a lower extent than the computer and office equipment sector.

Concepts such as downsizing (offering products with lower price/performance ratios that has fostered the development of the mass consumer market) and down pricing (i.e., unitary price dropping) are adaptable to the software business. The standardisation of software platforms (DOS, Windows, MAC, OS/2, UNIX, etc.) has promoted the development of new products to satisfy a broader range of applications, allowing in-house software developers to concentrate more on business specific (strategically important) issues and less on routine aspects.

So far, the larger volumes have balanced software price reductions, establishing a large installed base with a growing potential market for new software modules and applications.

Moreover, the structural change from a "product/technology" demand push to a "market/application" demand pull is favouring the software vendors who are application driven, as well as the services vendors. Because of this, hardware vendors are facing a rapidly changing business environment.

The investments in computers and, to a certain extent, in office equipment, increasingly have to be justified in terms of return on investment and the positive impact they will have on the user companies' organisation and business; customers are looking for business solutions rather than for technology tools only. This customer orientation creates new demand for top-down consultancy services (from strategic to organisational management, all the way down to system integration consultancy) but, more than this, what is changing are the supplier selection rules in the IT market.

With computing hardware becoming more commodity-like, professional and software service companies are developing into the main contractors of large projects by supplying even the hardware needs of their clients. This trend towards a vertical industry orientation is helping service companies maximise their value added. System integration firms now present themselves as business and organisation integrators.

The current recession is shifting demand from traditional services, such as in-house software development and processing, to new ones such as facilities management or outsourcing, to find cost reduction opportunities.

The fastest growing market segments are the low end market for low cost, horizontal application packages (productivity tools, netware, etc.) or the large vertical segments (like CAD/drafting, desk top publishing, etc.). Industries experiencing business and/or organisational change (such as banking, transportation, health, logistics, etc.) create rich and complex growth opportunities.

The personal electronics systems market is an important one for the future, particularly for hardware manufacturers and media publishers since they appear to be in a better position to exploit this market than software and service companies.

Supply and competition

The competitive environment of the software and services market is mainly characterised by the presence of specialised software and services suppliers and systems/hardware vendors looking for new means with which to diversify their range of activities. Most of the traditional hardware giants are now also significant software and service players and have clear and explicit goals concerning the expansion of this aspect of their business. The telecoms and consulting groups are equally pushing to extend their sources of income by moving in to adjacent software related activities. The changing nature of the competition is a major issue for the established players.

According to their core business, the competitors can be identified in the following groups:

- independent software and professional services companies (Cap Gemini Sogeti, F; Sema Group, UK; Finsiel, I; etc.);
- packaged software developers, (Sap, D; Microsoft, USA; Matra Datavision, F; etc.);
- strategy , management and audit consulting firms (Andersen Consulting, USA)
- data processing departments and subsidiaries of end-user companies;
- hardware vendors, software departments and solution units.

Generally speaking, there is a weak presence of global competitors, apart from system software and the most popular packaged software segments where American companies are absolute leaders. Both large and small companies can take advantage of their size to be competitive: the former can rely upon financial and marketing resources and large contracts to give them bargaining power in the market. Small companies can base their activities on innovation, flexibility and ingenuity. Local players still dominate the European market because of the closeness to the end-user and their specialised vertical market-focused activities. This is particularly true for custom software and processing services. European companies dominate the professional services segment too, as their required skills are highly specialised.

The competitive environment of this sector has recently evolved very rapidly. This is mainly due to the changing of end-user requirements. The suppliers must correctly understand the needs of their destination segments and offer specific solutions to particular problems. That is why key factors of success are the capability to control vertical markets and to develop specialised application skills.

This sector is also characterised by low entry barriers, allowing small, specialised newcomers to enter market niches at the local level. This condition is changing as the larger installed base and distribution/marketing barriers are causing an increasing concentration in the most standardised and horizontal product segments. There are also some global hardware vendors, telecommunication operators and consulting companies that are widening their range of activities.

Production process

The industry is characterised by fast technological evolution, particularly towards user specified standardisation.

The EC is supporting quality standards in relation to the services business. This is seen by the service industry firms as an opportunity to establish competitive advantage and differentiation and is shown by the fact that there are a growing number of companies adopting ISO 9000 standards. The variety of the hardware environments forces end users to use tools that facilitate the shift towards open systems, decentralised computing and requirements concerning integration of platforms and operating systems. The importance of systems software and utilities in enabling greater user friendliness and hardware optimisation is increasing.

The functional level development of UNIX, personal computer and network operating environments is bringing about a convergence of operating systems. The most prevalent operating systems currently are UNIX, Windows and MS-DOS; in the near future, Windows NT is expected to gain in numbers of installations. The operating systems vendors, in general, are aiming towards interoperabilty, portability and modularity, as end-users are demanding to be independent from suppliers and to be free to adopt the best available solution to their present requirements.

Application tools are evolving towards a third generation of languages and utilities. Among system development tools, the C++ language and SQL (standard query language) are gaining in importance.

On-line transaction processing is an important area that covers many issues such as operating systems, communication protocols and graphical interfaces. Middleware also has a strategic importance because it allows the integration of hardware and software with the focus on a vertical market approach. Middleware is also an important element in providing interoperability and portability and the move towards open systems is causing more "middleware" and more application programming interface standards to be produced. In turn, this creates more business opportunities for potential middleware producers. Specific tools are emerging as important means to improve the use of IT in an organisational context, such as performance management, business management and problem management software.

INDUSTRY STRUCTURE

Companies

In Europe, more than 16 000 firms are listed as sector participants. There are many local companies operating in the market; the few international ones have low market shares. Local market entry is generally made by larger firms through acquisitions of existing local companies.

Cap Gemini Sogeti (F) is the leader in the EC market, recording a turnover of 1.44 billion ECU and 17 971 employees in

Table 8: Software and computing services

1991. The Sema Group (UK) is the second largest European company with a 1991 turnover of 588 million ECU and 7 450 employees.

Strategies

The software and computing services sector saw an increasing amount of alliances, partnerships and mergers geared towards sharing competencies and capabilities, strengthening market positions, achieving R&D synergism for common basic technologies, exploiting diversified distribution and trade channels and widening market access.

The trend towards mergers is mostly linked to French companies, the European market leaders, who typically are professional services vendors pursuing a European-wide presence.

Microsoft and other American companies such as Novell, Oracle and IBM were involved in world-wide agreements to create R&D and marketing synergism.

Among European companies, Cap Gemini Sogeti (F) was the most active European company in forming partnerships and alliances. The most notable recent European corporate marriages in the software and computing services sector were: Cap Gemini Sogeti (F) with Sap (D), Software AG (D) with Apple Computer (USA) and the technological agreement between Andersen Consulting (USA) and Sap.

Entry into new markets is usually pursued through establishing subsidiaries. This facilitates the liberalisation of trade and the standardisation of infrastructure investment. Also, it is not uncommon for consultant firms to accompany their clients' new investment projects abroad, thus giving the smaller consultant firm international exposure.

OUTLOOK

The trend towards globalisation and international competition will have a strong impact on the market evolution and competitiveness. The context differs by products and/or service offered. As far as packaged software is concerned, European companies will be increasingly threatened by the American vendors who already dominate the market.

In the professional services and custom software areas however, Europe can compete at high levels due to the competencies and the experience achieved in these segments. Only in the professional services segment is competition among European players particularly strong. This is due to the openness of the EC single market that has recently been extended to the banking, insurance and public contracts areas. Small vendors stand to loose out on open market benefits if they resist expansion under the belief that there will always be little or no competition in their niche market.

The future demand trend will remain positive, but with lower growth rates than in recent years. Of course, the software and computing services sector also depends on the trend of other sectors, but economic downturns also place a demand on consulting products that assist in cost cutting measures such as company re-organisations, outsourcing, optimisation of core business activities, etc. Despite the domestic trend of the IT sector towards price reduction, decreasing profits, and company failures, the software and computing services area will maintain positive growth rates. In fact, end user demands for custom and sophisticated products and services create more room for developing the existing segment and possibilities for the birth of new ones.

Some other factors that will change the competitive rules and create new opportunities in Europe are: the re-industrialisation process involving the East European markets, the increasing integration of the European markets and the obsolescence of the installed base.

The industry is represented at the EC level by: European Computing Services Association (ECSA). Address: Avenue de Cortenbergh 79-81 Box 7, B1050 Brussels; tel: (32 2) 736 6003; (32 2) 736 6006.

Electronic information services
NACE 839.2

The sector includes four key segments: "classical" online database services, videotex services, publications on optical disk (including interactive multimedia) and audiotex and fax-based information services. Total revenues of electronic information are rapidly increasing: they reached 3.3 billion ECU in 1991 not including audiotex; 12% more than the previous year. More than 90% of the revenues came from on-line databases, 9% were from off-line information services, while just 2% came from CD-ROM.
The most consulted on-line information services were, by far, financial and business data bases: altogether they accounted for more than 90% of the total turnover of the on-line information market. Most of the segments are typically international, such as scientific and financial telematics services. In these markets, global suppliers are the most important players. In spite of the dominance of the USA competitors, Europe has several world ranking information and media corporations that can compete globally. In some other important segments, such as in the company profiles segment, national suppliers are the most important ones because they have an in-depth knowledge of their domestic market. Banks and financial companies are the most important users of professional services, but the individual consumers are growing in importance. Audiotex proves to be a very fast growing medium because it is easily accessible with only a telephone. The diffusion of videotex services, on the contrary, is very slow, with the notable exception of Teletel services in France

INDUSTRY PROFILE

Description of the sector

The sector includes on-line and off-line electronic information services such as on-line databases, realtime or not realtime electronic information and CD-ROM databases.

Electronic information is related to various kinds of subjects: financial data, market research, business information, international and national laws and regulations, news, science and technology, patents, etc. In fact, the field of information is unlimited and continuously growing.

The major companies in this sector come from different categories of business where they functioned as publishers, producers, vendors or brokers. In addition, it is not very easy to collect reliable data about this market since electronic information is an immaterial good. The Information Market Observatory (IMO), working as part of DG XIII/E, strives to improve the knowledge and understanding of the European electronic information services market. In the '70s when the sector started developing in Europe, it was highly linked to the science and technology field and the majority of databases were on scientific subjects and came from public organisations. Afterwards, electronic information services increasingly became a specific business area with the growth in popularity of the financial and economic databases. Videotex technology was introduced in the early 1980s by telecom carriers that wanted to offer a very easy access to information (data, text, graphics) via telephone lines. Videotex is billed to customers through a central billing system, or kiosk. Audiotex services - information services offered by telecom carriers and is also billed through a kiosk - were launched in the late 1980s and early 1990s.

Source: TFPL

Recent trends

Total revenues of electronic information averaged 3.3 billion ECU in 1991 (not including audiotex revenues), recording a growth rate of 6.5% in comparison with the previous year. More than 90% of the revenue (3 billion ECU) came from on-line database while just 9% (298 million ECU) came from off-line information.

As far as on-line services are concerned, turnover increased more than 14% from 2.6 billion ECU in 1990 to 3 billion ECU in 1991. In 1991, 59.6% of the revenues originated from real-time services (mostly financial services), the rest came from non real-time services. Employment is increasing as well. In 1991, the EC total number of employees in the Electronic Information sector was 28 805 (8.5% more than in 1990).

Off-line information services grew more slowly: from 1990 to 1991 with a growth rate of less than 5%. A remarkable leap in the off-line information services market is expected because of the planned introduction of many new multi-media titles by the major computer companies. Of the overall EC production of commercial CD-ROM titles, 39% came from the United Kingdom, 16% from Germany and 12% each from Italy, France and Holland.

Most of the on-line revenues of EC suppliers came from Member States' consumption, this was 70.7% of total revenues in 1991. Almost 35% of supplier revenues came from national markets and 36% from intra-EC trade. Since 1989, the incidence of revenues coming from EC domestic consumption has been increasing due to increased intra-EC trade. Exports accounted for 29% of total revenue, which was a decrease in comparison with the previous years. Figures about imports are not available, though a trade deficit with USA seems very likely.

By far, the most consulted databases are financial and business data bases: together they accounted for more than 90% of the total turnover of the online information market in 1991; this was a decrease from the 1990 figure of 96%. Other kinds of electronic data bases, like scientific, technological and government data bases played a minor, but increasing role; the latter had the highest growth rate. From 1990 to 1991, financial data base turnover grew 3.7% while business data bases had a double digit growth of almost 25%.

Rest of the world	182	121	25
Total	2 243	818	93

Source: Directory of On-line Databases, Cuadra/Elsevier, July 1992

International comparison

North America is the greatest worldwide producer of on-line ASCII databases: at the beginning of 1991, there were 1 269 database producers. At the same time, there were 792 of them in EC and 182 throughout the rest of the world. In the USA, there were also 451 hosts, while there were 246 in the EC and only 121 in the rest of the world. America had the highest number of gateway services (43), while 25 gateways existed in the EC and 25 in the rest of the world.

There was a total of 4 million CD-ROM drives installed worldwide in 1992, nearly doubling in numbers from the previous year. The USA has the highest installed base of drives (67% of the total or 2.7 million) in 1992. In the same year, there were 400 000 (almost 10% of the total number) of CD-ROM players installed in Europe, while in Asia, the amount was nearly 1 million units (because of the large Japanese market).

Table 4: Electronic information services

MARKET FORCES

Demand

Information services end users are a very broad category which can be divided into business and residential customers. By far, the most important customer segment has been the business users due to their bargaining power and their use of the most sophisticated on-line data bases. The latter mainly use cheap and user-friendly technologies such as audiotex and videotex. CD-ROM are used by both segments of users. Most of the demand, however, came from the professional users (lawyers, accountants, tax advisors, etc.) who are dependent on external information sources.

Business end-users of electronic information services can be grouped into the following categories: banks and finance, services and research companies, media, manufacturing and commercial companies, institutions, universities, unions and other associations. Banks, finance and insurance companies are the most important users of on-line financial and business data bases, followed by the main industrial and commercial companies.

The most requested subjects are related to financial and business information. As far as industrial and commercial companies are concerned, the demand for on-line information services mainly came from the need to verify clicnt backgrounds and suppliers' reliability (consulting business data bases), while the enquiry of scientific, technological and patents databases supports the R&D activities.

Audiotex is a fast growing, easily accessible individual consumer segment (only a telephone is needed for access). In 1993, audiotex services were already available in almost all of the EC countries thanks to the deregulation (formerly the public carrier supplied both the network and the information services, the latter is now provided by private competitors). The growth of the service is favoured by the penetration of the dial tone multi-frequency (DTMF) telephone sets. In 1992, the United Kingdom, the largest EC market, reached a turnover of about 350 million ECU: the total EC market was worth more than 800 million ECU.

Entertainment services (adult services and chat lines) are the most frequently used ones, followed by information services (news, sport and financial). Regulations have a big impact on the market, especially on adult entertainment services.

The success of a videotex service depends on heavy investments on the part of the service provider in placing terminals with end-users, implementing the network and marketing the products. These costs will be regarded by most firms as "normal" operating costs to develop their business in this competitive environment.

Videotex technology was mainly developed by France Telecom. In the 1980s, France Telecom supplied free terminals to a large number of users (substituting them for telephone books), creating demand for the products offered on their system. Currently, there are about 7 million Minitel service users and more than 10 000 information providers. The French market was worth more than 80% of the total European market in 1992. The most popular Minitel services are telephone directories, tourism and transport information, reservation services, home banking, home shopping, weather news and other information and entertainment services.

Table 5: Electronic information services

Videotex is growing in Germany (where about 360 000 terminals were installed at the end of 1992) and Spain (400 000 terminals), while its spread in the United Kingdom and Italy is still limited. In Germany and Spain, many customers use personal computers to access the services rather than specialised terminals. Professional information services are the most popular ones in these countries. Because of the different technical standards of the videotex systems, there is no integrated EC market in this area.

Supply and competition

The professional data base market is divided into many segments according to the content of the data bases. Generally, a few operators dominate the market in each segment. For instance, Reuters (UK), Telerate (USA), Telekurs (CH) and a few other companies control the market for real time financial information services; while operators like Dun & Bradstreet (USA) and the Japanese Teikoku Databank are among the main firms in the company profile niche of data bases. Esa-Irs (I), Questel (F), Dialog (USA) are the main competitors in the scientific and technological services.

Scientific and financial information services are typically an international market where global suppliers are the most important players. Global competitors are generally USA and EC companies. In some other important market segments, (such as the company profiles), national suppliers (with the exception of the Dun & Bradstreet (USA) are the most important because of the deep knowledge of their domestic market.

United Kingdom data base publishers are the most important producers of commercial CD-ROM titles in Europe, followed by suppliers from Germany, Italy and the Netherlands. The majority of companies that provide audiotex and videotex entertainment and information services are nationally based. Each country has hundreds of companies supplying these kinds of services. There are, for instance, about 500 suppliers of audiotex services in United Kingdom and the Netherlands. In the videotex business, there are more than 14 000 service codes offered in France and more than 3 000 information providers in Germany. Cultural, linguistic and, to a certain extent, technical differences, prevent services from going international.

INDUSTRY STRUCTURE

Companies

In spite of the dominance of the USA competitors, many EC information and media corporations can compete worldwide, like Reuters, Reed International (UK), Pearson-Financial Times (UK), Bertelsmann (D), and VNU (NL).

However, a disadvantage for European companies is the linguistic fragmentation and national boundaries that still hinder the development of the EC unified market and slow down the development of the sector. To overcome this, companies look for new partnerships, new distribution networks and technological innovations.

OUTLOOK

The demand for electronic information services is expected to develop at a compound growth rate of about 12% over the next five years.

The main users of professional services and CD-ROM will remain the banks and the financial companies, but the diffusion of the services towards industrial and commercial sectors is underway. Many large companies use information services to assist their planning, marketing, and production functions. As their use becomes easier and less expensive, professional information services should see user growth expanding into the small to medium sized enterprise range. The spread of the services will be aided by the expansion of new, high performance networks like ISDN (Integrated System Digital Network) and new technologies such as expert systems that allow the access of foreign language databases in the user's home language and new software for automatic language translation. Harmonisation of the rules covering government owned data bases is also expected.

The development of the market will likely be faster for CD-ROM as the major computer companies launch multimedia personal computers in the mass market and sell more and more PCs with CD-ROM drives. The price of CD-ROM drives has dropped dramatically, and many publishers are working hard to publish new and appealing CDROM titles for expanding the new consumer market.

Table 7: Electronic information services

EC audiotex services are at the beginning of their life cycle and it is expected that they will have a double digit growth in the next few years. After the success of the adult services, which characterised the period immediately following the launch of audiotex, it is expected that more professional services will consolidate and become more important audiotex providers in many countries. Greater penetration of touch tone telephones will facilitate the use of telephone services such as voice recognition and fax on demand, which is the combination of audiotex and fax for automatically ordering and receiving information.

