

Examining the Relationship between employee Resistance to changes in job conditions and Wider Organisational Change: Evidence from Ireland

Hugh Cronin<sup>a</sup> and Seamus McGuinness<sup>bc,d,e</sup>

*Abstract:* This paper uses a linked employer-employee dataset, the National Employment Survey, to examine the determinants of organisational change and employee resistance to change and, specifically, to examine the influence of employee inflexibility on the implementation of firm-level policies aimed at increasing competitiveness and workforce flexibility. Key finding arising from the research is that while workforce resistance to job-related change often forces firms to seek alternative means of achieving labour flexibility, there appears little that firms can do to prevent such resistance occurring. The presence of HRM staff, consultation procedures, wage bargaining mechanisms, bullying and equality polices etc were found to have little impact on the incidence of workforce resistance to changes in job conditions.

*Keywords:* Workforce resistance, organisational change, linked employer-employee data.

# Examining the Relationship between employee Resistance to changes in job conditions and Wider Organisational Change: Evidence from Ireland

## Background and Introduction

Ireland's economic difficulties have been well documented. The international financial collapse had a severe effect on Ireland, the combination of a banking crises and the bursting of a property bubble led to a dramatic fall in economic output and a rapid rise in unemployment. The crises began to be felt by firms towards the latter part of 2008, the data point relevant to this study, with GDP falling by 2% in that year.

Within a deteriorating economic environment, firms - both domestic and foreign-owned - struggle to maintain competitiveness, particularly given that wages remain downwardly rigid even in times of recession (Babecky *et al.*, 2009, 2010; 2012; Bertola *et al.*, 2010; Christopoulou *et al.*, 2010; Autor and Katz, 1999; Fuss, 2008). The majority of the research has found that wage levels generally exhibit downward rigidity, with the probability of wage cuts being lower the more skilled the worker. In terms of theoretical frameworks, downward wage rigidity is consistent with a number of theoretical labour market models such as the efficiency wage theory (Shapiro and Stiglitz, 1984), adverse selection theory (Weiss, 1980) and insider-outsider theory (Lindbeck and Snower, 1988). Consistent with the international evidence, a recent study confirmed that both real average wages and average labour costs increased in Ireland during the course of the recession (Bergin *et al.*, 2012). Given the inflexibility of earnings, it stands to reason that firms tend to seek to improve competitiveness during a recession primarily through other forms of organisational change. In addition, Pfeffer (1994) notes that, with a decreasing competitive advantage provided by traditional sources of success such as product and process technology, how the workforce is managed is comparatively more important.

The ability of firms to implement organisational change will undoubtedly be impacted by the extent of co-operation of the workforce which, itself, may be a function of many factors such as the nature and scale of HRM practices, bargaining arrangements and industrial sector etc. Nevertheless, the link between workforce resistance and organisational change is under-researched perhaps due to a lack of available data that allows for a linking of employee sentiment to firm-level management strategies. This paper utilises data from a matched employer-employee survey captured at the beginning of the Irish downturn in October 2008. The study captures activity at the very beginning of the economic crises, when the decline in output was still relatively modest and the scale of the recession to come remained largely unforeseen. The research provides a unique assessment of the determinants of firm-level organisational change over a range of dimensions related to employee performance and,

more importantly, measures the extent to which such change was impeded or stimulated as a consequence of levels of workforce resistance.

There is a relatively limited literature relating workforce resistance to organisational change. Dow and Perotti (2008) develop a theoretical construct of resistance to change by attempting to explain why established firms fail to adjust to take advantage of opportunities when new firms typically succeed. Dow and Perotti (2008) argues that radical adjustment of assets within the firm can create winners and losers and, consequently, employees whose skills are less valued as a result of proposed changes will tend to resist. The paper predicts modest shifts in the role of different skills can be implemented by consensus but that the likelihood of success diminishes as the desired shift gets larger. Choi (2011) reviews the literature on attitude and organisational change using the keywords 'readiness for change', 'commitment to change', 'openness to change' and 'cynicism about organisational change'. The review highlights research that demonstrates that change-specific commitments, such as commitment to change and cynicism about organisational change, are better predictors of either support for change or resistance to it than general attitudes, such as organisational commitment and organisational cynicism. They conclude that, given their propensity to evolve according to the situation, attitudes to change are better conceptualised as states rather than personality traits.