A major expansion of videotex services outside of France is not very likely because of the national technical differences that continue to exist between systems. The increased use of personal computers that have the necessary hardware to connect to videotex networks and the spread of ISDN services (that allow the transmission of images) could favour the service, although it will be into the next century before these technologies make a difference for videotex growth.

Written by: Databank
The industry is represented at the EC level by: European Association of Information Services (EUSIDIC). Address: B.P. 1416, L-1014 Luxembourg; tel: (35 2) 250 750 220; fax: (35 2) 250 750 222.

Telecommunications services
NACE 79

In 1991, revenues generated by EC telephone carriers nearly reached 90 billion ECU, and the gross investment of public carriers totalled more than 32 billion ECU. The sector will expand at the annual growth rate of 6% over the next few years. This favourable growth will be assisted by the development of new digital technologies, a wide range of intelligent services, a fall in prices and the growing need to communicate globally. However other sectors based on information technology such as telecom will pass through a period of crisis. The main EC telecom operators are the national telephone carriers who generally are large, profitable and state owned companies (with the exception of the United Kingdom). In spite of the variety of the telecom services, 85% of the EC telecom carriers' revenues still mainly come from telephone services, while mobile and data communication and other new services account for the remaining 15%. However, these services are foreseen to have the most exciting growth rates. As for telephone lines, the EC is the largest market in the world with 147 million lines.
Public carriers still have the monopoly of the basic telecom services, but competition is increasing in the international and domestic arena because of the liberalisation of data services and mobile communications markets. New competitors, particularly American carriers and computer companies, are emerging. Users are getting very sophisticated and differentiated: paradoxically, the more the EC telecom market moves towards integration, the more demand moves toward segmentation.

INDUSTRY PROFILE

Description of the sector

Telecommunication Services permit interactive interconnection between persons, between persons and computers, and between machines, through many different media networks such as cable, microwaves and satellite networks. They also permit the diffusion of information from a single point to multiple points such as direct satellite broadcasting for television or data transmission.

Telecommunications services are services provided by public or private networks, such as telephone or telex, where the messages are simply transmitted by the networks, or value added services (VAS) like electronic mail, EDI (electronic data interchange) or protocol conversion, where the messages are stored, processed and repackaged along the route before being received by the addressee.

The transmitted information can be voice, data or images. Until recently, each type of information required the use of a specific network (telephone, telex, or packet switching networks). However, new networks like ISDN (Integrated Services Digital Network) allow for integrated distribution of all three information types (fixed or full motion images).

Recent trends

New technologies derived from microelectronics, optics and information technology, such as digitalisation of exchanges and transmission, fibre optics and advanced software, allow the transmission of an increasing variety of intelligent services for the benefit of many different customer segments. Due to new networks, such as ISDN and broad band lines, the lack of bandwidth for new services that require a vast amount of data (like video transmission) promises to no longer be a bottleneck for the customers.

These new technologies are also prompting the prices of all the telecom services, particularly the long distance services, to fall dramatically. Price cuts, especially for the business customer, are also strongly pushed by the emerging competition.

Because of the monopoly of the telephone services, the main EC telecom operators are public carriers; only in the United Kingdom has the telephone carrier been privatised, allowing the entry of competition into the data and local telephone services. Therefore, the geographical distribution of the production of telecom services in EC depends mostly on the size of the public telephone carrier and on the strength of the economy of the country of origin. Germany, the United Kingdom, France, Italy and Spain are the main markets of the EC in this ranking.

In spite of the telephone monopolies, many newcomers are entering the newly opened EC mobile and data commercial telecom markets. USA carriers and, to a lesser extent, computing companies, are taking advantage of these new opportunities.

From 1980 to 1991, gross investments and revenues for telecom services in EC Member States showed a notable increase.

Source: Eurostat using ITU data, national telecom administrations

In 1990, EC telecommunication services receipts totalled about 2% of the EC gross domestic product. In 1991, the EC revenue generated by telecom services by public operators totalled 90 billion ECU, for a corresponding gross investment of more than 32 billion ECU.

In the same year, the EC was the largest region in the world when considering the total number of main telephone lines with 147 million compared to 130 million in the USA and 56 million in Japan. The number of lines per 100 inhabitants in the EC was 43 compared to 51 in the USA and 45 in Japan. This number varies considerably between Member States and ranges from 27.3 in Portugal to 57.7 in Denmark.

In 1991, total employment averaged 899 000, a decrease of 28 000 from 1990. Since the average growth rate is about 10% per year, this decrease means that the sector is rapidly changing with technological innovation and is gaining in productivity.

The mobile communication subsector is expected to increase dramatically in the EC: in mid-1993 there were 7 million subscribers to analogue cellular telephone services. The subscriber base is increasing rapidly: the penetration level now is about 20 subscribers per 1 000 inhabitants. Also, the private networks - mostly user built to obtain reliable and cheaper communications inside the company- increased in the last few years: between 1988 and 1990 they increased more than 17%. It was estimated that more than 14 000 private networks existed in 1990.

The level of telephone line penetration in the EC is much higher than in Eastern Europe and the former USSR. In 1992, there were 11 main lines for 100 inhabitants in Hungary, 9 in Poland and 14 in the former Soviet Union. The quality of the services offered in East Europe is very low compared to western standards. Even if East European countries show a high potential for growth, telecommunication investment scenarios are very uncertain because of the economic problems and financial shortages of these countries. This is confirmed by the average rate of growth from 1986 to 1991, that varied from 4% to 8% per year depending on the country, far from the real potential of the sector.

Eastern countries are looking for EC technical and financial assistance and partnerships. Western partners must bring genuine commitment and expect only long-run returns on investment. In the last few years, there has already been a flurry of activity as EC and American companies (like Deutsche Bundespost Telekom, France Telecom and US West) have signed many partnerships with telecom carriers of East European countries (that still maintain the majority stake in the joint ventures) such as the partnerships made in Poland, Romania and Estonia. Typically, the investments by western countries have been made in the areas where there is the possibility of faster returns on investments, like in mobile and international services. There is no denying the need for these services, but it is also clear that a major effort is needed for upgrading basic telephone services; Deutsche Bundespost Telecom is already deeply engaged in rebuilding the telephone network in the former East Germany.

Foreign trade

International telecom services are regulated by a very stable mechanism by which revenues are shared by the international carriers. The revenue of the carriers depends on the traffic and also on the different tariffs fixed by each country. Large price differences between countries for international calls explain much of the trade surplus or deficit of the countries in this sector. Because of its high tariffs for international telecommunications, the EC has traditionally had a trade surplus with the USA, the principal partner for extra-EC communications. It is very likely that, because of the general drop of EC long distance tariffs, the surplus trade will diminish.

MARKET FORCES

Demand

The telecommunication market is as diversified as in the past, with technologies and needs (both of residential and business users) rapidly evolving and becoming more sophisticated. As a result, the more the EC telecom market becomes global, the more the integrated market segments itself along the lines of technologies and type of service.

Networks are becoming increasingly intelligent and, for this reason, they are very good platforms for the provision of new services that could meet the expanding user requirements.

In spite of the fact that the number of new telephone subscribers is diminishing in the EC, the demand for telephone services is still growing, as indicated by the high annual growth rate of both local and long distance traffic. It is not surprising that intelligent services are the most important means used by the EC telephone carriers to increase traffic and revenue per line. In the USA, intelligent services already generate about 20% of total telecom income of the carriers.

As a result of widespread use of newer methods of information and data transfer, telex use is dwindling rapidly. From 1989 to 1991, the number of telex lines in the EC decreased by 23%; in Japan they decreased by 32% and in the USA, the numbers increased 6% from 1989 to 1990 only to plunge 65% from 1990 to 1991. In 1991, Luxembourg had the highest concentration of telex lines with nearly 6 lines per 1 000 persons.

Intelligent networks provide services for both the residential users, the price sensitive segment of the telecom market, and for the business and corporate users, the performance sensitive segment. New intelligent services such as caller identification, follow me, credit card calling, audio conference, free phone, intelligent fax, audiotex and Virtual Private Network (VPN) are bound to spread fast. So far, banks, insurance companies, building societies, hotels, airlines and services companies are the major business users of the services offered through intelligent networks.

Mobile services permit easy communication with very few constraints. Mobile communication has been very successful, being accepted by both business users and an elite group of residential customers. Due to economies of scale and new technologies such as PCN (personal communication network) that have been designed from the outset for the domestic customer and small business markets, prices will decrease over the next few years and a major share of residential users will be able to afford mobile telephone services. Tariffs have also been adjusted to take into account customer discrimination.

Datacom services are also at the brink of a major leap ahead in technologies. The increasing need to exchange data among the computers of departments within companies, and also among different companies linked through business relations, pulls demand for data networks like X.25 public and private networks. There is also an increasing demand expected for transmitting large data flows and video signals through ISDN and high speed broad band lines and networks of both private and public origin. Fast transmission of data and video could change the way people work and live and could also favour the growth of less developed regions and countries.

Also, the demand for very personalised data services like VPN is emerging. VPN is based on a public network but completely controlled and configured by the customer according to his or her needs. VPN (like ISDN) could be seen by the customers as an alternative to their own private data network.

The VAS (value added services) market, on the contrary, is still suffering from bottleneck problems. Demand exists, but the lack of diffused and accepted standards still hampers its further expansion. Demand is also rising from multinational enterprises, as management of worldwide facilities requires negotiation with many different national authorities. Large companies would prefer to deal with a single telecom company for worldwide communications provision. Through this kind of user demand, it is obvious that global solutions for business, entailing sophisticated services and guaranteed reliability, are better achieved through a single global carrier, or "supercarrier", with sole responsibility for genuine end-to-end provision.

Supply and competition

The development of the market (and therefore the pace of new service offerings) has been traditionally limited by national monopolistic regulations. But new technologies and liberalisation push for the offering of a broader range of services. New competition pushes the public carriers to fix the prices of each service according to the cost specifically sustained. In fact, there is a general trend with regard to the tariffs. Public carriers are bound by strong competition to heavily decrease their prices for long distance calls and for services directed to the business users, while a lower decrease occurs for local calls and for services addressed to the residential users. Therefore, the norm of cross-subsidisation between long distance and local calls and between business and residential users will diminish in importance.

The increasing risk derived from the liberalisation of Data and VAS markets, and from the entrance into the market of powerful players like IBM (USA) and DEC (USA) and other computer companies and foreign carriers, is tackled by the domestic carriers through the increasing supply of new intelligent services and high performance digital networks like ISDN.

EC public carriers in the most regulated markets may have an incentive to invest heavily in ISDN in order to offer a new range of advanced services which might help them to compete against new private competitors entering the market after deregulation. ISDN is a major challenge for public carriers: their goal is to push the big business users to migrate from their own private networks or other service providers, to the public digital network.

Public carriers are engaged in building mobile communications networks on the GSM (Global System for Mobiles) standard, the European unified standard established by ETSI, to allow every subscriber to communicate easily with anyone else throughout Europe. As the EC chose a unified standard (GSM), public and private operators are ahead of the USA carriers who are currently implementing two different standards for digital mobile communications. GSM permits the use of multiple channels, security and a larger amount of digital services for the customer. However, prices for GSM services and terminals are currently higher than the prices for analogue services and terminals. It is foreseen that shipments of GSM telephones will overtake analogue shipments by 1994.

There is also increasing competition in the long distance market, which is the market that provides the highest profit margins and revenues for the carriers. Pushed by changing technology and rising competition, EC carriers are gearing for price cuts and searching for international partnerships. The new alliances target products for large multinational corporations; they generate the largest volume of long distance traffic and have the strongest bargaining power. As a result, new partnerships are taking place and new "supercarriers" are emerging.

Table 9: Telecommunications services
Top 9 companies in the EC, 1992 (1)

Rank	Company	Country	Service revenue (million ECU)	Number of employees

(1) Ranked according to service revenues.
Source: ITU Telecommunication Indicator Database; DG XIII

The most important partnership was set up between British Telecommunications PLC and MCI Communications, the largest USA long-distance carrier after AT&T. A second alliance was set up by France Telecom and Deutsche Bundespost Telekom. A third was formed by a three-way alliance, called Unisource, between the Dutch, Swedish and Swiss phone companies. Due to deregulation, American companies are entering the EC advanced services markets such as cable and satellite TV, mobile communications, "one stop shopping" and VAS.

Late in 1993, an announcement was made for the intended merger of Bell Atlantic, a regional USA telecom company and Telecommunications, Incorporated (TCI), the largest cable operator in the USA. If this acquisition is finalised, it will create a major American company that will offer not only the normal telecommunications services, but also interactive products such as video on demand, long-distance learning and home shopping. This type of merger may be the wave of the future for the EC telecommunications market as well.

Production process

Thanks to the digitalisation of networks and the introduction of OSS (Operating Support Systems), telecom carriers can heavily cut the expenses for monitoring and maintaining the networks and for supplying new services. Between 1985 and 1990, the annual average growth of productivity of EC telecom operators varied from 1.5 % in Holland to 11.4% in Portugal, while big countries like the United Kingdom, Germany, France, Spain and Italy had annual rates between 3 and 6%.

The diffusion of digital networks like ISDN, GSM and satellite telecommunications certainly will increase these trends. Therefore public carriers will be able to cut prices for the benefit of the customer.

INDUSTRY STRUCTURE

Companies

Generally speaking, public telecom operators are very large and profitable companies with a large number of employees. They also sustain large investment efforts for improving the networks and offering a broad range of services.

The top EC network operators are Deutsche Telecom Bundespost (D), British Telecom (UK), France Telecom (F), SIP (I), Telefonica (E). British Telecom and DBP Telekom are by far the top corporate performers: their profits as percentage of their revenues were 20.5% and 18%, respectively, in 1990/1991. On the contrary, because of the heavy investments made to modernise public networks in 1991, some public carrier, like those operating in Denmark and in Portugal, suffered losses.

Strategies

EC public carriers operating in a quasi-monopoly regime are preparing themselves to tackle new competitors in the open market.

EC carriers are deeply engaged in restructuring and increasing their productivity. Many carriers are changing their organisation in order to focus on emerging services and markets and be more flexible and nearer to the customer. Some telecom carriers, like BT and France Telecom have set up new companies for operating in specialised markets, like mobile communications or data network markets.

Many telecom carriers' goals are to introduce flexible pricing and sophisticated services (like network management and outsourcing), especially for the benefit of the most advanced business users, and to increase the traffic generated by the residential customers with products like intelligent services.

The need to introduce intelligent systems, data bases and software for monitoring the network and offering more services to the customers has a big impact on the telecom carriers strategies of partnerships with computer and software and computing services companies. For instance, France Telecom has recently signed a partnership with the service company Sema (F), while Stet (I) has bought Finsiel, an Italian software and services company.

Telecom carriers are also preparing offensive or defensive strategies concerning internationalisation. European Telecom carriers are very interested in the privatisation processes of many domestic carriers that are underway all over the world. France telecom and Stet, for instance, each hold a 32% interest of the Nortel consortium which, in turn, holds the majority share (60%) of the privatised Argentinean elecom carrier, Telecom Zona Norte, and are leading the modernisation of this Argentinean telephone network. Recently, France Telecom bought private data carriers in the United Kingdom, Germany and Italy.

In 1992, BT planned an investment of about 400 million ECU over 10 years to start the "Cyclone" project, designed for offering an international network and outsourcing service for large multinational companies.

ENVIRONMENT

Telecommunication services have a positive impact on the environment, as they reduce the need for physical transport. Many services such as satellite remote sensing and telemonitoring are used for monitoring air, water and soil pollution. Remote sensing services are also used for managing and preventing disastrous events. One minor environmental problem

Table 10: Telecommunication services Regulatory environment, 1991

	Main Operators	Regulatory body	Services markets liberalized	Rules concerning leased lines	Markets for terminal equipment
Belgique/ België	Régie des Téléphones et Télégraphes (RTT) a public utility	RTT and the Ministry	PBX only	Connection allowed Resale forbidden	All wide-diffusion terminals are still a monopoly of the RTT
Danmark	Tele Denmark, a state-holding, owns 4 regional monopolies and one functional	Telec. Inspectorate, a public authority, created in 1990	Only VAS Resale allowed	Connection allowed	Liberalized in 1990
BR Deutschland	Deutsche bundespost Telekom, a public utility	Department of Regulatory Issues (under the Ministry) created in 1989	All, except telephony lines only	Connection allowed for international	Liberalized in 1990

posed by telecommunications is the negative impact on the countryside from large transmission stations.

REGULATIONS

In spite of the general trend towards liberalisation of the telecom market, the pace and the method of introduction of liberalisation varies according to the laws and regulations in the EC Member States. The United Kingdom liberalisation example of the 1980s, the first EC opening of a telecoms market, is likely to be followed by other countries.

In the majority of countries, the VAS market and the terminals market are very open to competition. Because of an EC directive at the beginning of 1993, liberalisation came into force

for some other telecom services such as Videotex, intelligent fax and data networks. Resale of leased lines and satellite transmission of data trough VSAT are usually subject to national regulation, but are being approved at an increasing rate. In many countries, such as the United Kingdom, Germany and France, the mobile communications market is also competitive: in fact, in these countries, the public carrier compete with a private company. PCN is already a competitive market in the United Kingdom, Cable TV is highly regulated at the national level in France and Germany, but it is very open in the United Kingdom.

According to a recent EC deliberation, the liberalisation process will be completed in 1998, when all the EC countries, with few exceptions, will also be obliged to open the market for basic services. This will have a major impact on the growth rate of the sector, which is expected to increase very quickly.

So far, only two companies in the United Kingdom, BT and Mercury, compete in the market of basic telecom services.

The opening of the markets will continue to have two major consequences. The first is the creation of public authorities or regulatory bodies overseeing the telecom sector which, in the majority of cases (except in the United Kingdom), will be under the supervision of the ministry of post and telecommunications. The second consequence is the privatisation of the telecom national carriers that have traditionally been state owned. Stet , Deutsche Telecom and France Telecom are expected to be partly privatised in the next few years, although in different ways: in some cases the state will maintain a majority share, in other cases the majority share will be public-.

In many EC countries, regulatory bodies are being set up. They regulate competition between the domestic carrier and other national and foreign private operators, preventing monopolistic positions and also take into account the needs and

interests of end users. In many countries, the regulatory body still decides on the basic services tariffs but, following the United Kingdom example, the price cap mechanism for fixing tariffs has been increasingly adopted by other EC countries (the price cap mechanism generally is the automatic increase of the telephone tariffs according to the level of inflation minus a certain level of previously fixed productivity growth).

OUTLOOK

The telecommunication market will change rapidly because of the introduction of digital networks (broad band ISDN), new services and increasing competition. Completely original services are expected in the market, like, for example, video on demand. This service allows transmission on traditional telephone wire, thanks to ISDN networks and image compression techniques, of full motion TV images, interactive plays and other telematics services coming from a great variety of sources. All the major EC carriers are testing the technology and are trying to foresee the major applications and the degree of acceptability by potential users. Video on demand could have a major impact on the diffusion of other technologies and on markets such as cable TV, satellite TV and video recorders.

Among other services currently underway, there are the development of high speed networks based on the frame relay protocol (for connecting local area networks), virtual private circuits, broad band services (for transmitting high volumes of data and full motion picture) especially targeted to the business users, intelligent mobile services, based on GSM networks; satellite services for data transmission; network management and outsourcing. Also, the potential of growth in Eastern markets is very promising, notwithstanding their current financial troubles.

New players, together with the traditional national operators, will emerge. Worldwide, three or four global companies are likely to reinforce their market position in the international telecommunications area; these are AT&T, BT, and the Japan's NTT.

The customer will increasingly determine the trends of the new market, and telecommunications companies will be compelled to make greater use of sophisticated marketing research techniques to explore the needs of the users and to forecast the customers' reactions before offering and promoting their services.

Education
NACE 93

In a constantly changing world, education is called upon to play an increasingly important role in the preparation of young people for entry to the world of work.
Total public expenditure on education represents approximately 9% of total public expenditure in most EC countries, compared with figures of 12% in the USA, 16% in Japan and 18% in Switzerland. Europe's future will be built essentially on the quality of its human resources and therefore on the past and future ability of its Member States and economic participants to develop and disseminate training at school level. Through its content, organisation and the quality of its results creating expertise in each member country, education is the first way of satisfying demands and changing conditions in the labour market. In this sense, it is the most important investment in every country.

INDUSTRY PROFILE

Description of the sector

This sector includes all structured teaching activities in schools or universities which issue diplomas at any level.

The structure and evolution of the teaching sector reflect the way in which each country has attempted to build in historical components of its main demographic and economic factors (mainly in terms of activity and jobs), taking the best possible account of foreseeable and estimated developments, and the extent to which they have succeeded.

Its organisation is different according to countries, since each has organised its own educational system giving different priorities to technical and professional teaching, incorporating part time education at very different scales, and defining diploma types and levels in a specific manner, particularly in higher education corresponding to non homogeneous theoretical ages.

Also, the importance of private education is very variable within the various educational systems.

Recent trends

Participation

Participation in education is in most countries about the same level, though the growth rate is declining. The proportion of the population younger than 15 years old, is getting less in most countries. This means that more people receive education during a longer period of their life. Demographic changes in the EC Member States is characterised by a general weakness. Thus throughout the 1980-90 period the growth rate varied from close to zero in Belgium, Denmark and Portugal till 0.5 in France, Luxembourg and The Netherlands. Logically, this lack of demographic vitality is combined with a relative ageing of the population of the Member States. For example, the proportion of the population under 15 years old to the population between 15 and 65 years old in West Germany changed from 27% in 1980 to 21% in 1990, from 34% to 24% in Italy, and from 42% to 30% in Spain. In the USA in 1990 this proportion was 33, in Canada 31 and in Japan 28, which is a more positive perspective. These countries also have a smaller proportion of people in the age group older than 65 years.

The decreasing numbers of potential school entrants in the EC, is obviously a difficult trend which affects all Europe, and in which the less developed countries (particularly in Southern Europe) are reducing their differences with the more developed countries. It has a strong influence on the size of the educated population and on their proportion in the total population. Nevertheless the percentage of school attendance rises. One reason is due to changes in the period of compulsory education. The duration of compulsory education, varying form 8 years in Italy till 12 years full-time in Northern Ireland. In The Netherlands, Belgium and Germany the compulsory period is also 12 years, but the last 1 or 2 years are part-time.

The general trend of changes proposed recently is in the direction of extending the period of compulsory education, by either considering lowering the starting age (Belgium, Luxembourg) or raising the leaving age (Italy). Luxembourg has recently lowered the starting age from 6 years of age to 4 to help immigrant children to integrate better into the education system. Portugal has decided to extend the duration from 6 years old to 9 years old with a view to raising the overall level of education of the population, combating its very high illiteracy rate and enabling a greater number of young people to enter higher education. In the case of Spain, extending the period of compulsory education reflects both a desire to come into line with the other countries and the need to guarantee all its citizens a genuine complete basic education.

A significant increase in the educated population is caused by a relative diversification of some syllabuses (secondary technical and professional education, tertiary education) in order to take advantage of needs in the job market and technical developments. However, this increase also depends on the increased time that students have to spend (compulsory education) or need to spend in the educational system. This has to do with increased higher education, but also protection

against unemployment and the political desire of many countries to increase the opportunity for as many students as possible to complete their secondary studies.

The most significant point concerns the very large increase in the number of students registered for tertiary education. Over the last 15 years this growth was 60%, whereas the number of students receiving primary education decreased by more than 23% in 1989/1990. The drop in the total school population is almost equal to the difference between the increased number of higher education students and the reduced number of primary students. These two opposing trends work together, with the second in most countries only partly compensating the negative effect of the first.

The general trend of the participation of girls is undoubtedly towards seeing the same ratio in the educational system. However, differences in the proportion in secondary education can be seen as far as vocational training is concerned. In most of the countries, the girls are overrepresented in general education and underrepresented in technical/vocational studies.

Education as a labour market

According to the OECD, in the 1987-88 period about four million people were employed in the education sector in the EC (taking into account only primary, secondary and special education and excluding the administrative personnel). About 1.5 million people worked in primary education schools, about 2.4 million in secondary schools and 0.1 million in special schools.

Private education

In Europe, private education, in other words education that is not directly under the authority of the State, is given varying degrees of importance by country as a function of education level and the type of relation with the State, particularly concerning financing.

Thus, the proportion of private education in Belgium and the Netherlands is very high due to the fact that it is entirely covered by public funds. There are also hybrid formulas in which State participation methods vary. The higher the amount paid to private schools financing by the State is, the larger the proportion occupied by private schools in the educational system tends to be.

There are many reasons explaining why the private sector exists and the varying support given to it. These include religious and historic factors or image - related factors along with a possible difference in quality, and special training.

Recently in France an agreement was reached with the Catholic education sector (17% of all pupils), on the recruitment and training of teachers, contributing to more equal educational opportunities, irrespective of the type of school. In Denmark during the last ten years, the number of municipal primary and lower secondary schools has been subject to a drastic decline of 12%. On the other hand, the number of private schools has increased by 22.5%. The greater number of private schools means a reduction in the cost to the public authorities.

The pedagogic environment

A pedagogic reason based on the assumption that teaching efficiency improves when there are fewer students, and a logic reason of adapting to demographic changes, lead the trend towards a relative reduction in the number of students per teacher. Some age groups then benefit from better teaching ratio.

These numbers hide important differences in that they are national averages whereas there are reduced numbers of students per teacher due to population drops in some areas, and at the same time there are sometimes large increases in suburban areas. This urbanisational phenomenon, almost complete in north European (97% urbanisation ratio in Belgium), is continuing in other countries, particularly in the South (for example the urbanisation ratio of 32% in Portugal). It will result in further adjustments in the number of students per teacher, and will be affected by some hysteresis.

PRIMARY SCHOOLS

Apart from Spain, there are no countries where the structure of primary education is being changed. In the curricula the main point of innovation has to do with increasing attention to foreign languages, as it is the case in Greece, France, Spain, Italy and Scotland.

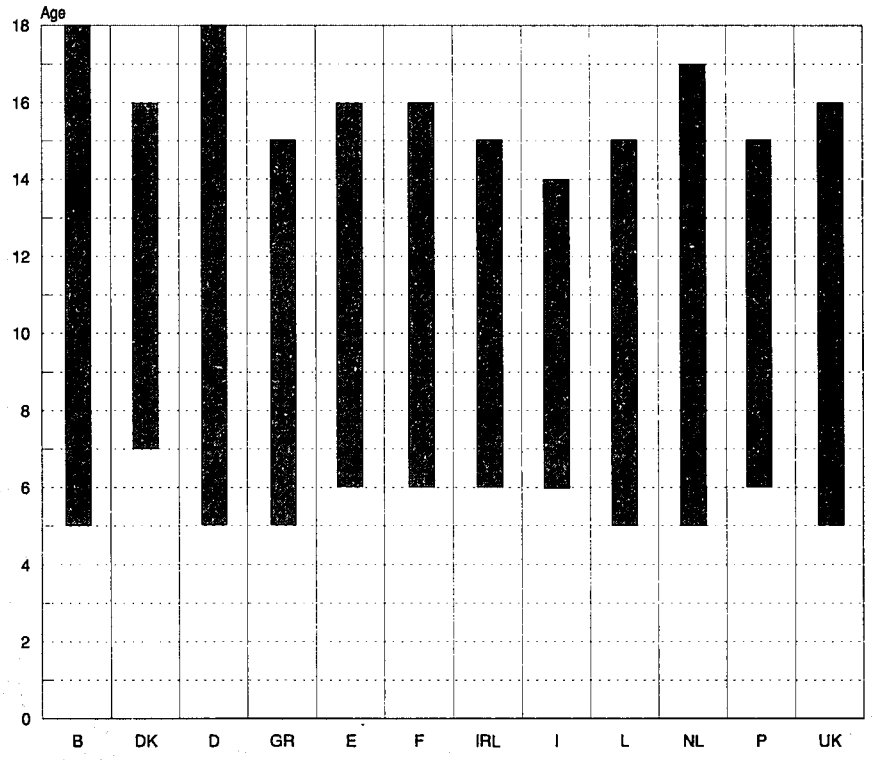
In some of the countries health and environmental education are subject of improvement.

SECONDARY SCHOOLS

This is the sector in which there are the largest differences in teaching among the various countries. These differences are related to teaching matter (general or polyvalent compared with technical or professional), and also to its organisation (full time and part time or apprenticeships). This is also the sector which is subject to attempts to improve effectiveness by changing the organisation of education. Two types of policy measures are to be seen.

The first one concerns specification of several routes that provide access either to university or to advanced vocational training, depending on the branch chosen. This is going on in France, The Netherlands and Spain.

Figure 2: Education
Duration of compulsory education in the European Community



Source: Eurostat (Working conditions)

The second one concerns policies which heterogeneously encourage the introduction of technical and professional components into education and therefore preparation for entry into the labour market.

In many countries growing attention is paid to the low achieving pupils and prevention of early school leaving. In 1991, general or polyvalent full time education (full time in all countries) represented 43% of all education in the second part of secondary education for the entire community. This ratio was 20% for Germany, 86% for Portugal and 63% for France, compared with 72% in Japan and 100% in Canada and USA.

Quantitatively, the senior secondary education across the community provides secondary education representing its concern with professional needs but also showing up differences in selected approaches.

HIGHER EDUCATION

The challenges faced by the European community (trade competition, research and development, demography) have already resulted in a relative drop in the proportion of unqualified labour. This trend will undoubtedly continue.

Higher education continues to be an important focus of current concern. Issues are changing conditions of access, systems of scholarships and bursaries, concern for autonomy and reforms.

In general a clear growth in the number of students in higher education and the number of diplomas can be seen. There are differences among Member States partly due to the initial situation, characterised in the case of Greece, Portugal and Ireland by a relatively low proportion of students. In these cases, there is a catching up effect, and also a political objective of creating the ability to meet the main economic and social challenges.

The proportion of women having received higher education increased from 40.4% in 1975 to 46.4% in 1985 (more than 50% in France and Portugal) therefore approaching the proportion of girls in the 5-24 year old population.

Scientific characteristics of the higher education

Qualitatively, in regard to changes in high level abilities related to new technologies, it is interesting to note the ratio of natural sciences and engineering sciences taught in universities (excluding non-university education which exists in some countries - for example Engineering Schools in France).

The diversity of situations in EC countries is related to two aspects:

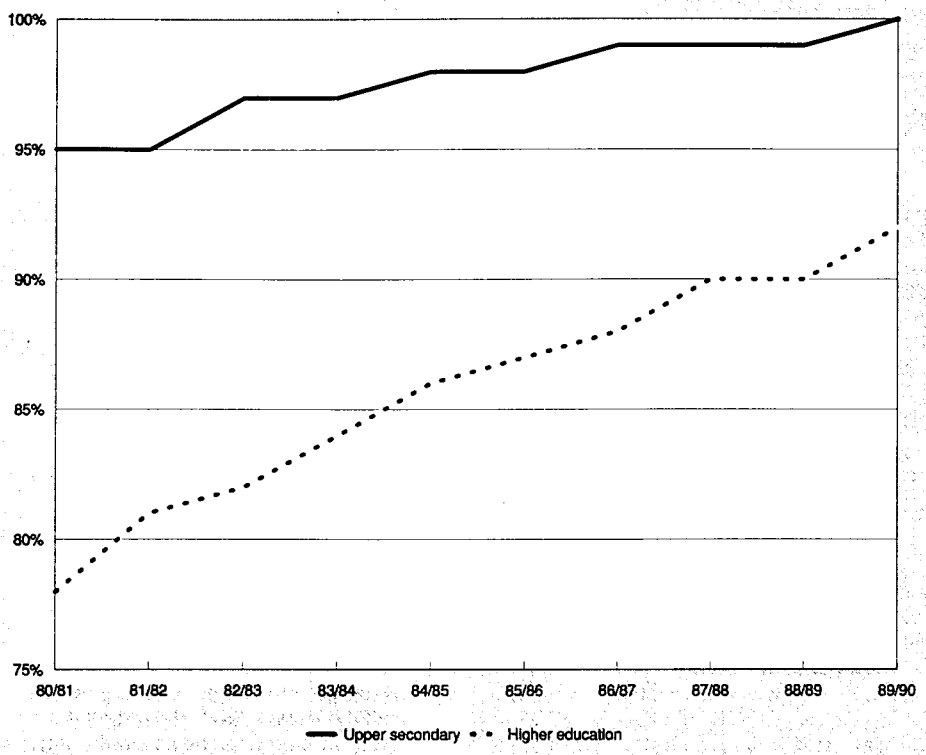
- the historical and cultural aspect which partly explains the ratio that each country assigns to engineering sciences and natural sciences in university education compared with the total number of programs, and the ratio for each of these sciences.
- the socio-economic aspect concerning the importance given to engineers in economic activities: as this increases, the engineering function is better recognised and rewarded; the case of Japan is significant in this respect.

Overseas students

There is a very big difference concerning the presence of foreign students in higher education, both in absolute and relative terms.

There is a very strong correlation in terms of origin, between the representation of some continents and the history of the country (former colonies, common language, which is obvious in the case of France, Belgium, The Netherlands, where the geographic mobility of students is still low, both globally and among countries in the community. In this case, origin is undoubtedly related to:

Figure 3: Education
Girls per 100 boys in full-time education



Source: Eurostat (Working conditions)

- the fairly limited knowledge of the characteristics and possibilities of higher education in other countries;
- the non-existence of a genuine community work market;
- the fear of additional financial costs;
- lack of understanding of the language.

ECONOMIC FACTORS

Education is generally considered as a public consumer item, with a price close to zero and which, in any case, does not reflect the costs to produce it. However, it is sometimes considered as a private consumer item for which the price is fixed freely by schools.

Education is also an investment item since it prepares the future of the individual and the nation.

The two main indicators that are used are the total public expenditures for education per student as a percentage of the GDP, and the total public expenditure for education as a percentage of the total public expenditure.

In general, public teaching expenditures are proportional to the Gross Domestic Product (7.4% for Denmark, 6.5% for The Netherlands, 4.7% for the United Kingdom, 2.8% for Greece). However these major differences are influenced by the catching up trend for less developed countries in which the demographic component has had a real influence on educational expenditures up to the end of the 1980s. Another influence to reckon with, is the change in compulsory education.

In general, the table shows a wide dispersion for this indicator, however, this is not surprising considering the difference in the development level of the observed countries. It is interesting to note that the countries with the highest levels in the early 1970s (the United Kingdom, and the United States and Canada on the other part) are precisely those which dropped during the period under consideration. The reverse phenomenon is true for countries with the lowest ratios, particularly Greece and Portugal. It is therefore possible to talk about a catch up phenomenon for the countries lagging behind, itself contributing to convergence of the observed ratios since differences are reduced.

These countries would therefore increase their efforts in the educational field as a function of the economic development level achieved.

It is interesting to consider the differences in expenditures for primary and secondary versus tertiary education. The ratio for public budgets for tertiary education as a proportion of earlier stages is very low in Luxembourg: 3.5% and in Japan 9.5%. In Japan, however, a lot of private money is invested in tertiary education. Looking at these budgets too, the ratio is 25%. High ratios are in The Netherlands: 51% and Canada 53%. Including private funds, the Canadian ratio is even higher: 55%.

Comparison by PPP

The complexity of the education concept and the various perceptions that it covers make economic and qualitative evaluations difficult and inaccurate, and also make comparisons among countries difficult.

In order to compare educational expenditures among countries, some common points are needed: the concept of Purchasing Power Parity (PPP) specific to education, recently developed by the OECD, allows to convert different foreign currencies into a same unit by taking into account the relative purchasing power of different currencies. Using this method, the relative

effects of educational expenditures and their changes may be analysed more precisely.

The first indicator shows a difference between less developed countries in the EC and the more economically advanced countries, although the difference between these two groups tended to reduce between 1970 and 1988. The fundamental reasons are unchanged - demographic changes and efforts made to reduce the differential by countries such as Portugal which increased by 100% between 1973 and 1988. Greece only maintains its level 50% relative to the Netherlands. This indicator has been fairly stable in other countries, except the United Kingdom which experienced a major drop, representing the relative disengagement of the government of this country from financing education in general, almost since the middle of the 1980s.

It also appears -taking account of the Purchasing Power Parity method- that a fairly constant relation has been maintained in recent years between public expenditures per student and the GDP per capita.

The second indicator shows another approach to public educational expenditures. The trend of the European countries studied is almost always downward, which would no doubt be a concern if part of this trend were not due to the influence of a relative reduction in the educated population.

EC countries classified as less developed generally have lower values than the other Member States or than the USA and Canada. This also confirms the fact that educational expenditures are a function not only for the development level, but also of priorities and choices defined by governments. The case of West Germany is undoubtedly partly a result of demographic changes and of efforts made in education in the 1960s. Convergence of this indicator over the same observation period (1970-1988) is a result of lower values recorded for all countries. This variation is also due to a less important relative increase in educational expenditures relative to other items in national budgets. Considering demographic changes in the EC countries and the ratio of 18 to 25 years old within the total population, it is interesting to note the attitude of the various governments towards higher education. This comment is particularly important because of the fact that European institutions are strongly encouraging the development of higher education and the mobility of European students by the implementation of EC programs.