A number of studies have sought to identify the determinants of resistance to change, some of which have linked workforce resistance with employee level performance. Iverson (1996), tests a causal model predicting employees' acceptance of organisational change in a public hospital in Australia. Using multiple regression, he finds that the most important determinant of acceptance to organisational change is union membership, with members less accepting than non-members. Oreg (2003) developed a measurement scale relating individual worker characteristics to resistance to change across and identifies four reliable factors: routine seeking, emotional reaction to imposed change, cognitive rigidity and short-term focus. Kunze et al (2013) interrogate the assumption of a correlation between age and resistance to change using the scale developed by Oreg (2003). The findings of Kunze et al (2013) contradict the common stereotype of older employees being more resistant to change and the authors suggest this may be due to older employees being more stable and better able to cope with negative emotional reactions to change. The study also finds tenure and occupational status have positive coefficients for resistance to change, while the examination of how resistance to change interacts with individual performance finds individual resistance to change has negative consequences, such as lower efficiency, higher absenteeism due to health problems and the emergence of fewer new ideas. Wanberg and Banas (2000) find that while the characteristic of resilience is not predictive of a more positive view of a given change, it is related to higher levels of change acceptance.

Finally, a number of papers examine the impact of organisational change on workers, thus providing some further understanding of the motivation for resistance. Black et al (2004) find that firms that implement high-performance practices compensate at least some of their workers for such work practices but that there is a significant association between such practices and increased wage inequality. Secondly, they find that some forms of organisational change, such as self-managed teams and job rotation, tend to reduce employment levels within the firm. Bryson et al (2013) use a linked employee-employer dataset to study the effects of organisational change on employee well-being in the private sector. The paper finds that change can be introduced without adversely affecting the employee's job-related anxiety by engaging with employees when implementing change but only where one or more unions operate in the workplace. Otherwise, organisational change always increases job-related anxiety.

### **Data and Methods**

The objectives of this paper are two-fold: firstly, we model the determinants of workforce resistance to job-related change and, secondly, we assess the impacts of such resistance on the probability that firms will implement various wider forms of organisational change. The data is taken from the October 2008 National Employment Survey (NES) and captures the very beginning of the Irish economic recession, when the need for organisational restructuring was likely to be relatively high. The NES is a linked employee-employer survey that is nationally representative of the distribution of employers in Ireland. The employer sample is drawn from the CSO's Central Business Register. Selected firms are asked to extract a systematic sample of employees from payrolls. The dataset covers 10,000 employers and 100,000 employees and the sample generated is representative of the proportion of companies in each economic sector and size class. The employer questionnaire requested information on employee earnings, hours worked and occupation. Information was also obtained on firm size, sector, the use of pay agreements, HRM procedures etc. Employees were issued with a separate questionnaire within which they provided information on age, gender, educational attainment, employment status (part-time or full-time), length of time in paid employment, length of service with current employer and also other job-related characteristics (for example, trade union membership, shift-work etc).

The October 2008 survey includes modules on employee resistance and organisational change, with separate employer and employee questions. Employers were asked "Has your business experienced any of the following forms of change in 2008?" with the respondent then providing dichotomous response to nine suggestions: (1) a greater reliance on temporary workers, (2) a greater reliance on part-time workers, (3) an increase in overtime hours, (4) a reduction in the number of management levels, (5) a greater reliance on job-

rotation and multi-tasking, (6) a greater reliance on external suppliers of products/services (outsourcing), (7) a downsizing the operation, (8) an increases in the level of staff absenteeism, and (9) increases in the level of involuntary staff turnover<sup>1</sup>. With respect to employee resistance to job-related change, employees were asked “If the following changes were implemented in your workplace over the next two years, how acceptable would you find: (1) an increase in your level of responsibility for your workload, (2) an increase in the level of technology involved in your work, (3) an increase in the level of supervision of your work, (4) an increase in the level of skills necessary to carry out your job, (5) having to work more unsociable hours, (7) an increase in your authority to make decisions, (8) changes to terms and conditions of your employment. In response, employees had the options of ‘acceptable’, ‘not acceptable’ and no response.