Three trends have developed over a long period (1970 - 1988): the trend characterised by Portugal which made a major effort

Source: Eurostat (Working conditions)

in its higher education and with an average ratio over this period of 11.4%, the trend in Ireland, Greece and Italy where the ratios were between 5.5% and 7.3%, and finally the one typical of other countries with ratios of between 1.5% and 2.1% which appears to characterise an apparent maturity of financial efforts made for this level of education.

In as much as higher education is increasing in all countries studied, this would appear to mean that -still using the Purchasing Power Parity method- it is difficult to place real expenditures in a genuine continuum; there are signs of individual efforts (major infrastructure or education projects) succeeded by periods of stability. Faced with the importance of the challenges to countries, it may be important to consider the public financial effect dedicated to higher education within a long term view essential to its effectiveness. Unfortunately, measurements of this effectiveness can often only be made based on economic and social results observed several years after the expenditures were made.

EC POLICIES AND FINANCING

The developed world is inexorably advancing into a society where everyone seeking secure employment will require a

qualification, where activities which in the past did not require special skills or knowledge now require such, and where the unqualified will largely be excluded from the labour market. The Community has taken into account these radical changes as well as the special needs of the post-1992 workforce when it decided on a number of strategic policy actions and programs.

In this context, the Community has implemented a number of programs to stimulate and encourage the provision of education and training and to improve its quality. The activities include support for joint European production of learning materials and learning technology solutions, exchanges of information and experience and encouraging mobility of learners and knowledge.

Up to now, community education and training measures have proved very successful. This year they have enabled around 100 000 students to take part in exchanges involving more than half of the universities and other institutions of higher education in the Community.

The major EC industrial training programs are:

- COMETT, which assists with the development of transnational education by cooperation between companies (particularly small and medium-sized companies) and universities in industrial and technological fields. COMETT aims to exploit, in particular, the continental dimensions of the Internal Market, plus EFTA, in an area characterised by increasing economies of scale, particularly via transnational, sectoral and regional networks and training projects. The program has so far financed 7 000 training courses, involving 150 000 persons, 10 000 firms, 2 400 universities and 4 000 other organisations. In 1993, 205 university busi-

ness associations are currently helping to forge extensive links between industry and universities.

- ERASMUS, contributing to increased mobility of students receiving higher education with recognition of study credits within the Community, and cooperation between universities (university cooperation programs, the implementation of the "ECTS" (European Capitalisable Credit Transfer System" experiment with a 1990-1992 budget of 192 million ECU. In 1993, more than 70 000 students are allowed to study in another country than their own.
- LINGUA, designed for the promotion of foreign languages through teachers and relations between students: 200 million ECU for the 1990-1994 period.
- EUROTECNET is an innovation promotion program within the professional training field, taking account of technological transfers and their consequences on employment, work and qualifications. It contributes to the development of new abilities and qualifications. EC support was 7.5 million ECU for 1990-1993.
- FORCE, which provides incentives for institutions and enterprises in the Member States to invest in continuing vocational training and the promotion of wider access to training and development of transnational measures at the EC level. It is organised to work interactively with the objectives and actions carried out by ESF (European Social Fund), the EUROTECNET and COMETT programs, IRIS

networks. Some 24 million ECU were allocated for 1990-1991, plus 61 million ECU from the ESF.

- EURYDICE, an information network about education within the EC for which the public consists of responsible national, regional and local authorities.
- YOUTH FOR PEOPLE which facilitates student exchanges.
- YOUNG WORKER EXCHANGES (18 to 28 years old), designed to complement and enrich their professional training in other Community countries.
- IRIS, European youth training program network.
- PETRA, an action program for training and the preparation of young persons for adult and professional life (transnational partnership projects, youth initiation projects). This program had a financial budget over 40 million ECU for the 1987-1992 period. It enables 900 young people per year to incorporate a European dimension into their apprenticeships.
- DELTA (Telematic Systems for Flexible and Distance learning) is a strategic R&D programme, part of the series of programmes "Telematic systems in Areas of General Interest" funded by the EC under the Third Framework Programme. The aim of the programme is to support the design and implementation of new telematic systems and services that will improve education and training provisions in Europe by making them more efficient, more widely available and able to meet the needs of individuals and industry. This phase of the DELTA programme began in 1992 and will run until January 1st 1995. The overall budget is 62 million ECU. Some 200 organisations (39% of which are SMEs) are active in DELTA projects. The DELTA budget funds a total of 30 R&D projects and 10 "Concerted Actions" (these are separate horizontal actions in areas such as language learning and the economics of distance learning.

OUTLOOK

The above information and comments raise a number of questions about future developments in this sector.

The first development initiated throughout the Community concerns developments in higher education. In this respect, it is worth mentioning the obligation of European education systems to:

- increase the proportion assigned to scientific and technical programs in order to satisfy the needs of senior technicians and engineers in the various economic sectors;
- increase relations between these economic sectors by making more use of engineers and research workers form industry in education or by increasing common projects;
- search for more harmonisation projects between universities and countries, while maintaining individuality, on syllabuses and teaching programs in order to improve collective vitality.

Some progress has already been made in these various fields, and this must not be only increased and consolidated, but also made better known and shared; the various EC projects contribute towards this.

The second development concerns globally improving the efficiency of education systems.

It is obvious that this efficiency may be measured individually by granting diplomas; in reality its effect as investment will be felt throughout the subsequent career.

A major effort must be undertaken concerning these two dimensions in order to integrate all education techniques as far as possible (remote education, interactive computer assisted education..), to allow teachers to concentrate more on their main objective that is to take the necessary steps to ensure that future workers learn how to learn and make a self-training effort that will stand them in good stead for self adaptation throughout their professional careers.

In regard to the above point, and taking into account the actual difficulties generated by viscosity in the educational system related to the labour market and resulting in about 15 million unemployed in 1990 (annual average), there is a more and more urgent need to make efforts in two directions. For the young, methods of reinserting them into school activities (giving the opportunity to approach, or to be comparable with those that have been able to follow standard syllabuses), or to include them in training programs to make them operational and satisfy the needs of various economic sectors. Major efforts have been made, frequently encouraged by the necessity to cope with practical situations and with a

real concern for foresight. For other job seekers who have already had a professional activity, experience has shown that reconversion problems are better solved when they are anticipated.

The example of a number of companies who have implemented reconversion operations (possibly leading to diplomas), sometimes months or years before a reduction in the workforce materialises, demonstrates the benefits of formulas which undoubtedly require public assistance, but also a confirmation of their will and commitment.

Finally, we should emphasise the influence, which will increase in the future years, of the arrival into the secondary educational systems of the smaller numbers of students currently in the primary educational system. The question of a reorganisation or redeployment of infrastructures and teaching facilities, and in terms of numbers and abilities of teachers, has already arisen in some countries and will arise in others. It is a controlling factor in the ability of all education systems to efficiently manage the situation with respect to the qualitative an quantitative development of higher education. In short, capital education resources and teachers must be provided to match these needs as well as possible, reducing differences among EC countries in order to optimise competitiveness and social harmony within the EC.

Health care services
NACE 95B1, 95C1

Health care expenditure amounted to 390 billion ECU in the EC in 1991. The industry provides employment to approximately 6.9 million people. Health care expenditure in the EC countries has increased dramatically. This fact together with the overall economic slowdown has resulted in incisive cost containment programmes being implemented throughout the EC. Governments face the challenge of increasing services, without reducing quality, and containing costs at the same time. In order to achieve this, new management techniques as well as effective policies must be implemented in the next few years. The 12 EC Member States have different health care systems with specific idiosyncrasies. In some cases common cost containment measures or solutions to problems are applicable to all Member States, but in other cases nationally tailored measures and actions should be undertaken.
During the 1990s, emphasis will be placed on transferring part of the institutional sector budget to the more cost effective home care and community care sector. In some Member States, there is still a need for substantial investment in health care. Even in the countries with the best developed health care systems, additional money will be required to provide for services in areas where the system has always been lacking, e.g. full reimbursement of medical supplies for the chronically ill.

INDUSTRY PROFILE

Description of the sector

Health care services include a wide variety of services such as: hospitals and clinics, registered nursing homes, special treatment centres, polyclinics, first-aid centres, health centres, dentists, paramedical centres, home medical supplies and nursing services, mobile medical equipment services, leased nursing care services, primary care provided by general practitioners, specialist medical and surgical cabinets, psychiatric institutions, rehabilitation services, community nurses, chemists, drug stores, pharmacies and parapharma medical supplies services, etceteras.

Because health care and social care services often overlap, it is difficult to draw a line between both. This also poses a major problem when it comes to assessing health care expenditure. This is the reason why health care expenditure data often differ from one official source to another.

Private hospitals account for an important percentage of institutional care services in most EC countries. Many had their roots as charitable hospitals, found by religious bodies, when the institutional system was in its infancy. Today many of them are included in national health systems.

Private commercial enterprises are newer to the system and provide additional hospital, clinic, day centre, and nursing home facilities (in the United Kingdom almost entirely private); they are mainly a result of developments in health insurance paid to private sickness funds or commercial insurance companies. In most European community countries they are an important part of the health care system, which would be unable to cope without them. In Italy private hospitals are an important part of the hospital system working under convention (law 833/78) within the national health service (SSN).

The home-care and primary care sector is new in its present form. Home-care probably existed before hospitals. Family doctor practices, which provided almost all primary care in the 1960s, are being replaced by health centres. There is also an important trend of specialised physicians leaving the institutional environment and opening practices in the community.

Day hospital care, enabling the patient to be sent home after a minor operation, is slowly spreading in the EC. More recently, some public hospitals in France have expressed interest in working with hotel groups. These would provide facilities next to hospital complexes to cater for aftercare of patients who have undergone minimally invasive surgery such as laparoscopic surgery.

Institutions which provide care for chronically ill patients and the elderly have had a sharp increase, corresponding to rising needs of an ageing population.

This monograph will concentrate the analysis mostly on private hospitals.

Recent trends

The main sources of revenue for the sector are national public health insurance plans and private health insurance contribu-

tions. Organisation of the former is very disparate across the EC. Public health funds are collected through sickness fund agencies (e.g. ziekenfondsen and mutuelles), national insurance contributions or by taxation. Private health insurances are paid by people who opt for additional or alternative coverage to national health provision.

Other sources of revenue are non-reimbursable contributions, made by patients directly to care providers or drug and medical supplies dispensaries. These payments amount to a substantial sum, and often are not accounted in estimations of health care expenditure. In some countries it is not necessary to make payments for most health services whereas in other payments must be made by the patients or their relatives and then reclaimed through sickness funds.

Private health insurances work in a similar way. Sometimes there are agreements between private and publicly owned hospitals to settle accounts directly, and in other instances the patient must pay directly and then claim from a private insurance body retrospectively.

There is still a long way to go before some categories of European society receive fair treatment. This applies to the chronically ill such as diabetics, ostomates, and incontinent people. Diabetes, the major chronic disease, is often poorly diagnosed according to health experts due to inadequate screening. Recently many national screening programmes have incorporated blood glucose monitoring. However, the majority of insulin dependent diabetics in the EC do not receive full reimbursement for all of the supplies they use, while other chronically ill people, get the whole or majority of the cost paid by the health care system.

Clearly the very high cost of health care has prevented some authorities from providing full support. The United Kingdom has one of the best programmes for people with chronic health and hygiene problems in terms of allowing them access to necessary supplies free of charge. Some sickness fund based health care systems act poorly in this area, e.g. those of Belgium and Germany.

Health care expenditure in total figures and per capita are highest in Germany, followed by France. Small countries such as Belgium, Denmark and the Netherlands have high per capital expenditure: 1 116, 1 113 and 1 165 ECU respectively. Health care expenditure in the EC has been growing at a rapid rate in the 1980s and early 1990s. In 1991 total health care expenditure increased by 14%.

International comparison

EC health care total expenditure reached in 1991, 389.3 billion ECU, well above Japan (150 billion ECU) and under the USA (470 billion ECU). Nevertheless, in 1991 per capita expenditure in the EC was lower than in Japan and the USA. Exchange rates affected the comparison, however. Expenditures per GDP are also not particularly good indicators of the state of nations' health care programmes, but can be used to show how health care expenditure is developing. In 1991 EC health care services provided more jobs, close to 7 million (see Table 7), than the United States and Japanese health care systems. In 1989 the EC and USA had an equal level of employment, slightly over 6 million people.

Ironically, the better health care systems become at treating people affected by life threatening illnesses, the more often these people will go through the system. In the 1950s for instance, when many health care systems were at an early stage of development, patients with heart disease, cancer, chronic kidney failure, and diabetes often died early. In the 1990s they can be successfully treated and sometimes cured. The health care system has thus tended to become more expensive, and more difficult to fund. Moreover, as more new treatments become available, some requiring high cost technology, a greater demand for medical care is created, and this adds to the problem of spiralling costs.

However, even with these improvements a large group of people still fail to get full treatment. This is another important measurement of health care quality. Apparently, a minority of people fail to obtain treatment in some health and social security systems because of their financial condition. Whereas most people receive excellent care, some minorities get virtually none. This applies both to Europe and to the USA.

Foreign trade

It is difficult to assess extra- and intra-EC exports of health care services, i.e. facilities for the benefit of non-residents, when they pay for this out of their own purse. The export of health care services payable by social security organisations within the EC is limited by Community regulations. It includes migrants and patients located near borders, emergency care during international transits (E111), and where treatment is authorised by the patient's own social security organisation (E112) because it is not available locally. Some centres of excellence rely upon patients travelling internationally to be able to maintain continuous specialty services or further develop pioneering work.

Private clinics provide services for residents of many extra-EC countries. These are either covered by international agreements or individual financing. Often they are related to historic relationships, especially with ex-colonies. Examples include Algerians and Moroccans treated in France, Libyans in Italy, and Latin Americans in Spain. These patients seek particularly the services of highly specialised private clinics that offer superior treatments to those found in hospitals in their own countries. Usually they are affluent members of society in those countries.

MARKET FORCES

Demand

Demand for continued improvements in health services, mainly by health care professionals, is one major reason for cost increases in health care in every country within the EC. This has resulted in improved quality of life and an increased life expectancy of individuals living in the EC, which is the system's main aim.

Health care in the 1990s often makes routine use of technologies unimaginable only two decades ago, and could not have been achieved without sending costs spiralling up. Other factors contributing to growth in health expenditure are multiple. Some important ones are: the public seeking more health services from the system, the development of new services including screening programmes, the development of professional personnel in the sector, increasing capital investments, and increasing costs of better treatments and medical supplies.

In some countries commercial enterprises are encouraged to participate in the provision of all aspects of health care (France, Spain, Germany, Greece, and more recently, the United Kingdom and Ireland). In other they are prevented by law or de facto from hospital ownership, (Belgium, Luxembourg, and the Netherlands). In the remaining countries (Denmark, Portugal and Italy) commercial clinics have to compete in environments where the major emphasis is on developing national health care through the establishment of publicly owned hospitals.

Private hospital chains probably consider the obvious barriers against them in some countries to be unfair, and not in the spirit of the single European market. Since state monopolies are being dismantled elsewhere the private professional hospitals could consider that they are being unfairly discriminated against.

The control of quality should be instituted by legislation, which is the direction currently being taken in most countries to ensure good practice. Throughout the 1990s the legal profession has increased its participation in discussions and conferences on this subjects. Health authorities are having to dismantle some protection they have built up for hospital staff, and make them accountable for all of their actions. In the United Kingdom, Crown protection of the national health service (NHS) is no longer in force; formerly no patient in the United Kingdom could sue the NHS.

Cost containment of health care in Germany was attempted in 1987 when the Bundesrat passed a law forbidding hospitals to have retrospective calculated claims for medical acts. It was thought by many observers that several less efficient hospitals would go out of business after this act. However, most were saved because of oil prices falling. This had the consequence of reducing heating bills, which is an important part of hospital expenditure for hospitals in the northern part of Europe. Many German hospitals still rely heavily on making profits on the sums they get for convalescence following surgery. Even patients that have undergone only minimally invasive surgery are kept more than eight days following surgery in most German hospitals, in stark contrast to other countries where patients that are treated using the same technique are sent home after two or three days.

Developments in the United Kingdom are currently providing important opportunities for private enterprises. After many years strongly supporting centrally controlled publicly owned facilities, the conservative government has opted for a decentralised system. It aims at achieving greater efficiency by allowing market forces to find some more efficient organisation, and do away with nugatory practices of the civil service based system. Hospitals that can fulfil certain conditions, which prove they can be self-governing, have the option of becoming trusts within the NHS.

Already more than 150 hospitals and other services have become NHS Trusts, and many primary health centres are now fund budget holders on a per capita basis. Services remain available to all, paid for mainly out of general taxation and mostly free at the point of use. Local health authorities are now purchasers of services and hospitals public or private are providers.

NHS Trust hospitals have the power to make all of their own managerial and financial decisions, and must compete for business against other hospitals, although central government is still setting targets for patient waiting lists and national returns on the capital employed. Units providing high quality, value for money, services will be more successful in attracting contracts and funds to provide services to patients. They may even choose to make subcontracts for some services. If a service offered by private initiative is less costly than the equivalent national health services facility it would be selected. Patients would be transferred from the later to the former by the budget holder, or by the NHS Trust hospitals' managers.

Supply and competition

There are very few recent EC figures on health care services. Nevertheless, more data are available for some sectors such as hospitals.

In all of the analysed countries, except Belgium, public general hospitals had a larger number of beds than private general hospitals. This is normal because private hospitals tend to specialise in short stay patients, which provide higher profitability. Italy has the largest public general hospitals and Belgium the largest private general hospitals, of the analysed countries.

Average length of stay of EC patients in general hospitals varies widely. In the general hospitals in Belgium the average length of stay was 10.39 days in 1991. On the other hand in public general hospitals in the United Kingdom, average stay was only 6.10 days in 1990/91. Attendance rate to general hospitals, was much more similar in the analysed countries, around 80%, with the exception of Italy's public general hospitals which had a very low attendance rate, 66.96% (see Table 5).

In 1991 the 12 EC health care systems employed a total of 935 000 physicians. Germany (including former East Germany) is the country with the highest number, 280 000 in 1991, followed by France and Spain with 150 000 each.

The total number of nurses and midwives in 1991 in the EC reached 1 927 300. Most nurses and midwives worked in Germany (including former East Germany) (490 000), the United Kingdom (425 000) and France (335 000)

The number of dentists in the EC, 166 300 in 1991, was higher than in Japan or the USA. Germany (including former East Germany) had 55 000 dentists followed by France and the United Kingdom with 38 500 and 20 500 respectively (see table 7).

In early 1993 there were 107 340 pharmacies in the EC, based on a survey of the Pharmaceutical Group of the European Community. France houses the largest number of pharmacies in the EC, 22 325, followed by Germany with 20 296. The total number of Community pharmacists in early 1993 reached 187 510. Again France had the most pharmacists, 43 221, followed by Germany with 40 480 (see Table 9).

In early 1993 the total number of optometrists and opticians in the EC reached 49 426 (according to figures of the European Council of Optometry and Optics). The United Kingdom and Germany had the highest number: 10 544 and 10 500 respectively.

INDUSTRY STRUCTURE

Companies

There are currently more than three thousand owners of commercial enterprise health care services. Most have been formed by small groups of medical professionals. In Italy there are almost 700 owners (natural and juridical persons) of commercial enterprise health care services. However, bigger investors are getting involved. The earliest were health insurance companies, but now they include all types of companies, from venture capital groups to water companies. Several private hospital chains have been established within the EC that are run by financial groups, which draw funds from finance centres or insurance companies.

The largest EC private health care group is the French chain Compagnie Générale des Eaux (CGE), which owns 60 institutions. With Clinivest and Alphamed, this chain owns almost 7% of all private clinic beds in France. Through its subsidiary, American Medical International, it has acquired 18 institutions located in England.

The combined turnover of more than 435 million ECU placed CGE just ahead of the British company, BUPA. BUPA had a turnover from health services of just over 290 millions ECU in 1991. BUPA has expanded its health service and insurance operations in Spain through the acquisition of Sanitas which had a turnover of 245 million ECU in 1991.

REGIONAL DISTRIBUTION

The EC health care institutional environment contains a panoply of facilities. They have the titles of hospital or clinic. They range from large high tech purpose-built hospitals to an older generation of hospitals housed in buildings of a bygone age (sometimes even former workhouses). Clinics vary in character. Often they are indistinguishable from hospitals (sometimes they are prevented by law from being called hospitals).

It would be inaccurate to say that private clinics are generally inferior or subordinate to public hospitals. Where inferiority exists, it is often one of size or the variety of services. However, many well equipped major facilities in Europe are privately run.

Hospitals have obtained fair compensation per medical act or for bed occupancy from the health (or sickness) insurance funds. In these systems, most health care costs are funded through employees' and workers' and their employer's health care insurance contributions. Individuals who are self-employed are encouraged to cover themselves adequately for hospitalisation. Sometimes an obligatory minimum hospitalisation coverage is imposed, while primary care coverage can be optional.

The sections below describe the health care industry structure by country.

Belgium

In theory all Belgians have health coverage through social security. Social insurance has two general schemes: for paid workers and for self-employed. Self-employed have the choice of whether they wish to have full or partial coverage. Companies in Belgium are increasingly offering group insurances to their employees, included in employment benefit packages. These cover extra hospital costs, such as private rooms, other comforts, plus all non reimbursed medical products.

Almost all hospitals in Belgium are non-profit public or private organisations. Most of the private hospitals were founded by religious bodies. A minority were started by groups of doctors or associations. Private "for profit" hospitals have been largely forced out of the system by hospital funding regulations which prevent them from benefiting from state subsidies for equipment and construction.

Considerable investments have been made to rebuild the Belgian hospital system. The average size of hospitals has increased. This is largely due to a cost containment measure, taken by the Ministry of Health and Social Affairs in 1987, to close the smaller hospitals. In early 1992 there were 77 868 beds in Belgium hospitals; 45 008 of them were acute beds. The total number of private beds in early 1992 was 48 112 (61.8% of total beds). At primary care level general practitioners, the Yellow and White Cross association and others offer community services. Paramedical and primary care services are increasingly being organised by private professional groups.

In Belgium, hospital physicians, general practitioners and specialists in the community are paid on a fee basis, which can be a fee for service or a fee per capita. Some physicians choose to supplement their income from hospitals by running their own practice in the community. Other hospital staff are salaried. Sick fund societies manage reimbursement claims for most of the population.

Luxembourg

The public health system in Luxembourg is organised through a national compulsory social security scheme. The distribution of hospital beds by service between the three regions (northern, central and southern) is determined by law. Approximately 40% of the private hospitals in Luxembourg are "not for profit" enterprises. Private health insurance in Luxembourg amounts to a few percent of the total health care expenditure. Hospital staff are employed on a salary basis, whereas general practitioners work on a fee per act basis. The patient is free to select any physician, any service and any hospital. The public also uses the services of some hospitals in countries surrounding Luxembourg, particularly Germany.

Denmark

Denmark has an universal national health service funded by general taxation. The Danish public health scheme covers the entire population and practically all treatment is provided by publicly owned hospitals. In 1989 there were a total of 111 hospitals. There are only two private fee-charging hospitals with 70 and 32 beds respectively, which represent 0.3% of total hospital beds. The private insurance market has declined because practically the whole population has its complete hospital costs paid. Most primary care is provided by general practitioners, who usually work in group practices. Hospital personnel are salaried whereas medical professionals working in the primary health sector charge fees per act.

France

Almost every person in France is covered by health insurance. Some workers pay additional health insurance schemes to have full reimbursement for all services.

The French state's commitment to the national hospital programme is revealed in the public hospitals (centres hospitaliers) in every major town in France. About 40 of these are very large complexes with university affiliations. Public hospitals are autonomous and can try to borrow money from private companies for capital investments. They often apply for government subsidies when they run into liquidity problems.

In France, hospital doctors can be salaried or charge fees per service. Many work for several establishments simultaneously, and some also practice in the community. However, the level

of fees they earn is regulated for about 95% of them. Patients are free to select the doctor of their choice.

France has the largest number of private hospitals in Europe and also the largest number of commercial enterprise private hospitals. The health private sector has one third of all health facilities. Roughly 54%, of the approximately 200 000 beds in the private hospital sector, are owned by commercial enterprises (2% of these are psychiatric institutions). Private hospitals tend to be much smaller than public hospitals in size, and it has often been said they are less intimidating for some people.

Private hospitals tend to concentrate on offering specific therapies which provide sufficient profitability. This is illustrated by the very low percentage of long stay beds in the private sector. But here is a trend to increase the private sector in this area. The data for medium stay patient entries, from the Ministry of Social Affairs and Employment, shows that more patients are treated in private hospitals than in public hospitals.

Germany

Approximately 90% of the population is insured under GKV, the statutory health insurance system, which covers all the low and medium employees. High income employees may join voluntary. In fact the rest of the population, roughly seven million (10%), are either privately insured or receive supplementary benefits with automatic health insurance cover. Patients are free to select the doctor and hospital of their choice.

The German health system is undergoing a difficult adaptation process, trying to harmonise the Western system with that of East Germany. Full harmonisation will take several years.

The state and local governments account for less than half of the hospitals. In 1989, Germany (West) had 3 046 hospitals. The number of hospitals is declining. Private hospitals compete on an equal footing. They obtain funds through a dual financing system. Funds for capital items are provided by the state and local governments, and other income comes from earnings against treatments. The fees are agreed between hospitals and local sickness fund organisations and are calculated on a sum per day basis. Many hospitals, public and private alike, compete for specific surgery or medicine services.

Less than a third of the German private acute care hospitals are commercial enterprises. Many are small and specialised clinics. There is an evolution in the number of parapharma hospitals run by commercial enterprises. The private sector is now expected to rapidly develop home-care services. Home dialysis, including nursing assistance, is now provided by medical supply companies.

Hospital doctors are either paid salaries or fees per medical procedure or surgical act; the hospital they work for decides its payment policy. General practitioners charge fees which vary according to the nature of the service they are providing, on a fee per act basis.

Greece

Greece has a health insurance system similar to that of Portugal. Approximately 95% of the population is covered by an insurance fund. There are 80 funds that provide health coverage, four of them major. The largest is the IKA (2.56 million employees and workers and 2.62 million of their families). Second is the OGA (1.91 million agricultural workers and 0.59 million members of their families). TEBE follows (0.48 million artisans and 0.82 million members of their families), and the government has the fourth largest fund (0.19 million directly insured plus 0.27 million members of their families and retired civil servants). Voluntary hospitals and private clinics are licensed to provide additional health care services. Provision of health care services in Greece is improving, as a result of legislation in 1983.

The Greek Ministry of Health reimburses hospitals on a fee basis. Fees only reached 10% of the real cost. The remaining amount is financed by the state budget. New legislation authorises physicians who work for the public health system to practice privately.

Ireland

Ireland's national health care system is financed from general taxation and covers its entire population. One fifth of the population is covered by additional private health insurance besides national health insurance. In recent years the Irish national health care system has made efforts to contain health care costs. Ireland's very young population has a very different demand to that of countries with older populations: instead of geriatric facilities it needs paediatric centres.

Italy

The Italian National Health service came into being in 1979, replacing a sickness fund service. Sickness fund offices still have an involvement in collecting contribution for old-age pensions, but sickness social insurance INPS (Istituto Nazionale Previdenza Sociale) is the only state organisation entitled to collect contributions. Health care is organised on a regional level. Of the private hospitals, 90% are permitted by the national health system to provide services to national health service patients. They work within a convention made by local health units (USL).

The process of reorganisation of the Italian NHS has been achieved with the issue of two legislative measures: the Law 421 and the Law by Decree 502. These legislative measures are bound to modify the global organisation of the Italian NHS and the function of private institutions within the Service. On the one hand, the legislator has considerably increased the number of persons qualified to work within the Service, among which citizens can freely choose; on the other hand, a uniform system is adopted for the payment of the above mentioned persons. The passage to the new model of distribution is bound to introduce in the NHS gears of competition among the subjects offering medical services in such a way to allow an improvement in the use of resources.

An Italian law of December 1991 requires that for 1 000 inhabitants there must be 6 beds, one of which must be for rehabilitation or long-stay. The standard applies to public and private hospitals. But private hospital bed numbers are calculated at 50%, to avoid reducing too much of the system's flexibility assured by their essential contribution. These private hospitals are paid on a daily rate basis and must be profitable to continue.

Italian private hospitals that are accepted in the plan are reimbursed by local health units for services that they provide to patients insured under the national health service plan. By law this payment should take 90 days to be reimbursed. However, payment can take seven months in some areas of the country. Private insurance patients are a valuable source of additional funds to private hospitals and clinics. The 10% of private health care institutions providing specialised and general acute care treatments are licensed to provide services within the Italian national health service plan, but not within the convention. These hospitals have to comply with the relevant laws to be licensed, but not with the requirements to obtain a convention with a local health unit.

Many Italians are increasing their health care coverage through private insurance. There are approximately 1.5 million private polices providing coverage, for approximately 3.7 million people. Generali is the main insurance group involved in the private insurance system in Italy. It accounts for roughly 14% of private policies. RAS, SAI, and Fondiaria have respectively 9%, 7% and 5%.. The remaining polices are distributed among many insurance companies.

Netherlands

Health care in the Netherlands is decentralised and organised to a large extent by sickness funds and local authorities. There are more than 70 of these funds. The entire population is covered. Public and privately owned hospitals operate under the same conditions. A part of their budget is provided by the Ministry of Health, and the rest comes from reimbursement given by ziekenfondsen (sickness funds).

The Netherlands has 752 hospitals, most of them private, although most are owned by religious groups or non-profit organisations.

Most new major private hospital investments have been made by Dutch universities. Community care is provided mainly by the Cross Associations (private and religious in character), which run many nursing homes (verpleeghuis). The Netherlands has the most developed nursing home system in the EC. General practitioners provide most primary care. They are nearly all self-employed. Some have grouped to form health centres, and obtain subsidies from the central and local governments.

Not every person has the same rights concerning coverage. Persons with higher than average incomes are not entitled to full reimbursement by the national system; however, their hospitalisation is mostly free of charge. Regarding payments, fees and costs of products must be paid by the patients, but most are recoverable from the ziekenfonds retrospectively. Reimbursement rules also vary from one locality to another.

Portugal

The Portuguese health care system is largely run by the public authorities. In the 1980s significant investments were made in upgrading the hospital sector. Several new major hospitals were built during the 1980s to ensure the Portuguese population a health service comparable with the rest of Europe.

Private hospitals contribute about 20% of the total number of beds which amounted to about 54 090 in 1990. A significant number of hospital beds in the Portuguese private clinic sector belong to institutions of religious and social security character. Some specialised services such as dialysis centres have been set up by private companies, e.g. WR Grace; these do not have beds. More than 200 health centres and more than 1 500 medico-social clinics provide the country's primary care services.

Spain

Spain has a widespread public health care system which covers approximately 97% of the population. Dental care (except extractions) is not covered by the public system. There is also a strong private system which provides secondary coverage to millions of people. The public system often contracts services with the private system.

Physicians in Spain are paid salaries or fees per service. There is a well developed family doctor establishment, working either

for social security or privately. Primary care is also provided by private centres, emergency centres and outpatient clinics. Some dialysis centres are run by commercial companies, and the Ministry of Health and Social Security allows companies to provide a peritoneal dialysis home service on a fee per day basis.

The major Spanish publicly owned hospitals have either regional or municipal status. These are supplemented by private hospitals owned by the Red Cross, universities, religious concerns and private companies. The number of private hospitals is much greater than the number of public ones. However, in terms of number of beds they account for only about one third.

Private enterprise hospitals in Spain, of foreign and local ownership, account for about 15% of all beds. Many have closed since the late 1980s owing to the Ministry of Public Health and Social Security's policy to make the public hospitals more efficient by increasing bed occupancy rates. However, this has allowed many new investors to establish themselves by buying up failing private hospitals.

Towards the end of the 1989s the British private health group, BUPA (a provident society), decided to invest in Spain. It owns, Sanitas, one of Spain's major private health care groups. Another major group is Agbar-Salud.

United Kingdom

The United Kingdom has a national health care service (NHS) which provides for the whole British population. NHS services are free at the point of use (only a few patient charges are levied on such items as drugs and eye tests). The system is mainly funded by the central government, from general taxation. The public health care sector is going through a process of decentralisation of hospital management, by offering many hospitals "trust status". The private and "not for profit" (independent) sector is now able to compete for services against publicly owned hospitals.

Primary care in the United Kingdom is being organised into health centres. These are rapidly replacing specialist practices. Most general practitioners are paid fees on a per capita basis, but a few are salaried. However, in health centres they can also apply to become fund holders. This allows the doctors to keep budgets and select where their patients should go for treatment.

Medical supply companies offer home care services such as parenteral nutrition, and peritoneal dialysis, e.g. Baxter Healthcare and Fresenius. Baxter also owns some dialysis centres through a subsidiary company.

BUPA, Britain's largest health insurance company (with about 50% of the UK's private health care market), has increased its scope. Besides offering health insurance for private treatment it now has its own hospital and nursing homes. Among others, manufacturers of commodity products such as alcoholic beverage and hotel groups are participating in the rapidly growing registered nursing homes' sector, which caters for Britain's old and infirm.

REGULATIONS

Laws forbid hospitals to make profits in Belgium, the Netherlands, and Luxembourg. There are no small private cooperative hospitals in Belgium or in the Netherlands. In the case of Belgium, this is a result of a regulation which says that the minimum number of beds a hospital can have is 150. It must also provide a certain minimum in terms of the scope of services. In the Netherlands, hospitals must have a minimum of 180 beds, unless they are within 15 km of another hospital, in which case they must have a minimum of 120.

In Italy private hospitals are accepted within the national health care hospital plan which works according to a convention of six beds per 1 000 patients per annum. This is not aimed to limit short-term treatments, but to control the number of beds in areas of over capacity. Private hospital beds are counted at only 50% because their presence is judged essential. This rule may seem out of place within the next few years as laparoscopic surgery and other minimally invasive therapies replace traditional surgery which required more time to convalesce.

Private clinics in Greece, which account for about one fifth of the country's health care expenditure, are facing a law which threatens to close about 95% of them, according to the Greek private clinic association. Greek law did forbid the establishment of further private clinics between 1982 and September 1990. The same law prevented existing clinics from increasing their number of beds. For economic reasons, Greece private clinics had to reduce their overall bed number by 8 000 beds to 15 512 beds by the end of 1982. During this period the public hospital sector only increased its number of beds by 2 900 beds. The law, since December 1991, authorises the establishment of new private clinics, but the minimum requirements of services which must be provided are roughly three times greater than those before the regulation. The investment necessary, being so large, resulted in no new registrations before June 1992. The current private clinics must also increase services to meet the new standards within 18 months of the December 1991 law.

The CEHP, UEHP, and UIHP would like to see more freedom for patients to seek hospitalisation at a hospital of their choice within the EC. An obvious problem is the disparities existing among health insurance systems within the 12 Member States. In the short term it is unrealistic to expect someone in Portugal to make the same contribution to health insurance as someone in Germany. It is also unrealistic to accept massive movements of patients within the European Free Space until greater equality of health provision has been achieved. On the other hand patients should not be prevented from seeking treatment anywhere in the EC, after having their national health insurance cover considered. Agreements already exist between countries, although these contain cumbersome administration formalities and restrictions for the main part.

OUTLOOK

In the early 1980s governments in Europe and the USA began closer monitoring of the mounting costs, and most implemented health care cost containment measures. These have

affected many aspects of health care provision programmes. In particular they have led to the rationalisation of some services and a greater control of expenditure. Circumstances vary significantly from one country to another, and demand is tied to factors such as age structure and general nutritional status of a population.

Future demands on health care systems will depend mainly on these two factors. By 1990 a great deal had been learned about controlling health care costs. One major finding was that the systems needed better management. This management needed to focus on value for money. The idea is being developed even further.

Another important consideration is that de institutionalisation can bring benefits to patients able to convalesce at home; it allows them to recover in often more agreeable surroundings, and hence reduces institutional costs significantly. This is at an early stage of development in Europe. In contrast, the USA is far ahead in this field.

Changing policies of health ministries will increasingly allow private enterprises to become involved in the provision of certain health-related services, although they are not being given the same consideration in every country. The clearest example of a country with a very positive interest in the development of the private health care sector is the United Kingdom's NHS. It is undergoing the most radical change since its formation. The idea of "money following patients" is a radical departure from earlier arrangements. The other major EC countries, Italy, France and Germany all appear to favour the development of private health care.

Evidently, privately run health-related services are increasing in scope and also in number. A new direction for private enterprise will be to examine niche opportunities in the acute care sector. They would protect their stake by investing in the best technology available.

Health care services need not be stationary structures, nor do they need to be capital intensive. A good example of the former is the mobile screening service of BUPA in the United Kingdom. The General Electric Company has participated in a similar venture in Germany. Smaller scale hospitals can achieve savings by hiring the services of mobile units. This may be a good business strategy for the short-to-medium-term, but could have limitations in the longer-term if there is a concerted trend toward closing small hospitals.

On the other hand, home intravenous therapy and peritoneal dialysis programmes organised by medical supplies companies Kabi Pharmacia, Baxter, and Fresenius, appear to have better longer-term potential. The home-care sector, which is only at its initial stages of development, will continue to expand in the EC.