Given that our objective is to identify the factors that influence workforce resistance and the subsequent impact of such resistance on various forms of organisational change, we reduce our linked employer-employee data to the level of the firm by retaining one observation per organisation. In doing so, our employee resistance terms now relate to the average level of resistance within the employing organisation. We retain information from the employer survey and derive a range of organisational average variables based on the employee responses within each organisation. We apply establishment-level weights to our firm-level observations to ensure that our data is representative of the population of firms in Ireland during 2008. Our sample is restricted to private sector organisations only on the grounds that public sector organisations are more insulated from market forces and thus both employees and managers are likely to behave differently both in terms of resistance to change and the need for organisational reform. After exclusions for missing data etc, we retain an effective sample of 4,035 firms.

Moving onto the econometric analysis, our specifications are based around the assumption that our key outcome variables (workforce resistance and organisational change) at the level of the firm will be driven by a combination of the human capital characteristics of the workforce and a range of organisational attributes. Given this, we begin by estimating equation 1 where the dependant variable is binary in nature and indicates that the firm has a incidence of workforce resistance to change in specific areas of job performance that places it in the top quartile of resistant firms. The choice of the cut-off point is somewhat arbitrary -- nevertheless, it is fair to conclude that firms selected in this manner can be classified as having the most resistant workforces. Equation 1 is estimated for each of the 7

---

<sup>1</sup> As changes in the levels of absenteeism and staff turnover are not determined by management, these are not subsequently included as measures of organisational change. Similarly, down-sizing is not considered as this may also be an exogenous influence largely outside of management control.

job-related areas of potential reform. Resistance is modelled as a function of the firm-level characteristics, measured either in terms of variables derived from average employee responses (H), which typically reflect the firm's human capital such as average levels of education and experience, or single response measures (F) taken from the employer survey which capture firm-level characteristics such as firm size, sector, HRM practices etc. Subsequent to identifying the drivers of employee level resistance, we then estimate equation 2, which models the determinants of firm-level organisational change as a function of firm-level characteristics (H and F) and the binary measures of employee resistance to change (Res). On the grounds that organisational change may be non-random with respect to employee resistance i.e. firms may select into various modes of organisational change based on their observable characteristics which may also be related to levels of employee resistance, a Heckman selection adjustment is added to the models. The selection terms are derived by extracting inverse Mills ratios from equation 1. In order to ensure that the models are properly identified, equation 1 includes a number of additional controls that are omitted from equation 2<sup>2</sup> (see Puhani, 2000).

$$\overline{Res} = \alpha + \beta_1 \overline{H} + \beta_2 F + \varepsilon \quad (1)$$

$$Orgch = \alpha + \beta_1 \overline{H} + \beta_2 F + \beta_3 Res + \lambda Res + \varepsilon \quad (2)$$

## Results

Table 1 reports the average proportions of employees stating that a specific change in employment conditions is unacceptable by industrial sector. There was a relatively low level of variation in the level of workforce resistance to change on the various dimensions of employment conditions, with between 20 and 25 per cent of workers indicating that they would resist any attempt to alter aspects of their employment (Table 1). At 20 per cent, workforce resistance was lowest with respect to proposed increases in the number of unsociable hours worked. At 26 percent, workforce resistance was most pronounced with respect to any increase in the skill content of jobs.