A new peer infrastructure is needed for doctors, and it may be difficult to change professional habits. Some hospital physicians will not wish to temporarily pass the control of some patients to doctors in the community, while the patient is still under the care of the hospital. It may also be difficult for some physicians to accept to place high-tech medicine in the hands of primary care doctors and community nurses.

The primary health care sector will need a good overhaul to cope with secondary care. There is a need for greater professional competence at community level. Some retraining will be necessary. Doctors in the community will need to have greater contact and guidance from central hospitals. Dismantling more of present institutional structure and consolidating it into broader units will continue in the future with resistance of hospital personnel.

The idea of having large supra-regional centres of excellence supported by many dependent hospitals has a great deal of merit, but small specialised surgery and medicine clinics can also play an important role. The private sector will continue to invest in the expansion of registered nursing home facilities across the EC. More than 100% growth can be expected in this service over the next five-year period.

The UEHP states that "the European private hospitals', clinics', and nursing homes' sector must maintain and strengthen its commitment to provide its patients with the high quality medical technical and human assistance, performing quality control and revision (quality assurance) within its structure, according to standard methods designed to guarantee homogeneous results".

Overview

NACE 971, 972, 973, 974, 345.2

Demand in the audio-visual sector has experienced double-digit growth during the past decade despite recent effects from the economic downturn. Future prospects remain very positive in continued growth.
The EC music recording industry remains the global leader, but it still suffers from a weak economy, maturing CD markets and competition from new entertainment media (video games). Sales in 1992 grew by only 0.8% from 1991.
The European audio-visual industry continues to feel the effects of further growth of extra-EC imports (mainly from the USA) in film and television productions. Growth in film production remained stagnant while decreases in both cinema attendance and the number of cinemas further weakened prospects for an EC industry upsurge.

INDUSTRY PROFILE

Description of the sector

The audio-visual sector contains four main sub-sectors: film production (NACE 971); film distribution (NACE 972); cinemas (NACE 973) and radio and television broadcasting (NACE 974). The music recording sector, although being part of NACE 345, is also considered within this chapter.

Recent trends

Although information abounds on the audio-visual sectors, consistent data is rare. However, it is estimated that the leading 100 audio-visual companies worldwide had achieved global sales of 102 ECU billion in 1991.

Broadcasting represented the bulk of the market (68%), followed by cinema distribution (15%) and integrated companies (in both broadcasting and cinema). Music recording holds approximately 4% of the global audio-visual market.

There has been an increasing move towards television film viewing. As a result, cinema attendance, as well as the number of cinemas, has decreased while TV and VCR penetration has increased slightly. The decline in cinema viewing appears to have slowed down with the main markets (France, Germany, Italy and the United Kingdom) stabilising at around 100 million spectators per year each.

The development of TV films and videos is at the heart of the difficulties the cinema industry has encountered over the past few years. This phenomenon is accelerated by growing VCR penetration across Europe and by the explosion of private TV channels (notably pre-paid and cable) in many countries. A more recent "bridge" has appeared through video-disks, a medium that allows the music recording sector (and its key European players) to offer complete audio-visual entertainment to its existing customers. There is a growing interconnection between these two activities which points towards the future of the audio-visual industries.

Film production has been slow to develop in Europe. European production continues to be affected by the growing importance of American films, which today represent 73% of EC's cinema revenues.

By contrast, a real explosion of TV broadcasting has occurred in Europe following deregulation in the 1980's. The number of TV channels grew from 40 in 1981 to more than 140 in 1991, 50% of which were private.

Although 1992 was a more difficult year for the music industry, growth is still to be found in markets where CD penetration remains low (Italy and Spain). Significant hopes have also been placed in the maturity of new media such as Philips' (NL) Digital Compact Cassette (DCC) or the Sony (JPN) MiniDisk.

International comparison

In 1991, the EC had a 39% share of the world audio-visual market, followed by the USA (31%) and Japan (6%). Broadcasting in Europe represented almost a third of the global audio-visual market (this may be explained by the high fragmentation of EC markets and the multiplication of channels). American cinema held two-thirds of the world cinema market.

Foreign trade

Overall, the European audio-visual industry has a heavy negative trade balance with the United States:

Table 1: Audio-visual services
Market strength by region, 1991

(million ECU)	Companies	Audio-visual turnover	% of total

Share (%)	35	2	33	23	7	100
Number of companies	39	5	31	15	10	100

Source: Screen Digest

In the case of film production, this has partly been the result of insufficient European supply and the inability of European producers to match growing internal demand.

For some sectors of the industry, customs figures are less relevant; music recording companies, for example, organise manufacturing independently of market locations. In addition, individual country situations vary. For example, in France, Greece, Spain and Italy national recording artists make up 40-50% of the market, while in others, local talent claims much less of a market share.

Intra-EC trade remains relatively limited, though some countries are more favourable to European products than others: France and Spain are significant importers of other European films (10% of their respective markets).

MARKET FORCES

Demand

The world audio-visual market has grown by more than 11% since 1990. In Europe, this growth has been fuelled by a number of factors that include: increasing penetration of equipment (still below US levels); technology changes bringing in new equipment (CD's) or new transmission methods (cable and HDTV); more hours per day dedicated to audio-visual entertainment (though films, TV and music demand is increasingly undermined by the rise of electronic games); and the commercial dynamism of producers (particularly the Americans) and the aggressive marketing of distributors such as Virgin Megastores (UK) which have helped push music/video demand.

In addition, consumer demand is characterised by an increasing sophistication in terms of quality of service and levels of choice. This development is in turn being encouraged by the revolution in equipment types, transmission and reception methods.

While audio-visual sales have grown overall, there has been a shift in the balance of sales which reflect evolving consumer tastes, technology changes and price/quality trade-off. Between 1981 and 1991, cinema film receipts dropped by up to 50% in most European countries and represented only a tenth of TV film consumption in 1991. Similarly, music recording sales grew by 11% per annum between 1989 and 1991, driven by a 25% per annum increase in CDs compared to a 41% decrease in LP's.

Supply and competition

Major changes in the industry's environment are leading to a restructuring of supply within the European audio-visual market.

These developments include deregulation (for example, that of television in the 1980's), technological innovation (development of cable and satellite TV, as well as HDTV in the future) and the increasing capital intensity of the audio-visual industry.

High growth sectors attract new entrants, often from other media sectors. A striking example of this has been the explosion in the number of broadcasting channels - in particular private, cable and specialist stations - since deregulation.

In addition, investment requirements and economies of scale are increasingly driving industry consolidation across Europe, despite the continued existence of specialised independent companies. There is an increasing development of multi-media audio-visual groups emulating the US "majors" (Bertelsmann, D) and large industrial groups (Bouygues, F) investing in the sector.

Production process

The production process and technological development play a key role in the audio-visual industry as major drivers of future demand.

An innovation that already has a major impact on the different media, and that will have a significant influence on developments in the next decade, is the introduction of digitised pictures and sound.

In the music industry, the DCC, the Sony MiniDisk and digital cable radio transmitted directly along cables are important new technologies being developed to rival the CD.

Source: Screen Digest

The next few months will see the broadcasting in the wide-screen 16:9 format in standard definition, using analogue transmission systems like PAL Plus and D2-MAC initially, then digital ones when available. The Community has its Action Plan for the Introduction of Advanced Television Services in Europe to assist broadcasters and producers in the transition to wide-screen. The rationale behind this plan is both commercial (movie screen format interests broadcasters and manufacturers) and technical (wide-screen receiver installed base would make HDTV introduction easier).

Innovations in the audio-visual industry also have an impact on large computer groups which have, for some time, been operating digital systems. These groups are currently investing in research and development for a new tool, the multi-media, capable of treating sound, image and text. Apple, for example, has already joined forces with Sony and IBM for research into a product combining video with the microcomputer.

INDUSTRY STRUCTURE

Companies

The EC accounted for 34.5% of the top 100 companies in turnover terms. Within the EC, the United Kingdom is in the lead position with a 10% share, closely followed by the Germans who account for 8% of turnover of the top 100 audio-visual companies.

Source: Screen Digest

Within the different European countries, levels of industry consolidation vary. Italy derives a 5% share from two large groups, Fininvest and RAI, whereas 6 companies in France make up just under 4%. Germany has 6 companies in the top 100 and the United Kingdom has 15. Indeed, two German groups, ARD and Bertelsmann, rank among the top 10 audio-visual enterprises worldwide.

The increasing importance of European groups - which, as a block, have overtaken the US - is in part due to the growing importance of private broadcasting. Nevertheless, not one group in the European film, video or TV sectors as yet can rival the global approach and the easier access to (or even control of) the distribution chain of the US "majors", which in part explains the EC trade deficit in this sector.

In the music recording sector, however, European companies have not only been successful in taking a significant share of the world market (49%) but they also account for 4 of the top 6 global companies after Sony and Time Warner.

Strategies

Strategies of the major European audio-visual groups have focused around the need to achieve critical mass, the desire to diversify into new growth areas and the aim to secure access to larger international markets. A series of important mergers and acquisitions have taken place, though many have been limited to a national scale (those of Bertelsmann and Fininvest).

Within each media segment, the specific drivers behind this consolidation have varied. In music recording (Polygram, NL or Thorn EMI, UK) and in cinema film distribution (UFA, D and Rank Odean, UK) expansion strategies have derived from the need to secure a strong local and international European network. In TV and film production, a recognition of the need to counter American professionalism and domination has prompted much of the restructuring.

OUTLOOK

While economic recession has undoubtedly had some impact on growth in demand, the audio-visual industry overall has enjoyed double digit growth over the last decade. Rapid technological change and the increasing convergence of the audio-visual market with other sectors such as electronics and information technology make precise forecasts difficult, though prospects continue to look very positive.

The European audio-visual industry is facing a number of key challenges in the countdown to the twenty-first century. These include the need to build a European production industry

which can seriously compete with the commercial and technical professionalism of its American counterparts; capitalise on the strong positions in the home and global markets of the broadcasting and music recording industries, respectively, and remain at the forefront of the technological revolution in transmission and reception (including digital systems, HDTV and multi-media tools).

Film and video
NACE 971, 972

The European film industry is dominated by two long-term trends which deeply influence its current and prospective financial situation. One is that the supply of feature-length motion pictures, as well as fictional TV works, is facing ever increasing competition from American producers with their strong marketing edge in both cost and quality of releases and public acceptance. Number two is that demand for films is moving steadily away from public consumption in cinemas to more individual access via TV or VCR.
As a result of these two developments over the past few decades, the European film and video industry has been faced with rapidly evolving rules in the marketplace such as: the decline in global marketable film output, lower short-term returns from diminishing attendance in cinema houses, deferred revenues from TV and Video sales and the reduction of production costs to levels offered by competing countries.
In response to these changes, most European players in the industry are currently restructuring their activities by country, with specific patterns such as: defining the financial and legal framework for government support of national production as a vehicle for national culture; merging or associating to set-up European groups with international leverage; integrating the process of financing, manufacturing and distributing movies; integrating international trade (importing and exporting films or technical skills) into local operations; and monitoring the commercial and financial impact of distributing through channels as different as the cinema, TV or video.

INDUSTRY PROFILE

Description of the sector

The film and video industries operate three types of activity: production, manufacturing and distribution. Production is the financial and artistic conception of motion pictures and TV presentations and is project-managed by "producers" from inception to release. European producers are concentrating both horizontally (through alliances) and downstream (through integration of operational/commercial activities).

Manufacturing is the physical making of films and is supported by a host of specialised technical contractors: studios, laboratories, equipment manufacturers, sound specialists.

Distribution is the commercial release of films and is performed by cinema operators (either networked or independent), by video publishing companies and through portfolio management of stocked works.

These activities are today frequently consolidated through the development of large groups combining production and technical capabilities (Granada, UK; Bavaria, D; and SFP, F) or production and distribution (Gaumont, F; and MGM, USA). Multi-media conglomerates are also seeking to add value to their distribution assets by entering into production (Bertelsmann, D; Canal+ and Bouygues, F; Polygram, UK/NL; and Fininvest, I).

Recent trends

Overall, the European film industry had estimated total sales of 2 billion ECU, second only to the American movie industry that had estimated sales of 3.9 billion ECU.

The European film and video industries continue to be affected in a number of different ways by two long-term trends: the

increase in international competition and the move towards more individual viewing on TV screens.

Production

The overall production of feature-length motion pictures in the EC is stagnating below 500 films per year, a level similar to that of USA output.

In turnover terms, however, European production yields only half that of its US counterpart. Diminishing attendance (-18% between 1982 and 1991) and the related reduction in the number of cinemas (-14%) undermine prospects for a much larger European offering. Indeed, latest attendance reports for 1992 confirm that only the United Kingdom had a steady upturn, with a 57% increase over 10 years.

The market share of imported works is huge (83%) and still increasing. Over the last ten years, American films have doubled their market share in France and Italy, while increasing it by more than half in Germany, Belgium and Spain. Currently, American productions represent 73% of EC cinema revenues, with more than 80% of the proceeds in Germany and the United Kingdom.

This decline runs parallel to an increase in the production of fictional works for television (e.g., a doubling over the last ten years in France), which in turn has been a vector for a growing involvement of multi-media groups in movie production.

Manufacturing

The technical manufacturing of films is a sector which has remained relatively resistant to the changing market-place. On the one hand, the turnover of contractors of feature-length pictures is stagnant at an estimated 350 million ECU, of which 70% is derived from French and Italian producers. On the other hand, an increasing share of revenue is coming from fiction TV: for example, the latter accounts for 55% of United Kingdom producers' expenditure in 1992 - an increase of 11 percentage points over 1991. Non TV-oriented contractors have frequently run into financial trouble (e.g. Cinecittà, I). Although it is still a sector characterised by small to medium sized specialised companies, technical contractors (studios, visual and sound laboratories) are frequently being purchased by large financial holdings (Arnold & Richter, D; Rank, Virgin and Brent Walker, UK; Tectis, F; and VDM, F) or integrated into production or distribution groups as capital expenditure requirements are growing.

Distribution

The distribution of films reflects the shift towards TV screen viewing. Television is overtaking the traditional cinema houses as a channel of access to movies.

Europeans are being offered ten times more films by TV networks than by cinemas (23 000 films compared to 2 700 films, respectively, in 1991); Italians and Germans are offered an average of 15 to 20 films a day, the French and British an average of 4 or 5. From 1985-1995 the average global EC offering on all networks is expected to have grown from 30 to 100 films per day. A similar growth rate is observed for TV fictions.

Video sales are increasing in line with VCR sales. With a 50% penetration rate of VCR equipment, European households spend an average 70 ECU per year on video cassettes: twice the amount devoted to cinema tickets (25 ECU).

Cinema houses have stabilised their decline after a drastic reduction of both average attendance and number of cinemas. In 1991, seat sales per cinema had dropped 30% over the early 1980s in France, Germany and the Netherlands. Per capita film consumption at cinemas in this period dropped by between 20% and 50% in all countries but the United Kingdom where the decline had taken place earlier. These figures, however, when put in perspective over the last three decades show a marked slowdown of the decline, not to mention a resumption in attendance in the United Kingdom. Each of the major markets (France, Germany, Italy and the United Kingdom) seems to be converging towards the 100 million spectators per year mark.

International comparison

The European situation is not unlike that observed in Japan and the USA with regard to TV screen viewing, despite a different industrial outlook in the USA. In both countries, progressive TV and VCR penetration of households has been accompanied by a decline of cinema attendance. However, in the USA and Japan, cinema attendance began to stabilise in the early 1970s, a process which did not occur until recently in all European markets except for the United Kingdom. The share of Western Europe in the world market for cinema film consumption moved from a peak of 48% during the 1960s to approximately 30% in the early 1990s.

The USA film industry has aggressively expanded its export sales during the 1980s. Its market share in the EC progressed from 45% to 73% in ten years. In 1992, domestic sales in the USA (4.2 billion USD) accounted for just less than half of industry revenues. Overall, worldwide market share of the major producing EC Member States has fallen slightly from 1980 to 1990. From 1960 to 1990, the picture is much different; over that period, cinema production originating in France was the only EC Member State industry to gain market share (24% increase). Germany suffered a decrease in their world market share of 43% and Italy and the United Kingdom both lost about 54% each.

Foreign trade

Intra-EC trade (150 million ECU) is limited in comparison with the bulk of film imports from the USA: USA audio-visual (films and TV fictions) sales to the EC amounted to 3.2 billion ECU or 13 times the EC sales to the USA.

Intra-EC trade is unevenly shared between countries: France and Spain are strong importers of other European films (10% of each market); other countries (e.g. Germany, Italy and the United Kingdom) devote less than 5% of their markets to their neighbours' productions. French and British movies are favourites among Europeans, whereas Italian and German movie-makers have lost ground during the last decade. In all countries (except France), demand for European films has collapsed over the past few years.

MARKET FORCES

Demand

While the global demand for movies has never been as strong as today, European consumer preferences in terms of product content and viewing mode do not favour a strengthening of national film and video industries in the EC in their current state of operation. Faced with a need for wider geographical diffusion to compensate for restricted national audiences, European producers are failing to foster an appropriate product-policy.

The European audio-visual consumer, provided with an unprecedented offering of movies on TV screens, has considerably increased his consumption. It is estimated that the individual spectator watches 50 movies per year on his TV as opposed to 2 in a cinema.

This dominance of the television offering (most of it free of variable charge) is reinforced by the increase in cinema seat prices. Ticket prices have tripled in real terms in most European countries since 1955. While this has softened the impact of

attendance decline on cinema revenues, notably in France, it has rendered cinema an expensive access to films, thus perpetuating the vicious circle of declining attendance.

Faced with a limited customer base in households, distributors tend to favour film releases which fit best with customer demand: most analysts of the industry acknowledge the fact that the marketing and financing techniques used by American producers are the key to their obvious competitive edge with the public. The high budgets invested call for careful market research and testing to be integrated into film conception; the making of American box office successes is therefore closer to an industrial product policy approach as it takes into consideration the commercial appeal of speed of action, dialogue efficiency, special effects and empathy with characters. Most European surveys indicate that the final impact of such commercial care is reflected in public acceptance of American releases, with slight nuances in France and Italy where the public seems more attached to films specific to their culture (in both countries, the share of indigenous releases is consistent with their share of box office ratings).

Supply and competition

As the economics of film-making change with the diversification of distribution channels, players in the industry adjust their approaches to multimodal viewing and the necessity to reduce financial risk through international distribution. During the 1970s, American producers restructured their approach and are now reaping the dividends. The Europeans began the same process in the late 1980s and are accelerating it in the 1990s.

The key challenge to European film-makers is to develop a capacity to engineer films likely to attract a large international audience. Many obstacles have delayed the acquisition of such a skill: language barriers for films shot in German, Spanish, Italian or French which have to be dubbed before international release; conservative financing that prevents producers from integrating some ingredients of a commercial approach (expensive casting, special effects, market testing); dependence on government support (especially in France, Germany and Spain); and the favouring of films with a more artistic and cultural content.

However, the industry outlook is rapidly evolving in the 1990s and the formation of large, integrated, multi-media groups as key players is likely to increase European producers' ability to offer works with large geographical and access mode potential. Groups that integrate the various production through distribution stages can plan the return on their investment with due knowledge of the spread over time of modern film exploitation . If ticket sales are the major constituent of cash flow during the first year of a box office release, there is a gradual diversification as the film is exploited in various channels (Video, Pay-TV, Pay per view, and international sales). Thus, achieving pay-back of invested capital is easier for financially strong conglomerates.

As a result, the European film offering is likely to be more focused on two concepts in the future. One focal point will be low-budget, low-revenue movies reflecting the personal talent of a director (such movies also co-exist with blockbusters in American production) or a particular element of national culture. The other focal point is that commercially conceived works are adequately financed to sustain both the cost of commercial ingredients and a large life-cycle with a wide and international audience. The financing, casting, directing, technical making and marketing of such products are likely to lose much of their national root and will become European or European/American ventures.

Production process

New technologies (video, digitalisation, HDTV) are being progressively integrated into the production process (e.g., synthetic imaging). They tend to reduce the technical difference between cinema and TV work. Their final impact is therefore likely to strengthen the move towards private viewing on TV screens.

The reduction in production costs is a matter of concern for producers and is a prime cause for the delocalisation of some contracted activities. The latter, when labour intensive (e.g., studio work) are sensitive to the differential in wage levels in Southern and Eastern Europe. Productivity gains in the classical sense are not expected outside limited technical operations (computer-assisted special effects and final cut and video sequences).

Rationalisation is also being forced upon distribution: operating costs are better spread in multiplex theatres, advertising and marketing expenses are syndicated by the large networks and a possible future transfer to digitised copies will reduce the celluloid duplication cost inherent to a large and simultaneous distribution.

INDUSTRY STRUCTURE

Companies

In reaction to their loss of market share, European producers are tending to organise into larger groups with some degree of control on distribution or production facilities:

Although it is premature to speak of European entities, significant national groups are being created through mergers and acquisitions integrating production and technical contracting: Granada in the United Kingdom (sales of 2.1 billion ECU), Bavaria in Germany (46 million ECU) and SFP in France (205 million ECU). A far cry from the American "majors" such as Time Warner, MGM or Viacom Paramount, they are nevertheless close to the stage where they can offer the financial and technical backing for truly international products.

Other large production groups have developed from the growing interest of industrial, financial or audio-visual companies in cinema investment: Canal+, Bouygues and Chargeurs in France, Kirch, Bertelsmann, Scriba & Deyhle, Neue Constantin in Germany, Polygram in the United Kingdom and the Netherlands and Penta and RCS in Italy.

Distribution and exhibition are also areas of important concentration: MGM-Pathé-Nordisk-Canon (536 screens), UFA cinema (445 screens), UGC (374 screens), Pathé Cinema (331 screens), UCI/Cinesa (319 screens) and Rank Odeon (309 screens). Many of these chains are offspring of American producers who seek to secure access to the European spectator. This concentration is having the beneficial effect of modernising and upgrading the theatres, the dereliction of which had been an effect as well as a cause of the attendance decline.

Strategies

The strategies of the key players and the resulting consolidation process are still very much limited to a national scale. In Italy, Fininvest (the largest communication group in Europe) has fostered Penta which can be considered as the first European " major" with a strategy of expanding into production and distribution throughout Europe and North America.

In the United Kingdom, the TV companies diversified early into film production: BBC Films, Channel 4, Zenith, Granada, Euston and LWT concentrate, with the music giant Polygram, much of the capacity to produce international movies, in some cases in close association with American interests (e.g., Island's World).

In France, Canal+ (with Studio Canal+) and Bouygues (with Ciby 2000) follow the same strategy of vertical integration to produce a larger share of the films and TV presentations needed to fill their programs and thus cumulate production and distribution margins. Their ultimate target is also the North American market where Canal+ is already producing movies.

In Germany, large groups such as Kirch and Bertelsmann are following a more prudent strategy than Penta and Canal+, keeping a lower profile on the international scene. Independent producers (e.g.,. Neue Constantin and Scriba u. Deyhle) participate financially in international (American) works without yet producing directly at that level. The latter also reinforce their integration of a distribution network in Germany.

Overall, the strategies aimed at expanding the network of modern, multiplex cinemas are likely to boost growth in cinema attendance, as was the case in the United Kingdom. In this respect, Pathé Cinema and Gaumont (Seydoux family), UFA Theatre, Warner Bros and MGM/Pathé are voicing the most ambitious strategies: their planned investment implies a growth of 37% in European multiplex theatres in the next two years.

REGULATIONS

Public financing was introduced as early as the 1960s (the Golden Age of European film industry) in several countries to help cinema resist the new competition from TV and later its competitive disadvantage against the US "majors".

Goals assigned to public funding vary between countries: Germany, Luxembourg and Greece primarily seek to support the technical industries associated with film-making; Italy, Belgium, the Netherlands and Portugal try to foster artistic creation; and Spain and France aim at both the industrial and creative goals.

Two European bodies enact policies vis-à-vis the film industry: the European Commission through the five years MEDIA Programme (200 million ECU) and the Council of Europe through the EURIMAGES scheme.

OUTLOOK

The issues that the European film and video industries will be facing in 1994 and beyond are already clearly perceptible. There is a need for pan-European alliances between the key players to enable production risks for films with international potential to be better supported. Producers, authors and technicians must create a new team approach and jointly strive to achieve a balance between the commercialism sought by producers, while retaining the quality and personality of European films.

The motivations behind state incentives need to move from a defensive to a more offensive stance on the international scene, albeit continuing to support the expression of national cultures.

Cinema distribution must continue to upgrade its service, offering a competitive alternative to TV viewing. Distributors need to adjust to a longer product life-cycle by better monitoring the long term marketing of a film through its various channels.

Written by: LEK

Television
NACE 974

The television market encompasses three main activities: production, methods of transmission and reception and finally, broadcasting. Programme production, undermined by the competitiveness of American imports, is a poorly developed sector in Europe despite support from both the EC and national levels. Transmission and reception systems are constantly evolving through technological development in areas such as cable or satellite and High Definition Television (HDTV). The broadcasting industry is extremely competitive following deregulation in the 80's and the explosion in the number of private channels.

INDUSTRY PROFILE

Description of the sector

Production

Films, game shows, documentaries, series, cartoons - the television programmes which count for more than three and a half hours of European viewing time daily - are produced by independent companies and multimedia groups. The smaller independents rely extensively on service providers and specialists in audio-visual equipment to whom they subcontract the technical aspects of production.

Transmission and reception

Televisions operate on analogue transmission systems using three different norms (NTSC in North America, PAL in most of Europe and SECAM in France and Francophone countries). Hertz transmission is the most widely used in Europe but poor reception and problems of frequency capacity have led to the development of cable and satellite. Among wide-screen systems, one can recall D2-MAC and PAL Plus.

Broadcasting

This is the responsibility of the television channels. In the 1980's, technological developments and deregulation led to the increasing emergence of private channels in Europe. The number of national broadcasting stations grew from 40 in 1981 to more than 140 in 1991, of which more than 50% were private. These include pay and specialised channels, as well as private generalist channels competing directly with their public counterparts.

Recent trends

Production

The production industry in Europe has suffered from structural weaknesses (few large companies that are all too often undercapitalised) that have prevented it from keeping up with the rapid growth in broadcasting demand. Between 1985 and 1990, the hourly volume of programmes broadcast increased by 175% while the available European supply increased by a mere 60%. This explains the important share of repeat showings (27% in 1990) and the significant development of purchases outside the Community (38% in 1990).

Transmission and reception

There are 122 million households in Europe housing 127 million television sets. Of these, 15% receive television by cable and 5% by satellite. Major differences exist between Southern Europe, where cable penetration is low (only 23% of Greek households in cabled areas are connected, while in Spain, Italy and Portugal, cabling is practically non-existent), and more northerly Member States (Belgium has a 99% penetration in cabled areas; Holland, 95%). Satellite penetration follows a similar geographical pattern.

Finally, HDTV, the new standard of television reception, promises to be one of the major developments of the future, together with digital techniques and multimedia.

Broadcasting

Since the end of the 1980's, increased competition has led to growing financial problems for the broadcasting channels, which have been faced with a reduction in their shares of advertising revenue. This in turn led to the development of new services such as pay channels and specialised channels.

International comparison

The Americans have the highest rate of penetration of televisual equipment in the world: 2.4 television sets per household and a penetration rate of 77% for video recorders. Close behind are the Japanese, with 1.5 television sets per household and a penetration rate of 81% for video recorders. By contrast, the EC averages just over 1 television per household. Video recorder penetration is only 50%, though there are significant country variations (Italy with 31% and the United Kingdom

with 71%). The high level of household penetration in the UK is presumably partly a function of the availability of imported software from the USA in its original language, without dubbing or subtitle costs. The availability of imported software can have a positive impact on sales of hardware (hence on the European manufacturing industry).

Foreign trade

The EC trade deficit for programme production was 0.5 billion ECU in 1990. On average, European countries import around two thirds of fictional broadcasts.

American producers control a significant share of the fictional programming in Europe, though the presence of the Japanese is increasingly felt, particularly in cartoons. In 1990, the Americans exported 2.4 billion ECU of programmes of which 62% was destined for the EC. By contrast, American imports from the EC represented a mere 221 million ECU.

The trade deficit in production revolves around European producers' dependence on programme demand from the national broadcasting channels, a function of their insufficient size and inability to risk investing in more speculative projects. Broadcasters in turn are hostage to the needs of audience maximisation, limiting the possibilities for development of programmes with international appeal. European producers have therefore been unable to build up a sufficient stock of programmes to promote the export market as well as to meet growing internal demand.

MARKET FORCES

Demand

Despite the fact that penetration of television sets already exceeds 100% in European households, there remains potential for growth in the installed base owing to the advent of video games and the decrease in equipment prices. This phenomenon

is already manifesting itself in countries such as the United Kingdom and Spain where 50% and 39% of households, respectively, possess a second television.

In more recent times, the video recorder has shown a rapid growth (between 1989 and 1991, penetration moved from 40 to 54% in Germany, from 59 to 71% in the United Kingdom and from 35 to 50% in France).

The effect of this development in the installed base of audio-visual equipment on demand for television may in part be counterbalanced by other factors. For example, the Institute Médiamat has noted a 20% reduction in viewing time in the last three years by young Europeans of 14 to 20 years. This may be the result of the development of the electronic games market.

Television viewers are increasingly sensitive to the choice and diversity of programmes (hence, the success of pay TV and specialist channels such as MTV and Eurosport) and the possibility of customising their viewing (e.g. through development of interactive systems).

Supply and competition

The deregulation of the 1980's has led to a wide diversity of channels (3.5 times more channels in 1991 than in 1981) and to a number of pan-European broadcasters resulting from the development of cable and satellite TV. According to a study carried out by the CSA (Centre Supérieur de l'Audiovisuel) in 1992, these can be grouped into the categories discussed below.

The "Generalists" (ARD, DK; BBC1, UK; RAI1, I; FR3, F; and TVE2, E) are principally public channels in competition with the private stations, aiming for a balance between public service (information, education, culture) and commercial appeal for the sake of audience maximisation. The "Americans" (RTL, L; Rete4, I; M6, F; Antenna, GR; and TELE 5, E) were created in the 1980's. These channels have a commercial emphasis and are mainly dedicated to fictional programmes imported from the USA. The "Fighters" (TF1, F; Canale 5, I; and RTL4, NL) attempt to compete with the supremacy of the public channels by an aggressive choice of entertainment programmes.

The "Culturals" (La 7, F; Eins+, DK; and Channel 4, UK) aim to promote a national audio-visual cultural heritage. The "Educationals" (BBC2, UK and Nederland 3, NL) show programmes with primarily an educational emphasis. And finally, the "Basics" (TV1/2, SF; DR & TV2, DK; and Kanal 1, S) have low viewing figures, devote much time to supply of information, show a high percentage of repeats and survive essentially on television licence fees.

The new areas of research and development in the supply of televisual products centre around three main axes: the search for increased viewing comfort and perfection with HDTV; the increase in supply of programmes through the multiplication of channels as a result of digital methods; and the development of interactive methods, a veritable combination of micro-computer and CD technology.

Production process

The digital system has numerous advantages. It is possible to compress up to one hundred times more information on a channel, i.e. between three to eight programmes. The immediate result is a reduction in the cost of transmission of these programmes. The information is evenly recorded (unlike with analogue systems) and blurring between channels presents less of a problem. This creates the possibility of broadcasting the same programme on the same frequency from different

points. Digital production, transmission and reception offer a better and more constant quality of image; and with digital TV, it is possible to transmit programmes on mobile and portable TV sets via hertz transmission.

Despite financial and technical obstacles, the race for high definition television has started. This revolution owes much to the development of digital technology, a process of codification and transmission of binary elements. The stakes are high, involving the replacement by the years 2000 to 2010 of 800 million television sets and 250 million video recorders: a jackpot of 250 billion USD.

INDUSTRY STRUCTURE

Companies

Production

The three main independent producers in Europe are Granada in the United Kingdom (270 million ECU turnover in production in 1991), SFP in France (205 million ECU total turnover in 1991) and Bavaria from Germany (46 million ECU total turnover in 1990). They are able to invest more heavily than their smaller competitors, but nevertheless suffer from a high level of indebtedness that has limited their development.

In partial response to this, large communications groups such as Fininvest, News Corp. and Canal Plus, already involved in broadcasting networks, have vertically integrated into programme production.

Transmission and reception

Two main types of companies are involved in the development of new technologies of transmission and reception: electronic groups such as Philips (NL, 11.9 billion ECU of turnover in consumer electronics in 1991), Thomson (F, 4.4 billion ECU), Nokia (SF, 1.1 billion ECU) in the area of HDTV equipment; and cable operators such as France Telecom that are developing future techniques of transmission.

Table 7: Television

Broadcasting

In Europe, a hundred or so broadcasting stations figure among the 6 diversified communications groups: Bertelsmann (D, 2.7 billion ECU of audio-visual turnover in 1991) with three channels (RTL Plus, Premier and Vox), focused on the German market; the group Kirch (D), which holds stakes in Sat 1, Premiere, DSF, Pro 7 and Kanelkanal, is also focused on the German market; Fininvest, belonging to Silvio Berlusconi (2.8 billion ECU of audio-visual turnover in 1991) controls 3 channels in Italy (100% of Canale 5 and Rete 4 and 55% of Italia 1)-it also has involvement in the German market (21% of Tele 5) and the Spanish market (25% of Tele Cinco); and the CLT (L, 1.1 billion ECU of audio-visual turnover in 1991) remains the group with the most extensive presence in Europe: 66% of the Belgian channel RTL TV1, 25% of RTL 4 (NL), 25% of M6 (F), 46% of RTL Plus (D) and 29% of RTL Luxembourg. The last two groups are present in the pay television market. They are: (1) Canal Plus (F) with 1.13 billion ECU of turnover in 1992, which owns 25% of Canal Plus Espagne, 42.7% of Canal Plus Belgique and 37.5% of Premiere in Germany and (2) the Murdoch group (News Corp., 2.3 billion ECU of audio-visual turnover in 1991) has a quasi-monopoly in the United Kingdom with BSkyB.

Strategies

Production

Aware of American leadership in the area of programme production, European producers have increasingly aligned themselves with groups in the United States. Since 1989, the number of joint ventures has developed steadily.

Transmission and reception

France Telecom, having launched the satellite Telecom 2 for broadcasting programmes in D2 MAC, is currently working on digital television transmission systems and HDTV.

In the equipment market, smaller European players such as the Finnish group Nokia are hard pressed to compete with the Japanese electronics giants (Matsushita with 43 billion ECU audio-visual turnover in 1991, Hitachi with 21 billion ECU and Sony with 22 billion ECU). Philips have made a major commitment to the interactive compact disk. Thomson is looking to develop digital technology while still continuing to support D2-MAC.

Broadcasting

Already present in newspapers and publishing, the Bertelsmann group has taken advantage of the opportunities presented by the appearance of the private television channels in Europe.

Kirch, which supplies most of the public German channels with films and series has also followed a strategy of moving into broadcasting via the private channels.

The lead position of the group Fininvest in private Italian television allowed Silvio Berlusconi to invest rapidly in related activities - private channels elsewhere in Europe, international film production and advertising - and to diversify into other media forms such as newspapers and publishing.

The CLT, with its eight channels in five European countries, has a clearly stated strategy: to develop its presence abroad through the profitable specialist channel segment.

Canal Plus (F) is the only operator to have concentrated principally on its original core business: pay television. Today, its strategy is one of vertical integration into cinema production

Source: FEMIS

and a search for partners in the development of new technologies.

The other pay TV group, Murdoch's BSkyB bases its strategy on the emulation of the great American success stories (MTV, CNN and ESPN).

REGULATIONS

Production obligations

These vary according to Member States. For example, British channels are obliged to obtain 25% of their hourly volume from independent producers. At the same time, the EC Directive on "Television Without Frontiers" (89/552/EEC) stipulates that "where practicable and by appropriate means, that broadcasters reserve at least 10% of their transmission time, excluding the time appointed to news, sports events, games, advertising and teletext services, or alternatively, at the discretion of the Member States, at least 10% of their programming budget, for European works created by producers who are independent of broadcasters.".

Broadcasting obligations

Various national obligations fix European broadcasting volume at between 25 and 60% of total volume depending on the Member State. The "Television Without Frontiers" Directive stipulates that, where practicable, Member States should ensure that broadcasters "reserve for European works, ..., a majority proportion of their transmission time, excluding the time appointed to news, sports events, games, advertising and teletext services.".

The Media programme, adopted in December 1990, has 200 million ECU dedicated over 5 years to the European audiovisual industry: up to 85 million ECU in support of distribution, up to 65 million ECU in support of production, 20 million ECU in support of developers of new technologies in audiovisual production, 10 million ECU for professional development and 15 million ECU for development in countries with limited production capacity. It is implemented by the European Commission.

OUTLOOK

Continued European efforts to make headway in the programme production industry may begin to reap rewards in the coming decade, though the battle is by no means won. It is likely that increasing cooperation with American groups will assist in this process, as would the development of a system of centralised production, favouring the emergence of a major European production group.

Digital technology seems to have found its place as the transmission system for the future due to its numerous advantages. Cable operators, electronics groups and computer giants are set for the race for HDTV and multichannel digital TV. In addition, computer groups are developing multi-media tools integrating voice, text and image.

As for the broadcasters, the market will continue to be competitive, with public channels increasingly unable to survive on licence fees, and TV stations generally suffering from a drop in advertising revenues. In parallel, the trend towards pay stations and particularly, specialist stations (with narrower targets and smaller market shares) is expected to continue.