There was some substantial variation in the extent of workforce resistance to altered employment conditions across sectors. Subjective resistance was somewhat higher than average in the Financial and Insurance industry, particularly with respect to potential changes to terms and conditions and increases in unsociable hours. Conversely, workforce

---

<sup>2</sup> The exclusions instruments should ideally have a theoretical basis. In our models we adopt management and individual development programmes and employee incentive schemes such as profit sharing, share incentive, group incentives (productivity incentives based in group performance) and individual incentives (bonuses etc) on the grounds that while such measures may impact employee resistance they will be relatively unimportant in a firms decision to implement change.

resistance to many dimensions of job-related change was lower than average within the Construction sector, perhaps reflecting a higher tolerance for harsher working conditions among construction workers. With respect to specific dimensions of workforce resistance across sectors, the potential introduction of new technologies was associated with low levels of resistance in the Real Estate, Professional and Construction industries. Employees in the Health and Social Care sector appeared relatively hostile to the introduction of additional technologies or increased job autonomy.

Table 2 cross-tabulates workforce resistance to changing job conditions by organisational size and demonstrates, very clearly, that workforce resistance across all dimensions of change is strongly and positively correlated with organisational size.

**<Insert Table 1 around here>**

**<Insert Table 2 around here>**

Table 3 presents the result from equation 1, which models the determinants of employee resistance at the level of the firm across a range of areas related to job performance. The dependant variable takes the value 1 if the proportion of employees indicating that they would find change in a particular area unacceptable lies above the 75<sup>th</sup> percentile, and zero otherwise<sup>3</sup>. As such, the models identify the characteristics of highly resistant firms. We estimate the model using a binary variable, as opposed to the continuous alternative, in order to facilitate the Heckman adjustment in equation 2; nevertheless, the results from a model estimated using a continuous dependant variable are comparable to those presented in Table 3<sup>4</sup>. The explanatory variables in our model capture the education and experience composition of the firm, existing work practices, management/HRM structures and employee incentive schemes.

A number of variables are significant with respect to all or most dimensions of workforce resistance, specifically, resistant firms tended to employ lower shares of educated workers. Similarly, a relatively high level of workforce resistance to change in various dimensions of employment conditions was consistently more common in larger firms. Pay levels were largely unimportant; however, workforce resistance to the introduction of new technologies was lower in higher paying firms. Firms employing higher shares of more experience --

---

<sup>3</sup> The exception relates to the variable capturing resistance to an increase in skill requirements. The distribution of this measure was highly skewed to the left and, consequently, the cut-off point was raised to above the 90<sup>th</sup> percentile in this case.

<sup>4</sup> Results available from the authors.

typically older -- workers were more likely to experience workforce resistance to any increases in workloads or changes to terms and conditions.

Interestingly, both trade union density and the presence of collective bargaining arrangements were not consistently related to workforce resistance; nevertheless, some results were detected. In line with prior expectations, workforce resistance to proposed changes in terms and conditions was positively related to trade union density. The presence of collective wage bargaining arrangements was also found to raise workforce resistance to any proposed change involving increases in either the skill requirements of jobs or levels of supervisory responsibility. Employee consultation also had little impact; however, the collection of worker suggestions was related to a 7 per cent reduction in the probability of workforce resistance to any proposed increases in workloads. The share of workers employed in HRM and the existence of management development procedures had minimal or no impact on workforce resistant to potential changes in employment conditions. The presence of equality policies within the organisation tended to lower the probability of workforce resistance to increases in levels of supervisory responsibility; however, no impacts were found with regard to bullying, health or grievance policies. Organisations implementing individual performance management systems were somewhat less likely to have a workforce resistant to the introduction of new technologies into existing jobs.

The presence of certain financial incentive schemes was found to have some impact on the probability of workforce resistance to changes in working conditions -- specifically, the higher the proportion of employees in profit sharing schemes, the lower probability of resistance across most dimensions of change. However, individual incentive schemes raised the likelihood of workforce resistance to any proposed changes in levels of supervision, terms and conditions of employment and skill requirements. The presence of group incentive schemes also exerts a positive impact with regard to resistance to any proposed increase in supervisory requirements. Presumably, if efforts are rewarded on a group basis, this reduces the incentive to take on supervisory duties. Finally, with respect to the Industrial sector, in line with the descriptive statistics, the probability of workforce resistance across most dimensions of change was higher within the Information and communication industry.