Music recording
NACE 345.2

The combination of difficult economic conditions, maturing compact disc (CD) markets and increased competition from new media (e.g. computer games) have adversely affected sales in the EC for the recorded music sector in 1992. Sales grew by only 0.8% (in nominal terms) compared with 1991. But the few European corporations that lead the industry are building their hopes on the development of new recording media such as the DCC (Digital Compact Cassette) and the MiniDisk.

INDUSTRY PROFILE

Description of the sector

The recording industry ranges from the selection, management and production of artists to the manufacturing, marketing and distribution of "Long Play" or "Singles" recorded on media such as Compact Discs, Vinyl Discs and Compact Cassettes. This sector represented 7.9 billion ECU in 1992 for the EC as a whole. Three European groups, PolyGram (NL), Thorn EMI (UK) and BMG (D), captured close to 50% of the world market; Germany, the United Kingdom and France represent 70% of EC consumption and 23% of the global market.

Recent trends

This sector follows a long term cyclical variation closely correlated to the introduction of new technologies. Vinyl LPs peaked (with 1.2 billion units worldwide) in 1981; cassettes reached a plateau in 1989 (1.5 billion units), and further growth is still expected from CDs (1.2 billion units in 1992). Philips's (NL) DCC and Sony's (JPN) MiniDisk are expected to capture, in their turn, most of the momentum gradually lost by cassettes.

Another underlying trend is industry consolidation in a market where production economies of scale are critical. The acquisition of Virgin records (production and distribution) by Thorn EMI in 1992 was a clear illustration of this trend. Indeed, a large number of independent EC record companies have been acquired by the "majors" over the past years such as Vogue (F) and Avrep (F).

International comparison

In 1992, the EC represented 32% of world sales, ahead of the USA (31%) and Japan (15%). Consumption patterns remain quite different in these markets; the importance of record rentals in Japan (where there are as many rental shops as record retail outlets) is combined with the highest CD hardware penetration in the world (90%). In the USA, CD penetration is much lower (45%) but portability has proved a key growth factor (the success of the "Walkman" pushed cassette player penetration in American homes to a peak 3.2 units versus 2.3 in the EC).

EC Member States offer a very contrasted picture. In 1992, Dutch consumers spent on average 37 ECU per capita on music recording, benefiting from high CD penetration at an EC record 64%; in contrast, Greek consumers only parted with some 5 ECU per head with 10% CD penetration.

The three leading EC markets, Germany (2.05 billion ECU), the United Kingdom (1.7 billion ECU) and France (1.6 billion ECU) today rank among the top five in the world.

Foreign trade

Because of their trans-national market positions (and the low cost of transport), record companies tend to organise manufacturing independently of market locations; custom statistics are therefore not meaningful. However, two patterns are worth noting. The first one is that most European markets are heavily penetrated by the "international pop" repertoire. This category typically represents 60% of national sales, despite notable exceptions such as Greece, Spain, Italy or even France where national artists make up 40-50% of the markets. Classical recordings fill the remaining 10%. The second pattern is that beyond visible trade of records and tapes, the impact of invisible exports is extremely significant for exporting countries; the Policy Studies Institute in the United Kingdom estimated in 1988 that the ratio of invisible to visible exports for the United Kingdom was 7, thereby generating over one billion Pounds Sterling, i.e. twice as much as films, video and broadcasting combined.

MARKET FORCES

Demand

In value terms, music recording is one of the few economic sectors that has enjoyed two-digit compound growth across Europe since 1989 (annual growth was even higher than 20% in Portugal and Belgium). A number of factors have an impact on this level of demand. General economic conditions obviously prevail. Hoare and Govett Investment Research have recently illustrated the close correlation between GDP growth and "music value growth" in Europe over the past 10 years. In addition, it is often believed that younger age groups represent key buyers for this sector. It appears that this was indeed true when older generations had not had the opportunity to buy records in their youth. Recent USA data suggests that music buying habits are carried up the age profile (the share of USA music sales taken by the 15-19 year group has already fallen from 24% to 17% in the four years to 1991, while the amount accounted for by the 30-39 year old group increased from 19% to 23% over the same time period. Europe's ageing population is therefore expected to follow a similar pattern and not to have too negative an impact on the sector's future growth.

Technology changes are obviously critical. The "technological cycle" described earlier seems to peg demand to new hardware development (CD, soon DCC & MiniDisk). The move to CDs has radically altered the balance of sales by media; CDs have grown in the EC by 25% (compounded annually) since 1989 while LPs annually decreased by 41%. The impact of the switch has led to an annual value growth of 11% over the same period.

Indeed, the CD segment still grows very fast in countries where CD hardware penetration is still low (Greece, Portugal and Spain), but strong growth has also been recorded over the past 4 years in the more "penetrated" countries of Belgium, Denmark and Germany.

Another positive impact from new media is that they allow enhanced price realisation for record producers (although this is not true on a per minute basis with CDs lasting much longer than old vinyl LPs). Increased value-added has led to much higher price points thus helping to increase market values in spite of sluggish volume growth.

Lastly, commercial dynamism cannot be underestimated. Record marketing has become more professional in the EC (e.g. owing to TV advertising, which provided a welcome boost to the French market in 1988). More recently, distribution has played a significant role in helping to build up markets, often competing on prices; Virgin Megastores have opened in most EC countries, and mass retailers such as hyper/supermarkets (which represent 50% of retail market in France) have helped push demand.

Supply and competition

Some 60 CD production plants exist today within the EC. Most of them are owned by major record companies, although some independent companies remain active such as MPO (F) and Nimbus (UK). The music recording industry has obviously become a highly capital intensive business where competitiveness is a direct function of economies of scale, thus driving industry consolidation across Europe.

With retailers gaining in influence on buying decisions, price positioning becomes a more critical element of the marketing-mix. Beyond exchange rate fluctuations (particularly with the USD), a CD could be purchased in November 1992 at £ 12.78 in the United Kingdom, against some 34% more (£ 17.13) in Ireland. This in turn was then 71% more expensive than the equivalent cost in the USA (£ 10.00). Yet, by early 1993, member countries had largely succeeded in realigning VAT rates so that their range has become much narrower. Italy has the lowest rate (12%) and Belgium the highest (19.5%). France experienced a very favourable boost when the rate was brought down from 33.3% to 18.6%, in 1987.

Production process

Technological development is a key driver for this industry. The impact of CDs has considerably rejuvenated the market, fast offsetting the LP's rapid decline. It is generally believed that CD growth is not about to disappear in Europe. This is true even for highly penetrated markets such as the Netherlands. For example, estimates expect CD hardware penetration in Japan to grow from a current 90% to over 140%. A similar revolution is under way with the take-off of two new technologies promoted by two of the electronics giants.

The cassette had become a fantastic worldwide success (in 1988, cassettes attained volumes in the world 50% larger than those of LPs and CDs combined; in Western Europe, cassette recorders reached 230% penetration), which industrialists hope to emulate with new media forms.

DCC (Digital Compact Cassette) has been developed to offer digital quality on a medium very close to the traditional analogue cassette. Its real portability (superior to CD) is key, as is its "back-compatibility" (traditional cassettes can be played on DCC hardware). The Dutch group Philips, allied to Mat-

sushita (JPN), is the contender for this system. It is estimated that some 26 000 DCC were sold worldwide in 1992, growing to over 157 000 by 1995. Multiple copies are prevented by way of an internal "deteriorating" device. The Minidisk (developed by Sony) also offers recording capabilities (and multiple copying prevention) but is not back-compatible.

Another technology worth mentioning is direct transmission of recorded music along cables, telephone lines or via satellites. Such systems (e.g. DMX/BSkyB or Digital Cable Radio Associates/Warner/Sony), are already operative in the USA.

INDUSTRY STRUCTURE

Companies

The recorded music industry is highly concentrated, with five multinational groups sharing more than 80% of the world market. However, beyond the few independent companies that have managed to survive (e.g. Harmonia Mundi, F or Nimbus, UK), the majors are careful to expand through carefully positioned local presence (for example, Thorn EMI, UK, own 61 record companies in 37 countries). Local labels generally enjoy a large degree of freedom in their management. Overall, the International Federation of Phonographic Industries (IFPI) comprises some 600 members in the EC, 250 in Germany alone.

The five leading groups in the music industry are generally vertically integrated in hardware and/or retail. They are Warner (Time Warner, USA), PolyGram (80% controlled by Philips, NL), Thorn EMI (UK), Sony Music (JPN) and BMG (Bertelsmann Music Group, D).

European dominance is striking: three of the 5 world leaders are EC companies, together representing close to 50% of the world market.

Strategies

The combination of capital intensity with market internationalisation (the majority of European markets are dominated by international pop and classical), means that economies of scale are critical and, fortunately, achievable.

Most players have therefore sought to secure a wider international position, as well as to enrich their repertoire. Vertical integration upstream brings substantial marketing power and flexibility (e.g. Virgin/EMI). Technologically, synergies between Sony Music and Sony's MiniDisk or PolyGram and Philips' DCC are not less significant.

PolyGram

It is the "purest" of all competitors with 83% of its sales in music. Its position is particularly strong in Europe (22% market share, up to 34% in France). PolyGram has been busy building up its international network recently, through the acquisition of several USA companies (A&M, Island Records and, more recently with Motown). PolyGram is strong in the classical department with international labels such as Decca. Philips Classic or Deutsche Gramophon.

It is also one active in the European music mail order business through Britannia Music (UK), Dial (F), Karussel (D) and PolyMond (I). The group has recently started building a position in the music publishing business, as well as in the video production and distribution, with a 6% shareholding in the USA retailer "Blockbuster".

Thorn EMI

The much-publicised Virgin acquisition in June 1992 boosted Thorn EMI's global market share to 17%, thus giving them the third position in front of Sony Music. Thorn EMI is more diversified than PolyGram and only derived a third of its £ 4.4 billion revenues from music in 1993. It employs over 8 000 people.

The group benefits from a strong presence in the very profitable activity of music publishing (EMI Music is a world leader with 25% market share). It is also diversified in TV, VCR and other electronic hardware rental, as well as lighting fittings and security electronics.

One of Thorn EMI's objectives is also to balance its international portfolio, which led them to acquire Chrysalis in 1990.

Bertelsmann Music Group (BMG)

With 11% of the world market, BMG is the third largest European music record company and ranks 5th in the world. Of its 4 billion DM of sales, 50% were achieved in Europe in 1992 compared to 29% in North America. International expansion has, over the recent years, remained a key objective owing to acquisitions such as Vogue and Avrep (F), or joint ventures with Pressing (I) or Stageway and Norsk (N).

More recently, BMG has been expanding its lead in the low-priced CD segment - of particular relevance in eastern Germany - through Ariola Express and Europa labels.

ENVIRONMENT

It is worth noting that the main environmentally related issue in the music recording industry only recently surfaced in the USA where the conventional "longbox" CD packaging (an anti-theft measure), unknown in Europe, was recently dropped (April 1993), following an initiative from the Recording Industry Association of America (RIAA). This will considerably reduce consumption and disposal of packaging material.

REGULATIONS

Piracy is the major problem for the industry. It is estimated that, over the last decade, some 10.2 billion ECU were lost in the world as a direct result of piracy, mostly through cassettes but increasingly with CDs.

Although this issue is more relevant in some developing countries and Central and Eastern Europe, the problem has also affected Europe. A major battle was fought and won in Greece where a 1983 Supreme Court decision has led to a reduction in piracy from 75% down to 20% in 1992. Piracy rates are much lower in other EC countries, but its annual cost to German industry was still estimated in 1990 to be close to 68.4 million ECU.

The second largest problem for the industry is related to technological development associated with digital technology. The industry is faced with the challenge of maintaining control of the use made of their property as cable and satellite systems provide new methods of distribution of pre-recorded music. The combination of electronic delivery and the phenomenon of private copying, if left unregulated, will have a dramatic impact on the industry.

The European Community has recently adopted or is in the process of adopting harmonisation measures to strengthen the protection afforded to rightowners, including phonogram producers. These measures include the following:

- Council Resolution of 14 May 1992, on increased protection for copyright and neighbouring rights, by which the Member States have committed themselves to become parties by 1 January 1995, to the Paris Act of the Berne Convention for the protection of literary and artistic works and to the Rome Convention for the protection of performing artists, phonogram producers and broadcasting organisations which guarantee certain minimum levels of protection;
- Council Directive 92/100/EEC of 19 November 1992, on rental right, lending right, and on certain rights related to copyright, which grants to authors, performers, phonogram and film producers an exclusive right to control rental of copies of phonograms and also harmonises at EC level

Source: Hoare Govett UK Investment Research

protection in relation to public lending, the fixation of performances, the rights of reproduction and distribution for neighbouring rightsholders. The date for entry into force in the Member States is 1 July 1994;

- Council Directive 93/98/EEC of 29 October 1993, harmonising the term of protection of copyright and certain related rights by which authors' rights will last the lifetime of the author plus 70 years and phonogram producers', performing artists' and broadcasting organisations' rights will last 50 years. The date of entry into force is 1 July 1995;
- The proposal for a Council Regulation laying measures to prohibit the release for free circulation, export or transit of counterfeit and pirated goods (COM(93)329) of 13 August 1993. This proposal aims at enabling owners of author's rights and phonogram producers', performing artists' and broadcasting organisations' rights to request the customs authorities to seize for a limited period of time goods which infringe their rights, until an action is brought to court. The proposal is presently being considered by the European Parliament and the Council of the European Union.

The EC has also sought to obtain in its international negotiations with third countries either in the multilateral forums (World Intellectual Property Organisation, or the GATT) or on a bilateral basis (Association agreements with Central and Eastern European countries, partnership agreement with Russia), adequate and effective protection for intellectual property rights.

OUTLOOK

The recent impact of generally poor economic conditions has slowed down the traditionally buoyant growth of the music recording sector in Europe. This is unlikely to last and technological development should offer very positive prospects for the music recording industry in the coming years.

In geographical terms, European firms have clearly anticipated competitive developments. They have built a strong worldwide position, and appear concerned to build upon the local strengths of their previously independent acquisitions.

Continuing progress in CD penetration for many Member States will probably be reinforced by the explosion of new "recording" digital media. The opening of substantial new markets (e.g. Eastern Europe) will also benefit European producers.

Panorama of EC industry

Short-term supplement

To complement the annual publication *Panorama of EC Industry*, Eurostat, in collaboration with DG III, produces a supplement six times a year. This bimonthly offers comments, tables and graphs on the latest available information on Community industry.

Each issue starts with a macroeconomic overview and a review of general industry trends. Then the short-term trends and structural aspects of two specific sectors are analysed. The sectors vary from issue to issue within the year, with a view to covering the main industry sectors once a year.

Contents of the publication

Statistical indicators

Short-term indicators

- index of production
- producer price index
- capacity utilisation
- external trade indexes

Structural indicators

- value added, turnover, investment
- employment, productivity, labour costs
- trade balance
- trade indicators

There are methodological notes at the end of the publication.

The sectors by issue

no. 1:	Chemicals and man-made fibres (nace 25 + 26) Rubber and plastics (nace 48)
no. 2:	Manufacture of metal articles (nace 31) Mechanical engineering (nace 32)
no. 3:	Electrical engineering (nace 34) Clothing and accessories (nace 453)
no. 4:	Manufacture of non-metallic mineral products (nace 24) Paper, printing and publishing (nace 47)
no. 5:	Iron and steel (nace 221) Transport equipment (nace 35 + 36)
no. 6:	Food, drink and tobacco industry (nace 41/42) Analyses by country

Order form

Please send me a one year subscription for Panorama of EC Industry – Short-term supplement *(6 copies, price: ECU 50 excl. VAT and P&P; catalogue number: CA-CV-94-000-EN-C, also available in German and French).*

ENTERPRISES IN EUROPE, THIRD REPORT

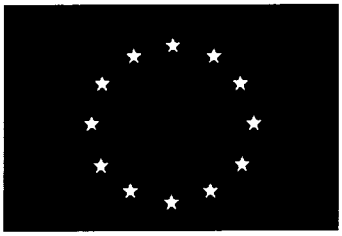
- How many enterprises are there in Europe; how many are small and medium sized (SMEs)?
- What is their structure - size, activity?
- What are their average size and turnover and value added; and their productivity by size and sector?
- How are the number of firms, the people they employ and their sales distributed among EU Member States?
- What are the differences and similarities between each Member State and the EU average?
- What is the financial position of SMEs compared to large businesses (and how is it measured)?
- How many businesses are created; how many disappear?

plus

- How many SMEs are there in the EFTA countries, Australia, Canada, Japan and the United States and how does this compare to the EU?
- How big is the average EU industrial enterprise compared to its American, Australian, Canadian and Japanese counterparts; what is the situation in the services sectors?
- How does the turnover of micro-enterprises vary in different European countries; what is the share of the smallest enterprises?
- How many enterprises employ fewer than 50 and fewer than 250 persons - what thresholds are used in Community definitions of SMEs - and in different countries? What is their share of total employment and turnover?

All these questions and many more are answered in *Enterprises in Europe, Third Report*. This comprehensive statistical study consists of a descriptive analysis (Volume I) and data by size of firm for the 19 EU and EFTA countries (Volume II).

Specially recommended for decision-makers, businesses, consultants, researchers and anyone with an interest in the development of SMEs.



Enterprises in Europe, Third Report is a joint effort by Directorate-General XXIII of the European Commission and Eurostat, the EC statistical office.

PUBLICATION ON SERVICES

eurostat

What are services in Europe?

Services in Europe are:

1 ♦ **Distributive trade**

2 ♦ **Transport**

3 ♦ **Hotels, restaurants, catering, travel agencies**

4 ♦ **Credit institutions**

5 ♦ **Insurance**

6 ♦ **Information, communication, business services**

7 ♦ **Audio-visual services**

What does the publication contain?

The publication contains:

AN OVERVIEW ON SERVICES IN EUROPE

This chapter gives a global description of services through national accounts figures.

With **more than 30 diagrams**, this chapter outlines the composition of services, compares market services at international level in terms of **value added at market prices and employment**.

Methodological comments are also included.

BUSINESS STATISTICS ON SERVICES

This chapter is divided into seven sectoral parts. It provides data on key figures on EU and EFTA countries for the period of 1985 - 1991.

Six economic variables have been selected from the MERCURE database: **number of enterprises, number of local units, turnover, value added at market prices, number of persons employed and number of employees.**

Where is the publication available?

This publication is available at:

OFFICE FOR OFFICIAL PUBLICATIONS OF THE EUROPEAN COMMUNITIES, L - 2985 Luxembourg

*The projects related to the **MERCURE** Information System on Services are conducted by the **D4 Unit : "Distributive trades, services and transport"** headed by Mr. Lancetti*