**<Insert Table 3 around here>**

In Table 4, we model the probability that firms implementing a range of strategies related either the increased labour force flexibility or downsizing. The explanatory variables again include a range of firm-level characteristics; however, we now also include measures of workforce resistance to examine the hypothesis that employee-level inflexibility to changes in job conditions can stimulate, or inhibit, some forms of change related to labour flexibility and competitiveness. As the dependant variables are binary in nature, we estimate probit models (equation 2). We augment the model with inverse Mills ratios (taken from equation

1) to control for the possibility that firms that are workforce resistant will possess characteristics that are also correlated with organisational change. Failure to control for these selection effects may result in biased estimates of the impact of workforce resistance on wider organisational change.

The results from the organisational change models are presented in Table 4. Although the models are well specified, there are few consistent impacts with respect to general firm-level characteristics. Nevertheless, some patterns were evident. Larger firms were more likely to have increased their use of temporary and part-time workers, to have increased their reliance on job rotation/multi-tasking and reduced management levels in the preceding period. Firms employing more experienced staff were less likely to have increased their use of part-time workers<sup>5</sup>. Employee relations variables were more significant, with organisations that had a system of staff consultation more likely to have reduced management levels, increased job rotation/multi-tasking or downsized during 2008. Workplaces with an employee suggestions system were more likely to have outsourced products or services in the months previous to the survey. Firms with a higher share of migrant workers were less likely to have increased their reliance on part-time workers during the year, providing some evidence that some employers may treat migrants and part-time workers as substitutes.

Economic sector was an important determinant of organisational change across a number of dimensions. In general, there was broad similarity across sectors, with most sectors displaying negative coefficients, relative to the Mining and quarrying reference group. Positive coefficient effects were more common with respect to outsourcing. The negative coefficient for an increased reliance on job-rotation and multi-tasking was largest in the Transport and storage and Administrative sectors. Firms in the Information and communication, Administrative and Education sectors were least likely to have increased the use of part-time workers. Water and waste firms were most likely to have downsized, while firms in the Administrative and Education industries were least likely to take on part-time workers. Finally, a greater reliance on outsourcing was most common in the Accommodation and Information and communication sectors.

With respect to workforce resistance controls, a number of interesting results emerged. On the whole, there was no strong evidence of sample selection; however, some relationships were detected. Firms whose workforces were resistant to increasing skill requirements and

---

<sup>5</sup> Organisations employing higher shares of part-time workers were, unsurprisingly, more likely to have increased their reliance of part-time throughout the year. The result is potentially highly endogenous and should be interpreted with caution.

unsociable hours had characteristics also associated with organisations that were more likely to implement change in the areas of management reductions and increased outsourcing. Furthermore, organisations with workforces resistant to changes in terms and conditions tended to have characteristics that generated a lower ex ante expectation that they would introduce job rotation/multitasking.

With regard to the impact of the workforce resistance terms on organisational change, the increased reliance of temporary workers was positively associated with workforce resistance to increased levels of supervision. The result is potentially consistent with a scenario whereby a lack of supervision results in a less employee flexibility and/or lower productivity, either of which could necessitate the occasional use of peripheral workers. With regard to an increased usage of part-time employees, this appears to be positively correlated with workforce resistance to proposed increases in workload, technology and supervision; conversely, additional part-time workers were less likely to be hired when workforces were resistant to increased levels of job autonomy. Increases in overtime were more likely in organisations with workforces resistant to changes in terms and conditions, suggesting that such workforces may tend to argue that any benefits arising from increases in product demand should benefit existing employees as opposed to new part-time and/or temporary workers. Management levels were more likely to have been reduced in firms where employees expressed resistance to increases in workloads and were less likely in the presence of resistance to increases in skill requirements. An interpretation of the result is that management levels will tend to be reduced in firms where management have been unsuccessful in delivering worker flexibility and also in low skilled firms.

A number of competing effects were detected with respect to the increased use of job rotation/multitasking, with this form of worker flexibility positively influenced by workforce resistance to increased levels of workload, unsociable hours and changes to terms and conditions. Resistance to increases in technology, supervision and skill content tend to reduce the likelihood of multitasking being introduced. The results suggest that attempts to increase the range of tasks adopted by employees are often a reaction to employee resistance to changing core aspects of their working conditions; however, resistance among workers to acquiring new skills and adopting new technologies constitute a key barrier to the introduction of such policies. Finally, a greater reliance on external suppliers was positively related to workforce resistance to technology and negatively correlated with resistance to working unsociable hours.

**<Insert Table 4 around here>**

## **Summary and Conclusions**

Workforce resistance to proposed changes in job conditions was found to be lower in organisations employing higher shares of educated workers and also in smaller firms. HRM

and employee relations measures were found to have little impact on worker resistance to changing employment conditions, while trade union density was important with respect to alterations to core terms and conditions. The level of experience among the workforce and rates of pay was also of relatively little importance in explaining resistance to proposed changes in job conditions. Employee share schemes were found to lower workforce resistance across a range of job-related dimensions; however, the marginal impact of such initiatives on the probability of workforce resistance was low.

Overall, we found that high levels of workforce resistance to proposed changes in a range of areas related to existing employment conditions tended to influence firms' decisions to place a heavier reliance on part-time and temporary workers. With respect to the increased use of job rotation/multitasking, the results suggest that such policies tended to be introduced in firms where the workforce was highly resistant to any changes in their core terms and conditions, suggesting that the need for change may be related to existing worker inflexibility. However, resistance among workers to acquiring new skills and adopting new technologies are a key barrier to the introduction of job rotation/multi-tasking policies. A greater reliance on external suppliers was positively related to workforce resistance to increased technology and negatively correlated with resistance to working unsociable hours. Finally, workforce resistance to increases in workload and higher levels of acceptance of new skills was found to be related to management down-sizing decisions.

From a policy perspective, the key finding arising from the research is that while workforce resistance to job-related change often forces firms to seek alternative means of achieving labour flexibility, there appears little that firms can do to prevent such resistance occurring. The presence of HRM staff, consultation procedures, wage bargaining mechanisms, bullying and equality policies etc were found to have little impact on the incidence of workforce resistance to changes in job conditions.

## Data Appendix

Variable name	Description
Mean wage	average gross weekly wage paid to employees in firm
Mean exper	average years spent in employment by employees of firm
% Male	% share of employees in firm who are male
% Part-time	% share of employees in firm who are part-time
% basic education	% share of employees in firm who have a primary level education
% Secondary education	% share of employees in firm who have a secondary level education
% Post-secondary	% share of employees in firm who have a post-secondary level education
% Sub-degree	% share of employees in firm who have a sub-tertiary level education
% Third-level	% share of employees in firm who have a third level education
% Shift-workers	% share of employees in firm who are shift workers
% Professional	% share of employees in firm who belong to professional bodies
Firm size	number of employees in firm
TU density	% share of employees in firm who belong to a trade-union
Collective bargaining	Binary variable indicating that firm has a collection agreement with trade-unions
Consult on change	Binary variable indicating that firm has a system in place for consulting with employees
Worker suggestions	Binary variable indicating that firm has a employee suggestion scheme
HRM share	% share of employees in firm who work in HR
Manage develop	Binary variable indicating that firm has a system for developing management competency
Team perform man	Binary variable indicating that firm has a system of team-based performance management
Indiv develop	Binary variable indicating that firm has a system of individual performance management
% Migrants	% share of employees in firm who are immigrants
Grievance policy	Binary variable indicating that firm has a clearly specified grievance policy
Health policy	Binary variable indicating that firm has a clearly specified health policy
Equality policy	Binary variable indicating that firm has a clearly specified equality policy
Bullying policy	Binary variable indicating that firm has a clearly specified bullying policy
Indiv incent scheme	% share of employees who participate in individual incentive schemes
Group incent scheme	% share of employees who participate in group incentive schemes
Employee share scheme	% share of employees who participate in share schemes
Profit sharing	% share of employees who participate in profit sharing schemes
<b>Workforce resistance</b>	
Resist workload	Binary variable: firm is in highest quartile for workforce resistance to increased workload
Resist technology	Binary variable: firm is in highest quartile for workforce resistance to increased technology
Resist supervision	Binary variable: firm is in highest quartile for workforce resistance to increased supervision
Resist skills	Binary variable: firm is in highest quartile for workforce resistance to increased skills
Resist unsociable	Binary variable: firm is in highest quartile for workforce resistance to unsociable hours
Resist authority	Binary variable: firm is in highest quartile for workforce resistance to increased autonomy
Resist terms	Binary variable: that firm is in highest quartile for workforce resistance to changes in terms
$\lambda$ Workload	continuous variable, mills ratio from resistance to increased workload equation
$\lambda$ Technology	continuous variable, mills ratio from resistance to increased technology equation

Δ Supervision	continuous variable, mills ratio from resistance to increased supervision equation
Δ Skills	continuous variable, mills ratio from resistance to increased skills equation
Δ Unsociable	continuous variable, mills ratio from resistance to unsociable hours equation
Δ Authority	continuous variable, mills ratio from resistance to increased autonomy equation
Δ Terms	continuous variable, mills ratio from resistance to changes in terms and conditions equation

**Organisational change**

Temp workers	Binary variable indicating that firm increased its reliance on temporary workers
PT workers	Binary variable indicating that firm increased its reliance on part-time workers
Over time	Binary variable indicating that firm increased its reliance on overtime
Manage	Binary variable indicating that firm reduced management numbers
Rotate	Binary variable indicating that firm increased its reliance on job rotation / multitasking
Extern	Binary variable indicating that firm increased its reliance on external suppliers

Year	Number	Title/Author(s) ESRI Authors/Co-authors <i>Italicised</i>
2014	489	Estimating Building Energy Ratings for the Residential Building Stock: Location and Occupancy <i>John Curtis, Niamh Devitt, Adele Whelan</i>
	488	Gaming in the Irish Single Electricity Market and Potential Effects on Wholesale Prices <i>Darragh Walsh and Laura Malaguzzi Valeri</i>
	487	Household Formation and Tenure Choice: Did the great Irish housing bust alter consumer behaviour? <i>David Byrne, David Duffy and John FitzGerald</i>
	486	Changing Time: Possible Effects on Peak Electricity Generation Sara Crowley (UCC), <i>John FitzGerald and Laura Malaguzzi Valeri</i>
	485	Changes in Labour Market Transitions in Ireland over the Great Recession <i>Adele Bergin, Elish Kelly, Seamus McGuinness</i>
	484	Examining the Relationships between Labour Market Mismatches, Earnings and Job Satisfaction among Immigrant Graduates in Europe <i>Seamus McGuinness and Delma Byrne</i>
	483	Worth a Try: A Statistical Analysis of Brian O’Driscoll’s Contribution to the Irish Rugby Team <i>Pete Lunn and David Duffy</i>
	482	Who Should We Ask? Employer and Employee Perceptions of Skill Gaps within Firms <i>Seamus McGuinness and Luis Ortiz</i>
	481	Trends in Socio-Economic Inequalities in Mortality by Sex in Ireland from the 1980s to the 2000s <i>Richard Layte, Joanne Banks</i>
	480	Innovation and Productivity in Services: Evidence from Germany, Ireland and the United Kingdom Bettina Peters, Rebecca Riley, <i>Iulia Siedschlag, Priit Vahter and John McQuinn</i>
	479	What Can I Get For It? The Relationship Between the Choice Equivalent, Willingness to Accept and Willingness to Pay <i>Pete Lunn and Mary Lunn</i>
